JOURNAL OF HEPATOLOGY

The Home of Liver Research

EDITOR IN CHIEF

Vlad Ratziu, France

CO-EDITORS

Annalisa Berzigotti, Switzerland I Tom H. Karlsen, Norway | Phil N. Newsome, UK | Lorenza Rimassa, Italy I Frank Tacke, Germany | Heiner Wedemeyer, Germany

ASSOCIATE EDITORS

Alcohol and Drug-Related Liver Diseases
Guruprasad Aithal, UK
Bin Gao, US
Alexandre Louvet, France

Basic science
Anna Mae Diehl, US
Yasuko Iwakiri, US
Robert Schwabe, US

Cholestasis and Autoimmune Diseases
David Assis, US
Gideon Hirschfield, Canada
Verena Keitel, Germany

Complications of Cirrhosis and Liver Failure
Agustin Albillos, Spain
Alastair O'Brien, UK
Aurelie Plessier, France
Thomas Reiberger, Austria
Puneeta Tandon, Canada
Dominique Thabut, France

Disease Burden and Public Health
Marianne Martinello, Australia

Gut-Liver Axis
Bernd Schnabl, US

Hepatic and Biliary Cancer
Stephen Chan, Hong Kong
Tim Greten, US
Katie Kelly, US
Angela Lamarca, Spain
Tom Luedde, Germany
Jean-Charles Nault, France
Matthias Pinter, Austria

Imaging and Non-Invasive Tests
Maxime Ronot, France

Immunology
Barbara Rehermann, US

Liver Surgery and Transplantation
Andrea Schlegel, US
Nazia Selzner, Canada

MASLD
Quentin Anstee, UK
Jérôme Boursier, France
Amalia Gastaldelli, Italy
George Ioannou, US
Stefano Romeo, Sweden
Vincent Wong, Hong Kong

Paediatric liver diseases
Valerie McLin, Switzerland

Pathology
Dina Tiniakos, UK

Statistics, A.I. and Modelling Outcomes
Julius Chapiro, US
Sylvie Chevret, France
Elise Dumas, Switzerland
Julia Kozlitina, US
Terry Yip, Hong Kong

Viral Hepatitis
Eike Steinmann, Germany
Rachel Wen-Juei Jeng, Taiwan
Sabela Lens, Spain

Specialist consultants
Peter Jepsen (Epidemiology), Denmark
Alexandra Zhernakova (Genomics and big data), Netherlands

Web and social media editor
Rui Castro, Portugal

BREAKTHROUGHS BEYOND THE JOURNAL

Florent Artru, France
Valerie Chew, Singapour
Cornelius Engelmann, Germany
Panu Luukkonen, Finland
Thomas Marjot, UK
David Pinato, UK
Prakash Ramachandran, UK
Lisa Sandmann, Germany
David Trampert, Netherlands

EDITORS EMERITUS

Dame Sheila Sherlock†, Founding Editor, UK (1985-1989)
Jean-Pierre Benhamou†, France (1990-1994)
Gustav Paumgartner†, Germany (1995-1999)
Juan Rodés†, Spain (2000-2004)
Massimo Colombo, Italy (2005-2009)
Didier Samuel, France (2010-2014)
Rajiv Jalan, UK (2015-2019)
Paolo Angeli, Italy (2020-2024)

This journal and the individual contributions contained in it are protected under copyright, and the following terms and conditions apply to their use in addition to the terms of any Creative Commons or other user license that has been applied by the publisher and the European Association for the Study of the Liver to an individual article:

Photocopying: Single photocopies of single articles may be made for personal use as allowed by national copyright laws. Permission is not required for photocopying of articles published under the CC BY license nor for photocopying for non-commercial purposes in accordance with any other user license applied by the publisher and the European Association for the Study of the Liver. Permission of the publisher and the European Association for the Study of the Liver and payment of a fee is required for all other photocopying, including multiple or systematic copying, copying for advertising or promotional purposes, resale, and all forms of document delivery. Special rates are available for educational institutions that wish to make photocopies for non-profit educational classroom use.

Derivative Works: Users may reproduce tables of contents or prepare lists of articles including abstracts for internal circulation within their institutions or companies. Other than for articles published under the CC BY license, permission of the publisher and the European Association for the Study of the Liver is required for resale or distribution outside the subscribing institution or company. For any subscribed articles or articles published under a CC BY-NC-ND license, permission of the publisher and the European Association for the Study of the Liver is required for all other derivative works, including compilations and translations.

Storage or Usage: Except as outlined above or as set out in the relevant user license, no part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, mechanical, photocopying, recording or otherwise, without prior written permission of the publisher and the European Association for the Study of the Liver.

Permissions: For information on how to seek permission visit www.elsevier.com/permissions.

Author rights: Author(s) may have additional rights in their articles as set out in their agreement with the publisher and the European Association for the Study of the Liver (more information at http://www.elsevier.com/authorsrights).

Notice: Books and Journals published by Elsevier comply with applicable product safety requirements. For any product safety concerns or queries, please contact our authorised representative, Elsevier B.V., at productsafety@elsevier.com or Radarweg 29, 1043 NX Amsterdam, Netherlands.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds or experiments contained herein. Health care practitioners must exercise their professional judgement and make all treatment-related decisions based solely on the specific conditions of each patient. Because of rapid advances in the medical sciences, independent verification of diagnoses and drug dosages should always be made. The content is provided "as-is" and neither Elsevier nor Society make any representations or warranties, whether express or implied, as to the accuracy, completeness, or adequacy of any content. To the fullest extent permitted by law, neither Elsevier nor Society assume any responsibility for any damages, adverse events, or liability arising from use of information contained herein including for any injury and/or damage to persons or property, whether as a matter of product liability, negligence or otherwise. Inclusion of any advertising material in this publication does not constitute a guarantee or endorsement of the quality or value of such product or service or of any of the representations or claims made by the advertiser.

Publication information: Journal of Hepatology (ISSN 0168-8278). For 2026, volumes 84 and 85 are scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/jhep). Further information is available on this journal and other Elsevier products through Elsevier's website: (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Orders, claims, and journal inquiries: Please visit our Support Hub page https://service.elsevier.com for assistance.

Advertising information: For advertising and solutions inquiries, please contact Joe Skey, email: joe.skey@formedics.com or Bill Hipple, email: bill.hipple@formedics.com. For reprint queries, please send an email to sales@contentednet.com.

Author enquiries: Visit the Elsevier Support Center (https://service.elsevier.com/app/home/supporthub/publishing) to find the answers you need. Here you will find everything from Frequently Asked Questions to ways to get in touch.
You can also check the status of your submitted article via https://service.elsevier.com/app/answers/detail/a_id/29155/ or find out when your accepted article will be published via https://service.elsevier.com/app/answers/detail/a_id/5981/.

Funding body agreements and policies: Elsevier has established agreements and developed policies to allow authors whose articles appear in journals published by Elsevier, to comply with potential manuscript archiving requirements as specified as conditions of their grant awards. To learn more about existing agreements and policies please visit http://www.elsevier.com/fundingbodies.

Special regulations for authors: Upon acceptance of an article by the journal, the author(s) will be asked to transfer copyright of the article to EASL. Transfer will ensure the widest possible dissemination of information.

Publishing Office: *Journal of Hepatology* (ISSN 0168-8278, USPS 11087) is published monthly by Elsevier B.V., Radarweg 29, Amsterdam, 1043 NX, Netherlands. Airfreight and mailing in the USA by agent named World Container Inc, 150-15, 183rd Street, Jamaica, NY 11413, USA. Periodicals postage paid at Brooklyn, NY 11256.

POSTMASTER: Send address changes to *Journal of Hepatology*, Air Business Ltd, c/o World Container INC 150-15, 183rd St, Jamaica, NY 11413, USA.

Registration of Clinical Trials
The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.
More detailed information regarding clinical trials and registration can be found in New Engl J Med 2004; 351:1250–1251 and New Engl J Med 2005; 352:2437–2438.

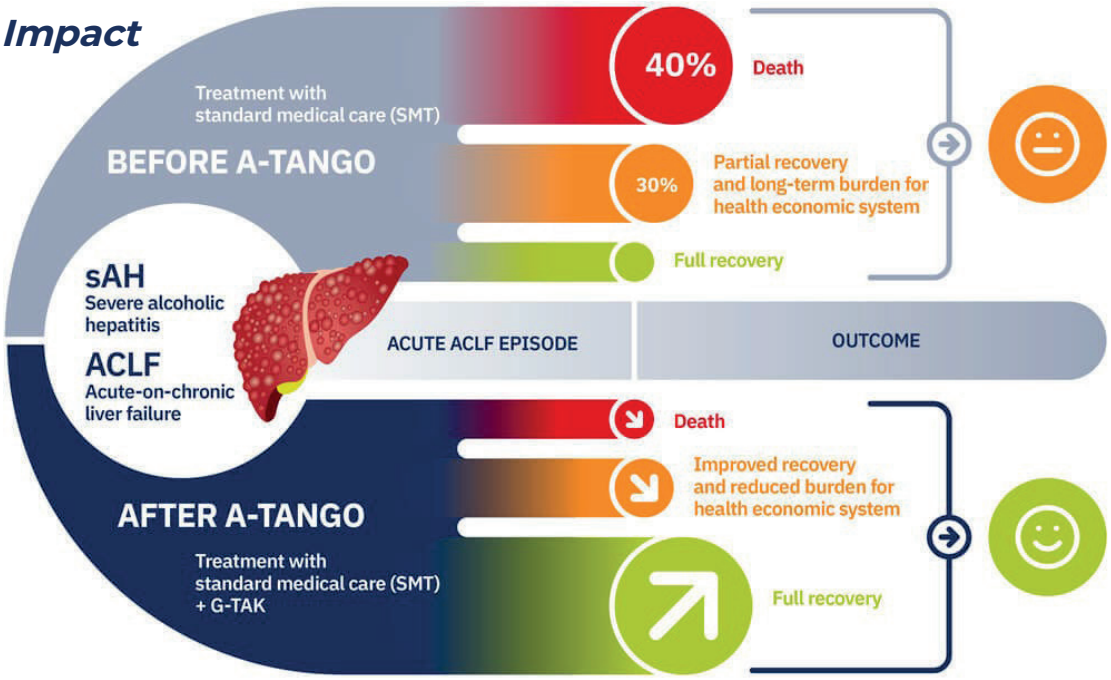
A-TANGO

Featuring G-TAK, a novel combinatorial therapy for acute-on-chronic liver failure (ACLF)

Expected Impact



- More than **10 million people** suffer from **decompensated cirrhosis** worldwide.
- Effective treatment of ACLF is an urgent and unmet need.
- A-TANGO performs **Phase II clinical studies of G-TAK,** a novel and innovative therapeutic strategy that aims to **reduce inflammation** and **improve hepatocyte proliferation.**
- A-TANGO also strives to identify **reliable biomarkers** for better patient stratification and increased survival.

13 partners, one goal: Helping cirrhosis patients in Europe and beyond

kick-off
1st March 2021

project duration
5.0 years

grant amount
6.0 million €

a-tango.eu

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 945096.

DECISION

decision-for-liver.eu

DEcompensated CIrrhoSIs: identification of new cOmbiNatorial therapies based on systems approaches

Key facts

- **Project start**: 1st April 2020
- **Duration**: 6.5 years
- **Members**: 21 institutions from 10 European countries
- **EC funding**: € 6 million

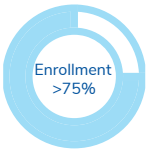
AIM 1
Understanding at systems level

- Using **high-throughput technologies** to understand decompensated cirrhosis at systems level
- Re-analyzing standardized biobank samples from **2,200 patients** with decompensated cirrhosis by characterizing
  - **epigenetics »** manuscript in preparation
  - **transcriptomics**
    » Aguilar F et al. J Hepatol (2025)
  - **metabolomics »** manuscript accepted in *Nature Communications*
  - **microRNA »** manuscript in preparation
  - **extracellular vesicles »** presented at EASL2024

AIM 2
New combinatorial therapy

COMBAT-Trial: proof-of-concept, phase II randomized controlled clinical study

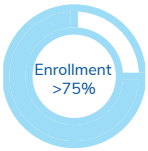
- **Goal**: Evaluate safety and tolerability of a novel combinatorial therapy (human albumin and enoxaparin) in patients with decompensated cirrhosis discharged from the hospital; comparison to standard medical treatment



- First patient enrolled in July 2024

PROSPECT study: prospective, multicenter observational cohort study on post-discharge outcomes in patients with cirrhosis and AD

- **Goal**: Test the prognostic accuracy of novel biomarkers identified within DECISION



- First patient enrolled in March 2025

AIM 3
Pre-clinical models

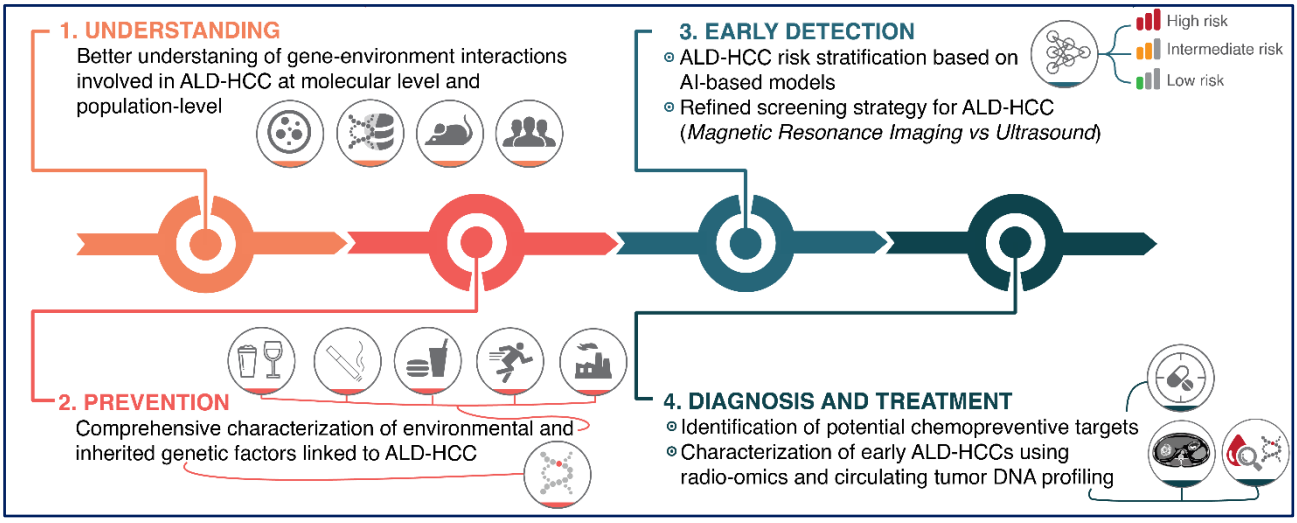
- Existing rat models for acute decompensation of cirrhosis leading to ACLF lack full replication of human disease heterogeneity
  » We therefore aim to refine existing animal model-s
- Publications:
  - Development & characterization of **novel rodent ACLF models »** manuscript submitted
  - Acceleration of an advanced **NASH model** by acute and toxic effects of Phenobarbital
    » Kraus N, Uschner FE et al. Cells (2024)

AIM 4
Prognostic and response tests

- Novel and robust **stratification method** identifies three clusters of patients with acute decompensation of cirrhosis (AD)
  » Palomino-Echeverria S et al. J Transl Med (2024)
  » Ortega-Lagerreta A, Palomino-Echeverria S et al. PLOS Comp Bio (2024)
- Potential tool for healthcare providers to enhance patient monitoring or preventative measures using existing electronic health record data and method could guide future clinical trial design
- Further results will be published soon

This project received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No. 847949.

GENIAL is a pioneering initiative targeting **alcohol-related liver cancer** (**ALD-HCC**). Our primary goal is to identify **genetic** and **environmental** factors contributing to ALD-HCC risk and unravel how their **interactions** drive alcohol-related liver carcinogenesis. By pinpointing individuals at risk, GENIAL will pave the way for innovative **prevention strategies** and potential **chemopreventive targets** to tackle this devastating disease. Moreover, GENIAL is dedicated to **educating** and empowering the entire EU community with vital knowledge for effective disease prevention and **early detection**.



The GENIAL Project is funded by the European Union within the Horizon Europe programme under grant agreement No 101096312.

AIM LIVER

A biomarker-based platform for early diagnosis of chronic liver disease to enable personalized therapy

ACADEMIA AND INDUSTRIES ARE CONDUCTING THE LARGEST PROJECT EVER IN THE FIELD OF LIVER DISEASES

AIM:

To design and validate an AI-powered screening platform using biomarkers for the early diagnosis of liver diseases in the general population, and to establish links to care through personalized interventions

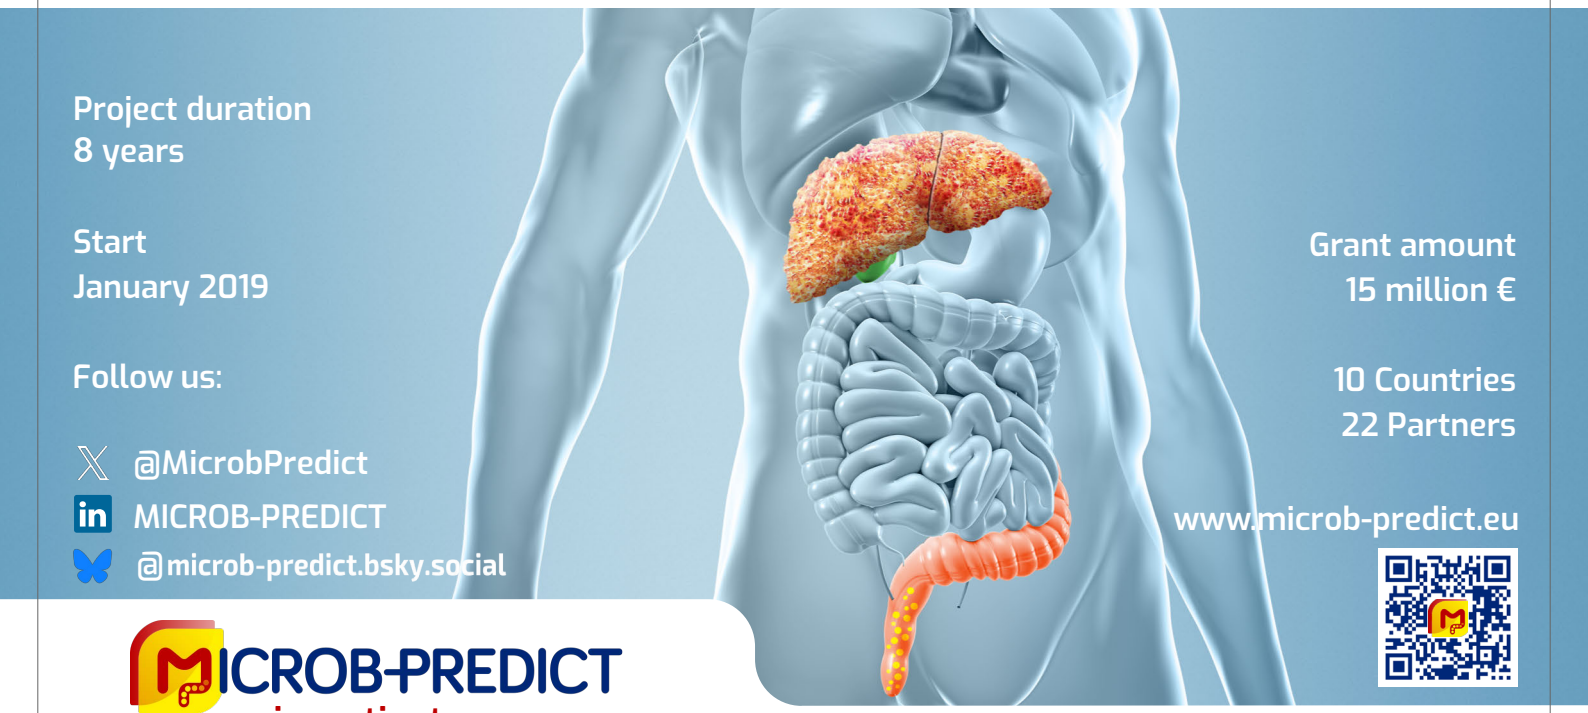
MICROBiome-based biomarkers to PREDICT decompensation of liver cirrhosis and treatment response

MICROB-PREDICT



Project duration
8 years

Start
January 2019

Follow us:

@MicrobPredict
MICROB-PREDICT
@microb-predict.bsky.social

Grant amount
15 million €

10 Countries
22 Partners

www.microb-predict.eu

MICROB-PREDICT investigates

the human microbiome to identify predictors and mechanisms associated with the development of decompensation of cirrhosis and progression to acute-on-chronic liver failure (ACLF).

- → New microbiome-based tests for better stratification of cirrhosis patients
- → Personalized prediction and prevention of decompensation and ACLF
- → Clinical trial to predict response to treatment
- → Modern, effective nanobiosensors as clinical tools with improved specificity
- → More personalized treatment
- → Increased survival times
- → Decreased costs for the health systems

Background and aims: Functional cure (FC), hepatitis B surface antigen (HBsAg) loss and hepatitis B virus (HBV) DNA < lower limit of quantification (LLOQ) 24 weeks off therapy, is the treatment goal in chronic HBV infection. Bepirovirsen (BPV), an antisense oligonucleotide, is the first anti-HBV therapy in global Phase 3 trials with FC as the primary outcome.
Method: B-Well 1 and 2 are global double-blind Phase 3 trials. Non-cirrhotic adults with nucleos(t)ide analogue (NA)-suppressed chronic HBV infection (HBV DNA <90 IU/mL) and HBsAg > 100–≤ 3000 IU/mL were randomised 2:1 to BPV 300 mg or placebo (PBO) weekly for 24 weeks. Participants (pts) discontinued NAs at Week 48, if eligible. The primary outcome was FC response rate at Week 72 for all pts; defined as HBsAg not detected (qualitative; < 0.05 IU/mL) and HBV DNA < LLOQ (< 20 IU/mL or target not detected) 24 weeks after discontinuing all HBV treatment. Key secondary outcomes included FC response rate for pts with baseline HBsAg ≤ 1000 IU/mL. Safety was assessed via adverse event (AE) and laboratory monitoring.
Results: The full analysis set comprised 650 BPV and 328 PBO pts in B-Well 1 and 570 BPV and 286 PBO pts in B-Well 2. Pts were 71% male, mean age approximately 49 years, 68% Asian, 8% HBeAg positive, and 63% had baseline HBsAg ≤ 1000 IU/mL. No PBO pts achieved FC. Among BPV pts with baseline HBsAg ≤ 3000 IU/mL, 20% and 19% achieved FC in B-Well 1 and B-Well 2, respectively ($p < 0.001$ vs PBO). In BPV pts with baseline HBsAg ≤ 1000 IU/mL, 25% in B-Well 1 and 28% in B-Well 2 achieved FC ($p < 0.001$ vs PBO). Most common AEs with BPV (pooled safety: BPV = 1223, PBO = 611) in Week 1–72 included injection site erythema (31%; PBO 2%), injection site pain (23%; PBO 5%) and alanine aminotransferase (ALT) increase (23%; PBO 4%). ALT increases were transient and generally occurred in Week 5–10; 6% of BPV pts had ALT ≥ 10x upper limit of normal (vs PBO <1%). No cases were adjudicated as meeting drug-induced liver injury criteria. Few AEs were serious (BPV 7%; PBO 4%) or led to permanent treatment discontinuation (BPV 3%; PBO < 1%). Two deaths unrelated to study treatment occurred in the BPV arm.
Conclusion: 24-week BPV treatment induced clinically meaningful and statistically significant FC rates versus PBO in virologically

 © 2026 All rights reserved.

suppressed pts with chronic HBV infection, with an acceptable safety profile, showing the potential for BPV to be a first-in-class finite therapy for FC.

Background and aims: Although the gut-liver axis is implicated in primary sclerosing cholangitis (PSC), robust clinical and translational evidence of intestinal drivers are scarce. Here, we used an unbiased metabolomic approach to identify microbially produced molecules associated with PSC and its outcomes and experimentally defined their mechanistic role in bile duct inflammation and fibrosis.
Method: We profiled more than 1,100 plasma metabolites in people with PSC (n = 161) before or after liver transplantation (LT) and healthy controls (HC, n = 32) using untargeted LC–MS/MS. Putative microbiota-derived drivers were identified by prioritizing metabolites that (i) were differentially abundant in PSC, (ii) predicted LT-free survival, (iii) remained altered despite LT. Targeted technical and clinical validation were performed in more than 1,600 PSC blood samples from Norway, Sweden and USA, and 560 control samples from inflammatory bowel disease (IBD) without PSC and people with primary biliary cholangitis or metabolic dysfunction-associated steatotic liver disease. Metagenome sequencing was performed in people with PSC (n = 144). Experimental validation was performed by challenging patient-derived cholangiocyte organoids and chow-fed and 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-fed mice with key disease-associated metabolite.
Results: The histidine metabolite imidazole propionate (ImP) emerged as the most robustly increased metabolite in PSC. ImP was persistently elevated after LT, and consistently predicted reduced LT-free survival in geographically distinct cohorts. PSC-related gut bacteria correlated with ImP concentration in blood and proctocolectomized individuals had reduced ImP levels. People with PSC had higher ImP levels than disease controls, unaffected by IBD status. When challenged with ImP, cholangiocyte organoids secreted pro-inflammatory and pro-fibrogenic factors, and cholangiocyte cell lines displayed mTORC1 activation, which previously has been identified to mediate ImP signaling. In wildtype mice, chronic ImP administration caused biliary fibrosis, portal inflammation and ductular reaction, and ImP exacerbated the biliary injury in DDC-fed mice. The ImP effects were abolished in mice deficient in p38γ/δ MAP kinase isoforms.
Conclusion: We identify gut microbial ImP as a key player in PSC pathophysiology via activation of p38γ/δ-dependent mTORC1 signaling. Targeting ImP production or signaling can represent a therapeutic strategy for PSC.

GS-003

A PNPLA3 antisense oligonucleotide, AZD2693, for the treatment of MASH in I148M homozygous participants: results from the phase 2b FORTUNA study

Rohit Loomba[1], Atsushi Nakajima[2], Marco Arrese[3], Elisabetta Bugianesi[4], Alok Pachori[5], Ola Fjellstrom[6], Janeli Sarv[7], Mathias Liljeblad[8], Kalra Shruti[9], Javier Armisen[10], Lars Hansen[11], Vincent Wai-Sun Wong[12]. *[1]MASLD Research Center, Division of Gastroenterology and Hepatology, University of California at San Diego, La Jolla, United States; [2]Department of Gastroenterology and Hepatology, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Departamento de Gastroenterología, Escuela de Medicina, Pontificia Universidad Católica de Chile, Santiago, Chile; [4]Department of Medical Sciences, University of Turin, Turin, Italy; [5]Late Cardiovascular, Renal and Metabolism, BioPharmaceuticals, R&D, AstraZeneca, Boston, United States; [6]Early Cardiovascular, Renal and Metabolism, BioPharmaceuticals, R&D, AstraZeneca, Gothenburg, Sweden; [7]Biometrics, Late Cardiovascular, Renal and Metabolism, BioPharmaceuticals, R&D, AstraZeneca, Gothenburg, Sweden; [8]Translational Sciences and Clinical Development, Early Cardiovascular, Renal and Metabolism, BioPharmaceuticals, R&D, AstraZeneca, Gothenburg, Sweden; [9]Global Patient Safety, AstraZeneca, Gothenburg, Sweden; [10]Translational Sciences and Clinical Development, Early Cardiovascular, Renal and Metabolism, BioPharmaceuticals, R&D, AstraZeneca, Cambridge, United Kingdom; [11]Late Cardiovascular, Renal and Metabolism, BioPharmaceuticals, R&D, Gaithersburg, United States; [12]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong*
Email: roloomba@ucsd.edu

Background and aims: The *PNPLA3* I148M genetic variant (rs738409) is the strongest genetic risk factor for MASH and cirrhosis. AZD2693, a *PNPLA3*-targeted, GalNAc-conjugated antisense oligonucleotide, reduced *PNPLA3* mRNA and protein levels in pre-clinical and Phase 1 clinical studies. The Phase 2b FORTUNA study evaluated

the efficacy, safety, and tolerability of AZD2693 versus placebo in homozygous carriers of the *PNPLA3* I148M risk allele with non-cirrhotic MASH and F2–F3 fibrosis.
Method: In this international, multicenter, randomized, double-blind, placebo-controlled trial, 217 participants were randomized across either AZD2693 at 25 and 50 mg or corresponding placebos (pbo) in a 2:2:1:1 ratio and were treated for 52 weeks followed by a 12-week follow up period. Primary endpoint was MASH resolution without worsening of fibrosis based on histology. Secondary endpoint was the proportion of participants with at least one stage of liver fibrosis improvement with no worsening of MASH. Safety and tolerability were assessed.
Results: 87% of randomized participants completed end of treatment biopsy. After 52 weeks of treatment, there was a robust decrease in the PNPLA3 protein as determined by immunostaining. For the primary endpoint, the percentage of responders was 1.4%, 5.5% and 6.8% in the 50 mg, 25 mg, and pbo, respectively. Percent point difference from pbo was −5.2% (95% CI, −15.4% to 5.1%; p = 0.116) and −1.4% (95%CI, −12.0% to 9.2%; p = 0.783) for the 50 mg and 25 mg, respectively. For the secondary endpoint, the percentage of responders was 8.7%, 16.4% and 10.8% in the 50 mg, 25 mg, and pbo, respectively. Percent point difference from pbo was −0.3% (95%CI, −11.9% to11.3%; p = 0.693) and 4.3% (95%CI, −7.2% to15.9%; p = 0.320) for the 50 mg and 25 mg groups, respectively. In a sub-study, there was no significant improvement in liver fat content (mean change from baseline: −1.52 vs −1.65 p = 0.899) and liver stiffness (geometric mean ratio to baseline: 1.17 vs 1.03; p = 0.030, nominal) in the AZD2693 50 mg group vs pbo. AZD2693 was generally well tolerated. Adverse events were similar across groups. Mild, dose-dependent increases in mean alanine aminotransferase levels were observed.
Conclusion: After 52 weeks of treatment, AZD2693 (25 mg or 50 mg) was not better over placebo for either the histological resolution of MASH or the improvement in fibrosis in homozygous carriers of the *PNPLA3* rs738409 risk allele with non-cirrhotic MASH and fibrosis.

GS-004-YI
Hepatocyte-macrophage crosstalk reprograms liver zonation in metabolic dysfunction-associated steatotic liver disease by regulating hepatic HNF4A

Shuai Chen[1], Dabao Shang[2], Xiaogang Xiang[2], Frank Tacke[3], Adrien Guillot[3], Hanyang Liu[3]. [1]*Nanjing Medical University, The Third Affiliated Hospital, Changzhou, China;* [2]*Shanghai Jiao Tong University School of Medicine, Ruijin Hospital, Shanghai, China;* [3]*Berlin, Germany*
Email: brandenliu@live.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is among the most prevalent chronic liver diseases worldwide and a major contributor to liver-related malignancy. Hepatocytes, organized along the liver lobular axis into periportal (zone 1), mid-lobular (zone 2) and pericentral (zone 3) regions, exert distinct physio-pathological functions, via interactions with microenvironmental factors and non-parenchymal cells. Such zonal heterogeneity is increasingly recognized as a determinant of MASLD initiation and progression, yet its regulatory mechanisms remain under investigation.
Method: Transcriptomic and metabolomic analyses of human MASLD liver samples were performed at single-cell and spatial resolution to define hepatocyte metabolic phenotypes and intercellular interactions. MASLD mouse models were established using a high-fat diet and a choline-deficient, L-amino acid-defined, high-fat diet. Clodronate liposome-mediated macrophage depletion and hepatocyte-specific genetic manipulations were employed to MASLD mouse models. *In situ* multiplex immunofluorescence staining and cultivating primary hepatocytes with macrophages were utilized to study hepatocyte–macrophage crosstalk.
Results: Spatial single-cell analyses demonstrated a progressive dominance of zone 3 metabolic programs over zone 1 with staging steatosis. Zone 2 hepatocytes displayed elevated lipid and carbohydrate metabolic activity, accompanied by increased expression of hepatocyte nuclear factor 4 alpha (HNF4A) during MASLD progression, suggesting a role in maintaining liver functions. In vivo, hepatocyte-specific HNF4A limited hepatic steatosis, whereas zone 2 hepatocytes with reduced HNF4A expression showed enhanced interactions with lipid-associated macrophages (LAMs). Macrophage depletion attenuated liver fibrosis and restored hepatocyte *Hnf4a* expression across the lobular axis. Lipid-associated macrophages modulate metabolic zonation features by regulating hepatocyte HNF4A.
Conclusion: Hepatocyte HNF4A is identified as a key regulator of hepatic metabolic zonation in MASLD, determining a novel metabolic-immune crosstalk mechanism. Targeting hepatocyte-LAM communications may represent a therapeutic strategy to reprogram hepatic metabolism and mitigate disease progression of MASLD.

GS-005
Transjugular intrahepatic portosystemic shunt for refractory hepatic hydrothorax in cirrhosis: a multicenter European study

Email: dottcarloalessandria@gmail.com

Background and aims: refractory hydrothorax (RH) develops in up to 15% of patients with cirrhosis and significantly impairs quality of life and clinical outcome of these patients. Transjugular intrahepatic portosystemic shunt (TIPS) has been suggested as a potential treatment, but data is limited. We aimed to evaluate TIPS clinical efficacy and impact on survival in patients with RH.
Method: retrospective study including all consecutive patients with cirrhosis who underwent TIPS for RH in a 16-year period (2008–2023) across 18 European centers. Endpoints were assessed: after 12 months from TIPS, at the date of liver transplant (LT) or death or of the last available visit during the 12-month follow-up. Clinical response was classified, compared to baseline, as: I - complete (CR) in case of disappearance of symptoms and no further need for thoracenteses; II - partial (PR) as decrease of symptoms and ≥50% reduction of thoracenteses; III - null (NR) as minor or no relief in symptoms and <50% reduction or same/increased number of thoracenteses.
Results: overall, 155 patients were included. Alcohol was the predominant etiology (47%), with moderately impaired liver function (Child-Pugh class B 78%, median MELD-Na 15), prevalent right unilateral hydrothorax (85%) and very common dyspnea (87%). TIPS improved RH in the majority of patients (88% overall), with 61% of CR. At 12 months after TIPS, 76 patients (49%) were alive, 23 (15%) had been transplanted, 36 (23%) had died and 20 (13%) were lost during the follow-up. Mean overall survival was 11.0 ± 0.3 months for CR patients vs 8.4 ± 0.8 months vs 6.9 ± 1.2 months, for PR and NR patients respectively (Log-rank test: $p < 0.001$; Cox regression: HR = 0.22, 0.11–0.43; $p < 0.001$). Significantly improved survival for CR patients was also confirmed when considering CR to TIPS as a time-varying covariate (HR = 0.25, 0.13–0.48; $p < 0.001$). At multivariable analysis, considering LT as competitive event, clinical CR was the only variable independently associated with improved survival (sHR = 0.28,0.15–0.55, $p < 0.001$); conversely, bilateral hydrothorax and higher MELD-Na score were independently associated with poorer survival (sHR = 2.55, 1.34–4.85, p = 0.004 and sHR = 1.10, 95% CI 1.05–1.15, $p < 0.001$, respectively).
Conclusion: our study supports the use of TIPS in patients with cirrhosis and RH, showing that clinical CR is achieved in a relevant proportion of patients and is associated with improved survival.

GS-006

Stereotactic body radiotherapy versus radiofrequency ablation for small (≤3 cm) hepatocellular carcinoma (STEREO): a randomized, non-inferiority, phase 3 trial

Jinhong Jung[1], Jonggi Choi[1], So Yeon Kim[1], So Jung Lee[1], Hyung Jin Won[1], Yong Moon Shin[1], Won-Mook Choi[1], Sung Won Chung[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1]. *[1]Asan Medical Center, Seoul, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: Radiofrequency ablation (RFA) is a well-established curative treatment for hepatocellular carcinoma (HCC) but is limited by tumour location and visibility. While stereotactic body radiotherapy (SBRT) may overcome these technical limitations, prospective randomised evidence comparing SBRT with RFA for HCC measuring ≤3 cm is lacking.
Method: In this phase 3, randomised, non-inferiority trial, adults with unresectable primary or recurrent HCC presenting with one to two lesions measuring 1–3 cm were randomly assigned (1:1) to receive SBRT or RFA. Technical feasibility was assessed prior to treatment, with a predefined crossover allowed if the assigned procedure was not feasible. The per-protocol (PP) population served as the primary analytic cohort. The modified intention-to-treat (mITT) population included all participants who received treatment for the target lesion. The primary endpoint was 2-year local progression-free survival (LPFS), evaluated using a non-inferiority margin of −15%. Secondary endpoints included local control, progression-free survival (PFS), and overall survival (OS) (ClinicalTrials.gov identifier: NCT05433701).
Results: Among 178 randomised participants, 170 comprised the PP population (RFA n = 68; SBRT n = 102). The median follow-up duration for LPFS was 31 months. The 2-year LPFS rates were 92·0% with SBRT and 89·7% with RFA (difference 2·3%; 90% confidence interval [CI] −5·2%–9·9%), meeting the non-inferiority criterion. Local recurrence at two years occurred in 4·4% of RFA-treated patients and 2·0% of SBRT-treated patients. The 2-year PFS rates in the PP population were 55·6% for SBRT and 51·5% for RFA (HR 0·96; 95% CI 0·64–1·44). The 2-year OS rates were 94·0% for SBRT and 94·1% for RFA. Most adverse events were grade 1–2, and no treatment-related deaths occurred.
Conclusion: SBRT was non-inferior to RFA for local tumour control in patients with small, unresectable HCC and represents an effective alternative local therapy.

THURSDAY 28 MAY

GENERAL SESSION II

GS-007

Abbreviated gadoxetic acid–enhanced magnetic resonance imaging versus ultrasonography for hepatocellular carcinoma surveillance in high-risk patients: a randomized controlled trial

Hyo Jung Park[1], Jonggi Choi[1], Dong Wook Kim[1], Sang Hyun Choi[1], Won-Mook Choi[1], Sung Won Chung[1], Danbi Lee[1], Ju Hyun Shim[1], Han Chu Lee[1], Young-Suk Lim[1], Amit Singal[2], So Yeon Kim[1]. *[1]Asan Medical Center, Seoul, Korea, Rep. of South; [2]University of Texas Southwestern Medical Center, Dallas, United States*
Email: sykim.radiology@gmail.com

Background and aims: The AMRIUS trial (Abbreviated Magnetic Resonance imaging using gadoxetic acid versus Ultrasonography for Surveillance of early-stage hepatocellular carcinoma in high-risk patients) aimed to prospectively compare gadoxetic acid-enhanced abbreviated MRI (HBP-AMRI) and ultrasonography (US) for hepatocellular carcinoma (HCC) surveillance in high-risk patients with cirrhosis.
Method: This open-label, randomized controlled trial was conducted at a tertiary referral center in South Korea. Adults (≥20 years) with high-risk cirrhosis (annual HCC incidence > 5%), Eastern Cooperative Oncology Group performance status performance status 0–2, Child–Pugh class A or B, and no prior liver cancer or recent malignancy were enrolled. Participants were randomized 1:1 to biannual HBP-AMRI or US for two surveillance rounds. The primary endpoint was the

detection rate of Barcelona Clinic Liver Cancer (BCLC) stage 0 or A HCC. Secondary endpoints included detection rates of BCLC stage 0 and all-stage HCC, false referral rate, and BCLC stage distribution at initial HCC diagnosis.
Results: Between August 2022 and October 2024, 806 patients were randomized to the HBP-AMRI (n = 403) or US (n = 403) group. A total of 44 participants (5.5%) were diagnosed with HCC (32 in the HBP-AMRI group and 12 in the US group). BCLC stages at diagnosis were stage 0 in 59.1% (26/44), stage A in 31.8% (14/44), stage B in 4.5% (2/44) and stage C in 4.5% (2/44).The median size of detected HCCs was 1.5 cm (range, 1.0–5.0 cm). The detection rate of BCLC stage 0 or A HCC was significantly higher in the HBP-AMRI group (7.7% [29/377]) than in the US group (2.9% [11/382], p = 0.003). HBP-AMRI also showed higher detection rates of BCLC stage 0 HCC than US (6.1% [23/377] vs. 0.8% [3/382], p < 0.001) and all-stage HCC (8.5% [32/377] vs. 3.1% [12/382], p = 0.002). The false referral rate was lower in the HBP-AMRI group (2.1% [15/704]) group than in the US group (4.4% [32/731], p = 0.02). The HBP-AMRI group demonstrated an earlier BCLC stage distribution compared with the US group (p = 0.04).
Conclusion: HBP-AMRI using gadoxetic acid demonstrated superior performance to US for HCC surveillance in high-risk cirrhotic patients, with higher detection rate of early-stage HCC and fewer false referrals (ClinicalTrials.gov, NCT06312826).

GS-008
RNA editing for the treatment of alpha-1 antitrypsin deficiency (AATD)

Pavel Strnad[1], Kenneth Chapman[2], Alice Turner[3], Matthew Conron[4], William J H Griffiths[5], Paul Hernandez[6], John R Hurst[7], Heli Yla-Outinen[8], Varun Goel[9], Joseph Haegele[9], Ken Longo[9], Mark McLaughlin[9], Prashant Monian[9], Michael Monine[9], Padma Narayanan[9], Shushma Patel[9], Abu Siddiqui[9], Andrew Strahs[9], Chikdu Shivalila[9], Lanyie Xie[9], Christopher Wright[9], Cynthia Caracta[9].

Email: pstrnad@ukaachen.de

Background and aims: Severe AATD commonly results from homozygous mutations in the *SERPINA1* gene (Pi*ZZ genotype), where misfolded Z-AAT protein accumulates in hepatocytes, leading to liver injury and disease. Liver retention results in serum and pulmonary deficiency of wild-type M-AAT and increased risk of lung disease. Standard of care aims to address lung disease by augmenting serum protein levels through weekly infusions with human plasma-purified AAT. Liver disease is not addressed by this intervention.
WVE-006, an investigational *N*-Acetylgalactosamine-conjugated RNA editing oligonucleotide, is designed to recruit endogenous ADAR enzymes to edit the *SERPINA1* mRNA in hepatocytes and replace Z-AAT with M-AAT. This approach aims to increase circulating M-AAT protein levels while reducing Z-AAT and address both lung and liver manifestations of severe AATD.
Method: RestorAATion-2 (NCT06405633) is an ongoing phase 1b/2a clinical trial evaluating the safety, tolerability, pharmacodynamics, and pharmacokinetics of single- and multiple-ascending doses of WVE-006 (200, 400, 600 mg; n = 8 all cohorts) in ZZ individuals. Participants receive a single subcutaneous dose of WVE-006 with a 12-week observation period, followed by biweekly (200 mg) or monthly dosing (400, 600 mg) for 12 weeks with a subsequent observation period. M-AAT, Z-AAT and total (M + Z) AAT protein in serum were measured by LC-MS/MS. Functional AAT levels were measured by a neutrophil elastase inhibition assay.
Results: In the 200 mg multidose cohort, mean peak serum M-AAT levels reached 7.2 uM in ZZ individuals. M-AAT levels represented 64.4% of total AAT (11.9 uM) and remained above 50% throughout the observation period. Increases in functional AAT activity were consistent with M-AAT production and were accompanied by a 60.3% reduction in Z-AAT protein. In the 200 and 400 mg single dose cohorts, M-AAT levels increased to 4.8 uM and 5.3 uM, respectively. In the 200 mg cohort, one participant experienced an acute-phase response due to a kidney stone, during which total serum AAT levels reached 20.6 uM (10.6 uM M-AAT). WVE-006 has been generally safe and well tolerated; all adverse events have been mild to moderate, with no serious adverse events.
Conclusion: These data, which show production of M-AAT, lowering of Z-AAT levels, and endogenous upregulation of AAT protein in ZZ individuals during stress provide proof-of-concept for the first RNA editing therapy to enter clinical testing.

GS-009
Safety, feasibility, impact, and proteomic perturbations with growth hormone treatment in alcohol-related hepatitis: a randomized clinical trial

Nipun Verma[1], Parminder Kaur[1], Pratibha Garg[1], Rohit Nadda[1], Arun Valsan[2], Arka De[1], Sunil Taneja[1], Ajay Kumar Duseja[1].
[1]Postgraduate Institute Of Medical Education And Research Chandigarh, Chandigarh, India; [2]Amrita Institute of Medical Sciences and Research Centre, Kanayannur, India
Email: nipun29j@gmail.com

Background and aims: Growth hormone (GH) regulates regeneration, inflammation, and gut barrier function, which are profoundly impaired in alcohol-related hepatitis (AH). This trial evaluated the safety, feasibility, and impact of GH treatment in AH.
Method: Assessor-blinded open-label randomized trial between 2023 and 2025 at a tertiary center (CTRI/2022/12/048572). Patients with AH without malignancy, sepsis, respiratory, circulatory, or renal failure were randomized to standard medical therapy (SMT; n = 34) or GH plus SMT (n = 34). GH was given 2 U/day subcutaneously. Insulin-like growth factor 1 (IGF-1) levels above the population median were recorded. Endpoints included 90-day overall survival (primary endpoint), infection incidence, Model for End-stage Liver Disease (MELD) and Child-Turcotte-Pugh (CTP) scores, day 30 biomarkers, and plasma proteomics (analyzed through a linear mixed-effects model).
Results: Groups were comparable at baseline (median age 41.5 years, all males, 73.5% with acute-on-chronic liver failure). IGF-1 rise was more frequent with GH than SMT (85.3% vs 58.8%; p = 0.031). The GH group had higher 90-day survival (97.1% vs 82.3%; p = 0.044), fewer infections (12.2% vs 57.8%; p < 0.001), and greater improvement in 90-day MELD (beta = –0.24; p = 0.021) and CTP (beta = –0.15; p = 0.005). At day 30, GH treatment was associated with lower cytokeratin 18 (beta = –0.15; p = 0.001), lipopolysaccharide (beta = –0.20; p = 0.004), zonulin (beta = –0.49; p = 0.008), and TNF-alpha (beta = –0.32; p = 0.002), with an increase in IL-10 (beta = 0.40; p = 0.043). Proteomics showed upregulation of pathways related to epithelial barrier integrity (tight junctions, immunoglobulin A-related networks), immune regulation (phagosome function, leukocyte trafficking), cytoskeletal remodeling (Rap1 signaling, actin–myosin organization), regeneration (phosphoinositide 3-kinase-Akt, hypoxia-inducible factor 1 signaling), and modulation of complement-coagulation, ferroptosis, and cell adhesion processes. GH was well tolerated with no treatment-related serious adverse events or discontinuations.
Conclusion: In this initial trial, GH was found to be safe and feasible in AH. It was associated with improved survival, fewer infections, and biomarker and proteomic changes consistent with reduced bacterial translocation, improved intestinal integrity, and regenerative-immune remodeling. Further multicenter studies are needed to test

its efficacy in diverse settings and the mechanisms underlying its action in AH.

GS-010

Circadian disruption drives MASLD by impairing FABP5-dependent incretin secretion via gut microbial TUDCA depletion

Dekai Zheng[1], Zhixin Fang[1], Xuelian Gao[1], Changhao Cheng[1], Xun Wang[1], Ting Zhang[1], Yinghong Zhu[1], Xianhui Qin[2], Kangsen Yang[1], Yuchuan Chen[1], Routing Wang[1], Ziyan Wang[1], Zhixian Lan[1], Jian Sun[1]. *[1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Key Laboratory of Infectious Diseases Research in South China, Ministry of Education, State Key Laboratory of Multi-organ Injury Prevention and Treatment, Guangzhou, China; [2]Division of Nephrology, Nanfang Hospital, Southern Medical University, National Clinical Research Center for Kidney Disease, State Key Laboratory of Multi-organ Injury Prevention and Treatment, Guangzhou, China*
Email: doctorsunjian@qq.com

Background and aims: Circadian rhythm disruption is a potent driver of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), yet the underlying mechanisms remain unclear. We aimed to elucidate the gut-liver signaling pathways linking circadian disruption to MASLD, focusing on the microbiota, metabolites, and enteroendocrine function.
Method: Accelerometer data from 89,695 UK Biobank participants was analyzed to link circadian disruption to MASLD. A chronic jet lag (CJL) mouse model was established to mimic circadian misalignment. Metagenomics, metabolomics, and fecal microbiota transplantation (FMT) were used to identify microbial drivers. Mechanisms were dissected using drug affinity responsive target stability (DARTS), cellular thermal shift assays (CETSA), microscale thermophoresis (MST), and intestinal-specific *Fabp5* knockout mice. Clinical relevance was validated in night-shift workers and acute jet-lagged volunteers.
Results: Epidemiological analysis revealed that blunted circadian amplitude increased MASLD risk independent of genetic susceptibility. In mice, CJL exacerbated diet-induced steatohepatitis. Microbiota depletion and FMT confirmed dysbiosis causality, while metagenomics pinpointed *Lepagella muris* expansion as a key driver. Possessing intrinsic bile salt hydrolase (BSH) activity, its expansion drives enzymatic depletion of tauroursodeoxycholic acid (TUDCA). Mechanistically, we identified Fatty Acid Binding Protein 5 (FABP5) as a direct TUDCA target in enteroendocrine cells. TUDCA competitively displaces fatty acids from FABP5, increasing bioavailability to activate FFAR-mediated GIP and GLP-1 secretion. In CJL, TUDCA depletion allows FABP5 to sequester fatty acids, blunting incretin secretion and promoting metabolic dysfunction. Restoring this axis via BSH inhibitors, TUDCA supplementation, or DPP-4 inhibitors ameliorated CJL-driven MASLD. Crucially, mechanistic signatures including expanded *L. muris*, elevated BSH, TUDCA depletion, and suppressed incretins were mirrored in shift workers and jet-lagged humans. Furthermore, FMT from these donors transferred disease susceptibility to mice.
Conclusion: We identify a novel axis wherein circadian disruption promotes *L. muris*-mediated TUDCA depletion, impairing FABP5-dependent incretin secretion and driving MASLD. Targeting the BSH-TUDCA-FABP5 pathway offers a rationale for precision interventions in circadian-disrupted populations.

GS-011-YI

Underdilated TIPS strategy improves survival and reduces hepatic encephalopathy in refractory ascites: a multicenter international study

Email: fschepis@unimore.it

Background and aims: The optimal dilation strategy for transjugular intrahepatic portosystemic shunt (TIPS) placement in refractory ascites remains debated. Underdilated TIPS (≤7 mm) has been proposed to reduce overt hepatic encephalopathy (OHE), but its survival benefit remains unproven. We compared underdilated versus standard (≥8 mm) TIPS in a multicentric international study.
Method: Data of patients with cirrhosis and refractory ascites undergoing TIPS using ePTFE-covered stents between 2009 and 2025 in 11 centers of 6 countries were retrospectively collected. Primary outcomes were all-cause mortality and OHE, analyzed using Fine–Gray competing-risk models accounting for liver transplantation (mortality) and death or transplantation (OHE). A propensity score-weighted analysis was also performed to account for baseline imbalances. Secondary outcomes included ascites control (need for large-volume paracentesis, LVP) and TIPS dysfunction.
Results: The study included 1,019 patients (mean age 59 ± 10 years; 71% male); 412 (40%) received underdilated TIPS. Baseline MELD score (13.3 vs 13.2; p = 0.687) was comparable between groups. Underdilated TIPS was more frequently performed in patients with alcohol-related cirrhosis (60% vs 52%; p = 0.011) and prior episodes of OHE (23% vs 18%; p = 0.036). Median follow-up was 19 months (IQR 18 months). Underdilated TIPS was associated with a significantly lower cumulative incidence of death compared with standard TIPS

(2-year: 22% vs 27%, p = 0.001; 4-year: 30% vs. 40%; p = 0.001) and a reduced incidence of OHE (1-year: 29% vs 39%, p = 0.003). On multivariable competing-risk analysis adjusted for age, sex, MELD, etiology, PCPG reduction, and prior OHE, underdilation independently reduced the risk of death (sHR 0.74; p = 0.017) and OHE (sHR 0.68; p = 0.001). Results were consistent in propensity score-weighted sensitivity analysis. Ascites control was similar between groups, whether considering all post-TIPS LVPs (39% vs 40%; p = 0.7) or excluding early LVPs (≤30 days post-TIPS; 29% vs 32%; p = 0.3). The incidence of TIPS dysfunction did not differ between underdilated and standard strategies (13% vs 15%; p = 0.2).
Conclusion: In this large international study, underdilation TIPS strategy is associated with improved survival and a lower risk of OHE in patients with cirrhosis and refractory ascites, without impairing ascites control or increasing TIPS dysfunction. These findings support underdilated TIPS as a preferred strategy and may inform future guideline recommendations.

GS-012
Efficacy and safety of tobevibart (VIR-3434) alone or in combination with elebsiran (VIR-2218) in participants with chronic hepatitis delta virus infection: week 96 endpoint results from the phase 2 SOLSTICE trial

Email: tarik.asselah@aphp.fr

Background and aims: Hepatitis delta virus (HDV) infection is the most severe form of viral hepatitis with limited treatment options. The ongoing phase 2 SOLSTICE study is investigating the antiviral activity and safety of the monoclonal antibody tobevibart alone and in combination with the small interfering RNA (siRNA) elebsiran in participants with chronic HDV infection, with or without compensated cirrhosis, on NRTI therapy (NCT05461170).
Method: Safety and efficacy, including trends in HDV and HBV antiviral activity and biochemical markers, were assessed in participants receiving either tobevibart 300 mg plus elebsiran 200 mg subcutaneously (SC) every 4 weeks (tobevibart +elebsiran Q4W) or tobevibart 300 mg SC every 2 weeks (tobevibart Q2W) for 96 weeks.
Results: Data are summarized for all participants at week 72 and ~75% of the cohort at week 96. At week 72, HDV RNA TND (target not detected, no amplification on PCR) was achieved by 77% (24/31) and 53% (17/32) receiving tobevibart+elebsiran Q4W and tobevibart Q2W, respectively. At week 96, HDV RNA TND rates were 88% (21/24) and 46% (11/24) in the tobevibart+elebsiran Q4W and tobevibart Q2W cohorts, respectively. ALT normalized in 55% (17/31) and 69% (22/32) receiving tobevibart+elebsiran Q4W and tobevibart Q2W at week 72, and at week 96, rates were 54% (13/24) and 58% (14/24), respectively. At week 72, 94% of tobevibart+elebsiran Q4W and 19% of tobevibart Q2W participants had HBsAg <10 IU/mL and rates remained similar at week 96. Treatment-emergent adverse events were primarily Grade 1–2, transient, with the most common being influenza-like syndrome occurring with the first dose and generally resolving within 24–48 hrs in both treatment groups. No treatment-related serious adverse events occurred. Seven participants receiving tobevibart +elebsiran Q4W and eight participants receiving tobevibart Q2W have not yet reached the week 96 visits but remain on treatment. Full cohort data through week 96 will be presented.
Conclusion: Participants receiving tobevibart+elebsiran Q4W showed numerically greater rates of HDV RNA TND and HBsAg <10 IU/mL, at weeks 72 and 96 than those receiving tobevibart Q2W. TND rates increased over time with combination therapy, while rates plateaued with monotherapy. Adverse events were generally mild to moderate and transient. These results support further development of tobevibart+elebsiran Q4W, which is now being evaluated in the phase 3 ECLIPSE program for chronic HDV infection.

Late breakers oral session

Email: rvuppala@iu.edu

Background and aims: Saroglitazar, a dual PPARα/γ agonist, improved serum alkaline phosphatase (ALP) in patients with primary biliary cholangitis (PBC) in a phase 2a study. We conducted a phase2b/3 study of saroglitazar in patients with PBC who had an inadequate response to or intolerance to ursodeoxycholic acid (UDCA).
Method: EPICS-III is a phase 2b/3 adaptive, double-blind, randomized control trial to evaluate saroglitazar in patients with PBC who had an inadequate response to or intolerance to UDCA. The phase 2b dose-finding portion included 37 participants who received placebo or saroglitazar magnesium 1 mg or 2 mg for 16 weeks. Based on its results, saroglitazar magnesium 1 mg (0.97 mg of saroglitazar) was selected for phase 3, which randomized 148 patients to saroglitazar (n = 97) or placebo (n = 51) for 52 weeks. *The p*rimary endpoint was the biochemical response at week 52, defined as (ALP) <1.67 × ULN, with at least a 15% reduction from baseline, and total bilirubin below ULN. The key secondary endpoint was ALP normalization at week 52.
Results: Baseline characteristics between the two groups in phase 3 were comparable, except for higher baseline ALP and other liver biochemistries in the saroglitazar group. Biochemical response was achieved in 56.7% with saroglitazar compared to 9.8% with placebo (difference, 48.0%; 95% CI, 35.3 to 60.8; p < 0.001). In participants with baseline ALP ≤3 × ULN, biochemical response was 83.1% (49/59) and 14.7% (5/34), respectively. ALP normalization occurred in 8.2% of patients with saroglitazar versus 0% with placebo (difference, 8.5%;

95% CI, 2.9 to 14; p = 0.016), with improvements in ALP levels observed as early as 2 weeks. In participants with moderate-to-severe pruritus, saroglitazar showed greater improvement in pruritus than placebo at week 24 with a treatment difference of −3.2 (95% CI, −5.66 to −0.82; P = 0.009). Adverse events (AE) were reported in 81.1% with saroglitazar versus 90.5% with placebo, and serious adverse events occurred in 6.3% and 11.1%, respectively. Four participants with saroglitazar and 1 participant with placebo reported fractures as AEs. Saroglitazar was not associated with significant weight gain, DILI, renal dysfunction, or increased CPK.
Conclusion: In this Phase2b/3 EPICS III program, saroglitazar significantly improved biochemical response and ALP normalization in individuals with PBC who had an inadequate response to or intolerance to UDCA. Saroglitazar is an effective second line therapy for PBC.

Email: jfdez@clinic.cat

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by organ failure(s) and high short-term mortality. Liver transplantation (LT) is currently the only life-saving treatment, and therapies to increase survival remain an unmet need. This pivotal trial evaluated the efficacy and safety of high-volume plasma exchange with Albutein 5%® (PE-A5%) in patients with ACLF grade 1b, 2, or 3a (EASL-CLIF criteria).
Method: APACHE was a phase 3, multicenter, randomized, controlled, parallel-group, open-label trial (NCT03702920). Patients were randomized to standard medical treatment (SMT)+PE-A5% or SMT alone. PE-A5% consisted of 2 sessions on consecutive days followed by sessions every other day for a min. of 4 to a max. of 9 sessions depending on clinical response. The primary endpoint was 90-day overall survival (OS) with censoring on LT. Secondary and exploratory endpoints included 90-day transplant-free survival (TFS), 28-day OS, and ACLF grade subgroup analyses. Safety assessments included treatment-emergent adverse events (TEAEs), suspected adverse drug reactions (SADRs) and adverse reactions (ARs).
Results: The study was terminated early for non-clinical reasons at 72% of target patient randomization with 274 patients randomized to SMT+PE-A5% (n = 135) or SMT (n = 139) in 29 centers worldwide. Baseline characteristics were balanced. Median PE sessions in the SMT+PE-A5% group were 4. SMT+PE-A5% significantly increased 90-day OS compared to SMT (Hazard Ratio [HR] [95% CI] = 0.65 [0.45, 0.94]; p = 0.021). 90-day OS HR [95% CI] for ACLF grade 1b, 2, and 3a subgroups were 0.73 [0.27, 2.02], 0.55 [0.34, 0.90], and 0.83 [0.43, 1.59], respectively. For 90-day TFS, 36 LTs and 51 deaths occurred in the SMT+PE-A5% group compared with 20 LTs and 69 deaths in the SMT group with a HR [95% CI] of 0.83 [0.62, 1.12], p = 0.22. 28-day OS HR [95% CI] was 0.67 [0.44, 1.01], p = 0.06. Total TEAEs were more frequent in SMT+PE-A5% group, consistent with known PE side effects; however, TEAEs resulting in death were similar between groups (SMT+PE-A5%: 12 in 9 (7.0%) patients; SMT: 11 in 10 (7.2%) patients). SADRs or ARs to Albutein 5% occurred in <5% of SMT+PE-A5% patients.
Conclusion: SMT+PE-A5% significantly increased 90-day OS compared to SMT in ACLF patients with a numerically greater benefit in ACLF grade 2. TEAEs reflected known safety risks for PE-A5% in ACLF patients. APACHE demonstrates a favorable benefit-risk profile for treatment of ACLF patients with SMT+PE-A5%.

LBO-003

Tune-401: a first-in-class epigenetic silencer of HBV demonstrates deep and durable antiviral activity in the phase 1b/2a proof of concept Tune-401-001 study

Edward J. Gane[1,2], Alina Jucov[3,4], Kendra Congdon[5], Brian Cosgrove[5], Rickey Reinhardt[5], Oluwatobi Olorunyomi[5], Derek Jantz[5], Heidi Zhang[5], John McHutchison[5], Christian Schwabe[6], Kosh Agarwal[7], Man-Fung Yuen[8]. *[1]The University of Auckland, Auckland, New Zealand; [2]New Zealand Liver Transplant Unit, Auckland City Hospital, Auckland, New Zealand; [3]Arensia Exploratory Medicine GmbH, Dusseldorf, Germany; [4]Nicolae Testemitanu State University of Medicine and Pharmacy, Chişinău, Moldova; [5]Tune Therapeutics, Durham, United States; [6]New Zealand Clinical Research, Auckland, New Zealand; [7]Institute of Liver Studies, Kings College Hospital, London, United Kingdom; [8]Queen Mary Hospital, The University of Hong Kong, Hong Kong, China*
Email: edgane@adhb.govt.nz

Background and aims: Tune-401 is a first-in-class epigenetic silencing therapy designed to shut down HBV by directly targeting and silencing both covalently closed circular DNA (cccDNA) and integrated HBV DNA sequences. mRNA encoding an epigenetic silencing protein and guideRNA targeting the HBV genome are delivered intravenously within lipid nanoparticles to hepatocytes. The ongoing Phase 1b/2a Tune-401-001 study is evaluating safety, pharmacokinetics, and pharmacodynamics in patients with chronic hepatitis B (CHB).
Method: Twenty-one CHB patients on nucleos(t)ide therapy (12 HBeAg-negative; 9 HBeAg-positive) have been enrolled. Four single-dose cohorts received either 0.2 mg/kg, 0.45 mg/kg, 0.65 mg/kg, or 0.85 mg/kg (N = 2/6/3/3). An additional multi-dose cohort received three doses of 0.65 mg/kg at approximately 4-week intervals (N = 7).

Primary endpoints are safety and tolerability, with assessment of quantitative serum pgRNA, HBeAg, HBcrAg, and HBsAg. Cohort baseline characteristics for 0.2/0.45/0.65/0.85 mg/kg and multi-dose cohort were: % female 0/50/33/67/14; median age 51/50/51/45/47 years; mean qHBsAg 3.60/3.03/3.11/3.04/3.36 $\log_{10}$ IU/mL.
Results: Tune-401 was generally safe and well tolerated. Most adverse events (AEs) were transient and resolved within two weeks. The most common AEs were infusion-related reactions (Grade 1/2/3, n = 14/6/2). Transient ALT/AST elevations were predominantly mild (Grade 2/3, n = 5/3). Dose-dependent antiviral activity that has been maintained over time has been observed. At 20 weeks post a single dose, mean HBsAg reductions from pre-dose baseline were 29.6% in the 0.45 mg/kg cohort and 54.0% in the 0.65 mg/kg cohort. Multiple patients achieved durable >95% reductions in pgRNA levels and >99% reductions in HBcrAg levels, indicating direct cccDNA silencing. Furthermore, 3/10 patients in the 0.65 mg/kg cohorts achieved pgRNA and HBcrAg biomarker negativity. Two participants (0.85 mg/kg cohort) achieved HBeAg loss with one seroconversion. Preliminary results from the multiple dosing cohort suggest increases in antiviral efficacy from additional doses with no additional safety concerns.
Conclusion: This study provides the first clinical results from targeted epigenetic silencing of HBV with evidence of direct cccDNA repression. The favorable emerging safety profile and deep, durable antiviral activity support continued development of Tune-401 into Ph2 to define the optimal, maximally efficacious dosing regimen to achieve HBV cure.

Safety, pharmacokinetics, and clinical activity of HRX215 after hepatectomy due to colon carcinoma metastases: interim results from pilot cohort of a 1b/2a clinical trial
Patrick Starlinger[1], Rory L. Smoot[1], Susanne Warner[1], Scott Nyberg[1], Lars Zender[2], Hedda Wold[3], Tillmann Taube[3], Wolfgang Albrecht[3], Elias Papatheodorou[3], Linda Greenbaum[3,4]. Email: starlinger.patrick@mayo.edu

Background and aims: Insufficient future liver remnant (FLR) associated risk for post-hepatectomy liver failure (PHLF) represents the major source of morbidity and mortality after liver resection and is the main cause of technical inoperability in patients with colorectal cancer liver metastasis (CRCLM). HRX215 is a potent and selective oral inhibitor of the dual-specific protein kinase mitogen-activated protein kinase kinase 4 (MKK4) and represents the first ever targeted therapy with potential to improve liver regeneration and thereby reduce PHLF risk in patients undergoing hepatectomy. The aim of the study is to assess the safety, pharmacokinetics and efficacy of HRX215 in patients undergoing liver resection for CRCLM.
Method: This phase 1b/2a study consists of two open label (OL) pilot parts (phase 1b) followed by a randomized placebo controlled phase 2a. Safety, pharmacokinetic and liver volume data are available for five participants undergoing minor liver resection for CRCLM who have been enrolled in the first OL pilot part.
Results: Percent liver resection ranged from 2–30%. Four SAEs were reported in study participants, none of which were considered to be causally related to HRX-215. Other reported adverse events (AEs) were mostly mild or moderate (CTCAE severity grade 1–2). No PHLF events were observed. Full recovery of liver volume (measured by MRI) and function as measured by INR and total bilirubin was achieved by postoperative day 7 for all 5 patients. Pharmacokinetic analysis demonstrated HRX215 plasma concentration-time profiles similar to healthy participants. Liver volumes remained at similar levels at the end of the 28 day treatment period and during the ongoing 6 month safety follow up period.
Conclusion: HRX215 was well tolerated in participants undergoing minor liver resection for CRCLM, with safety profile consistent with expected AEs in this patient population and comparable pharmacokinetics to healthy participants. Rapid restoration of liver volume and liver function was observed in all 5 participants. The potential for HRX215 to accelerate liver volume recovery in participants undergoing more extensive liver resections will be investigated in the next phases of the study.

Background and aims: Cellular senescence, a stress-induced program characterized by stable nncell-cycle arrest, is a hallmark of aging and a key driver of liver inflammation and fibrosis. Senolytic agents that selectively eliminate senescent cells may modify or reverse key features of metabolic dysfunction–associated steatohepatitis (MASH). Dasatinib plus quercetin (D+Q) is a candidate senolytic therapy for fibrotic MASH. Here, we report a phase 2 double-blind randomized controlled trial evaluating the efficacy and safety of D+Q in patients with fibrotic MASH.
Method: Patients with biopsy-confirmed fibrotic MASH (F2–F3) were randomized (1:1) to receive intermittent D+Q (dasatinib 100 mg/day, quercetin 1000 mg/day) for 3 consecutive days per week for 3 weeks, followed by a 4-week drug-free period, or matching placebo; this 7-week cycle was repeated three times. The primary endpoint was ≥1-stage fibrosis improvement without worsening of MASH, assessed by liver histology using the SAF (Steatosis–Activity–Fibrosis) score on paired biopsies obtained at baseline and end of treatment. All biopsies were centrally scored by three independent pathologists blinded to timepoint and treatment allocation. Efficacy was analysed by intention-to-treat using a chi-squared test. Secondary endpoints included MASH resolution and safety.
Results: A total of 31 patients were randomized (median age 56 years [IQR 47–62.5]; 76% male; Type 2 Diabetes 58%); 17 received D+Q and 14 placebo. There were 4 discontinuations, D+Q (n = 3), placebo (n = 1). Improvement of fibrosis without worsening of MASH was achieved in 8 (47%) patients in the D+Q group vs. 1 (7%) with placebo (p = 0.041). Resolution of MASH occurred in 71% of patients receiving D+Q compared with 15% receiving placebo (p = 0.011). Improvement of the NAFLD Activity Score (NAS) was better with D+Q (−1.43 ± 1.22 vs. −0.39 ± 0.77; p = 0.012). In the D+Q group, 14/17 participants reported adverse events (AE) compared to 6 with placebo. Most reported side effects of D+Q were headache and gastrointestinal complaints. Reported severity of these AEs was mild or moderate and all AEs were resolved without intervention.

Conclusion: Intermittent senolytic treatment with D+Q significantly improved fibrosis and resolved MASH in fibrotic MASH with a favourable safety profile. Our data suggest that senescence drives fibrotic MASH and may be reversible with pharmacological intervention. These findings need confirmation in larger trials with longer follow-up. Clinical trial number NCT05506488.

LBO-006

Efficacy and safety of volixibat, an IBAT inhibitor, in patients with primary sclerosing cholangitis and moderate-to-severe pruritus: results of the VISTAS trial

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholangiopathy frequently accompanied by severe cholestatic pruritus and fatigue, leading to substantial impairment in quality of life. No approved pharmacologic treatments are available. Volixibat (VLX) is a minimally absorbed ileal bile acid transporter (IBAT) inhibitor that interrupts the enterohepatic bile acid recirculation, reducing the total bile acid pool, a mechanism implicated in cholestatic pruritus. VISTAS is a 28-week, multicenter, randomized, double-blind, placebo (PBO)-controlled, pivotal study which evaluated the efficacy and safety of VLX for pruritus in PSC. Here we report

an overview of the trial design and baseline characteristics; topline results will be available at the time of presentation.
Method: Following a dose-selection period with a blinded interim analysis, the confirmatory portion of the study evaluated oral VLX 20 mg BID versus PBO in patients with PSC. Eligible participants with moderate-to-severe pruritus (based on a score of ≥4 on a 0–10 numerical rating scale [Adult ItchRO]) were selected for primary endpoint analysis. Primary endpoint was defined as change from baseline (CFB) in worst itch over 28 weeks. Key secondary endpoints included CFB through 28 weeks of: serum bile acid (sBA); PROMIS Fatigue and Sleep Disturbance; proportion of responders with ≥2-point reduction in Adult ItchRO. Safety endpoints included adverse event reporting and laboratory measurements.
Results: In total, 132 participants were eligible for primary endpoint analysis and were randomized to receive either VLX or PBO. At baseline, 47.7% were male, mean (SD) age at enrolment was 43.5 (14.7) years, 90.2% had large-duct, and 9.8% small-duct PSC. 72% had inflammatory bowel disease (IBD); among these, 72.6% had ulcerative colitis, 25.3% Crohn's disease, and 2.1% had unclassified IBD types. Additional baseline characteristics (mean [SD]) included: Adult ItchRO (6.2 [1.5]), sBA (μmol/L; 41.8 [30.0]), ALP (U/L: 357.7 [225.7]), AST (U/L: 68.2 [39.0]), ALT (U/L: 82.1 [55.2]), TB (mg/dL: 10.8 [13.3]) and DB (mg/dL: 5.9 [8.9]). Results for the primary endpoint, key secondary endpoints, and safety will be presented at the congress as the trial was ongoing at the time of abstract submission.
Conclusion: VISTAS is the largest interventional study investigating the efficacy and safety of an IBAT inhibitor in PSC. The results will represent the first controlled evidence of a potential therapy addressing the symptom burden in PSC patients.

Hepatocyte biology and fibrosis

OS-001-YI
Vascularized liver spheroid-on-chip with liver specific vascular cells

Negar Vahdani[1,2,3], Karin Schmid[1,3], Keely Keller[4], Deborah Stroka[4], Olivier Guenat[1,2]. *[1]Organs-on-Chip Technologies Lab, ARTORG Center, Medical Faculty, University of Bern, Bern, Switzerland; [2]Multidisciplinary Center for Infectious Diseases, Medical Faculty, University of Bern, Bern, Switzerland; [3]Graduate School for Cellular and Biomedical Sciences, Medical Faculty, University of Bern, Bern, Switzerland; [4]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland*
Email: negar.vahdani@unibe.ch

Background and aims: *In vitro* liver models have evolved from 2D monocultures to advanced 3D spheroid and organoid models; however, most existing models lack a functional microvasculature and rely on passive diffusion for oxygen and nutrient delivery. This limitation restricts hepatocyte metabolic activity, functional stability, and long-term culture and does not reflect the highly vascularised nature of the liver. Recent advances in organs-on-chip technology offer a promising strategy for developing perfused, vascularized liver spheroid models. The aim of this study is to develop and characterize a perfused, vascularized liver spheroid-on-chip that enhances hepatocyte functionality.
Method: An open-top microfluidic device was designed with a central chamber to support the formation of a self-assembled microvasculature and the subsequent vascularization of liver spheroids. Liver spheroids were generated by co-culturing primary human hepatocytes (PHH) with human stellate cells (HSCs) and liver sinusoidal endothelial cells (LSECs) and were assessed for albumin secretion, urea production, and CYP3A4 activity. Self-assembled LSECs and HSCs microvasculature were analyzed for vascular morphology, perfusability and permeability. Liver spheroids were transferred onto the microvascular network and fixed for immunostaining after vascularization.
Results: Liver spheroids were generated by co-culturing PHH, HSC, and LSECs cells in 2:1:1 ratio, resulting in spheroids with diameters of 200–250 μm. Compared with PHH monoculture spheroids, co-culture spheroids exhibited increased sphericity and significantly higher albumin secretion and CYP3A4 activity. The self-assembled microvasculature formed connected, perfusable and permeable network. Finally, the spheroids were transferred into a fibrin gel on the microvasculature bed on chip and fixed after 4 days in culture. Immunofluorescent staining showed integration of the vascular network with the spheroids, with vessels extending into the spheroids.
Conclusion: This study successfully developed a vascularized liver-on-chip by integrating co-cultured liver spheroids with a self-assembled microvasculature. The liver spheroids maintained metabolic activity, as evidenced by albumin, urea, and CYP3A4 expression, while the microvasculature exhibited perfusable vessel formation. This model addresses the lack of functioning microvasculature in spheroids and holds promise for advancing translational hepatology research by providing a more physiologically relevant environment.

OS-002-YI
Hepatocyte lipolytic disruption by ATGL-deficiency contributes to MASH-fibrosis via lipotoxic stress in vivo: molecular and single-cell transcriptomic insights

Henriette Horstmeier[1], Tanmoy Chakma[1], Katharina Bonitz[2,3], Thomas Sorz-Nechay[2,3], Katja Sommer[4], Vlad Taru[2], Robert Brettner[1], Hubert Scharnagl[4], Veronica Moreno-Viedma[1], Veronika Mlitz[1], Claudia Fuchs[1], Philipp Schwabl[1,2,4], Thomas Reiberger[2,3], Michael Trauner[1]. *[1]Hans Popper Laboratory of Molecular Hepatology, Medical University of Vienna, Vienna, Austria; [2]Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, Vienna, Austria; [4]Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria*
Email: henriette.horstmeier@meduniwien.ac.at

Background and aims: Adipose triglyceride lipase (ATGL/PNPLA2) is the key lipase hydrolysing intracellular triglycerides to glycerol and free fatty acids and thereby regulating hepatic energy balance, and cellular crosstalk. However, the role of ATGL-mediated lipolysis as potential disease modulator via impact on liver fibrosis and portal pressure (PP) remains unclear.
Method: Metabolic dysfunction-associated steatohepatitis (MASH)-fibrosis was induced in hepatocyte-specific ATGL knockout ($Pnpla2^{fl/fl}$Alb-Cre^{+}) mice and controls ($Pnpla2^{fl/fl}$Alb-Cre^{-}) by feeding of a choline-deficient, aminoacid-defined high-fat diet (CDAHFD) or a matched control diet for 12 weeks. PP was measured invasively; fibrosis severity was assessed by serum biochemistry and histology and the liver immunophenotype was profiled by flow cytometry. In a sub-cohort (n = 4/group), hepatocytes (HC), cholangiocytes and non-parenchymal liver cells were isolated before pooling and scRNA-seq using the 10x Chromium Flex platform.
Results: Hepatocyte-specific ATGL knockout (HepATGL-KO) under CDAHFD resulted in hepatocyte lipid loading, reflected by increased liver-to-bodyweight ratio [7.25 ± 0.37 vs. 13.59 ± 0.64%; p < 0.001] and reduced serum FFA levels [0.52 ± 0.04 vs. 0.39 ± 0.03 mmol/L; p = 0.018]. Moreover, HepATGL-KO aggravated fibrosis [collagen proportionate area, CPA: 2.17 ± 0.31 vs. 4.35 ± 0.55%; p = 0.002] and increased PP [6.64 ± 0.24 vs. 7.63 ± 0.30 mmHg; p = 0.028], spleen-to-bodyweight ratio [0.47 ± 0.03 vs. 0.56 ± 0.19%; p = 0.02] and liver

injury [AST: 279 ± 23 vs. 429 ± 35 U/L; $p < 0.001$]. The generated scRNA-seq dataset of 101490 hepatic cells supported by flow cytometry indicated the strongest transcriptomic changes within HC and macrophages. Besides a shift in macrophage identity towards lipid-associated macrophages (LAM), pseudo-bulking analysis of HepATGL-deficient HC subclusters in MASH revealed a lipid-stress response characterized by *Scd1, Lpl* and *Orm3*. Moreover, upregulation of *Col3a1, Col4a3* and *Acta2* supported enhanced profibrotic remodelling in HepATGL-KO.

Conclusion: Our data underlines the crucial role for ATGL as key contributor to MASH-fibrosis, since hepatocyte-loss of ATGL aggravates liver injury, fibrosis and portal hypertension. In our scRNA-seq dataset, ATGL-KO in hepatocytes show disrupted hepatocyte lipid handling and lipotoxic stress which in turn seem to impact HC-LAM crosstalk and cause downstream pro-fibrotic remodelling.

OS-003

A single-cell fixed RNA profiling uncovers key transcriptional and signalling programs in liver fibrosis progression and regression

Le Thi Thanh Thuy[1], Pham Minh Duc[2], Hoang Hai[1], Norifumi Kawada[3]. [1]*Department of Global Education and Medical Sciences, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan, Osaka, Japan;* [2]*Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan, Osaka, Japan;* [3]*Endowsed Departments of Liver Cancer Treatment and Homeostatic Regulation, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan, Osaka, Japan*
Email: thuy@omu.ac.jp

Background and aims: Single-cell fixed RNA profiling (FLEX) is a novel technique that captures RNA expression in frozen tissues at a single-cell resolution. We applied FLEX to mouse model of liver fibrosis progression and regression to identify novel anti-fibrotic targets.

Method: Mice were administered intraperitoneal thioacetamide (TAA) for 10 weeks to induce fibrosis, and regression was assessed 2 weeks after cessation. The livers were fixed, dissociated, and analysed using FLEX. Molecular validation included immunoblotting, immunohistochemistry, gene silencing/overexpression, cytokine/phosphokinase arrays, and human liver samples.

Results: Approximately 40,000 liver cells were profiled, integrated, and annotated into 10 major cell types using lineage-specific markers. Pericentral signature restoration in hepatocytes, scar-resolving genes (Mmp14 and Ctsl), fenestrae restoration in liver sinusoidal endothelial cells, anti-inflammatory Kupffer cells, reduced fibrogenic cholangiocytes, and recovery-associated immune cell subsets were observed. During fibrosis, monocyte-derived macrophages secrete semaphorin-4D (SEMA4D), which binds to Plexin B2 on hepatic stellate cells (HSCs). SEMA4D$^+$ cells were upregulated in mouse and human fibrotic livers. Recombinant SEMA4D induces type I collagen in HSCs, whereas humanised monoclonal IgG4 SEMA4D blockade (VX15/2503) attenuates fibrosis *in vivo*. LIM and cysteine-rich domains 1 (LMCD1) was enriched in fibrotic HSCs and suppressed during regression. LMCD1 knockdown reduced the expression of fibrotic protein, while LMCD1 overexpression promoted the expression of fibrotic protein via AKT/mTOR signalling. LMCD1 and SEMA4D are localised in the fibrotic septa and are correlated with the fibrotic stage in humans.

Conclusion: This FLEX-based single-cell atlas revealed critical transcriptional programs and cell-cell interactions, identifying SEMA4D and LMCD1 as promising therapeutic targets for liver fibrosis.

Email: fcolell2@ed.ac.uk

Background and aims: Regardless of cause, chronic liver disease (CLD) is characterised by progressive fibrosis which can drive poor clinical outcomes. Monocyte-derived macrophages (MDMs) play a central role in both the progression and resolution of liver fibrosis and represent a promising target for antifibrotic therapies. Recent work has identified TREM2$^+$CD9$^+$ MDMs, termed scar-associated macrophages (SAMac), as the key human MDM population regulating fibrosis. However, it remains unknown how to specifically target SAMac to inhibit their pro-inflammatory pro-fibrotic properties across different causes of CLD.

Method: Human liver single-cell RNA-sequencing (scRNAseq) data from 77 patients (42 healthy, 35 CLD) were analysed. Human liver spatial proteomics was performed using a 34-plex antibody panel on the PhenoCycler-Fusion. Deconvolution of liver bulk RNA-seq data from different CLD aetiologies and stages was carried out using BayesPrism. Mouse CLD was induced by chronic CCl4 or bile duct ligation (BDL). OLR1 modulation was performed on human cells using RNA interference or antibody blockade via MEDI6570.

Results: ScRNAseq identified a distinct CLD-enriched cluster of OLR1$^+$ SAMac with a pro-inflammatory pro-fibrotic gene expression profile. Spatial proteomics confirmed expansion of OLR1$^+$ SAMac in CLD which mapped to areas of fibrosis. Bulk RNA-seq data demonstrated a significant upregulation of OLR1 and expansion of OLR1$^+$ SAMac with histological fibrosis stage across MASLD, ALD, PSC and PBC patients. Expansion of OLR1$^+$ SAMac was further confirmed in the CCl_4 and BDL models of CLD. In primary human MDMs, *OLR1* and *IL1B* expression showed a strong positive correlation across 67 stimulation conditions, suggesting a pro-inflammatory role. Functionally, silencing of OLR1 reduced *IL1B* expression in both THP-1 and primary human MDMs. Co-culture assays demonstrated that OLR1 silencing or blockade in MDMs reduced *COL1A1* and *COL3A1* expression in hepatic stellate cells. Furthermore, OLR1 silencing in multilineage human liver spheroids significantly attenuated fibrillar collagen gene and protein expression.

Conclusion: These data identify OLR1 as a regulator of SAMac phenotype in CLD and highlight the potential of OLR1 blockade as a novel anti-inflammatory antifibrotic therapy. Crucially, OLR1$^+$ SAMacs accumulate across multiple aetiologies of CLD, suggesting that targeting OLR1 could have broad applicability to CLD patients.

OS-005-YI

Plasma cell-free DNA fragmentomics for non-invasive detection of hepatocellular carcinoma (HCC) in chronic liver disease (CLD)

Venkata Ramana Mallela[1], Sultan N. Alharbi[1], Mathew Vithayathil[1], Giulia Manfredi[2], Rosalba Minisini[2], David J. Pinato[3], Rishi Patel[4], Rohini Sharma[1]. [1]*Division of Surgery and Cancer, Imperial College London, Hammersmith Hospital, London, United Kingdom;* [2]*Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy;* [3]*Division of Surgery and Cancer, Imperial College London, Hammersmith Hospital, Department of Translational Medicine, Division of Oncology,*

University of Eastern Piedmont, London, United Kingdom; [4]Eastman Dental School, University College London, London, WC1E 6DE, UK, London, United Kingdom
Email: v.mallela24@imperial.ac.uk

Background and aims: Early detection of hepatocellular carcinoma (HCC) remains difficult in patients with chronic liver disease (CLD undergoing surveillance. Plasma cell-free DNA (cfDNA) fragmentomics, which reflects genome-wide fragmentation patterns influenced by chromatin organisation and nuclease activity, represents a promising non-invasive biomarker. This study aimed to characterise cfDNA fragmentomic differences across healthy controls (HC), CLD, and HCC, and to develop a machine learning model to distinguish these conditions.
Method: A total of 700 participants were included. Plasma cfDNA from 475 individuals (HCC, n = 139; CLD, n = 186; HC, n = 150) in the training cohort underwent shallow whole-genome sequencing. In the training set, CLD etiologies were mainly attributed to alcohol (n = 42), HCV (n = 32), autoimmune liver disease (n = 30), MASLD (n = 24), HBV (n = 19), other causes, n = 3; or unknown etiologies (n = 36), with participants recruited from the United Kingdom and Italy. External validation included 225 participants (HCC, n = 75; CLD, n = 75; HC, n = 75), with CLD predominantly due to viral hepatitis and cirrhosis, including HBV (n = 26) and cirrhosis (n = 49). Fragmentomic features, including genome-wide fragmentation profiles, tumor fraction, fragment size distributions, end-motif frequencies, and mitochondrial cfDNA content, were extracted and integrated using ensemble machine learning models.
Results: HCC exhibited a distinct multidimensional fragmentomic profile compared with CLD and HC. Genome-wide fragmentation scores, tumour fraction, and mitochondrial cfDNA levels were significantly higher in HCC (all $p < 0.0001$). Short cfDNA fragments (<150 bp) were enriched in HCC, minimal in HC, and intermediate in CLD. End-motif analysis demonstrated progressive disease-related changes, with GC- and adenine-rich motifs in HC, thymine-rich motifs in CLD, and tumour-associated GC-rich cleavage patterns in HCC. In external validation, the classifier showed moderate discrimination between HCC and CLD (AUC 0.724) and strong discrimination between CLD and HC (AUC 0.935).
Conclusion: Plasma cfDNA fragmentomics identifies robust biological differences across the liver disease spectrum and enables accurate non-invasive detection of HCC. Integration of multiple fragmentomic features using machine learning supports improved surveillance strategies in at-risk populations and warrants validation in larger prospective cohorts.

Email: hofihelgad@gmail.com

Background and aims: Predicting liver transplantation or death in primary sclerosing cholangitis (PSC) is challenging due to its heterogeneous course and complex pathogenesis, hindering the design of effective follow-up strategies and clinical trials. We aimed to determine whether a multi-biomarker model, integrating markers of fibrosis, extracellular matrix turnover, inflammation, and microbial metabolism, could improve risk prediction beyond single markers or clinical scores.
Method: We assembled a large cross-sectional PSC cohort from Norway, Sweden and the United States and analyzed biomarkers in frozen serum samples. Prediction models for two and five year liver transplantation-free survival were created using multivariable Cox regression analysis. A full model included eight biomarkers: enhanced liver fibrosis (ELF) test, type III and V collagen formation (PRO-C3, PRO-C5), degradation of type III and IV collagen (C3M, C4M), kynurenine-tryptophan ratio (KTR), neopterin, and pyridoxal 5′-phosphate (PLP). Internal validation and subset-fitting assessed overfitting and generalizability across regions, we compared pragmatic subset models with the full model, and benchmarked all models against the ELF test and established PSC risk scores.
Results: We included 906 PSC patients (64% male, 79% with inflammatory bowel disease, 57% on ursodeoxycholic acid). Median age at sampling was 47 years (IQR 34–60) and half were followed for at least seven years. At two and five years, 12% and 23%, respectively, reached the composite endpoint of liver transplantation or death. On internal validation of the full model, the optimism-corrected C-index was 0.834 (IQR 0.832–0.836) and 0.822 (IQR 0.821–0.822) at two and five years, with corresponding calibration slopes of 0.880 and 0.916. A pragmatic model of ELF, KTR and PLP had a C-index of 0.817 at five years and an improved calibration slope (0.970 vs. 0.917 for the full model). Both models outperformed the ELF-only model (C-index 0.79, calibration slope 0.99) and provided incremental predictive value beyond the Amsterdam-Oxford PSC model and the PSC Risk Estimate Tool.
Conclusion: Our models showed strong discrimination and good calibration. A pragmatic model, capturing fibrosis, inflammation and gut microbial metabolism, achieved predictive performance comparable to the full model. Both models outperformed the ELF test and clinical scores. These findings provide proof-of-principle that integrating markers of distinct disease processes can improve risk prediction in PSC.

Background and aims: Currently no pharmacological therapy is approved for the treatment of primary sclerosing cholangitis (PSC) in most countries. Recently, norucholic acid (NCA) demonstrated superiority over placebo (PBO) in a phase 3 pivotal trial (NUC-5) in PSC that included patients with and without concomitant UDCA as background therapy. The efficacy of NCA in these two cohorts is compared in this subgroup analysis.
Method: NUC-5 was a 192-week double-blind trial investigating 1,500 mg NCA versus PBO once daily in adults with PSC. Inclusion criteria included alkaline phosphatase (ALP) levels ≥1.5-fold upper limit of normal (ULN). Patients on a stable dose of UDCA (≤20 mg/kg body weight/day) for at least 8 weeks prior to baseline could maintain their UDCA regimen throughout the trial. The primary analysis was performed after 96 weeks, with the primary combined endpoint of no worsening in histological disease stage by Ludwig classification plus partial normalization of ALP to <1.5-fold ULN. Secondary endpoints included histological, biochemical, and safety parameters.
Results: Within the full analysis set, 77.1% of NCA and 81.3% of PBO patients took background UDCA, respectively (NCA+UDCA n = 158, PBO+UDCA n = 78, NCA alone n = 47, PBO alone n = 18). Most baseline characteristics were balanced between the subgroups except for ALP levels (NCA+UDCA: 359 U/l, PBO+UDCA: 324 U/l, NCA alone: 373 U/l, PBO alone: 467 U/l). At the primary analysis, 12.7% of NCA patients and 5.1% of PBO patients taking UDCA achieved the primary endpoint ($p = 0.08$) compared with 23.4% and 0% without UDCA ($p < 0.001$), respectively. Improvement in Ludwig histologic disease stage was observed for 23.4% of NCA+UDCA vs. 11.9% of PBO+UDCA patients ($p = 0.18$), compared with 30.3% of patients with NCA alone vs. 6.7% with PBO alone ($p = 0.13$) among patients with paired biopsies. Partial normalization of ALP was more frequent with NCA monotherapy (NCA alone: 25.5%, PBO alone: 5.6%, $p = 0.10$; NCA+UDCA: 18.4%, PBO+UDCA: 15.4%, $p = 0.51$) as was a 40% reduction in ALP from baseline (NCA alone: 31.9%, PBO alone: 0%, $p < 0.001$; NCA+UDCA: 14.6%, PBO+UDCA: 11.5%, $p = 0.50$). Adverse events were generally balanced between NCA patients with and without UDCA.
Conclusion: Treatment with NCA led to improvement in histologic and biochemical outcomes both with and without concomitant UDCA. Co-therapy with NCA plus UDCA was tolerated as well as NCA monotherapy. Higher rates of improvement were observed across all parameters in patients without concomitant UDCA as background therapy.

OS-008

Latest liver stiffness best predicts long-term outcomes in autoimmune hepatitis undergoing serial assessment: a large multicentre cohort study from canal

Email: wongyujun1985@gmail.com

Background and aims: While liver stiffness measurements (LSM) are widely used for monitoring and prognostication in chronic liver disease, their dynamic prognostic value in autoimmune hepatitis (AIH) remains controversial. We assessed whether dynamic changes in LSM improve the prediction of liver-related events (LRE) in treated AIH.
Method: We analyzed the multicentre Canadian Network for Autoimmune Liver Disease (CaNAL) registry, including AIH patients diagnosed (2010–2025) across 13 Canadian centres, who underwent serial LSMs after diagnosis and treatment. Patients with hepatic decompensation (HD) before LSM, unreliable LSM or LSM<6 months of diagnosis, prior liver transplantation (LT), or follow-up<6 months were excluded. Using a landmark approach, we compare the

prognostic performance of baseline LSM (LSM1, ≥6 months after AIH diagnosis) and the *most recent LSM* (LSMc), to predict the occurrence of HD and LRE (HD, HCC, LT & death) using Cox regression analysis.
Results: Among 523 patients who underwent serial LSMs (median age 46 years, 16% with advanced disease(cACLD) suggested by LSM1≥15 kPa); median LSM decreased from 11.0 kPa (IQR:7–11) to 7.9 kPa (5–9) at LSMc. Over a median follow-up of 150 months, 4.2% developed HD, 1% underwent LT, and 3% demised. Patients who developed HD had higher LSM1 and LSMc, greater absolute and relative LSM changes, lower platelet counts, and IgG levels ($p < 0.05$ for all). In contrast, biochemical responses at 6 months were not associated with subsequent HD or LREs. Despite low event rates reflecting effective contemporary therapy, both LSM1 and LSMc independently predicted HD (HR: 1.07 per kPa for each, $p < 0.001$), with superior discrimination for LSMc (AUROC: 0.812 vs 0.788). Among patients with advanced disease (LSM1≥15 kPa), regression to LSM<15 kPa or ≥20% LSM reduction was associated with a significantly lower risk of LRE ($p < .05$). Importantly, similar risk stratification was observed in patients without advanced disease. An LSMc ≥15 kPa independently predicted LRE, whereas neither complete biochemical response nor LSM change provided incremental prognostic value beyond LSMc in likelihood ratio testing.
Conclusion: In treated AIH, most recent liver stiffness is the strongest predictor of liver-related outcomes, outperforming baseline stiffness and biochemical response. Serial LSM enables dynamic risk stratification and identifies patients at ongoing risk despite apparent biochemical remission, supporting its role in post-treatment surveillance.

Background and aims: The CAMARO trial demonstrated that response rates and tolerability of 24-weeks treatment with mycophenolate mofetil (MMF) plus prednisolone in treatment-naïve autoimmune hepatitis (AIH) resulted in better tolerability and a higher response rate in comparison to azathioprine (AZA) plus prednisolone. We aimed to compare long-term tolerability and maintenance of response in both arms.
Method: We analyzed patients enrolled in the CAMARO trial, a 24-week multicenter randomized controlled trial comparing AZA with MMF, both combined with prednisolone, in treatment-naïve autoimmune hepatitis. Follow-up data were retrospectively collected until October 1, 2025 or the last outpatient visit, allowing up to 3 years of follow-up. The primary endpoint was continued treatment with the randomized study drug with normalization of ALT and/or AST according to local reference ranges.
Results: Three-year follow-up was achieved by 65 patients (93%; 30 AZA, 35 MMF; median follow-up 4.4 years). After 3 years, 53% of patients had continued randomized treatment with normal transaminases in the AZA group compared to 77% in the MMF group ($p = 0.04$). Discontinuation between 24 weeks and 3 years occurred in 21% in both groups (AZA 5/24; MMF 8/38), with intolerance responsible for two discontinuations in each group. Two MMF-treated patients achieved sustained remission and successfully stopped AIH therapy. Among patients without normal transaminases at 24 weeks, on-treatment normalization by 3 years occurred in 6/12 (AZA) and 7/15 (MMF). Median time to biochemical remission was shorter with MMF than with AZA (13 vs 60 weeks; $p < 0.05$). This was confirmed in a sensitivity analysis censoring patients at discontinuation of randomized therapy and in a 4-week landmark analysis to mitigate the influence of prednisolone. No significant differences were observed between AZA and MMF with respect to loss of response (1/12 vs 1/22 of patient with on-treatment normalization at 24 weeks), 3-year steroid-free response rates (54% vs 51%), or median time to prednisolone discontinuation (78 vs 90 weeks) ($p > 0.05$ for all).
Conclusion: MMF was associated with a higher proportion of patients with 3-year on-treatment transaminase normalization and a shorter time to biochemical remission compared to AZA. Among patients who remained on treatment at 24 weeks, with or without response, both AZA and MMF could be safely continued with comparable clinical efficacy. In treatment-naïve AIH, MMF may be considered a first-line maintenance therapy.

OS-010

Management of patients with primary biliary cholangitis in the post-obeticholic era: real-world effectiveness data on elafibranor and seladelpar from the ColHai registry

Background and aims: Obeticholic acid (OCA) withdrawal and approval of new drugs have represented a major shift in the management of patients with PBC. We evaluated the impact of these changes and the early use and effectiveness of elafibranor (ELA) and seladelpar (SEL).

Method: This was a retrospective analysis of 529 patients with PBC across 37 centres from the Spanish ColHai registry. Continuous data are presented as medians and interquartile ranges.

Results: Patients were mostly female (91%) with a median age of 60 years (51.4–67.9), median ALP 1.5 × ULN (1.1–2.1), GGT 1.9 × ULN (0.9–5), AST 1.03 × ULN (0.8–1.4), ALT 0.8 × ULN (0.5–1.3), and bilirubin of 0.6 × ULN (0.4–0.9), 20% had cirrhosis, 20% were on ursodeoxycholic acid (UDCA) monotherapy, 39% on OCA + UDCA, 13% on bezafibrate (BZF) + UDCA, 26% on OCA + UDCA + BZF, and 2% were UDCA intolerant. Follow-up data were available for 317 patients (60%) at month 1, 258 patients (49%) at month 3, and 102 patients (19%) at month 6. Aggregated response data consider the last available follow-up per patient. ELA was administered to 115 patients, with median ALP reduction from baseline of –24% (–38 to –1) at month 1, –24% (–35 to 2) at month 3, and –36% (–42 to –11) at month 6. Response rates by Paris-II and POISE were 42% and 53% in patients on UDCA monotherapy, 70% and 79% in those previously treated with OCA + UDCA, 37% and 47% in those on BZF, and 35% and 58% in those treated with OCA + UDCA + BZF, respectively. SEL was administered to 297 patients, with median ALP reduction of –19% (–34 to 0) at month 1, –26% (40 to –3) at month 3, and –33% (–47 to –2) at month 6. Response rates by Paris-II and POISE were 55% and 65% in patients on UDCA monotherapy, 59% and 69% previously treated with OCA+UDCA, 24% and 31% in those on BZF, and 41% and 56% in those treated with OCA+UDCA+BZF. Among patients previously treated with OCA+UDCA, 18 (10%) and 10 (6%) lost Paris II and POISE responses after OCA discontinuation. Similarly, 27 (23%) and 18 (15%) on OCA+UDCA+BZF lost Paris II and POISE responses after triple therapy discontinuation. Fatigue improved in 16 patients (39%) treated with ELA and 28 (28%) with SEL. Pruritus improved in 14 patients (47%) with ELA and 65 (64%) with SEL.

Conclusion: In this first real-world experience from the ColHai registry, ELA and SEL demonstrated clinically relevant reductions in ALP and early biochemical response in patients with PBC, even in those previously exposed to second-line therapies.

Liver tumours – experimental

Background and aims: Hepatocellular adenomas (HCA) are rare benign liver tumors whose genetic predisposition remains largely unexplained outside a few monogenic conditions. We aimed to identify inherited genetic factors predisposing to HCA and to determine how germline variation interacts with somatic evolution and environmental risk factors.
Method: We analyzed 669 unrelated HCA patients recruited across multiple European centers using an integrative approach that combined genome-wide association study (GWAS), exome-wide rare-variant burden analyses (ExWAS), and multi-omics profiling. Germline data were compared to large population reference cohorts. Somatic mutations, transcriptomes, and clonal architectures were characterized in 664 tumors from 561 patients using whole-exome sequencing, RNA sequencing, and targeted analyses. Non-tumor liver transcriptomes were analyzed to assess functional consequences of germline variants.
Results: We identified germline alterations in four genes of the TRAIL apoptotic pathway (*TNFSF10*, *TNFRSF10A*, *TNFRSF10B*, and *CASP8*) as the most frequent genetic predisposition to HCA, present in approximately 25% of patients. This architecture combined a common regulatory TNFSF10 risk allele with multiple rare loss-of-function variants, highlighting polygenic and allelic heterogeneity. TRAIL germline variants were strongly associated with the development of multiple adenomas, particularly HNF1A-inactivated HCA, despite shorter exposure to oral contraceptives. Integrated somatic analyses revealed a striking convergent selection of independent HNF1A inactivating mutations across multiple tumors within the same individuals, consistent with a benign tumor field effect. Transcriptomic profiling of non-tumor liver tissue from TRAIL variant carriers showed dysregulation of apoptosis-related pathways, hepatic metabolism, estrogen signaling, and circadian regulators, indicating that germline TRAIL deficiency reprograms the hepatic environment prior to tumor initiation.
Conclusion: Germline impairment of the TRAIL apoptotic pathway represents a major genetic predisposition to HCA and drives benign tumorigenesis through a field effect that biases somatic evolution toward HNF1A inactivation. These findings redefine the role of apoptosis in benign liver tumor development and highlight germline-somatic interplay as a key determinant of tumor multiplicity and subtype selection.

In vitro identification of immunogenic tumoral antigens in advanced hepatocellular carcinoma reveals new opportunities for therapeutic applications

Frederik Peeters[1], Orian Bricard[2], Razgar Seyed Rahmani[2], Jieyi Xiong[2], Gino Philips[2], Evy Vanderheyden[2], Thomas Van Brussel[2], Rogier Schepers[2], Sarah Cappuyns[1], Chris Verslype[1,3], Diether Lambrechts[2], Jeroen Dekervel[1]. *[1]Department of Digestive Oncology, UZ Leuven, Leuven, Belgium; [2]Laboratory for Translational Genetics, Center for Cancer Biology, VIB, Leuven, Belgium; [3]KU Leuven, Oncology, Leuven, Belgium*
Email: frederik.peeters@hotmail.com

Background and aims: The antigenic landscape underlying the antitumor immune response remains poorly characterized. Existing methods for antigen identification or prediction are limited in accuracy, often restricted to exonic mutations, and frequently lack experimental validation of immunogenicity. Systematic identification of tumoral antigens is critical for the development of novel immunotherapy strategies in advanced HCC (aHCC). We aimed to map the antigenic repertoire in aHCC using a novel unbiased, transcriptome-wide approach which includes functional validation.
Method: Pre-treatment and on-treatment tumor biopsies were obtained from a patient with aHCC who achieved a complete pathological response following treatment with durvalumab plus tremelimumab. By applying single-cell RNA and T-cell receptor (TCR) sequencing, we identified the TCRs of the 12 most expanded CD8+ T-cell clones in each tissue sample. After excluding duplicate TCRs between timepoints, 19 patient-specific, potentially tumor-antigen directed TCRs were selected. Each TCR was transfected in a T cell line and cocultured with an HLA matched antigen-presenting cell (APC) line expressing the patient-specific tumor transcriptome library. Clusters of APCs with activated T cells were isolated, expanded and the antigenic sequence incorporated in the APC was retrieved by sanger sequencing.
Results: We identified a tumoral antigenic sequence for 10 out of 19 TCRs analyzed. Only 2 of the antigens were based on a mutation, whereas the others represented the reactivation of a novel cancer-testis antigen, overexpressed genes and alternative open reading frames. Expression of several of the detected antigens identified in this patient was also detected in tumors from other HCC patients and across other tumor types within the TCGA dataset, indicating the presence of shared tumor antigens between cancer patients. Remarkably, 4 different TCRs were found to recognize the same antigen. For 9 out of 10 TCRs with an identified tumoral antigen, the corresponding T cell clonotype was detected in the tumor biopsy prior to immune checkpoint inhibition (ICI), indicating an ongoing immune response against these antigens before ICI.
Conclusion: Using a novel antigen detection platform, we confirmed that diverse genomic alterations, ranging from exonic mutations to events in the dark genome, can give rise to immunogenic antigens capable of eliciting T-cell responses. The identification of shared tumoral antigens opens new opportunities for therapeutic applications.

Email: magarfer@unav.es

Background and aims: Metabolic dysfunction–associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide and a growing global health burden. However, the molecular mechanisms driving progression from simple steatosis to steatohepatitis (MASH) and hepatocellular carcinoma (HCC) remain incompletely understood. Epigenetic regulators have emerged as critical mediators of this transition. The histone methyltransferase G9a (EHMT2) has been implicated in hepatocarcinogenesis, but its role in metabolically driven HCC remains unclear. This study aimed to define the hepatocyte-specific contribution of G9a to HCC development in a metabolic inflammatory context.
Method: Wild-type (WT) and hepatocyte-specific G9a knockout (G9aΔhepKO) mice were subjected to a Western diet combined with CCl_4 for 26 weeks, recapitulating key features of MASH-associated HCC. Liver injury, fibrosis, tumor burden, and metabolic alterations were assessed using biochemical, histological, transcriptomic, proteomic, and metabolomic approaches. In parallel, primary hepatocytes from both genotypes were exposed to lipogenic and inflammatory stimuli to model MASH in vitro.
Results: WT mice developed multiple HCC nodules, whereas G9aΔhepKO mice exhibited a marked reduction in tumor incidence and burden. Loss of hepatocytic G9a significantly attenuated fibrosis and induced profound metabolic remodeling, particularly affecting lipid and amino acid metabolism. Multi-omics integration revealed suppression of tumor-promoting, fibrogenic, and mitotic pathways in G9a-deficient livers. Consistently, G9a-deficient hepatocytes failed to sustain the lipogenic and inflammatory programs characteristic of MASH progression in vitro. Notably, Ogdhl, a mitochondrial enzyme with tumor-suppressive properties, was identified as a direct epigenetic target of G9a. Ogdhl was strongly repressed in WT HCC-bearing livers but preserved upon G9a deletion, suggesting that maintenance of OGDHL expression contributes to disrupted tumor metabolic homeostasis.
Conclusion: These findings identify G9a as a central epigenetic driver of MASH-to-HCC progression. Hepatocyte-specific G9a deletion limits fibrosis and hepatocarcinogenesis while restoring metabolic balance, highlighting a critical link between epigenetic regulation and metabolic reprogramming in liver cancer. Targeting G9a may therefore represent a promising therapeutic strategy for metabolically driven HCC.

OS-014-YI

The evolving heterogeneity of intrahepatic cholangiocarcinoma: clonal dynamics, spatial archetypes, and therapeutic opportunities

Claudio Zampato[1], Paula Cantallops Vilà[1], Gemma Garcia Vicién[1], Laura Sererols Viñas[1], Carmen Cárcamo Giráldez[1], Marsela Karemani[2], Daniela Grases[3], Roser Pinyol[4], Daniela Sia[5], Robert F. Schwabe[6], Anna Moles[7], Josep M Llovet[8], Eduard Porta-Pardo[9], Silvia Affo[1]. *[1]Tumor Microenvironment Plasticity and Heterogeneity Research Group, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [2]Institut de Recerca Biomèdica de Lleida (IRBLleida), Lleida, Spain; [3]Josep Carreras Leukaemia Research Institute, Badalona, Spain; [4]Liver Cancer Translational Research Group, Liver Unit, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, Universitat de Barcelona, Barcelona, Spain; [5]Mount Sinai Liver Cancer Program, Divisions of Liver Diseases, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [6]Columbia University, New York, United States; [7]Institut d'Investigacions Biomèdiques de Barcelona (IIBB-CSIC), Barcelona, Spain; [8]Liver Cancer Translational Research Group, Liver Unit, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, Universitat de Barcelona, Mount Sinai Liver Cancer Program, Divisions of Liver Diseases, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA; Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain, Barcelona, Spain; [9]Josep Carreras Leukaemia Research Institute (IJC), Barcelona Supercomputing Center (BSC), Barcelona, Spain, Badalona, Spain*
Email: zampato@recerca.clinic.cat

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is the second most common primary liver cancer, diagnosed at advanced stages and associated with poor prognosis. Its molecular and cellular heterogeneity complicates treatment and contributes to therapy resistance. Here, employing an integrative approach, we investigated structural vulnerabilities to guide innovative therapies for iCCA.
Method: R26R-Confetti mice were injected with AAV8-TBG-Cre for stochastic hepatocyte labelling, followed by iCCA induction via hydrodynamic injection of KRAS G12D/sg-p19 (n = 4) or YAP/AKT plasmids (n = 4). Three Confetti-derived tumor cell lines obtained from each model were used for bulk RNA-seq, CNV profiling, and drug testing. KRAS/p19 tumors (n = 4) and human iCCA (N = 4) underwent Visium CytAssist spatial transcriptomics (ST), integrated with bulk, using non-negative matrix factorization (NMF), and single-cell RNA-seq. CAF depletion was performed in Lrat-Cre iDTR (n = 4 Cre−, 6 Cre+) and aSMA-TK (n = 5 TK−, 8 TK+) mice, followed by spatial transcriptomic profiling using Xenium 5K ST.
Results: Confetti Cre-mediated recombination in hepatocytes enabled in vivo tumor clonal lineage tracing as confirmed by confocal microscopy in 2 iCCA models. Tumor clones showed transcriptomic and genomic heterogeneity and responded differently to Gem, Cis, and Gem/Cis in vitro. To investigate how this heterogeneity is organized and shaped within the TME, we integrated tumor clonal tracing, bulk and single-cell RNA sequencing with ST, unveiling 2 conserved spatial archetypes within each lesion. The core archetype, located in the central tumor area, correlated with tumor and dendritic cells, showed activation of MAPK, Hypoxia response, WNT and EGFR pathways, and was associated with the non-inflamed tumor classical STIM (stromal, tumor, immune microenvironment) class. The edging archetype, located at the tumor periphery, correlated with CAFs, T, B, NK, and macrophages, exhibited activation of TGF-B, PI3K, VEGF and Trail pathways, and was associated with the inflammatory stroma STIM class. Xenium ST revealed that CAF perturbation favored an edging archetype and inflammatory stroma STIM class in iCCA lesions, predicted to enhance immunotherapy response.
Conclusion: Using an integrative approach, we revealed conserved, yet dynamic archetypes shaped by the surrounding stroma, highlighting spatial engineering as a promising therapeutic strategy in iCCA.

Personalized RNA-based tumor vaccines targeting neoantigens in hepatocellular carcinoma

Paul Schneider[1], Jenny Schunke[2], Nadja Salomon[2], Akili Özlem[2], Barbara Schroers[2], Mustafa Diken[2], Jörn M. Schattenberg[3], Leonard Kaps[1,3]. *[1]Department of Dermatology, University Medical Center, Mainz, Germany; [2]TRON – Translational Oncology at the University Medical Center of the Johannes Gutenberg University Mainz gGmbH, Mainz, Germany; [3]Department of Medicine II, University Medical Center, Homburg/Saar, Germany*
Email: leonardkaps@googlemail.com

Background and aims: Immune checkpoint inhibitors (ICI) that stimulate the immune system represent an effective therapeutic strategy for hepatocellular carcinoma (HCC). Beyond ICI, mRNA-based tumor vaccines targeting tumor-specific neoantigens (NA) derived from somatic mutations hold promise as a novel personalized immunotherapeutic approach. In this study, mRNA tumor vaccination targeting NA was evaluated in a clinically relevant HCC model.
Method: NA were identified from Dt81Hepa1–6 murine HCC cells via RNA sequencing and prioritized in silico using the VaxRank algorithm. Selected NA were encoded into pentatope mRNA constructs and formulated in lipoplex nanoparticles (LPX). HCC was induced in cirrhotic C57BL/6JrJ mice by CCl_4 gavage (6 weeks), followed by i.s. injection of Dt81Hepa1–6 cells. HCC mice (n = 15 per group) received i.v. vaccinations with NA-mRNA-loaded LPX (LPX:NA-mRNA) or control mRNA (LPX:CTRL) on days 7, 14, and 21 after tumor cell inoculation (TCI). Overall mortality was assessed in vaccinated HCC mice, including cohorts receiving additional murine anti-PD-L1 therapy.
Results: At sacrifice on day 28 after TCI, vaccination with LPX:NA-mRNA elicited a robust cellular immune response. FACS analysis of digested livers revealed a significant increase in total $CD4^+$ and $CD8^+$ T-cell frequencies (both $p < 0.0001$), accompanied by enhanced T-cell proliferation ($CD4^+Ki67^+$ and $CD8^+Ki67^+$, both $p < 0.0001$) and a marked expansion of effector $CD8^+$ T-cells ($CD62L^-CD44^+$, $p < 0.0001$). In parallel, regulatory T-cells ($CD25^+FoxP3^+$) were reduced compared with controls ($p < 0.001$). ELISPOT assays confirmed that splenic T-cells from LPX:NA-mRNA–vaccinated mice mounted strong NA-specific responses to synthetic NA peptides. LPX:NA-mRNA vaccination resulted in a significant reduction in tumor burden, as demonstrated by a decreased number of liver metastases, lower AFP levels, and a reduced tumor area determined by morphometric analysis of H&E-stained liver sections (all $p < 0.05$). During the 56-day follow-up after TCI, mortality was lowest in mice treated with combined LPX:NA-mRNA vaccination and ICI (3/11 deaths), intermediate in LPX:NA-mRNA monotherapy (5/11) and LPX:CTRL plus ICI (6/11), and highest in the LPX:CTRL placebo group (11/12). Treatment was well tolerated without evidence of acute toxicity.
Conclusion: NA-targeted mRNA vaccination was well tolerated and induced a robust tumor-specific T-cell–mediated antitumor response in cirrhotic HCC mice. Combination with ICI further improved overall mortality.

MASLD: Clinical and therapeutical aspects I

Week 48 top-line results from the phase 2b, multicenter, randomized, placebo-controlled IMPACT trial of pemvidutide in metabolic dysfunction-associated steatohepatitis

Mazen Noureddin[1], Naim Alkhouri[2], Stephen A. Harrison[2], Rohit Loomba[3], Naga Chalasani[4], Shaheen Tomah[5], Julio Gutierrez[5], John Suschak[5], M. Scot Roberts[5], Rachel Garner[5], Sarah Browne[5], Christophe Arbet-Engels[5], M. Scott Harris[5]. *[1]Houston Methodist Hospital, Houston Research Institute, Pinnacle Clinical Research, Houston, TX, United States; [2]Summit Clinical Research, Clinical Research Institute of Ohio, San Antonio, TX, United States; [3]MASLD Research Center, Division of Gastroenterology and Hepatology, University of California at San Diego, San Diego, CA, United States; [4]Indiana University School of Medicine, Indianapolis, IN, United States; [5]Altimmune, Inc, Gaithersburg, MD, United States*
Email: noureddinmd@pinnacleresearch.com

Background and aims: Pemvidutide is a balanced 1:1 glucagon/GLP-1 dual receptor agonist in development for the treatment of metabolic dysfunction-associated steatohepatitis (MASH). IMPACT was a phase 2b, randomized, placebo-controlled, double-blind trial in patients with biopsy-confirmed MASH and fibrosis stage F2 or F3 (NCT05989711). At 24 weeks, pemvidutide treatment showed statistically significant histologic MASH resolution and high rates of fibrosis improvement. Here we present the 48-week endpoints, including non-invasive tests (NITs), weight loss, and safety.
Method: 212 patients were randomized 1:2:2 to receive once-weekly subcutaneous pemvidutide (1.2 mg or 1.8 mg) administered without dose titration, or placebo. Week 48 read outs included NITs of liver fat content (LFC), hepatic inflammation [corrected T1 (cT1), alanine aminotransferase (ALT)] and fibrosis [ELF, liver stiffness measurement (LSM) by FibroScan®], and weight loss. There was no histological assessment at week 48.
Results: The mean age was 53 years, the mean BMI was 39 kg/m^2, 58% were female, and 43% had type 2 diabetes. At week 48, pemvidutide treatment resulted in LFC changes of −45.2% ($p < 0.0001$), −54.7% ($p < 0.0001$), and −8.2% in the 1.2 mg, 1.8 mg, and placebo groups. Mean changes in cT1 relaxation time in the 1.2 mg, 1.8 mg, and placebo groups were −124 ms ($p < 0.0001$), −140 ms ($p < 0.0001$), and −21 ms. A greater proportion of patients treated with pemvidutide achieved a ≥ 30% reduction in LSM than placebo [1.2 mg (61.1%; $p < 0.0001$), 1.8 mg (63.9%; $p < 0.0001$), placebo (21.2%)]. ELF score changes of −0.49 ($p < 0.0001$), −0.58 ($p < 0.0001$), and +0.16 occurred in the 1.2 mg, 1.8 mg, and placebo groups. A greater proportion of patients receiving pemvidutide achieved concurrent responses in ELF score (≥ 0.5 reduction) and LSM (≥ 30% reduction) compared to placebo [1.2 mg (27.8%; $p = 0.0003$); 1.8 mg (32.4%; $p < 0.0001$); placebo (3.2%)]. The changes in ALT were −37.8 IU/L ($p < 0.0001$), −37.4 IU/L ($p < 0.0001$), and −10.3 IU/L in the 1.2 mg, 1.8 mg, and placebo groups. Mean weight loss in the 1.2 mg, 1.8 mg, and placebo groups was 4.5% ($p < 0.0001$), 7.5% ($p < 0.0001$), and 0.2%. Pemvidutide was well-tolerated with discontinuations due to adverse events of 0%, 1.2%, and 3.5% in the 1.2 mg, 1.8 mg, and placebo groups.
Conclusion: Treatment led to significant, dose-dependent reductions in NITs of MASH inflammation and fibrosis, as well as clinically meaningful weight loss at week 48.

OS-017

CAP-LS-ALT3+ and 4 scores for the prediction of MASLD-related liver related events: a derivation and global validation study

Hye Won Lee[1], Seung Up Kim[1], Terry Cheuk-Fung Yip[2], Vincent Wai-Sun Wong[2]. *[1]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [2]The Chinese University of Hong Kong, HK, Hong Kong*
Email: ksukorea@yuhs.ac

Background and aims: Fibrosis drives adverse outcomes in metabolic dysfunction–associated steatotic liver disease (MASLD). We developed and validated two open probability scores—CLA3+ (≥F3) and CLA4 (F4)—from controlled attenuation parameter (CAP) and liver stiffness (LS) by vibration-controlled transient elastography (VCTE) and alanine aminotransferase (ALT).
Method: In a multinational cohort of 16 tertiary centers, single-term fractional-polynomial logistic models produced CLA3+/CLA4 probabilities. Prognosis for liver-related events (LREs) was assessed using time-dependent area under receiver operating characteristic curve (AUROC), Brier score, integrated discrimination improvement (IDI), and serial-change analyses. Clinical implementation was evaluated with two-step pathways (FIB-4→CLA3+ for ≥F3; FIB-4→CLA4 for F4).
Results: The derivation cohort included 2,811 patients with liver biopsy. The validation cohort included 11,196 patients with baseline LS, among whom 8,046 had serial LS. Derivation AUROCs were 0.84 (CLA3+) and 0.89 (CLA4). In validation, both achieved the highest integrated AUROC (0.83) with lowest integrated Brier scores (0.0078–0.0081) across comparators for predicting LREs. CLA3+ classified 83.1%/10.8%/6.1% as low/intermediate/high risk (5-year LRE 0.4%/1.5%/11.8%; sensitivity of low-risk cut-off 0.72), and CLA4 92.0%/3.6%/

4.4% (0.5%/4.7%/13.0%; specificity of high-risk cut-off 0.93), achieving the smallest intermediate zone. IDI favored CLA3+ over Agile3+ (+0.013 at 3 years; +0.021 at 5 years), while CLA4 matched Agile4. Serially, categories were stable (86.7% CLA3+; 93.2% CLA4), and ≥10–30% decreases predicted lower subsequent LRE risk. In two-step testing, intermediates were minimized (FIB-4→CLA 3 + 3.9%; FIB-4→CLA4 1.4%) while achieving the highest rule-in enrichment (8.3% 5-year LRE).
Conclusion: CLA3+ and CLA4 generate interpretable, high-performing probabilities from CAP, LS, and ALT, with small indeterminate zones and actionable serial dynamics, and are clinically deployable as second-line tests within FIB-4–based two-step pathways.

OS-018
Hepatic transcriptomic signatures reveal mechanistic insights underlying improved metabolic dysfunction–associated steatohepatitis histology with survodutide, a glucagon/glucagon-like peptide-1 receptor dual agonist, in a phase 2 trial
Raphael Hesse[1], Panagiotis Papavasileiou[2], Ahmad Alhussein[3], Renee Marshall[4], Elena Startseva[3], Ramy Younes[3], Amalia Gastaldelli[5], Arun J. Sanyal[6], Corinna Schoelch[1]. *[1]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, Connecticut, United States; [5]Cardiometabolic Risk Unit, CNR Institute of Clinical Physiology, Pisa, Italy; [6]Virginia Commonwealth University, School of Medicine, Richmond, Virginia, United States*
Email: raphael.hesse@boehringer-ingelheim.com

Background and aims: Survodutide is a glucagon receptor (GCGR)/glucagon-like peptide-1 receptor (GLP-1R) dual agonist in phase 3 clinical development for the treatment of obesity, and metabolic dysfunction-associated steatohepatitis (MASH). We present data from a prespecified transcriptome analysis from baseline (BL) and W48 liver tissue samples from a phase 2 trial in people with MASH (NCT04771273). The aim was to investigate liver specific on-treatment changes on therapeutic responses to survodutide.
Method: 293 participants received ≥1 dose of survodutide or placebo. Liver biopsy samples were obtained from trial participants at visit 1 and W48. Following ribonucleic acid (RNA) extraction libraries were prepared and sequenced on a NovaSeq sequencer. The sequencing reads were processed with a Boehringer Ingelheim internal pipeline, building upon the implementation of the ENCODE "Long RNA-seq" pipeline followed by differential expression analysis with limma/voom. Pathway analyses were performed using GSEA, ssGSEA and IPA with REACTOME canonical pathways and curated gene sets from the literature.
Results: Biopsy samples that passed QC were available from 48 patients (10 Placebo/38 survodutide). Transcriptomic profiling revealed activation of GCGR signalling in liver tissue following survodutide treatment. Compared with baseline, several genes associated with fibrosis and inflammation, including those involved in TGFB1-, IL4-, and IL13-mediated pathways, were significantly downregulated. Notably, expression of LOXL1, LAMB1, MMP9, PLEC, TGFB1, and multiple collagen genes decreased upon treatment. Gene Set Enrichment Analysis indicated that cellular pathways involved in tissue remodelling, fibrosis, and inflammation were suppressed, while Ingenuity Pathway Analysis suggested that survodutide may mitigate fibrosis progression by limiting hepatic stellate cells migration, preserving hepatocytes, and supporting regeneration. TGFB1 and FOXA2 were identified as potential upstream regulators of these effects.
Conclusion: We present a comprehensive transcriptome analysis by next-generation sequencing from liver biopsies collected in a phase 2 clinical trial with the GCGR/GLP-1R dual agonist survodutide. The observed modulation of liver mRNA expression known to be regulated in fibrotic-and inflammatory processes provide a mechanistic basis for the improvement in fibrosis and supports the biological plausibility that survodutide reduces hepatic inflammation and fibrogenesis.

OS-019
Utility of noninvasive criteria based on vibration controlled transient elastography and enhanced liver fibrosis test in identifying patients with high-risk MASLD
Naim Alkhouri[1], Elizabeth Brombosz[1], Grazina Binkauskiene[1], Winston Dunn[2], Rashmee Patil[1], Rohit Puskoor[1], John Poulos[3], Alma Laura Ladrón de Guevara[4], Vlad Ratziu[5], Marcelo Kugelmas[6], Juan Pablo Arab[7], Meena Bansal[8], Jörn M. Schattenberg[9], Mazen Noureddin[1]. *[1]Summit Clinical Research, San Antonio, United States; [2]University of Kansas, Kansas City, United States; [3]Coastal Research Institute, Fayetteville, NC, United States; [4]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, Mexico City, Mexico; [5]Sorbonne University, Paris, France; [6]South Denver Gastroenterology, Denver, United States; [7]Virginia Commonwealth, Richmond, United States; [8]Mount Sinai, New York, United States; [9]Saarland University, Saarbrücken, Germany*
Email: naim.alkhouri@gmail.com

Background and aims: Histologic endpoints in MASH trials have several limitations including the invasive nature of liver biopsy, variability in pathologists' interpretation, and the fact that full regulatory approval still requires improvement in clinical outcomes. Therefore, new criteria based on noninvasive tests (NITs) have been proposed to identify patients with high-risk MASLD that are at the highest risk for progression to cirrhosis and major adverse liver outcomes (MALO). One proposed set of cutoffs for identifying these patients is the combination of LSM 10–20 kPa and ELF 9–10.8. This study aimed to evaluate the efficacy of these criteria in identifying subjects with high-risk MASLD in a multicenter database using fibrosis stage on biopsy as the gold standard.
Method: Patients with LSM, ELF, and available biopsy data were identified from a multicenter database of screening and baseline data from 12 MASH clinical trials. Patients that met LSM 10–20 kPa + ELF 9–10.8 criteria were further analyzed based on fibrosis stage and stratified into F0-F2 vs F3/F4, with F3/F4 individuals at the highest risk of MALO and those with F3 at the highest risk of progression to cirrhosis.
Results: 4,188 patients had liver biopsy, LSM and ELF available (8.0% with F0 on biopsy, 17.3% F1, 25.6.% F2, 23.7% F3, and 25.5% F4). Importantly, the LSM 10–20 kPa + ELF 9–10.8 criteria were met in 18.0% of F0 patients, 23.2% of F1, 33.6% of F2, 41.7% of F3, and 34.7% of F4 patients. Out of 1373 patients that met the LSM and ELF cutoffs and had liver biopsy data available, only 57% (784) had F3/F4, while 43% (589) had F0-F2, including 60 (10%) patients with F0 and 168 (29%) with F1. Patients with F0-F1 that met the LSM and ELF cutoffs were older, more likely to be diabetics, and had higher AST, AST/ALT ratio, HbA1C, and FIB4 index compared to those with F0-F1 that did not meet the criteria.
Conclusion: Using cutoffs of LSM 10–20 kPa and ELF 9–10.8 may overestimate the likelihood of developing cirrhosis and MALO in patients with no evidence of significant fibrosis on liver biopsy. Patients with F0-F1 that met the LSM and ELF criteria were older, more likely to be diabetics, with higher FIB4. More strict criteria are potentially needed in this population to increase the likelihood of identifying high-risk MASLD.

OS-020

Effect of empagliflozin alone or combined with low-dose semaglutide on metabolic dysfunction-associated steatohepatitis and type 2 diabetes – a histology-based randomized, placebo-controlled, double-blind phase 4 trial (COMBAT_T2_NASH)

Sabine Kahl[1], Georgia Xourafa[1], Angela Härtel[2], Berthold Amann[2], Ulrich Dischinger[3], Andreas Geier[3], Katharina Laubner[4], Jochen Seufert[4], Astrid Lerner[5], Ingolf Schiefke[6], Zoltan Kender[7], Stefan Kopf[7], Julia Szendrödi[7], Christian Herder[1], Andrea Tura[8], Birgit Knebel[1], Uta Drebber[9], Andrea Tannapfel[10], Vlad Ratziu[11], Kenneth Cusi[12], Andreas Birkenfeld[13], Martin Hrabe de Angelis[14], Annette Schürmann[15], Michele Solimena[16], Michael Roden[1]. *[1]German Diabetes Center, German Center for Diabetes Research, Duesseldorf, Germany; [2]Franziskuskrankenhaus Berlin, Berlin, Germany; [3]University Hospital Wuerzburg, Wuerzburg, Germany; [4]University Hospital Freiburg, Freiburg, Germany; [5]Eugastro GmbH, Leipzig, Germany; [6]Klinikum St. Georg gGmbH, Leipzig, Germany; [7]University Clinics Heidelberg, Heidelberg, Germany; [8]CNR Institute of Neuroscience, Padua, Italy; [9]Cologne University, Cologne, Germany; [10]Ruhr University Bochum, Bochum, Germany; [11]Sorbonne Université and Hospital Pitié Salpêtrière, Paris, France; [12]University of Florida, Gainesville, United States; [13]University Hospital Tübingen, Tübingen, Germany; [14]Helmholtz Center Munich, Munich, Germany; [15]German Institute of Human Nutrition, Potsdam-Rehbrücke, Germany; [16]University Hospital Dresden, Dresden, Germany*
Email: michael.roden@ddz.de

Background and aims: Whether sodium-glucose co-transporter-2 inhibitors and their combination with glucagon-like peptide-1 receptor agonists improve diabetes-related metabolic dysfunction-associated steatohepatitis (MASH) is currently unknown.
Method: This randomized controlled trial compared effects of empagliflozin (10 mg qd) plus semaglutide (1 mg qw; COMBI) with empagliflozin alone (10 mg qd; EMPA) versus placebo (PLAC) on biopsy-confirmed MASH with F1-F3 fibrosis in 61 people with type 2 diabetes. The primary endpoint was MASH resolution without fibrosis progression at 48 weeks. Secondary endpoints included changes in NAFLD activity score (NAS), activity component (lobular inflammation+ballooning) and steatosis. Statistical analyses included Fisher exact test, ANCOVA and 2-sided t-test as appropriate. Data are given as mean and standard deviation.
Results: Participants (47.5% female, age 56 ± 11 years, BMI 33 ± 5 kg/m^2, HbA1c 7.4 ± 1%) received COMBI (n = 23), EMPA (n = 17) or placebo (n = 21), of whom 54 had paired biopsies available. Body weight decreased with COMBI (-8.6 ± 5.4 kg) but not with EMPA (−0.4 ± 7.4 kg) vs. PLAC (0.1 ± 3.4 kg; p < 0.0001 and 0.82) after 48-week treatment. Also, HbA1c improved with COMBI only (−1.3 ± 0.9%) but not with EMPA (-0.4 ± 0.7%) compared to PLAC (−0.1 ± 0.9%; p = 0.0002 and p = 0.25). The proportion of participants with MASH resolution without progression of fibrosis was nominally higher in COMBI (9.5%) but not in EMPA (0%) vs. PLAC (5.6%; both p = 1.0). NAS improved in COMBI (−1.3 ± 1.0), but not in EMPA (−0.1 ± 0.7) vs. PLAC (−0.1 ± 1.1; p = 0.0002 and p = 0.9221). COMBI showed greater reductions in steatosis (−0.38 ± 0.35) and activity component (-0.90 ± 0.90) than PLAC (0.06 ± 0.38 and – 0.14 ± 0.97; p < 0.0001 and p = 0.0078), whereas EMPA (−0.17 ± 0.36 and 0.07 ± 0.68) lead to non-significant changes vs. PLAC. Likewise, transaminases and cytokeratin-18 fragments M30/M65 decreased only with COMBI (all p < 0.01 vs. PLAC).
Conclusion: In people with moderately-controlled type 2 diabetes, the proportion of participants achieving MASH resolution without progression of fibrosis was nominally higher with combined empagliflozin and low-dose semaglutide as compared to placebo after 48 weeks of treatment. Combined treatment was also superior to placebo for improvements in both MASH-related steatosis and inflammation. These effects were likely mediated by the semaglutide-induced reductions in body mass and glycemia.
Clinicaltrials.gov NCT04639414.

A nursing educational intervention positively impacts adherence in a cohort of patients with Wilson disease

Anna Miralpeix[1,2,3], Montserrat Rodríguez[4], Núria Fabrellas[2,3,5], Mercè Torra[2,6], Anna Pocurull Aparicio[1,2], Cristina Collazos[1], Elia Canga[1,2,3], Xavier Forns[1,2,5,7], Zoe Mariño[1,2,5,7,8]. *[1]Liver Unit, Hospital Clínic, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Facultat d'Infermeria, Escola de Doctorat, Universitat de Barcelona, Barcelona, Spain; [4]Pharmacy Service, Hospital Clínic, Barcelona, Spain; [5]Centro de Investigación Biomédica en Red, Enfermedades hepáticas y digestivas (CIBERehd), Barcelona, Spain; [6]Biochemistry and Molecular Genetics Service, Hospital Clínic, Barcelona, Spain; [7]Facultat de Medicina i Ciències de la Salut, Universitat de Barcelona, Barcelona, Spain; [8]ERN-RARE Liver, Hospital Clínic, Barcelona, Spain*
Email: amiralpeix@recerca.clinic.cat

Background and aims: Wilson Disease (WD) is a rare genetic disorder of copper metabolism requiring lifelong treatment with complex regimens and frequent adverse events. Poor adherence is associated with worse clinical outcomes and healthy habits are key to prevent progression and hepatic comorbidities. A nursing educational program was implemented at Hospital Clínic to empower patients, detect barriers and design individualized plans to improve adherence. Here we present the follow-up results.
Method: This single-center, prospective intervention included two visits (baseline V0 and 6-month follow-up V1) led by the same specialized nurse. Treatment adherence was assessed by: 1) medical chart review, 2) pharmacy refill data (low if <80%), and 3) self-reported by patients with the ARMSe questionnaire (low if score ≥16). Adherence to Mediterranean diet was evaluated with MEDAS-14 questionnaire (adapted for low-copper intake and hepatic disease) and physical activity with IPAQ questionnaire. Variables were compared using McNemar's, Chi-square and Mann–Whitney U tests and presented as median (IQR) or n (%), as appropriate.
Results: 54 WD patients were included and followed-up: 54% female, median age 39 (29–47) years, time since diagnosis 20 (14.5–28) years, 72% hepatic phenotype, 50% on chelators and 50% on zinc, treatment duration of 12 (2–20) years. No drug changes occurred between visits. Low adherence by ARMSe decreased from 39% at V0 to 24% at V1 (p = 0.039); with forgetfulness and multiple daily doses as the main barriers. At V1, non-adherent patients were younger (29 vs 40 years, p = 0.032), with non-significant trends to higher ALT and exchangeable copper. No differences were found by sex, phenotype, treatment, educational level or occupation. Clinical and pharmacy-based adherence did not significantly change, but agreement among the three methods improved from 55% to 69%. Non-significant improvement in physical activity was found, but adherence to the adapted Mediterranean diet significantly increased (54% vs 72%, p = 0.031).
Conclusion: This individualized nursing intervention showed a positive impact on treatment adherence and dietary habits in WD patients, despite the limitations of a small sample size and a single 6-month follow-up visit. Continued educational efforts remain essential, as nearly one-quarter of the patients remained non-adherent to treatment, and special attention should be given to younger patients who are generally less compliant. Long-term follow-up is planned to assess sustained impact.

OS-022-YI

Prolonged fasting during hospitalization is associated with poor prognosis in patients with cirrhosis

Astrid Ruiz Margáin[1], Sidney Lopez Moreno[1], Mariana Barrat Remes[1], Mariana Lopez Caracas[1], Renata Montemayor Salazar[1], Abraham Sanchez Gomez[1], Berenice M. Román-Calleja[1], Nayelli C. Flores-Garcia[1], Ricardo Macias-Rodriguez[1]. [1]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico*
Email: astrid.ruizm@incmnsz.mx

Background and aims: Prolonged fasting is common in hospitalized patients with cirrhosis due to procedures, clinical instability, or complications; however, data on its frequency, duration, and clinical impact remain scarce. Fasting may accelerate muscle loss and worsen malnutrition, contributing to functional decline and increased morbidity and mortality. We aimed to evaluate the frequency of fasting during hospitalization and its association with short-term mortality in patients with cirrhosis.
Method: Retrospective cohort study in hospitalized patients with cirrhosis between 2023 and 2025. Primary outcome was 3-month mortality. Total fasting days were defined as the cumulative number of full fasting days, whether continuous or intermittent. Descriptive statistics, chi-square test, independent and paired t-tests, Kaplan–Meier and Cox proportional hazards regression were used.
Results: 228 patients were included (median age 58 years); MASLD (17.1%), alcohol-related liver disease (16.2%), and HCV (11%) were the most common etiologies. Overall, 81.6% experienced at least one fasting period, with recurrent episodes during hospitalization; up to five fasting periods occurred in 5% of patients. Most fasting periods were related to clinically justified indications; however, fasting duration frequently extended beyond the immediate indication. The main reasons for fasting were pre-procedural (63.6%), high-dose vasopressors (14.1%), post-procedural (8.1%), delayed initiation of nutritional support (5.1%), hepatic encephalopathy (4%), and oral intolerance (2%). Phase angle, a validated marker of sarcopenia, declined significantly during hospitalization in both groups but was more pronounced in patients with fasting ≥6 days (3.8 to 3.0, $p < 0.001$) than in those fasting <6 days (4.0 to 3.8, $p = 0.005$). Baseline phase angle was similar between groups ($p = 0.151$), whereas final values differed significantly ($p < 0.001$). Three-month survival was lower in patients with fasting ≥6 days compared with <6 days (45% vs 70%, $p = 0.002$). In multivariable Cox models, fasting ≥6 days remained independently associated with higher 3-month mortality after adjustment for MELD-Na and length of hospital stay (HR 2.08, 95% CI 1.05–4.13).
Conclusion: Prolonged fasting during hospitalization in patients with cirrhosis is associated with worsening sarcopenia, and increased 3-month mortality, independent of liver disease severity and length of hospital stay, reducing the frequency of fasting periods may represent a potentially modifiable risk factor.

OS-023

Development and content validation of a symptom burden scale for liver cirrhosis

Laurence Seynhaeve[1], Tilde Penninck[2], Charlotte De Vloo[3], Sofie De Meulder[1], Jef Dewyspelaere[1], Luc Harlet[1], Jochen Decaestecker[1], Kymentie Ferdinande[1], Lise-Marie Kinnaer[4]. [1]*Department of Hepatology, AZ Delta Hospital, Roeselare, Belgium, Roeselare, Belgium;* [2]*Department of Hepatology, AZ Maria Middelares Gent, Belgium, Gent, Belgium;* [3]*AZ Delta, Department of Gastroenterology and Hepatology, Rumbeke, Belgium, Roeselare, Belgium;* [4]*Department of Public Health and Primary Care, University Centre for Nursing and Midwifery, Ghent University, Ghent, Belgium, Ghent, Belgium*
Email: laurence.seynhaeve@azdelta.be

Background and aims: Liver cirrhosis is a progressive condition in which healthy liver tissue is replaced by fibrosis, representing a major global health burden and accounting for nearly 2% of deaths in Europe. It results from chronic liver diseases such as alcohol use disorder, viral hepatitis, and MASLD, and may progress from a compensated to decompensated stage with reduced survival. Patients experience a substantial and heterogeneous symptom burden that significantly impairs quality of life. Existing generic and liver disease–specific instruments do not fully capture the multidimensional symptom burden and lived experiences of patients with cirrhosis. Therefore, a validated, patient-centered tool applicable to both clinical practice and research is needed. This study aims to develop a cirrhosis-specific symptom burden instrument and evaluate its content validity.
Method: A rapid review identified the most frequently reported symptoms in liver cirrhosis, grouped into physical, psychological, and social domains. A hepatologist, clinical nurse specialist, and patient education expert ensured clinical relevance. The preliminary instrument included 35 items. Content validity was assessed using a two-round Delphi study with healthcare professionals and patients. Items were rated for relevance, clarity, and feasibility on a 5-point Likert scale. Participants could also give qualitative feedback on clarity and missing elements. The Item-Content Validity Index (I-CVI; cut-off ≥ 0.78) and Scale-Content Validity Index (S-CVI; cut-off ≥ 0.90) were calculated to quantify agreement.
Results: After two Delphi rounds, 24 items met the predefined threshold for content validity I-CVI ≥ 0.78, resulting in a tool structured across four domains: physical, psychological, social and treatment adherence. The final S-CVI was 0.89 for healthcare professionals and 0.85 for patients. Qualitative feedback led to refinements in content, item formulation, response options and the removal of redundant questions.
Conclusion: We developed a symptom burden instrument specifically designed for patients with liver cirrhosis. The tool demonstrates good content validity and has the potential to serve as a patient-centered measure for systematic symptom assessment. Its implementation in clinical practice may improve symptom recognition, guide individualized care and enhance shared decision-making. Further psychometric testing in larger patient populations is warranted to confirm reliability and construct validity.

Becoming a different person - Living with hepatic encephalopathy

Rikke Werge[1], Marie Louise Hamberg[2], Susanne Lauridsen[2,3], Thora Thomsen[4,5]. [1]*Copenhagen University Hospital, Amager Hvidovre, Hvidovre, Denmark;* [2]*Copenhagen University Hospital, Herlev Gentofte, Herlev, Denmark;* [3]*WHO-CC Parker Institute, Copenhagen, Copenhagen, Denmark;* [4]*Zealand University Hospital, Koege, Denmark;* [5]*University of Southern Denmark, Odense, Denmark*
Email: rikke.parsberg.werge.02@regionh.dk

Background and aims: People living with liver cirrhosis experience a high symptom burden and low HR-QoL. Hepatic encephalopathy (HE) occurs in up to 75% of those with cirrhosis but is sparsely described from the individual's perspective. Due to recurrent cognitive impairment, a marginalized diagnosis, and a healthcare discourse emphasizing involvement and self-responsibility, these individuals appear vulnerable when navigating a complex healthcare system.
Research reveals a lack of qualitative insight into the lived experiences of HE among people with liver cirrhosis. This study aimed to explore how these people experience living with HE as a recurring condition in everyday life, and how they are met by healthcare professionals (HCPs).
Method: A qualitative explorative study was conducted within the framework of Interpretive Description. Semi-structured interviews were performed with four participants and four HCPs. Data were analyzed thematically using Braun and Clarke's six-step approach and reported according to COREQ guidelines.

Results: The overarching theme *"Becoming a different person"* captured the profound physical, cognitive, and existential transformations related to HE. Three main themes were constructed:
1. Change and loss – Participants described changes in identity, self-understanding, and social relationships, accompanied by loss of control and experiencing isolation.
2. New paths – Participants adopted mental and practical strategies to navigate fluctuating cognitive function in order to maintain daily life.
3. HE in clinical encounters – requires empathy, flexibility, continuity and unconventional approaches from HCPs. Stigma associated with cirrhosis, and it's expected association to alcohol use disorder further intensified vulnerability.
Conclusion: HE is experienced as a transformative and isolating condition, deeply affecting identity, autonomy, and social roles through increased vulnerability of those affected. The clinical encounter is shaped by the cognitive impairment caused by HE, requiring tailored and sensitive care from HCPs. Findings highlight the need for individualized care, early and repeated education of staff, as well as development of HE-specific consultations. Addressing the related stigma and supporting relatives are essential to improving quality of life.

OS-025
Dietary practices and beliefs in individuals with primary sclerosing cholangitis – Associations with symptoms and pleasure in eating

Catarina Lindqvist[1], Adam Schumacher[2], Martine Walmsley[3], Nora Cazzagon[4], Annika Bergquist[5]. *[1]Gastroenterology and Nutrition Unit, Department of Medicine Huddinge, Karolinska Institutet, Section Clinical Nutrition, Karolinska University Hospital, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Stockholm, Sweden; [2]Gastroenterology and Nutrition Unit, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden; [3]PSC Support, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Oxford, United Kingdom; [4]Department of Surgery, Oncology and Gastroenterology, University of Padova, Azienda Ospedale, Università Padova, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Padova, Italy; [5]Gastroenterology and Nutrition Unit, Department of Medicine Huddinge, Karolinska Institutet, Department of Upper Abdominal Diseases, Karolinska University Hospital, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Stockholm, Sweden*
Email: catarina.lindqvist.1@ki.se

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease commonly associated with inflammatory bowel disease (IBD) and currently has no cure. Individuals with PSC frequently seek information on diet and its potential influence on disease progression. The aim of this study was to investigate dietary practices and beliefs of individuals with PSC.
Method: A survey was developed by members of the PSC working group within the European Reference Network (ERN) Rare Liver. The survey included multiple-choice and open-ended questions on PSC, IBD, symptoms, dietary beliefs and practices, eating-related symptoms, and sources of dietary advice. The anonymous, open survey was available online on the EU Survey platform in 11 languages from January to June 2025 and was distributed via ERN newsletter and webpage, healthcare centres and patient organisations. Descriptive statistics were performed.
Results: A total of 839 individuals with PSC from 33 countries responded (mean age 48 ± 15 years; 55% female). IBD was reported in 57%, liver cirrhosis in 28%, and previous liver transplantation in 16%. While 88% reported wanting dietary advice, only 38% had received PSC-specific dietary guidance. More than half preferred consultation with a health-care professional. Vitamins or supplements were prescribed in 32%, self-initiated in 24%, and 16% had both prescribed and self-initiated use. Two-thirds reported changing dietary habits after PSC diagnosis. Specific foods were reported to worsen symptoms in 42%, with fatty foods most frequently mentioned, followed by red meat and dairy products. Only 26% reported no eating-related symptoms and 48% reported two or more symptoms. Abdominal pain (43%) was the most common symptom affecting normal eating, followed by diarrhoea (34%) and digestive difficulties (31%). Thirty-two percent stated that PSC reduced their enjoyment of eating, mainly because certain foods caused unwanted symptom. Among respondents with IBD, 44% considered IBD the main condition influencing their diet, 14% considered PSC, and 28% had difficulties determining which disease had the greatest impact.
Conclusion: Many individuals with PSC report dietary changes and symptom-related eating difficulties, yet few receive professional dietary guidance, highlighting an unmet need for structured nutritional support in PSC care.

Understanding long-term hepatobiliary morbidity after intrahepatic cholestasis of pregnancy in the UK, and how this varies by ethnicity

Rebecca Lissmann[1], Fabiola Eto[1], Stamatina Iliodromiti[1], Julia Zollner[2], Caroline Ovadia[3], Catherine Williamson[4], Jennifer Jardine[5]. *[1]Queen Mary University of London, London, United Kingdom; [2]University College London, London, United Kingdom; [3]The University of Edinburgh, Edinburgh, United Kingdom; [4]Imperial College London, London, United Kingdom; [5]University of Cambridge, Cambridge, United Kingdom*
Email: r.lissmann@qmul.ac.uk

Background and aims: Intrahepatic cholestasis of pregnancy (ICP) is associated with impaired bile flow in the liver and adverse pregnancy outcomes. Existing smaller studies in predominantly ethnically homogenous European populations have suggested an association between ICP and long-term hepatobiliary morbidity. We aimed to understand the association between ICP and subsequent hepatobiliary morbidity in England, and to explore how this varied by ethnic group.
Method: Hospital Episode Statistics records of births in 2000–2021 were linked to primary care (CPRD Aurum) and secondary care (Hospital Episode Statistics) data. Women with an ICP diagnosis during the first recorded pregnancy were compared with those without. Incidence of subsequent hepatobiliary morbidity (including composite hepatobiliary disease, gallstone disease, other liver disease, pancreatitis, infectious liver disease, fibrosis and cirrhosis, hepatobiliary malignancy, and end stage liver disease) was established. Cox regression was used to estimate time-related associations. Models incorporated maternal age at birth and ethnicity.
Results: 3,701,995 women were included in the analysis, of whom 31,082 (0.8%) were diagnosed with ICP in their first recorded pregnancy. Median follow-up time was 10.4 years (IQR 5.8–15.0). Incidence of ICP varied by ethnicity: 0.8% in white, 1.3% in South-Asian, 0.5% in Black, 0.7% in Mixed, and 0.9% in Other ethnic groups. Those with a recorded ICP diagnosis were more likely to progress to liver morbidity compared to those without: composite hepatobiliary disease aHR 2.38 (CI 2.29–2.48, $p < 0.001$), pancreatitis aHR 2.43 (95% CI 2.13–2.76, $p < 0.001$), gallstones aHR 2.24 (95% CI 2.14–2.34, $p < 0.001$), hepatobiliary malignancy aHR 4.05 (95% CI 1.91–8.56, $p < 0.001$), fibrosis and cirrhosis aHR 2.92 (95% CI 2.22–3.84, $p < 0.001$), other liver disease aHR 2.52 (2.30–2.75, $p = <0.001$), infectious liver disease aHR 2.10 (95% CI 1.75–2.52, $p < 0.001$)), and end stage liver disease aHR 2.05 (95% CI 1.42–2.98, $p < 0.001$). Compared to White women, Black and South Asian women had an increased risk of subsequent severe hepatobiliary morbidity.

Conclusion: This study provides the strongest evidence to date of an association between ICP and hepatobiliary morbidity. We have explored how this association varies by ethnicity. Postpartum follow-up and inclusion of ICP in hepatobiliary risk stratification appear to be important. Interventions should tackle health inequalities between ethnic groups.

OS-027

A prospective, randomized, double-blind, placebo-controlled, phase III, multicenter study to evaluate the immunogenicity and safety of recombinant hepatitis-e vaccine in healthy adults & adolescents

Premashis Kar[1], Ayush Jasrotia[1], Nikhil Nagre[1], Jata Shankar Kumar[1].
[1]*Max Super Speciality Hospital, Vaishali, W-3, Ashok Marg, near Radisson Blu Hotel, Sector-1, Vaishali, Ghaziabad, Uttar Pradesh 201010, Ghaziabad, Uttar Pradesh 201010, India*
Email: premashishkar@gmail.com

Background and aims: Hepatitis E virus (HEV) remains a major cause of acute viral hepatitis in developing countries, with significant morbidity among young adults and pregnant women. A recombinant HEV vaccine offers a promising preventive approach. This Phase 3 study was conducted to evaluate the immunogenicity and safety of a purified recombinant Hepatitis-E Vaccine (E. coli) in a healthy Indian population.
Method: This was a multicenter, randomized, double-blind, placebo-controlled trial. Healthy Indian adults and adolescents (aged 16–65 years) seronegative for anti-HEV IgG (IgG <0.9) were enrolled and randomized in a 1:1 ratio to receive either the Hepatitis-E vaccine or placebo. The vaccination schedule consisted of three doses administered at Month 0 (Day 1), Month 1 (Day 31 ± 7), and Month 6 (Day 181 ± 14), with final evaluation at Month 7 (Day 211 ± 14). The primary endpoint was seroconversion rate 1 month after the third dose. Secondary endpoints included changes in geometric mean titres (GMT) of anti-HEV antibodies and safety assessments based on adverse events (AEs) and clinical/laboratory monitoring.
Results: Out of 347 screened subjects, 190 were enrolled (96 males, 94 females; median age 34 years). At study completion, seroconversion rates were significantly higher in the vaccine group compared to placebo (ITT: 75% vs 18%, PP: 89% vs 22%; $p < 0.001$). Mean GMT increases were also significantly greater in the vaccine group (ITT: 3.17 vs 0.15; PP: 3.68 vs 0.13; $p < 0.0001$). A total of 29 adverse events were reported among 13 subjects. The most common AEs were headache (n = 7), pyrexia (n = 3), eosinophilia (n = 3), and fatigue (n = 3), all of which were mild and resolved without sequelae. No serious adverse events or deaths occurred. Laboratory, vital, and physical examination parameters remained within normal limits.
Conclusion: The recombinant Hepatitis-E Vaccine (E. coli) demonstrated strong immunogenicity with a statistically significant increase in seroconversion and GMT compared to placebo, and was well tolerated. These results support its use in HEV-endemic regions to reduce the burden of hepatitis E.

Background and aims: Early readmission after hospitalization for decompensated cirrhosis is associated with adverse outcomes, yet its predictors and global disparities poorly characterized. We aimed to identify determinants of 30-day readmission following index non-elective hospitalization and its impact on short-term outcomes.
Method: The CLEARED Consortium prospectively enrolled hospitalized patients with cirrhosis globally. Patients who died, underwent liver transplantation (LT) during index admission, or lost to follow-up were excluded. The primary outcome was 30-day readmission. Centers were categorized as high-income (HIC), upper-middle–income (UMIC), or low/low-middle–income countries (LMICs).
Results: A total of 8,263 hospitalized patients with cirrhosis enrolled in registry, of which 5,692 were analyzed with mean age of 56.16 ± 13.31 years, 64.1% male and predominant etiology being alcohol (41.1%). Within 30 days of discharge, 1,610 patients (28.3%) were readmitted. Readmitted patients had higher rates of prior ascites (70.3% vs. 61.5%), overt hepatic encephalopathy (22.7% vs. 13.4%), hyponatremia (31.2% vs. 24.4%), acute kidney injury (21.6% vs. 13.0%), hospitalization (61.2% vs. 44.0%) and infection (25.3% vs. 15.9%) within the preceding 6 months (all $p < 0.001$). Viral etiologies, particularly hepatitis C (13.9% vs. 10.1%, $p < 0.001$), higher MELD-Na scores (27 vs. 25, $p < 0.001$), and admissions with anasarca or dyselectrolytemia were common among readmitted patients. Thirty-day readmission was associated with higher mortality (10.4% vs. 4.8%) and LT rates (8.9% vs. 3.6%) (both $p < 0.001$). Readmission rates were highest in HICs (37.1%) with a low post-readmission mortality. On multivariable analysis, HCV etiology (OR 1.48), 6-month hospitalization (OR 1.66) or infection (OR 1.22), at admission presence of anasarca (OR 1.39) and higher MELD-Na (OR 1.02 per point) independently predicted readmission (all $p \leq 0.03$). LMIC (OR 0.41) and UMIC (OR 0.62) residence were independently associated with lower odds of readmission than HICs (both $p < 0.001$) but a higher mortality.
Conclusion: Early readmission and recent healthcare utilization occurs in one-quarter of hospitalized patients with cirrhosis and identifies a population with a poor short-term survival and higher need of LT. Higher rate of readmissions, lower mortality and higher transplant rate in high-income countries than the low- and middle-income countries, likely a reflection of barriers to access rather than lower disease burden.

OS-029

Impact of rapid testing and self-administered risk questionnaires on hepatitis C screening rates

Background and aims: Underdiagnosis remains a major barrier to Hepatitis C (HCV) elimination. The ATENEA study assesses whether the implementation of rapid testing combined with a self-administered risk assessment in Primary Care (PC) settings could enhance HCV detection.
Method: This is a cluster-randomized, stepped-wedge trial (clinicaltrials.gov ID: NCT06528626) conducted across eight PC centers between July 2023 and February 2025. An initial 4-month observation phase (July–October 2022) was implemented in all centers, followed by 4-month intervention periods: Control (standard practice after training on HIV screening) Rapid hepatitis C testing (RT) Combined intervention (RT + self-administered risk questionnaire; RT+Q) Intervention type was modeled as a categorical variable with four levels, using the observation phase as the reference. We calculated HCV screening coverage (HCV tests performed) and total and new HCV diagnoses per 100,000 patients attended. Poisson regression models, adjusted for period and clustering by center, were fitted to estimate incidence rate ratios (IRRs) with 95% confidence intervals.
Results: A total of 40 center-period observations were analyzed. The study population included 237,670 individuals, with 14,975 HCV tests performed, yielding 208 positive results (26 newly diagnosed). Compared with the observation phase (2,120 HCV tests were conducted with 23 positives), HCV Screening rates increased by 124% in the RT+Q phase (IRR = 2.24; 95% CI: 2.00–2.50; $p < 0.001$) and by 96% in the RT phase (IRR = 1.96; 95% CI: 1.34–2.87; $p = 0.001$), while Control phase demonstrated a non-significant increase (IRR = 1.54; $p = 0.131$). The Prevalence of Anti-HCV significantly increased in the RT+Q phase (IRR = 2.83; 95% CI: 1.95–4.13; $p < 0.001$), with non-significant upward trend in RT phase (IRR = 1.75; $p = 0.105$), and Control phase revealed no differences (IRR = 0.84; $p = 0.799$).
Conclusion: The implementation of rapid hepatitis C testing combined with self-administered risk questionnaires in Primary Care significantly enhances screening activity.

OS-030

A multicentre randomised controlled trial of screening for MASLD in patients with type 2 diabetes not known to have liver disease in primary care

Ryan Buchanan[1], Tina Reinson[1], Josh Bilson[1], Scott Harris[1], Chinonso Nwoguh[1], Keith Cooper[1], Mary Onoja[1], Karen Malone[2], Chris D Byrne[1]. [1]University of Southampton, Southampton, United Kingdom; [2]Woolston & Town Hill Primary Care Network, Southampton, United Kingdom
Email: rmb1d14@soton.ac.uk

Background and aims: Current guidance for liver disease assessment in type 2 diabetes mellitus (T2DM) varies, and in the United Kingdom (UK) testing for MASLD fibrosis is largely limited to individuals with ultrasound-confirmed steatosis or abnormal liver enzymes. We evaluated the clinical effectiveness and costs of alternative fibrosis assessment strategies.
Method: REFLEX was an unblinded, individual-level, 1:1 randomised controlled multicentre trial conducted across primary and secondary care in the Wessex region of England (population ~8 million). The protocol was published (BMJ Open 2025) and the study prospectively registered. Adults with Systematised NOmenclature of MEDicine code registered T2DM and no known liver disease or liver testing in the preceding two years were eligible. Participants were randomised

to either a 'FibroScan First' pathway or to Usual Care. The primary outcome was referral for hepatocellular carcinoma (HCC) surveillance within 12 months of randomisation. Secondary analyses modelled two-step strategies using ELF or Fib-4 as initial tests prior to FibroScan. A cost-effectiveness evaluation is ongoing.
Results: 634 participants were randomised (318 'FibroScan First'; 316 Usual Care). At 12 months, only 13 (4%) participants in Usual Care had undergone fibrosis assessment. In contrast, 313 participants in the 'FibroScan First' arm received a scan; 39 met criteria for hepatology referral. Twelve participants (4%) were diagnosed with F4 fibrosis and commenced HCC surveillance, and a further 64 (20.1%) were diagnosed with F2/F3 fibrosis. No cases of F4 or F2/F3 disease were identified in Usual Care. Total pathway costs were £33,518/€38,200 for 'FibroScan First' and £1,105/€1259 for Usual Care. Modelling two-step pathways reduced case detection: F4 disease fell to 6 (2%) cases using ELF and 5 (2%) using Fib-4. Costs were £33,103/€37,735 for ELF +FibroScan and Fib4+FibroScan £7,325/€8,350.
Conclusion: Usual care in this trial identified no cases for HCC surveillance over 12 months. A 'FibroScan First' screening strategy substantially increased detection of clinically significant disease leading to cancer surveillance. Two-step strategies using ELF or Fib-4 missed around half of cases with cirrhosis. Ongoing cost-effectiveness modelling analyses will determine whether early diagnosis offsets increased upfront costs.

Email: 93cool@hanmail.net

Background and aims: Alcohol-related liver disease (ALD) is a leading cause of morbidity, mortality and liver transplantation. Silencing of *hydroxysteroid 17-beta-dehydrogenase-13 (HSD17B13)* is a promising option, as loss-of-function (LOF) is associated with reduced ALD progression. GSK4532990, an N-acetylgalactosamine conjugated siRNA, selectively targets *HSD17B13* in hepatocytes to mimic the LOF mutation. We report safety and pharmacokinetics (PK) from a Phase 2 study safety lead-in of GSK4532990 in participants (pts) with ALD (NCT06613698).
Method: Eligible pts (18–70 yrs) had a history of alcohol consumption consistent with ALD/met-ALD, with either Child-Turcotte-Pugh (CTP) A or CTP-B hepatic impairment. Pts received a subcutaneous dose of GSK4532990 and were evaluated over 8 weeks for safety (vital signs, ECG, laboratory tests, adverse events [AEs]). Intensive PK were collected on Day 1 and analysed non-compartmentally.
Results: In total, 16 pts (n = 8 per CTP cohort) completed the study (no withdrawals). Eleven pts experienced treatment-emergent AEs (TEAEs); 4 had TEAEs related to study treatment. The most common treatment-related AEs were injection site reactions. Eight serious TEAEs were reported in 5 pts; none were related to study treatment. Two CTP-A pts experienced protocol-defined liver events, adjudicated as not causally related to GSK4532990. There were no safety findings regarding laboratory parameters, ECG and vital sign changes from baseline (BL). BL median (min, max) AST (U/L) was 120 (45, 194) for CTP-A, 56 (42, 120) for CTP-B pts; median change from BL (U/L) at Week (W)8 was −44 (−102, 201) for CTP-A, −7 (−67, 9) for CTP-B. Median ALT values at W8 were also reduced, despite similar median PeTH at W8 vs. BL. Median T_{max} was 6.0 hrs post-dose for CTP-A and CTP-B pts. Geometric mean apparent $t_{1/2}$ (coefficient of variation %) was 6.4 (10.4; CTP-A) and 7.2 (19.8; CTP-B) hrs. Geometric mean C_{max} and AUC_{0-24h} were at least 19- and 24-fold lower for both cohorts, compared with corresponding exposures maximum tolerated dose in monkey toxicology studies.
Conclusion: No safety concerns were identified in pts with CTP-A and CTP-B hepatic impairment after a single dose of GSK4532990. Liver biochemistry improved in both cohorts despite ongoing alcohol consumption. PK were comparable between CTP-A and CTP-B pts and demonstrated wide safety multiples relative to nonclinical toxicology. These results supported initiation of the main study and continued development of GSK4532990 in ALD.

Background and aims: Alcohol-related liver disease (ALD) and metabolic dysfunction and ALD (MetALD) represent an under-recognized part of the steatotic liver disease spectrum, particularly at early, asymptomatic stages. Population-level data on their prevalence and fibrosis severity are limited, and the joint impact of alcohol and cardiometabolic risk factors remains poorly defined. We aimed to estimate the prevalence and severity of ALD and MetALD in the European general population using the LiverScreen cohort.
Method: We conducted a prospective screening study in individuals aged ≥40 years from the general population in nine European countries. We recorded demographic, clinical, and standard laboratory parameters, and assessed liver fibrosis using liver stiffness measurements (LSM). Individuals with LSM ≥ 8 kPa and/or ALT ≥ 1.5 × the upper limit of normal were referred for hepatology consultation including liver biopsy in patients who agreed to the procedure.
Results: We included 30,199 individuals from the general population (mean age 58 ± 10 years; 57% women). Overall, 7.1% reported harmful alcohol use (women/men: ≥14/21 drinks/week) and 70% had at least one cardiometabolic risk factor. At inclusion, 31% had steatotic liver disease (ALD = 0.4%; MetALD = 2%; MASLD = 28%), while 69% had no steatotic liver disease. The prevalence of significant fibrosis was highest in ALD, with 10.9% having LSM ≥ 10 kPa, followed by MetALD (7.5%) and MASLD (4.3%). In patients with MetALD or ALD, only 5.2% had ALT ≥ 1.5 × the upper limit of normal; however, exceeding this threshold was associated with a markedly higher risk of MetALD or ALD (odds ratio 3.4, 95% CI 2.4–4.5; p < 0.001). Among the 2,457 individuals referred for hepatology consultation, 331 underwent liver biopsy. Advanced fibrosis (≥F3) was present in 28% (93/331). Among biopsied patients with ALD or MetALD, 39% had advanced fibrosis, significantly higher than in those with MASLD (27%).
Conclusion: In this large, population-based cohort, ALD and MetALD accounted for a small proportion of patients with steatotic liver disease but were associated with a higher burden of advanced fibrosis. These findings underscore a substantial yet underrecognized burden of ALD and MetALD in the general population, highlighting the need for earlier and more systematic identification.

OS-033
Efficacy and safety of bovine colostrum in the treatment of severe alcohol- associated hepatitis

Sandeep Sidhu[1], Ajay Kumar Duseja[2], Shalimar Shalimar[3], Sandeep Nijhawan[4], Dharmesh Kapoor[5], Omesh Goyal[6], Harsh Kishore[7], Prasanna Samuel Premkumar[8], Saravanaraj Karuppasamy[8]. *[1]Christian Medical College Ludhiana, Ludhiana, India; [2]Postgraduate Institute Of Medical Education And Research Chandigarh, Chandigarh, India; [3]All India Institute of Medical Sciences, Delhi, India, New Delhi, India; [4]Sawai Man Singh Medical College, Jaipur, India; [5]Yashoda Hospitals, Secunderabad, India; [6]Dayanand Medical College and Hospital, Ludhiana, India, Ludhiana, India; [7]Dayanand Medical College and Hospital, Ludhiana, India; [8]Christian Medical College, Vellore, Vellore, India*
Email: sandeepsidhu1963@gmail.com

Background and aims: Severe alcohol-associated hepatitis (sAH) is associated with high short-term mortality. sAH is linked to gut dysbiosis, intestinal barrier dysfunction, bacterial translocation, and heightened liver inflammation. Bovine colostrum is a naturallyoccurring, immunoglobulin G-enriched oral preparation containing lactoferrin and short-chain fatty acids. We evaluated the efficacy and safety of bovine colostrum in patients with sAH.
Method: This phase 3, parallel-group, double-blind, randomised, placebo-controlled trial was conducted at five academic tertiary care centres in India. Between 2017 and 2023, 174 patients with sAH were centrally randomised using the Trans European Network for Clinical Trials Services to receive freeze-dried bovine colostrum (20 g) or placebo (pasteurised bovine milk powder, 20 g) three times daily for 4 weeks. Eighty-nine patients were assigned to the colostrum group and 85 to the placebo group. Patients, investigators, and statisticians were masked to treatment allocation. The primary outcome was 90-day survival, assessed in the intention-to-treat population.
Results: Ninety-day survival was significantly higher in the colostrum group (86.5%; 95% confidence interval 77.2–92.5) than in the placebo group (43.5%; 32.9–54.7) (p < 0.0001), despite similar baseline Model for End-Stage Liver Disease (MELD) scores (median 30.2 vs. 31.5). Restricted mean survival time was 79.6 days (interquartile range 74.1–85.1) in the colostrum arm and 47.2 days (39.3–55.0) in the placebo arm (p < 0.0001). Secondary outcomes showed significant reductions in MELD scores, serum endotoxin and tumor necrosis factor-alpha levels, and thirteen episodes of sepsis in the colostrum group vs. 29 in the placebo arm (p = 0.009) in the first month. Serious adverse events reflected disease severity and were not due to the intervention.
Conclusion: This study demonstrated a significant improvement in 90-day survival with bovine colostrum in patients with sAH. Corticosteroids were not used as a comparator arm because MELD scores were ~30. However, this treatment warrants confirmation in additional populations.

OS-034
Multilevel remodeling of the glucocorticoid receptor axis underlies corticosteroid resistance in severe alcoholic hepatitis

Qun Cai[1], Marco Fidaleo[1], Graziella Privitera[1], Meiqian Hu[1], Changze Hong[1], MohammadMahdi Saeidinejad[1], Fausto Andreola[1], Rajiv Jalan[1]. *[1]University College London, Royal Free Campus, Institute for Liver and Digestive Health, London, United Kingdom, London, United Kingdom*
Email: quncai@zju.edu.cn

Background and aims: Severe alcoholic hepatitis (SAH) causes acute decompensation and high short-term mortality. Corticosteroids benefit only a subset of patients, and mechanisms of non-response are unclear. Because steroid effects depend on the glucocorticoid receptor (GR) and GR isoform balance shaped by alternative splicing, we investigated whether dysregulated GR signaling and splicing regulation in hepatocytes and peripheral monocytes contributes to steroid non-response in SAH.
Method: We prospectively enrolled patients with SAH(n = 25), stable cirrhosis (SC, n = 10) and healthy controls (HC, n = 10). In an independent SAH cohort (n = 50), patients were classified as corticosteroid responders (R, n = 21) or non-responders (NR, n = 29) using the Lille model. Liver biopsies were stained for GRα+β, GRβ and Serine-Rich Splicing Factor 3/5/9. Peripheral blood monocytes from HC, SC and SAH were analyzed for cytoplasmic/nuclear GRα/GRβ and GR transactivation after dexamethasone, with additional experiments using SAH plasma and the TLR4 inhibitor (YAQ005). Underlying mechanistic studies were performed in HHL-5 cells exposed to EtOH, LPS and DEXA.
Results: In SAH cohort, NR had higher mortality (28-day 14.2% vs 0%; 90-day 17.9% vs 4.8%). In liver biopsies, responders showed a GRα-high/GRβ-low pattern with an increased GRα/GRβ ratio, while non-responders exhibited reduced nuclear GRα, enhanced GRβ in ballooned/steatotic hepatocytes and reduced nuclear SRSF3. In monocytes, dexamethasone increased GRα nuclear translocation and GR transactivation in healthy and SC subjects, but not in SAH, which displayed relatively increased GRβ. SAH plasma induced a steroid-resistant phenotype in healthy monocytes, partially reversed

by YAQ005. In HHL-5 cells, dexamethasone increased nuclear GRα and the GRα/GRβ ratio in controls, whereas EtOH+LPS, but not EtOH or LPS alone, reduced nuclear SRSF3, shifted GR isoforms towards GRβ and blunted DEXA-induced GRα nuclear translocation.
Conclusion: SAH is characterised by multilevel disruption of the GRα/GRβ–SRSF3 axis in the liver and circulating monocytes, providing a mechanistic basis for corticosteroid resistance. The data provide potential candidate biomarkers and therapeutic targets focusing on ensuring GR balance, increasing SRSF3 expression and monocyte GR function. The restoration of GR balance following inhibition of TLR4 indicates a potential novel therapy and should be explored further in suitable models.

OS-035
Impact of glucagon-like peptide-1 therapy on alcohol-related outcomes in cirrhosis: real-world evidence from a multi-center United States cohort
Islam Mohamed[1], Basil Jalamneh[1], Mohamad Ibrahim[2], Judy Sheffeh[3], Prasun Jalal[2]. [1]*Cleveland Clinic Foundation, Cleveland, United States;* [2]*Baylor College of Medicine, Houston, United States;* [3]*Henry Ford Warren Hospital, Warren, United States*
Email: jalal@bcm.edu

Background and aims: Alcohol use disorder (AUD) is a major contributor to alcohol-related liver disease (ALD)-related complications, including hepatic decompensation and liver transplant waitlist removal. Sustained abstinence is central to improving outcomes and current pharmacologic strategies for preventing relapse show limited effectiveness. Glucagon-like peptide 1 (GLP-1) receptor agonists may reduce alcohol cravings through central reward modulation and improve metabolic dysfunction, which often coexists with ALD, but real-world evidence evaluating their clinical impact is limited. This study aimed to assess the effects of GLP-1 receptor agonists on alcohol relapse and liver-related complications among individuals with ALD using TriNetX United States Collaborative Network.
Method: We conducted a retrospective cohort study using the TriNetX global network of 111 healthcare organizations to evaluate adults with alcohol-related liver disease exposed to GLP-1 receptor agonists versus unexposed controls. The index date was the first prescription for exposed patients and the corresponding diagnosis date for controls, with outcomes assessed from 30 to 365 days. Propensity score matching balanced clinical and laboratory factors. Primary outcomes included alcohol-related events, liver disease progression, hospitalization, transplant listing, and phosphatidylethanol positivity. Time-to-event analyses used Kaplan–Meier methods with hazard ratios.
Results: After propensity matching, 9,293 patients were included in each cohort. GLP-1 RA exposure was associated with a significantly lower risk of alcohol remission events (HR 0.76, 95% CI 0.69–0.84), alcohol withdrawal (HR 0.43, 95% CI 0.37–0.51), and alcohol intoxication (HR 0.37, 95% CI 0.31–0.45). GLP-1 RA use was also associated with reduced risks of alcohol-associated hepatitis (HR 0.49, 95% CI 0.43–0.57), cirrhosis progression (HR 0.58, 95% CI 0.46–0.72), all-cause hospitalization (HR 0.46, 95% CI 0.39–0.55), and hepatic decompensation (HR 0.58, 95% CI 0.51–0.66). No significant differences were observed in liver transplant listing or PEth positivity.
Conclusion: In this large real-world cohort with alcohol-related liver disease, glucagon-like peptide 1 receptor agonists were associated with reduced alcohol-related events, slower liver disease progression, and fewer hospitalizations. These findings suggest a potential adjunctive role for glucagon-like peptide 1 therapy in mitigating relapse and improving outcomes, warranting further prospective evaluation.

CD74+ macrophage attenuates metabolic dysfunction-associated steatotic liver disease by driving efferocytosis-dependent metabolic reprogramming and phenotype switch
Yang Xiao[1], Tian Lan[1], Yuanshui Long[1], Chengwei Tang[1], Zhiyin Huang[1], Jinhang Gao[1]. [1]*Department of Gastroenterology and Hepatology, West China Hospital, Sichuan University, Chengdu, China*
Email: xiaoyangsg@foxmail.com

Background and aims: Macrophages clear hepatocytes that undergo programmed cell death (PCD) through efferocytosis to promote tissue regeneration. How efferocytic macrophages regulate metabolic dysfunction-associated fatty liver disease (MASLD) and liver fibrosis through metabolic reprogramming remains to be fully deciphered. We aim to investigate the role and mechanism of CD74$^+$ macrophages in efferocytosis and MASLD.
Method: RNA-sequencing and metabolomics were employed to analyze phenotypes of macrophages after efferocytosing apoptotic, pyroptotic, and necroptotic hepatocytes. Macrophage-specific *Cd74* knockdown mice were fed with CDAHFD diet for 12 weeks to induce MASLD. Single-cell RNA sequencing (scRNA-seq), spatial transcriptomics, and multiplex immunofluorescence (mIF) were performed in the liver of CDAHFD diet-fed mice, and fluorescence-activated cell sorting and live cell imaging in cells, to evaluate CD74$^+$ macrophages-mediated efferocytosis.
Results: Depending on the type of PCD, efferocytosis of dying hepatocytes triggered distinct transcriptional and metabolic phenotypes in macrophages, while *Cd74* expression was consistently upregulated. *Cd74* deletion in macrophages inhibited efferocytosis of dying hepatocytes *in vitro*. Mechanistically, Co-immunopercipitation assay showed that CD74 bind to GAS6, a bridging molecule crucial for the detection and engulfment of dying cells. ScRNA-seq and mIF from patients revealed that the number and proportion of CD74$^+$ macrophages and efferocytosis of dying hepatocytes were increased with the progression of liver fibrosis. Spatial transcriptomics revealed that macrophage-specific *Cd74* knockdown inhibited efferocytosis, resulting in an increased number of apoptotic hepatocytes and liver fibrosis and steatosis in MASLD mouse model, confirmed by staining. Metabolomics showed decreased level of S-adenosylmethionine (SAM), the main source of methionie essential for histone methylation, and increased level of nicotinamide in efferocytic macrophages, which further increased SAM consumption. These metabolic changes inhibited histone methylation and downstream transcription of macrophage cathepsin S, a profibrotic factor that induced hepatic stellate cell activation and liver fibrosis.
Conclusion: CD74$^+$ macrophages represent a macrophage subset characterized by high efferocytic capacity. Efferocytosis of dying hepatocytes triggered metabolic reprogramming-mediated histone modification, which reversed the profibrotic phenotype of macrophages and inhibited liver fibrosis.

Email: carmen.garcia@iibb.csic.es

Background and aims: Metabolic dysfunction–associated fatty liver disease (MAFLD) is associated with extrahepatic complications, particularly cardiovascular disease (CVD), yet the mechanistic liver–heart connection remains unclear. Cholesterol trafficking to mitochondria via STARD1 promotes MAFLD progression and hepatocellular carcinoma. Mitochondrial cholesterol is converted by CYP27A1 into 27-hydroxycholesterol (27-OHC), the most abundant circulating oxysterol, which is elevated in MAFLD patients and induces atherosclerosis in mice. This study investigated the role of hepatic STARD1 in MAFLD progression and cardiac remodeling, focusing on 27-OHC as a mediator of the liver–heart axis.
Method: Male hepatocyte-specific StARD1 knockout ($StARD1^{\Delta Hep}$) and control ($StARD1^{f/f}$) mice were fed a standard diet or a high-fat, high-cholesterol (HFHC) diet (60% fat, 0.5% cholesterol) for up to 10 months. Liver injury, steatosis, and fibrosis were assessed histologically. Cardiac remodeling was evaluated by fibrosis staining, magnetic resonance imaging (MRI), and lipidomic analyses of cholesterol esters (CE), triglycerides (TG), ceramides, and 27-OHC. Cardiac expression of LRP-1 and cathepsin D (CatD) was analyzed in mouse hearts and in human cardiac myocytes treated with 27-OHC. Circulating 27-OHC was measured in serum from MAFLD patients.
Results: HFHC-fed $StARD1^{\Delta Hep}$ mice showed reduced liver injury, hepatocyte ballooning, steatosis, and fibrosis compared with $StARD1^{f/f}$ controls, confirming STARD1's role in MAFLD progression. Hearts from HFHC-fed $StARD1^{\Delta Hep}$ mice exhibited reduced LRP-1 and CatD expression and preserved cardiac output by MRI. Cardiac CE and TG content increased with HFHC feeding but did not differ between genotypes. Hepatic 27-OHC was nearly undetectable in $StARD1^{\Delta Hep}$ mice, while cardiac 27-OHC was reduced by ~50%, indicating that a substantial fraction of cardiac 27-OHC originates from the liver in a STARD1-dependent manner. Ceramide profiles were unchanged between genotypes.In vitro, 27-OHC reduced viability, increased ROS, and induced LRP-1 and CatD in human cardiac myocytes. Serum from MAFLD patients showed elevated circulating 27-OHC, supporting translational relevance.
Conclusion: Hepatic STARD1 promotes MAFLD progression and generates 27-OHC, contributing to cardiac remodeling and dysfunction. Elevated circulating 27-OHC in MAFLD patients supports a mechanistic liver–heart axis and identifies STARD1–27-OHC as potential therapeutic targets to mitigate liver–heart complications.

Email: tuulia.hyotylainen@oru.se

Background and aims: Metabolic dysfunction–associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide, yet excess adiposity alone does not explain interindividual susceptibility or disease progression. Environmental exposures, particularly endocrine-disrupting chemicals such as per- and polyfluoroalkyl substances (PFAS), may act as disease modifiers by exacerbating metabolic stress and impairing hepatic adaptive capacity. Our aim was to identify associations between real-life chemical exposures and MASLD severity and to study underlying metabolic pathways relevant to liver pathology.
Method: We performed an exposome-wide analysis in 1,521 adults from the European Steatotic Liver Disease (SLD) Registry, covering the spectrum of steatosis, inflammation, and fibrosis. Plasma PFAS and metabolic profiles were analysed using liquid chromatography–mass spectrometry. Associations with liver-related phenotypes were assessed using multivariable and sex-stratified analyses. Findings were combined with PFAS exposure experiments in mice and hepatocyte-like HepaRG cells to support mechanistic interpretation.
Results: PFAS and parabens were associated with MASLD severity, correlating with histologically characterised steatosis, ballooning, and fibrosis, with non-invasive fibrosis measures (fib4 and fibroscan) as well as markers of insulin resistance in sex-specific manner. PFAS exposure was linked to disturbances in bile acid metabolism, lipid metabolism (phosphatidylcholines and sphingolipids), amino acids and gut microbiota–derived metabolites, with stronger associations in males. Upregulation of several bile acids was also associated with fibrosis, especially in males (9 bile acids with adjusted $p < 0.1$, $t > 2.8$), and with lipids in both females and males (182 and 167 lipids in females and males, respcectly, adj. $p < 0.01$). These metabolic signatures were directionally consistent across human, *in vivo*, and *in vitro* models and were most pronounced under steatotic conditions, suggesting synergistic effects.
Conclusion: Integrated human and experimental data indicate that PFAS exposure is associated with more advanced MASLD through disruption of bile acid homeostasis, lipid metabolism, mitochondrial pathways, and the gut–liver axis. Environmental chemical exposure may therefore represent a clinically relevant modifier of MASLD progression, supporting the inclusion of exposome-informed perspectives in risk stratification and preventive strategies in hepatology.

DNMT3A establishes an epigenetic macrophage immunometabolic program driving inflammation and fibrosis in MASH

Amaia Navarro-Corcuera[1], Naroa Goikoetxea-Usandizaga[1], Carolina Conter[1], Patricia Peña-Sanfélix[1], Leidy Estefanía Zapata-Pavas[1], Nerea Ferreiro[1], María Luz Martínez-Chantar[1]. [1]*CIC bioGUNE, Basque Research and Technology Alliance, BRTA, building 801A, 48160, Derio, Spain*
Email: anavarro@cicbiogune.es

Background and aims: Metabolic dysfunction–associated steatohepatitis (MASH) is a leading cause of cirrhosis, hepatocellular carcinoma, and liver transplantation, with fibrosis stage representing the strongest predictor of mortality. Current therapies show limited antifibrotic efficacy, underscoring the need to target core fibro-inflammatory mechanisms. Macrophages are central drivers of MASH progression, yet the epigenetic programs locking them into pathogenic states remain undefined. We hypothesized that the de novo DNA methyltransferase DNMT3A acts as a master regulator of macrophage immunometabolic reprogramming that sustains inflammation and fibrosis in MASH.
Method: We used a diet- and toxin-induced FAT-MASH mouse model that recapitulates human steatohepatitis and advanced fibrosis. Macrophage heterogeneity was resolved by single-cell RNA-seq. DNMT3A expression and localization were assessed in murine and human MASH livers by transcriptomic and protein analyses. Causal and translational studies integrated myeloid-specific *Dnmt3a* knockout mice, pharmacological DNMT3A inhibition, epigenomic profiling (EM-seq, ChIP-seq), metabolic assays, and comparison with Resmetirom.
Results: Single-cell RNA-seq analysis in FAT-MASH mouse livers identified Kupffer-like macrophages, monocyte-derived macrophages, and lipid-associated macrophages (LAMs) enriched within inflammatory and fibrotic niches. LAMs expressing Trem2, Cd9, Spp1, and Lgals3 accumulated within fibrotic septa and correlated with histological disease severity. FAT-MASH mice developed extensive macrophage infiltration forming crown-like structures around lipid-laden hepatocytes, accompanied by robust induction of pro-inflammatory cytokines (TNF-alpha, IL-1beta, IL-6), hepatic stellate cell activation, increased collagen deposition, and bridging fibrosis. DNMT3A was strongly upregulated in Trem2^high macrophage subsets in both murine and human MASH livers and spatially localized to fibrotic regions. Functional data supported a DNMT3A-dependent epigenetic program that stabilizes glycolytic, pro-inflammatory, and pro-fibrotic macrophage states in MASH.
Conclusion: DNMT3A defines a previously unrecognized epigenetic checkpoint linking macrophage immunometabolism to persistent inflammation and fibrosis in MASH. Targeting DNMT3A-dependent macrophage programs represents a compelling immune–epigenetic strategy with potential to enhance antifibrotic efficacy beyond current therapies.

Sexually dimorphic palmitoylation of UTY of liver sinusoidal endothelial cells drives advanced metabolic dysfunction-associated steatohepatitis (MASH) via PGF2α/SPIN1 axis

Rui-Qi Li[1], Xi-Xuan Wang[1], Jun Guo[2], Hao Ren[1], Tianhao Mao[3], Cai-Yun Zhang[3], Zihao Liang[4], Dawei Yang[5], Yuzheng Zhuge[6], Feng Zhang[6], Wei Chen[4], Changhua Yi[4], Qingfang Xiong[1], Shu-Ling Chen[5], Wei Zhang[6], Yongfeng Yang[1]. Email: 627364595@qq.com

Background and aims: The pronounced male predominance in advanced metabolic dysfunction-associated steatohepatitis (MASH) remains mechanistically undefined beyond hormonal influences. Here, we identify a Y chromosome-encoded epigenetic circuit centered on UTY (ubiquitously transcribed tetratricopeptide repeat-containing protein Y-linked) that orchestrates sex-specific MASH through metabolic reprogramming of liver sinusoidal endothelial cells (LSECs).
Method: Utilizing endothelial-specific Uty knockout (Uty EC-CKO) male mice subjected to GAN diets for 20 weeks (MASH), we combined multi-omics profiling, chromatin topology analysis, and intercellular communication assays to delineate the UTY-mediated sexual dimorphism in MASH progression.
Results: Male LSECs exhibited enhanced UTY demethylase activity through Cys379 palmitoylation, driving H3K27me3 erasure at the prostaglandin F synthase (PGFS) promoter. PGFS-derived PGF2α secretion from male LSECs was 2.5- fold higher than females, activating co-cultured hepatic stellate cells (HSCs) via SPIN1 stabilization. PGF2α binding to SPIN1 disrupted its MARCH9-mediated ubiquitination, enabling SPIN1-H3K4me3 complex formation at fibrogenic loci (TGFβ1, Wnt5a). PGF2α exacerbated proinflammatory cytokine release in M1 macrophages. Pharmacological inhibition of UTY palmitoylation (2-BP) or SPIN1-H3K4me3 interaction attenuated collagen deposition by 48–62% in male models, while female fibrogenesis remained unaffected.
Conclusion: Our work unveils a Y chromosome-driven paradigm wherein palmitoylated UTY licenses male-dominant MASH through epigenetic-metabolic coupling in LSECs. The UTY-PGF2α-SPIN1 axis represents a precision therapeutic target for addressing sex disparities in MASH.

Email: salvatore.piano@unipd.it

Background and aims: Recently, the ADQI/ICA consensus suggested shortening albumin expansion from 48 to 24 hours in patients with cirrhosis and AKI. However, a significant proportion of responses

occurs between 24 and 48 hours. We aimed to develop new criteria to assess response after 24 hours of albumin expansion.
Method: Consecutive inpatients with decompensated cirrhosis and AKI stage≥1b were enrolled at the Hospital of Padova and followed until 90 days, death, or liver transplant. All patients underwent diuretic withdrawal and 48-hour albumin expansion. Serum creatinine (SCr) was assessed at 24 and 48 hours. AKI response was defined as ≥1 stage reduction or resolution. Discrimination ability of 24-hour percentage SCr changes to predict 48-hour response was assessed by the area under the ROC curve, and optimal cut-offs for response and non-response were identified using a likelihood ratio(LR)–based approach (LR+≥6 and LR-≤0.2). External validation was performed in a cohort from Hospital Clínic of Barcelona.
Results: 387 patients with decompensated cirrhosis and AKI were included (mean age 61.6 ± 10.7 years; 72% male). AKI response occurred in 28% of patients at 24 hours and 53% at 48 hours. Among patients classified as non-responders at 24 hours, 35% achieved response at 48 hours (i.e. 48% of all 48-hour responders). 24–hour percentage sCr changes showed high discrimination ability for predicting 48-hour response (AUROC = 0.87, 95%CI = 0.83–0.90, p < 0.001). According to the LR, 24-hour response was classified as full response (≥10% sCr decrease, FR), partial response (0–<10% sCr decrease, PR), or non-response (any increase of sCr, NR). 45%, 25%, and 31% of patients were classified as FR, PR, and NR, with 48-hour response rates of 89%, 36%, and 14%, respectively. The new classification independently predicted AKI resolution during hospitalization /.(FR: OR = 10.19, p < 0.001; PR: OR = 2.09, p = 0.027) and 90-day mortality (FR: sHR = 0.54, p = 0.006; PR: sHR = 0.63, p = 0.031). In the validation cohort (n = 379), discrimination ability of 24-hour percentage sCr changes was confirmed (AUROC 0.85, p < 0.001) as well as the accuracy of the new 24-hour response classification in predicting AKI response at 48 hours, AKI resolution and 90-day mortality.
Conclusion: The ADQI/ICA recommendation to assess albumin response at 24 hours misclassifies many patients as non-responders. The proposed 24-hour response criteria reduce misclassification and may guide decision-making in cirrhosis and AKI.

OS-042

Pulmonary hypertension phenotypes and severity independently predict non–liver-related mortality in compensated cirrhosis: applying the 2022 ESC/ERS criteria

Dario Saltini[1], Antonio Piscopo[2], Tomas Guasconi[1], Marcello Bianchini[1], Andrea Salomè Velasco Mayorga[2], Giustina Lo Cascio[2], Giulia Catania[3], Nicolò Giglioli[4], Filippo Scianò[1], Fabiola Milosa[4], Rosina Maria Critelli[4], Filippo Schepis[1]. Email: fschepis@unimore.it

Background and aims: Pulmonary hypertension (PulH) is increasingly recognized in cirrhosis, yet its prognostic impact in asymptomatic compensated patients remains undefined. The 2022 ESC/ERS guidelines lowered the diagnostic threshold (mPAP >20 mmHg) and introduced a novel "unclassified PulH" phenotype, both untested in hepatology. We investigated whether PulH phenotype and severity independently influence long-term survival beyond liver disease progression.
Method: We retrospectively analyzed consecutive patients undergoing paired hepatic venous pressure gradient and right-heart catheterization between 2016 and 2023. PulH was classified according to 2022 ESC/ERS criteria as pre-capillary (mPAP >20 mmHg, PCWP ≤15 mmHg, PVR ≥2 WU), post-capillary (mPAP >20 mmHg, PCWP >15 mmHg, PVR <2 WU), or unclassified (mPAP >20 mmHg, PCWP ≤15 mmHg, PVR <2 WU). Severity was stratified as mild (mPAP 21–24 mmHg) or overt (mPAP ≥25 mmHg). Patients receiving beta-blockers, diuretics, or cardioactive drugs were excluded. Primary endpoints were 5-year transplant-free survival (5y-TFS) and 5-year non–liver-related mortality (5y-NLRM), censoring at first decompensation, HCC, or ACLF to isolate the extrahepatic impact of PulH.
Results: Of 1,632 screened patients, 325 met inclusion criteria. PulH prevalence was 61%, with unclassified PulH being most common (30%), followed by post-capillary (17%) and pre-capillary (14%). Liver function was preserved (MELD 10.4 ± 3.8; Child-Pugh 5.7 ± 1.2) and clinically significant portal hypertension was present in 83%. Over a mean follow-up of 4.9 ± 2.7 years, 115 patients died (35%) and 49 underwent liver transplantation (15%). Five-year TFS was 67%, 61%, and 53% for no-PulH, unclassified, and pre/post-capillary PulH, respectively (p = 0.01), with corresponding 5y-NLRM rates of 6%, 14%, and 26% (p < 0.001). Direct comparisons across severity categories showed significant differences in TFS and NLRM between no-PulH and both mild and overt PulH. A dose-response relationship emerged, with even mild PulH significantly worsening outcomes. On multivariable analysis, PulH phenotype and severity independently predicted mortality, together with age, Child-Pugh score, and hemoglobin.
Conclusion: In compensated cirrhosis, asymptomatic PulH—even mild or unclassified—independently predicts non–liver-related death, supporting integration of the 2022 ESC/ERS criteria into hepatological risk stratification.

OS-043-YI

Efficacy and safety of low-dose versus standard-dose human albumin in decompensated cirrhosis with acute kidney injury: a randomized controlled trial

Aman Agrawal[1], Deep Patel[1], Ajay Kumar[1], Ujjwal Sonika[1], Siddharth Srivastava[1], Ashok Dalal[1], Sanjeev Sachdeva[1]. [1]*Department of Gastroenterology, Govind Ballabh Pant Institute of Postgraduate Medical Education and Research (GIPMER), New Delhi, India*
Email: amanagrawal.sms96@gmail.com

Background and aims: Acute kidney injury (AKI) complicates 20–50% of decompensated cirrhosis (DC) hospitalizations and significantly increases mortality. Current guidelines recommend 20% human albumin at 1 g/kg/day (maximum 100 g) for 2 days as initial volume resuscitation, based primarily on expert consensus. However, this regimen carries substantial risks of fluid overload and poses significant cost burden, particularly in resource-limited settings. Evidence defining the minimal effective albumin dose remains scarce. This randomized controlled trial aimed to evaluate whether low-dose albumin could achieve comparable efficacy to standard dosing for AKI resolution while offering improved safety.
Method: Hospitalized patients with DC and ICA-defined AKI ≥Stage 1B (serum creatinine ≥1.5 mg/dL) were screened at a tertiary center (April 2024-August 2025). Exclusions included chronic kidney disease, heart failure, albumin allergy, and hemodynamic instability. Patients were randomized 1:1 to receive 20% albumin at either standard dose (1 g/kg/day, maximum 100 g) or low dose (0.5 g/kg/day, maximum 40 g) for 48 hours. Non-responders received vasoconstrictor therapy as per standard protocol. Primary endpoint was complete AKI resolution at 48 hours (serum creatinine within 0.3 mg/dL of baseline). Secondary outcomes included adverse events, hemodynamic response, and mortality.
Results: Sixty patients were enrolled (54 males [90%]; mean age 46.2 ± 8.7 years). Alcohol was the predominant etiology (75%). Baseline characteristics were balanced: mean MELD-Na 28.15 ± 7.33, Child-Pugh C 71.7%, mean creatinine 2.9 ± 1.52 mg/dL. Complete AKI resolution at 48 hours was identical in both groups (11/30 [36.7%]

each; p = 1.0), indicating comparable efficacy. Hemodynamic improvements in mean arterial pressure and IVC diameter were comparable. Fluid overload occurred exclusively in the standard-dose group (6/30 [20%] vs 0/30 [0%]; p = 0.024). In-hospital mortality trended lower with low-dose albumin (6.7% vs 20.0%; p = 0.254), as did 90-day mortality (20.0% vs 46.7%; p = 0.054). Kaplan-Meier analysis confirmed AKI resolution as a strong predictor of 90-day survival (86.4% vs 55.3%, log-rank p = 0.014).
Conclusion: Low-dose albumin (0.5 g/kg/day) achieved comparable efficacy to standard dosing for AKI resolution in decompensated cirrhosis while demonstrating superior safety and reduced costs. These findings align with recent 2024 EASL-ADQI-ICA guidance emphasizing individualized, cautious albumin use and warrant validation in larger multicentre trials.

Email: marcel.sorribas@gmail.com

Background and aims: Intestinal barrier dysfunction drives complications in advanced chronic liver disease (ACLD). Confocal laser endomicroscopy (CLE) enables real-time, high-resolution visualization of fluorescein leakage across the epithelium during endoscopy. We assessed intestinal permeability by CLE in two independent cohorts and introduced two novel quantitative approaches designed to overcome the limitations of the current scoring systems by providing objective, reproducible measurements; and investigate potential correlations of the CLE with ACLD disease severity and subsequent clinical course.
Method: After intravenous fluorescein administration, CLE of the small intestine was performed in two cohorts: (1) Bern cohort (n = 5 healthy individuals, n = 16 ACLD patients) and (2) Vienna cohort (n = 48 ACLD patients). Image analysis included established Confocal Leak, Gap, and Watson scores, plus two novel quantitative approaches: the 3-layer approach (fluorescence in lumen, epithelium and lamina propria) and the 3-line approach (fluorescence intensity from epithelial base, middle, and apex). These metrics were correlated with ACLD disease severity, liver function, hepatic venous pressure gradient (HVPG) and liver-related events (LREs: decompensation, ACLF, liver-related mortality).
Results: Healthy controls showed no evidence of fluorescein leakage, while ACLD patients frequently exhibited transepithelial fluorescein permeation into the gut lumen. Permeability increased with clinical stage (Vienna cohort: compensated vs. first vs. further decompensation: 24%, 57%, 71%; p = 0.019). Both new quantification methods clearly distinguished healthy, compensated and decompensated states, with negligible interobserver variability. Across cohorts, CLE surrogates of intestinal barrier dysfunction—especially 3-line apex/base ratios and slopes—correlated with HVPG (apex/base ratio: r = 0.575, p < 0.001), liver function (e.g., albumin: r = –0.553, p < 0.001) and higher LRE occurrence during follow-up.
Conclusion: CLE enables direct visualization of intestinal barrier dysfunction in ACLD, that is linked to severity of portal hypertension, liver failure, and to clinical prognosis. The novel 3-line approach provides robust, quantitative assessment of permeability, offering a promising tool for direct endoscopic assessment of intestinal barrier permeability and disease monitoring.

OS-045
Dysregulated Kynurenine metabolism promotes hepatic encephalopathy via neuroinflammation
Michitaka Matsuda[1], Shinji Kondo[1], Taiji Yamazoe[1], Masaaki Mino[1], Eiji Kakazu[1], Tatsuya Kanto[1]. [1]*Japan Institute for Health Security, The Research Center for Hepatitis and Immunology, Chiba, Japan*
Email: matsuda.m@jihs.go.jp

Background and aims: Dysregulated metabolites due to liver diseases are potentially neurotoxic and cause neurologic complications, including hepatic encephalopathy (HE). While hyperammonemia has been used as a biomarker of HE, currently available treatments targeting hyperammonemia are not always effective. The study aims to identify novel metabolites responsible for the development of HE.
Method: Bile duct ligation (BDL) was performed on a C57BL/6 mouse to create the HE model. The open field test evaluated the neurobehavioral changes in the mice. The cellular dynamics of the brain during HE development were evaluated by using bulk/spatial/single-cell transcriptome analyses. The metabolic profiling of the mouse brain, liver, and blood was conducted by an LC-MS-based metabolomics approach. HE-associated metabolites, including Kynurenine, were measured in the serum of patients with liver diseases. Microglia were isolated from the mouse brain and treated with Kynurenine. IDO, an enzyme that metabolizes Tryptophan into Kynurenine, was chemically inhibited by 1-MT in vitro and in vivo.
Results: From 6 days after BDL induction, the mice revealed abnormal behavior and upregulated the neuroinflammation-associated genes in the brain. Immune profiling revealed an increased number of pro-inflammatory macrophage populations in the brain, indicating that microglial activation is involved in the development of HE. Importantly, no hyperammonemia was observed until 14 days after BDL surgery, suggesting non-ammonia factors contributed to neuroinflammation at this early stage. Metabolomic profiling identified kynurenine as an abnormal metabolite increased in the blood, liver, and brain of the model mice. Systemic administration of Kynurenine induced neuroinflammation and abnormal behavior of the wild-type mouse. In vitro, Kynurenine treatment activated microglia isolated from wild-type mice, indicating that elevated Kynurenine induces neuroinflammation via microglial activation. In the liver of HE model mice and cirrhosis patients, IDO, an enzyme that metabolizes tryptophan into Kynurenine, was upregulated. Oral administration of 1-MT, an IDO inhibitor, decreased systemic Kynurenine levels and suppressed neuroinflammation in the HE model mouse.
Conclusion: The transcriptomic and metabolomic profiling of the HE model mice and patients identified kynurenine as a novel immunometabolic factor that is increased early in the development of HE. Kynurenine could be a novel biomarker and therapeutic target of HE.

Background and aims: The Baveno VII definition of recompensation of decompensated cirrhosis excluded patients with TIPS. However, patients achieving etiologic control/cure may still recompensate with/after TIPS, but the incidence of recompensation and its impact on survival is unknown. This study investigates the concept of recompensation in decompensated patients treated with TIPS.

Method: This retrospective multicenter study included prospective TIPS patients from the EuroTIPS consortium (derivation cohort, 8 centers) and retrospective patients from a national real-life cohort (validation cohort, 7 centers). Recompensation was defined according to Baveno VII criteria (except exclusion of TIPS): (i) control of etiology, (ii) resolution of decompensating events off diuretics and laxatives/rifaximin for 12 months, and (iii) improvement of liver function to Child Pugh A. Primary outcome was achievement of recompensation. Secondary outcomes were 1-, 3- and 5-year transplant-free survival.

Results: In total, 1106 patients with controllable etiology (alcohol: n = 819, 74%; viral: n = 121, 11%; autoimmune/PBC: n = 166, 15%) were included. The derivation cohort included 242 patients (82% male), median age of 57 years and MELD of 11. Median follow up was 3.2 years. Etiology was controlled in 202 patients (83.3%) at TIPS implantation. Of those, 27 (13.4%) achieved recompensation status at a median of 1.1 years after TIPS with a 1-, 3-, 5-year survival of 100%, 96%, 77% compared to 77%, 56%, 40% in the non-recompensated patients (p = 0.001). The validation cohort included 864 patients with 551 (63.8%) controlled etiology at baseline. Of those, 88 (15.9%) achieved recompensation at a median of 1.4 years after TIPS, with a 1-, 3-, 5-year survival of 100%, 90%, 87% compared to 82%, 68%, 53% in the non-recompensated patients (p = 0.001). Lower MELD (sHR 0.82, 0.69–0.96) and alcohol etiology (sHR 0.28, 0.11–0.69) were independently associated with recompensation in both cohorts.

Conclusion: Our data support the concept that recompensation after TIPS is indeed achievable. Patients with recompensation after TIPS show excellent transplant-free survival. These findings suggest that the role of post-TIPS recompensation may merit consideration in future refinements of current definitions.

OS-047

A longitudinal multi-modal cfDNA framework for early detection and adaptive monitoring of hepatocellular carcinoma

Email: rongfansmu@163.com

Background and aims: Current guideline-based surveillance for hepatocellular carcinoma (HCC) in patients with cirrhosis remains insufficiently sensitive and lacks flexibility for dynamic risk assessment under irregular monitoring intervals. This study aimed to develop a longitudinal, multimodal cfDNA framework that captures evolving molecular trajectories and enables flexible, adaptive monitoring across variable follow-up schedules.
Method: We conducted a prospective, multicenter cohort study (NCT03588442) enrolling 3444 patients with cirrhosis across 16 hospitals. A total of 6344 serial plasma samples were collected for cfDNA profiling at three predefined follow-up timepoints: T1 (baseline), T2 (6 months), and T3 (12 months). A multi-channel transformer framework, HepaTrack, built with attention-based temporal sequence modeling and incorporating a masking strategy to simulate irregular follow-up scenarios, was developed to integrate copy number, fragmentomic, and sequence-derived cfDNA features, capturing coordinated molecular dynamics for flexible longitudinal modeling of HCC occurence.
Results: During the 12-month follow-up, 109 participants were diagnosed with HCC and 3335 remained free of HCC. By integrating six cfDNA-derived molecular profiles, HepaTrack captured temporal molecular dynamics throughout hepatocarcinogenesis, enabling risk prediction, detection discrimination, and longitudinal monitoring in diverse settings. In the prediction scenario using cfDNA from 6 to 12 months pre-diagnosis, sensitivities were 0.65–0.78 at T1 and 0.74–0.80 at T2, rising to 0.80–0.85 when combining T1 + T2, with overall specificities of 0.93–0.98 across internal and external cohorts. In the detection scenario within 0-6 months pre-diagnosis, sensitivities were 0.82–0.81 at T3, 0.80–0.98 for T1-T3, 0.88–1.00 for T2 + T3, and 0.98–1.00 when all three timepoints (T1 + T2 + T3) were included, with specificities maintained between 0.94 and 0.98. Population-scale simulations showed that applying HepaTrack at single timepoints (T1, T2, T3) detected 1319, 1384, and 1609 HCC cases per 100000 individuals, compared with 619 using alpha-fetoprotein plus ultrasound, representing an approximately a 2.1–2.6-fold increase, with higher sensitivities (0.70, 0.74, 0.86 vs. 0.63) and specificities (0.96, 0.95, 0.97 vs. 0.84).
Conclusion: HepaTrack is a scalable cfDNA framework enabling dynamic HCC surveillance and early detection via multimodal trajectory integration.

Background and aims: Hypoalbuminemia from impaired hepatic synthesis is pivotal in cirrhotic ascites and poor outcomes. Plasma-derived human serum albumin (HSA) is standard but limited by resource scarcity and pathogen risks. Recombinant human albumin (rHA) is a scalable alternative. This phase III trial verified rHA's efficacy equivalence to HSA in serum albumin (ALB) improvement, non-inferiority in ascites reduction, and safety/immunogenicity.
Method: Multicenter randomized double-blinded trial planned to enroll 414 patients aged 18–75 years (BMI ≥18.0 kg/m^2, ALB <30 g/L, cirrhotic ascites Grade 1–2). Patients were randomized 1:1 to rHA (10 g/vial, 20%) or HSA (Alburaas®) 20 g daily IV for 7 days, then with a 12-week follow-up period. Primary endpoint: ALB change from baseline to Day 7 (including early discontinuation for ALB ≥40 g/L with Day 7 assessment). Key secondary endpoint: ascites improvement rate (non-inferiority margin −10%). Analyses used Full Analysis Set (FAS), Per-Protocol Set (PPS), Safety Set (SS), Immunogenicity Analysis Set; primary endpoint via mixed-effects model for repeated measures (MMRM), non-inferiority via stratified Newcombe method.
Results: 416 patients randomized (1:1 rHA:HSA), 414 dosed (rHA 206 vs. HSA 208). Baseline characteristics balanced. Primary endpoint: least squares mean (LSM) ALB change 13.047 (SE = 0.2564) g/L (rHA) vs. 12.302 (SE = 0.2566) g/L (HSA), between-group difference 0.745 (95% CI:0.065–1.425) g/L (within equivalence margin −2 to 2 g/L). Key secondary endpoint: ascites improvement rate 55.3% (rHA) vs. 54.3% (HSA), difference 1.1% (95% CI:-8.47%–10.61%, lower bound > −10%). ALB ≥35 g/L rate (89.8% vs. 88.0%, p = 0.5709), median time to ALB ≥35 g/L (7 days both), plasma colloid osmotic pressure (COP) change (3.69 ± 0.219 vs. 3.75 ± 0.216 mmHg, p = 0.8473), as well as changes in body weight, abdominal circumference, ascites depth, and clinical symptom improvement (dyspnea, shortness of breath, abdominal distension) were comparable. Median time to retreatment: not reached (rHA) vs. 96.0 days (HSA). No rHA-related serious adverse events (SAEs); 1.9% HSA-related SAEs. Immunogenicity: 3/206 (1.46%) patients had transient low-titer anti-drug antibodies (ADA), no efficacy/safety impact.
Conclusion: Recombinant human albumin is efficacy-equivalent to HSA in ALB improvement, non-inferior in ascites reduction, with sustained effects, favorable safety, and low immunogenicity, serving as a reliable HSA alternative for cirrhotic ascites-related hypoalbuminemia.

Email: rosamartinmat@hotmail.com

Background and aims: Cirrhosis-associated immune dysfunction is characterized by progressive systemic inflammation and immunodeficiency. Patients with acute-on-chronic liver failure (ACLF) display the highest grade of both components. The underlying dysfunctional mechanisms across the different immune cell populations and their prognostic relevance remain unclear. This study investigated the transcriptomic profiles and phenotypic alterations of circulating NK cells in ACLF.

Method: RNA sequencing was performed on whole-blood samples from 25 healthy controls and 422 patients included in the seminal ACLARA and PREDICT studies sponsored by the European Foundation CLIF (123 with ACLF and 299 with acute decompensation). Immune cell composition was inferred by cell deconvolution using SingleR and CIBERSORT, and differentially expressed genes were identified (log_2FC >1.5, FDR <0.05; DESeq2). Findings were validated in independent translational cohorts by multiparametric flow cytometry, assessing NK-cell phenotype and effector function both at baseline and after stimulation.

Results: Transcriptomic analysis revealed a marked dysregulation of the lymphoid compartment in ACLF, with a significant reduction in T and NK cells. Flow cytometry confirmed lower circulating NK-cell counts affecting both cytotoxic and immunomodulatory subsets, while a population with a partially deactivated or exhausted phenotype showed a relative increase. Patients who died had significantly fewer circulating NK cells, linking NK-cell loss to poor prognosis. Phenotypic analysis revealed an inhibitory and functionally exhausted NK-cell profile in ACLF, characterized by increased NKG2A (inhibitory) and decreased NKG2D (activating) expression. These changes were associated with reduced cytotoxic (↓CD57) and secretory activity (↓perforin and IFNγ after stimulation), together with changes in maturation, migration (↓CXCR3), proliferation (Ki67), and apoptosis (Annexin V/caspase), suggesting accelerated but ineffective cellular turnover and an overall state of effector hyperresponsiveness.

Conclusion: ACLF induces a profound immune dysregulation, with a major impact on the NK-cell compartment. Circulating NK cells are markedly reduced, and their phenotypic and functional profile reflects an exhausted effector state that may contribute to poor outcomes.

OS-050-YI

A genome-wide association study identifies SUSD1 as a risk locus for renal impairment in decompensated cirrhosis

Lukas Otero Sanchez[1], Joan Clària[2], Clelia Galvanin[1], Ferran Aguilar[3], Layese Richard[4], Matteo Serra[5], Laura Jiménez-Gracia[6], Darko Castven[7], Soňa Fraňková[8], Milan Jirsa[9], David Tornai[10], Anna Curto-Vilalta[3], Alberto Queiroz Farias[11], Maria Papp[10], Patricia Momoyo Zitelli[11], Paolo Caraceni[12], Giacomo Zaccherini[13], Luciana Lofego Goncalves[14], Carlo Alessandria[15], Gustavo Pereira[16], Wim Laleman[17], Adrian Gadano[18], Salvatore Piano[19], Angelo Z. Email: lukas.otero.sanchez@ulb.be

Background and aims: Renal impairment (RI) is a frequent and life-threatening complication of decompensated cirrhosis, yet genetic susceptibility factors remain unknown. We performed the first genome-wide association study (GWAS) to identify genetic variants associated with RI in this critically ill population and provide insights into pathophysiological mechanisms.
Method: The derivation phase included 3,220 patients across five cohorts (83% European, 17% Admixed American ancestry). The validation phase included 1,728 European ancestry patients across four independent cohorts. Linear regression models adjusted for the first 10 principal components, age and sex assessed genetic associations with serum creatinine (sCr) as a surrogate of RI. Separate analyses were integrated through trans-ancestry and cohort meta-analyses. Single-cell and spatial transcriptomics mapped GWAS signals to cell types in the liver, blood and kidney.
Results: The rs2099161[C > T] variant at the *SUSD1* locus showed genome-wide significant association with sCr (trans-ancestry derivation: beta = 0.16, 95% CI: 0.11–0.21; $p = 4.32 \times 10^{-10}$; independent validation: beta = 0.09, 95% CI: 0.03–0.16; $p = 5.34 \times 10^{-3}$). Combined meta-analysis of all nine cohorts demonstrated homogeneous effect sizes (beta = 0.13, 95% CI: 0.09–0.17; $p = 8.31 \times 10^{-11}$; $I^2 = 0\%$). This association was specific to decompensated cirrhosis, with no effect in compensated cirrhosis (n = 3,139; beta = 0.00, 95% CI: – 0.05 to 0.05; p = 0.99) or the general population (n = 402,683; beta = –0.01, 95% CI: – 0.01 to 0.00; $p = 3.78 \times 10^{-3}$). The rs2099161[C] risk allele was significantly associated with kidney failure at inclusion ($p = 6.34 \times 10^{-4}$), with CC homozygotes showing OR = 1.60 (95% CI: 1.21–2.11) compared to TT homozygotes. Similar associations were observed for terlipressin requirement (p = 0.027; CC vs TT: OR = 2.06, 95% CI: 1.06–3.92). Transcriptomic analyses identified plasmacytoid dendritic cells (pDCs) as the primary *SUSD1*-expressing cell type with elevated expression in patients with RI across compartments. Patients with RI showed increased pDC abundance and type I interferon signaling in liver and kidney tissues.
Conclusion: *SUSD1* is a risk locus for RI specifically in decompensated cirrhosis across diverse ancestries and cohorts. Our results highlight gene-environment interactions and implicate the pDC-interferon axis as a candidate mechanism linking liver dysfunction to kidney injury.

Olanzapine improves appetite, weight and quality of life in patients with hepatocellular carcinoma: a multicenter, randomized controlled trial

Sagnik Biswas[1], Vijay Alexander[2], Vignesh Dwarkanathan[3], Sanchita Gupta[1], Arun Valsan[4], Gurasis Boparai[1], Amruthavarshini Nagabhushana[2], Santhosh Kumar[2], Arnav Aggarwal[1], Goldwin Cecil[2], Sarthak Saxena[1], Arathi Venu[4], Monita Gahlot[1], George Puthusseril[4], Shubham Jain[1], Ayush Agarwal[1], Anoop Koshy[4], Shrinkhala Verma[1], Amitabha Mandal[1], Naman Singh[1], Samagra Agarwal[1], Soumyadeep Choudhury[1], Priya Nair[4], S Sudhindran[4], Ashish Singh[2], Ankur Goyal[1], Raju Sharma[1], Shivanand Gamangatti[1], Ashish Goel[2], Shalimar[1]. *[1]All India Institute of Medical Science, New Delhi, India; [2]Christian Medical College, Vellore, India; [3]ESIC Hospital, Chennai, India; [4]Amrita Institute Of Medical Sciences, Kochi, India*
Email: sagnik_biswas@yahoo.co.in

Background and aims: To assess the role of olanzapine (OLN) in improving weight, appetite and quality-of-life (QoL) in patients with intermediate/advanced HCC and cachexia along with its safety in this patient group.
Method: In this multicentre, open-label randomized controlled trial (December 2024-May 2025), 166 adult (18–70 years) patients with intermediate/advanced HCC and cachexia (defined as involuntary loss of ≥5% weight over the prior 6 months) were randomly assigned (1:1) to receive OLN (5 mg/day) with nutritional counselling (OLN +NC) or NC alone. We included patients who were treatment naïve or those who received prior therapy but had progressive disease with ongoing weight loss. Treatment modality for HCC was decided based on stage of disease and suitability for locoregional/systemic therapy. Primary outcome was to compare the proportion of patients reporting improvement in weight (>5% from baseline) over 12 weeks between the two groups (modified intention-to-treat

analysis). Secondary outcomes included change in anorexia (Visual analogue and Functional Assessment of Anorexia/Cachexia Therapy scale), muscle mass (assessed by computerized tomography scan), handgrip strength (dynamometry), exercise tolerance (6-minute walk test), caloric intake and QoL (Functional Assessment of Cancer Therapy-Hepatobiliary questionnaire).
Results: Baseline characteristics were comparable in both groups. A higher proportion of patients in the OLN+NC group (39.7%) reported weight gain (>5%) as compared to 15.3% in the NC alone group (absolute risk difference [ARD]: 24.4% [95% CI: 10.9 to 37.9]; p < 0.001). Weight gain was noted in both treatment-naïve and experienced patients. A higher number of patients in the OLN+NC group reported reduction in anorexia (36.5% vs NC: 15.1%, ARD: 21.4 [95% CI: 5.3–37.7]; p = 0.01) accompanied by improved median daily caloric intake (OLN+NC: +135 [−45 to 312.5] kcal vs NC: −29 [−355 to 210] kcal; p = 0.002). Patients using OLN also reported improved QoL (46.2% vs NC: 28.2%, ARD: 17.9 [95% CI: 3.5 to 32.4]; p = 0.02) with significantly better sense of physical well-being and lower incidence of negative symptoms due to HCC. No significant between-group differences were observed in muscle mass, handgrip strength or exercise tolerance. OLN was not associated with any major drug related adverse events.
Conclusion: A 12-week course of olanzapine improves weight, appetite and QoL in patients with intermediate/advanced HCC with cachexia and is well tolerated in this patient group (CTRI:2024/12/077603).

OS-052
Circulating methylated SEPT9 for detection of hepatocellular carcinoma in patients with cirrhosis: a prospective multicenter phase 3 diagnostic validation study

Abderrahim Oussalah[1], Maël Silva Rodriguez[1], Guillaume Conroy[2], Mouni Bensenane[3], Hélène Rousseau[4], Ahmet Ayav[5], Jean-Louis Guéant[6], Houda Camara[4], Cédric Baumann[4], Valérie Laurent[7], Jean-Pierre Bronowicki[3]. *[1]University Hospital of Nancy, Department of Genomic Medicine, Division of Biochemistry, Molecular Biology, and Nutrition, Faculty of Medicine of Nancy, INSERM UMR_S 1256, Nancy, France; [2]Mercy Hospital, Department of Gastroenterology and Hepatology, Metz, France; [3]University Hospital of Nancy, Department of Gastroenterology and Liver Diseases, Nancy, France; [4]University Hospital of Nancy, Methodology, Data Management and Statistics Unit, Nancy, France; [5]University Hospital of Nancy, Department of Hepato-Pancreato-Biliary Surgery, Nancy, France; [6]Joan Klein Jacobs Center for Precision Nutrition and Health, Cornell University, Ithaca, United States; [7]University Hospital of Nancy, Department of Radiology, Nancy, France*
Email: abderrahim.oussalah@univ-lorraine.fr

Background and aims: Hepatocellular carcinoma (HCC) surveillance in patients with cirrhosis remains suboptimal, with inadequate early-stage detection. Alpha-fetoprotein (AFP) demonstrates insufficient sensitivity. We previously showed promising diagnostic accuracy for methylated *SEPT9* (mSEPT9), a cell-free DNA-based epigenetic biomarker. The primary objective was to evaluate the diagnostic accuracy of plasma mSEPT9 compared with AFP for detecting HCC in patients with cirrhosis undergoing surveillance. Exploratory objectives included evaluation of combination strategies and assessment of the relationship between replicate positivity and circulating methylated DNA load.
Method: In this prospective, multicenter, phase 3 diagnostic validation study (NCT03311152), we enrolled 574 patients with cirrhosis undergoing HCC surveillance at two tertiary centers in France. HCC was diagnosed according to AASLD and EASL criteria by hepatologists unaware of mSEPT9 results. We compared mSEPT9 testing (triple-negative, single-positive, double-positive, or triple-positive based on three biological replicates) with AFP greater than 20 ng/mL. Combination strategies included Tier 1 (either biomarker positive, prioritizing sensitivity) and Tier 2 (both biomarkers positive, prioritizing specificity). The primary endpoint was diagnostic accuracy assessed by AUROC, sensitivity, specificity, predictive values, and likelihood ratios using frequentist and Bayesian approaches.
Results: Among 574 participants (median age 63 years; 72% male; median Child-Pugh score 5), 118 had HCC, with 51 (43.2%) at BCLC stage 0 or A. mSEPT9 achieved an AUROC of 0.79 (95% CI 0.74 to 0.84), compared with 0.71 (95% CI 0.66 to 0.76) for AFP (p = 0.002; Bayes factor 713, extreme evidence). Tier 1a (at least single-positive mSEPT9 or AFP greater than 20 ng/mL) achieved 87.8% sensitivity and 95.0% negative predictive value. Tier 2 (triple-positive mSEPT9 and AFP greater than 20 ng/mL) achieved 99.6% specificity and 95.1% positive predictive value. Tier 1c (triple-positive mSEPT9 or AFP greater than 20 ng/mL) achieved 74.8% sensitivity with 85.9% specificity. For early-stage disease (BCLC 0-A), Tier 1a achieved 74.5% sensitivity versus 23.5% for AFP alone (3.2-fold improvement).
Conclusion: Circulating mSEPT9 combined with AFP substantially improved HCC detection in patients with cirrhosis, particularly for early-stage disease amenable to curative treatment. These findings support integrating mSEPT9 into surveillance algorithms to enhance early detection.

OS-053
Fecal microbiota transplantation combined with atezolizumab plus bevacizumab in hepatocellular carcinoma refractory to atezolizumab plus bevacizumab: final results of the open label, single-arm, FAB-HCC pilot study

Katharina Pomej[1], Adrian Frick[1], Bernhard Scheiner[1], Maximilian Baumgartner[2], Klaus Schmetterer[1], Lorenz Balcar[1], Larissa Pajancic[1], Abelina Kreuter[1], Petra Pjevac[3], Joana Silva[3], Bela Hausmann[3], Thomas Köcher[4], Carlos Reyna-Blanco[1], Katharina Lampichler[1], Nataliya Rohr-Udilova[1], Adrija Chakrabarty[1], Anton Klotz[1], Annika Lampl[1], Kerstin Zinober[1], Katharina Regnat[1], Michael Trauner[1], David Berry[3], Thomas Vogl[1], Dietmar Tamandl[1], Christoph Gasche[1], Matthias Pinter[1]. *[1]Medical University of Vienna, Vienna, Austria; [2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [3]University of Vienna, Centre for Microbiology and Environmental Systems Science, Vienna, Austria; [4]Metabolomics Service and Research Facility, Vienna Biocenter Core Facilities, Vienna, Austria*
Email: matthias.pinter@meduniwien.ac.at

Background and aims: Modulation of the gut microbiome (i.e., fecal microbiota transplant (FMT)) may help to overcome resistance to immune checkpoint inhibitors.
Method: In this single-center, single-arm pilot study (ClinicalTrials.gov ID: NCT05750030), we included patients with advanced HCC who progressed on atezolizumab/bevacizumab. Patients received a single FMT via colonoscopy from an anti-PD-1-responding HCC donor or a healthy donor, combined with atezolizumab/bevacizumab q3w. The primary endpoint was safety, measured by incidence and severity of treatment-related adverse events (TRAEs). The main secondary endpoint was best overall response according to mRECIST and RECISTv1.1. For exploratory analyses, blood and stool samples were collected longitudinally. Stool samples were processed for 16S rRNA sequencing and HPLC-MS metabolomics; amplicon-sequencing-variants were analyzed using DESeq2, differential abundance of metabolites and bacterial taxa were assessed using Maaslin2. Peripheral blood mononuclear cells were analyzed on CYTOFlex flow cytometer. Phage-display immunoprecipitation sequencing was performed on plasma samples to profile systemic IgG-epitope repertoires against gut microbiota and environmental antigens using a phage library comprising 357,000 peptides.
Results: Between August 2023 and November 2024, 12 patients were included (male, n = 10; Child-Pugh A, n = 11; BCLC C, n = 10). Grade 3–4 TRAEs included arterial hypertension (n = 5) and proteinuria (n = 3), both related to bevacizumab, and diarrhea (n = 1), related to FMT. No serious TRAEs were observed. Objective response rate according to

mRECIST and RECISTv1.1 was 33% and 25%, respectively. Median progression-free survival was 6.9 (95%CI, 3.0–10.8) months (mRECIST) and 4.3 (95%CI, 0.2–8.5) months (RECISTv1.1). FMT resulted in a significant shift of recipient microbiome towards donor microbiome. Healthy-donor FMT was associated with higher engraftment compared with anti-PD-1-responder-FMT, and increased recipient fecal and plasma concentrations of certain bile acids. Responders had a higher proportion of peripheral naïve CD4+ CD45RA+ T cells at baseline, and we observed trends in certain T cell and monocyte populations after FMT. Responders showed greater shifts in systemic IgG antibody reactivity after FMT, consistent with a more pronounced early remodeling of humoral immune responses.
Conclusion: FMT combined with atezolizumab/bevacizumab was safe and achieved a high response rate in patients with atezolizumab/bevacizumab-refractory HCC.

Background and aims: Intrahepatic cholangiocarcinoma (ICCA) is a highly lethal primary liver cancer. Histologically, ICCA is difficult to diagnose as its morphological and immunohistochemical features significantly overlap with those of metastatic adenocarcinomas. This leads to additional workup and treatment delays. We aimed to develop and prospectively validate a clinically oriented artificial intelligence (AI) model that differentiates ICCA from metastatic cancers on routine liver biopsy whole-slide images (WSIs) and provides case-level confidence estimates.
Method: The retrospective cohort comprised 544 adults with ICCA (n = 281) or liver metastases (n = 263) from five European liver centres, split into training and internal test sets. The model was obtained by applying pathology foundation models and training the slide-level aggregators. To quantify prediction confidence, an out-of-distribution detection module (G-ODIN) was added and case-level confidence scores were derived from predictive entropy (PE). Diagnostic performance was assessed by area under the receiver operating characteristic curve (AUC) and false positive rate (FPR). PE distributions were compared using Mann–Whitney U tests. The model was further prospectively validated in two independent cohorts from France (Avicenne and Reims University Hospitals) and Asia (Rela Institute, India and Yonsei University of Medicine, South Korea).
Results: On the internal test set, the model achieved an AUC of 0.86 and an FPR of 0.19 (best performance using CONCH/TITAN). After addition of the G-ODIN module, we observed that PE was lower in correctly classified cases vs misclassified cases, confirming that it could be used as a confidence metric (p = 0.003). After PE thresholding (threshold of 0.54), AUC reached 0.944 with an FPR of 0. The model was further prospectively validated using the PE threshold. In the French prospective cohort (n = 25), all samples were correctly classified (AUC of 1, 32% of patients could be predicted according to PE thresholding). In the Asian cohort (n = 136), all but one patient were correctly classified (AUC of 0.965, 23.5% of patients could be predicted according to PE thresholding).
Conclusion: We developed and prospectively validated a confidence-based artificial intelligence model to assist the differential diagnosis between ICCA and liver metastases on routine liver biopsies. Our approach may help reduce unnecessary investigations and treatment delays for patients with suspected ICCA.

OS-055

Serum procalcitonin: a new tumor biomarker for the diagnosis and monitoring of fibrolamellar hepatocellular carcinoma

Jean-Charles Nault[1], Claudia Campani[1], Théo Hirsch[2], Ethan Neumann[3], Waqar Arif[3], Sandrine Imbeaud[2], Marina Baretti[3], Marianne Ziol[1], Sabrina Sidali[1], Pauline Roger[2], Manon Allaire[1], Mohamed Bouattour[4], Fabio Marra[5], Brice Fresneau[6], Neus Llarch[7], Jean Marie Peron[8], René Gerolami[9], Eric Nguyen Khac[10], Pierre Nahon[1], Nathalie Ganne[1], Julien Calderaro[1], Aurélie Beaufrère[1], Valérie Paradis[1], Catherine Guettier[1], Angela Sutton[1], Mark Yarchoan[3], Jessica Zucman-Rossi[2]. *[1]APHP, PAris, France; [2]Centre de Recherche Des Cordeliers, Paris, France; [3]John Hopkins Hospital, Baltimore, United States; [4]AP-HP, Hôpital Beaujon, Liver Cancer and Innovative Therapy, CLICHY, France; [5]Department of Experimental and Clinical Medicine, Internal Medicine and Hepatology Unit, University of Firenze, Firenze, Italy; [6]Institut Gustave Roussy, Villejuif, France; [7]Barcelona Clinic Liver Cancer (BCLC) Group, Barcelona, Spain; [8]Department of Hepatogastroenterology, Rangueil University Hospital, 31059 Toulouse, France, Toulouse, France; [9]Unité hépatologie, Hôpital de la Timone, Marseille, France, Assistance Publique-Hôpitaux de Marseille (APHM), Marseille, France; [10]Hepato-Gastroenterology Department, CHU Amiens, Amiens, France*
Email: naultjc@gmail.com

Background and aims: Fibrolamellar carcinoma (FLC) is a rare primary liver cancer that develops in non-cirrhotic livers, typically affecting young patients who usually present with normal levels of known serum tumor biomarkers. The observation of markedly elevated serum procalcitonin (PCT) in one patient led us to investigate the potential role of PCT as a biomarker in a larger cohort of FLC cases.

Method: Serum PCT concentrations were measured in 34 samples from 18 patients with metastatic FLC, as well as in 64 patients with hepatocellular carcinoma (HCC), 24 with cholangiocarcinoma (CCA), and 20 patients with cirrhosis without HCC, from European and U.S. cohorts. Using RNA sequencing, we analyzed the expression of the CALCA gene, which encodes PCT, in 27 FLCs, 331 HCCs, 39 CCAs, 71 hepatoblastomas, 34 hepatocellular adenomas, and 55 non-tumoral liver samples. Spatial transcriptomic analysis was performed on three FLCs, and PCT immunohistochemistry (IHC) was conducted on 13 FLCs and 34 other primary or secondary liver cancers.
Results: The median serum PCT level was significantly elevated in 8 FLC patients (55.2 µg/L) compared with HCC (0.14 µg/L), CCA (0.16 µg/L), and cirrhosis (0.11 µg/L; P = 0.0005) in the European cohort. These findings were independently validated in a U.S. cohort of 10 FLC patients compared with HCC and CCA cases (P = 0.0002). Across cohorts, elevated serum PCT was observed in 83% of FLC cases versus only 3% of HCC and CCA patients (P < 0.0001). In four patients followed longitudinally, PCT levels correlated with radiological response, stability, or progression according to RECIST 1.1 criteria. For example, serum PCT increased from 51 µg/L (102× the upper limit of normal) to 581 µg/L (1,162× ULN) following tumor progression under immunotherapy. RNA sequencing revealed significant CALCA overexpression in FLC compared to other primary liver tumors (P < 0.0001), with an AUC of 0.975 versus CCA, and 0.994 versus HCC, demonstrating excellent diagnostic sensitivity and specificity for this rare liver cancer. Spatial transcriptomics localized CALCA expression specifically to tumor cells harboring the DNAJB1-PRKACA fusion gene. Immunohistochemistry confirmed PCT overexpression in tumor cells in 77% of FLCs, but not in other primary or secondary liver cancers (P < 0.0001).
Conclusion: Procalcitonin is a sensitive and specific biomarker for fibrolamellar hepatocellular carcinoma, both in serum and tumor tissue, with potential clinical utility for diagnosis and monitoring of treatment response.

Rare liver diseases

Efficacy and safety of CAM2029 in patients with polycystic liver disease: phase 2b POSITANO study

Marie C. Hogan[1], Frederik Nevens[2], Arun Jesudian[3], K. Rajender Reddy[4], Richard Taubert[5], Jonel Trebicka[6], Peter Almgren[7], Ulrika Axling[7], Peter Jönsson[7], Fredrik Tiberg[7], Joost P.H. Drenth[8]. *[1]Mayo Clinic, Rochester, MN, United States; [2]University Hospitals KU Leuven, Leuven, Belgium; [3]Weill Cornell Medicine, New York, NY, United States; [4]University of Pennsylvania, Philadelphia, PA, United States; [5]Medizinische Hochschule Hannover, Hannover, Germany; [6]Universitätsklinikum Münster, Münster, Germany; [7]Camurus AB, Lund, Sweden; [8]Amsterdam University Medical Center, Amsterdam, Netherlands*
Email: hogan.marie@mayo.edu

Background and aims: Somatostatin analogues (SSAs; eg octreotide and lanreotide) have indicated efficacy in reducing liver volume in investigator-driven clinical trials in polycystic liver disease (PLD) but efficacy has not yet been established in randomised clinical trials. CAM2029 is a novel subcutaneous, extended-release octreotide depot, based on the FluidCrystal® technology, designed for convenient administration by patients using an autoinjector pen. Here we report the 53-week (W) core phase results of the Phase 2b POSITANO (NCT05281328) study evaluating CAM2029 in patients with PLD.
Method: The core phase consisted of a 53W double-blind, randomised, placebo-controlled period enrolling patients with symptomatic PLD and height-adjusted total liver volume (htTLV) ≥ 1800 mL/m. Patients received either CAM2029 10 mg weekly or every 2 weeks, or placebo weekly. Primary endpoint was difference in htTLV change from baseline to W53 between CAM2029 (combined doses) and placebo. Secondary endpoints included change in PLD-related symptoms (per newly developed PLD-Symptoms [PLD-S] score), change in total liver cyst volume and safety.
Results: Seventy-one patients were randomised (CAM2029 combined n = 48; placebo n = 23). Mean age was 54.1 years, 85.9% were female and median htTLV was 3070 mL/m. Treatment was completed by 87.2% for CAM2029 combined and 87.0% for placebo. The primary endpoint was met, with a statistically significant estimated relative treatment difference in htTLV from baseline to W53 of 4.3% (95% confidence interval [CI]: 8.4, 0.1; p = 0.0443) between CAM2029 and placebo. CAM2029 reduced total liver cyst volume growth, with an estimated relative treatment difference from baseline to W53 of 8.7% (95% CI: 15.2, 1.8; p = 0.0159) between CAM2029 and placebo. CAM2029 improved PLD-S score from baseline to W53; however, no significant difference was observed between CAM2029 and placebo (estimated relative treatment difference: 2.7; 95% CI: 10.5, 5.2; p = 0.5041). CAM2029 was well tolerated, with a safety profile consistent with other injectable SSAs. Most adverse events (AEs) were grade 1–2 for both CAM2029 and placebo. The most frequent AEs with CAM2029 were diarrhoea (68.1%), injection site pruritus (42.6%), injection site pain (40.4%) and abdominal pain (36.2%).
Conclusion: CAM2029 reduced total liver and liver cyst volume growth, supporting further evaluation as a potential PLD treatment. The study is ongoing to evaluate long-term CAM2029 treatment in an open-label extension period up to 120 weeks.

OS-057

Tiomolibdate choline stabilizes liver disease and improves neurological symptoms as well as quality-of-life in treatment-experienced Wilson disease patients

Valentina Medici[1], Aftab Ala[2], Karl Heinz Weiss[3], Edward J. Gane[4], Zoe Mariño[5,6,7], Chandler Robinson[8], Andrew Cittadine[8], Declan Tuffy[8], George Boon Bee Goh[9], Marina Berenguer[10], Thomas Sandahl[11], Fred Askari[12]. *[1]University of California Davis Medical Center, Sacramento, United States; [2]King's College Hospital NHS Foundation Trust, London, United Kingdom; [3]Krankenhaus Salem, Heidelberg, Germany; [4]University of Auckland, Grafton, New Zealand; [5]Hospital Clínic De Barcelona, Barcelona, Spain; [6]Liver Unit, Hospital Clinic, IDIBAPS, Barcelona, Spain, Barcelona, Spain; [7]Liver Unit, Hospital Clínic Barcelona, IDIBAPS, CIBERehd, Universitat de Barcelona, Barcelona, Spain, Barcelona, Spain; [8]Monopar Therapeutics, Wilmette, United States; [9]Singapore Health Services, Singapore, Singapore; [10]Hospital Universitario Y Politécnico La Fe, Valencia, Spain; [11]Aarhus University Hospital, Aarhus, Denmark; [12]University of Michigan-Ann Arbor, Ann Arbor, United States*
Email: vmedici@health.ucdavis.edu

Background and aims: Wilson disease (WD) is a rare autosomal recessive disorder characterized by excess copper (Cu) accumulation resulting in hepatic and neurologic damage as well as psychiatric symptoms. Tiomolibdate choline (TMC; ALXN1840), a once-daily oral agent with extremely high affinity for binding Cu, has been shown to improve Cu balance and prevent toxic effects of Cu overload in WD patients. A Phase 2 study was conducted in treatment-experienced WD patients to evaluate the effect of TMC on both liver pathology and clinical symptoms of WD.
Method: This open-label, multicenter Phase 2 trial evaluated the efficacy of TMC monotherapy through 48 weeks in treatment-experienced (≥ 1 year on standard of care) WD patients. Hepatic, neurologic, and quality of life assessments were performed at Baseline and Week 48; patients in the extension period had assessments repeated at Week 96. Liver biopsy was performed at Baseline and Week 48 to assess the impact of TMC on hepatic Cu concentration, stage of fibrosis, and grade of steatosis. Neurologic and clinical outcomes were assessed by the Unified WD Rating Scale

(UWDRS) and Clinical Global Impression (CGI) scale. Quality of life was assessed by the EuroQoL 5-Dimensions (EQ5D) UK Health Index.
Results: 29 WD patients were enrolled with a median [IQR] prior treatment duration of 13.8 years [10.9]; 23 continued in the extension period. At Week 48, the majority of patients showed improvement or stabilization in hepatic pathology, including Non-alcoholic Fatty Liver Disease Activity Score (NAS; 71% improved or stabilized) and Non-alcoholic Steatohepatitis Clinical Research Network (NASH CRN) fibrosis score (67% improved or stabilized). There was a statistically significant improvement in liver stiffness by transient elastography (mean [SD] – 1.19 kPa (2.15); p = 0.0122). Hepatic Cu concentration was not statistically different at Week 48. Statistically significant improvements in UWDRS, CGI, and EQ5D UK Health Index were observed at Week 48 and persisted through Week 96.
Conclusion: TMC treatment for up to 2 years resulted in improvement or stabilization of parameters of liver pathology as well as improvement in neurologic and clinical outcomes in heavily pretreated patients. Stability in hepatic Cu concentration indicates effective Cu control by TMC. Higher doses and/or a longer time period may lead to reductions in liver Cu. These results support TMC's role as a valuable treatment option for WD patients.

OS-058

Assessment of liver injury and genotype among children and adults with lysosomal acid lipase deficiency: analysis of the international LAL D registry

William Balistreri[1], Ali Canbay[2], Thomas Kerr[3], Sophie Kitchen[4], Florian Abel[5], Lorenzo D'Antiga[6]. *[1]UC Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, United States; [2]Department of Internal Medicine, Ruhr-Universitat Bochum, Bochum, Germany; [3]Department of Gastroenterology and Hepatology, UT Southwestern, Dallas, United States; [4]Epidemiology and Real World Science, Alexion, AstraZeneca Rare Disease, Boston, United States; [5]Department of Global Medical Affairs, Alexion, AstraZeneca Rare Disease, Boston, United States; [6]Department of Medicine and Surgery, University of Milano–Bicocca, Milan, Italy*
Email: william.balistreri@cchmc.org

Background and aims: Lysosomal acid lipase deficiency (LAL-D) is a rare inherited lysosomal storage disease characterized by liver injury and dysregulated lipid metabolism. This analysis assessed liver damage and dyslipidemia by genotype among patients with LAL-D.
Method: Children and adults enrolled in the International LAL-D Registry were included regardless of treatment status with sebelipase alfa (LAL enzyme replacement therapy [ERT]). Infants who started ERT at <6 months were excluded. Biochemical and clinical features, including liver biopsy results, and *LIPA* genotype were assessed at baseline (registry enrollment date for untreated patients, last assessment before ERT start for treated patients) in all patients. Transaminases were assessed longitudinally in treated patients.
Results: As of August 2025, 281 patients with LAL-D (163 children: 45% female, 92% White; 118 adults: 54% female, 90% White) were included. Median time from onset of manifestations to diagnostic testing was 1.6 y (children) and 10.0 y (adults). The most common manifestations that raised suspicion of LAL-D were elevated aspartate aminotransferase (AST; 77% of children, 47% of adults), elevated alanine aminotransferase (ALT; 76%, 53%), and hepatomegaly (67%, 50%). Among 142 patients with liver biopsy results at baseline, 60% had macrovesicular and microvesicular steatosis and 44% had lobular inflammation; proportions were similar among children and adults. Among 231 patients with *LIPA* sequencing results, most were homozygous (41%) and compound heterozygous (28%) for c.894G>A. ALT levels were ≥2 times the upper limit of normal in 49% of children and 25% of adults homozygous for c.894G>A; proportions for compound heterozygotes for c.894G>A were 63% and 22%. Among patients with ≥1 c.894G>A variant, fibrosis scores tended to be worse for younger versus older patients. Most patients of any genotype with elevated transaminases co-presented with dyslipidemia. The proportion of ERT-treated patients with elevated ALT decreased from 92% (157/170) at baseline to 53% (89/167) at last follow-up (median 7.4 years); results were similar between children and adults. The proportion of ERT-treated patients with elevated AST also decreased (86% [146/169] to 33% [54/165]).
Conclusion: Across *LIPA* genotypes, liver damage was a common feature of LAL-D among pediatric and adult patients; children typically present with elevated transaminases. ERT was associated with improvements in transaminase levels.

Prevalence and novel predictors of recurrent intrahepatic cholestasis of pregnancy using the 2023 EASL guidelines in a cohort of over 250 subsequent pregnancies

Nina Rodriguez[1], Jacqueline Slobin[1], Lauren Alpert[1], Cecilia Katzenstein[1], Keith Sigel[1], Rhoda Sperling[1], Caroline Ovadia[2], Catherine Williamson[3], Tatyana Kushner[4]. *[1]Icahn School of Medicine at Mount Sinai, New York, United States; [2]University of Edinburgh, Edinburgh, Scotland, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]Weill Cornell Medicine, New York, United States*
Email: nina.rodriguez@icahn.mssm.edu

Background and aims: The 2023 EASL guidelines propose a risk stratification framework for suspected intrahepatic cholestasis of pregnancy (ICP), but the predictive validity in subsequent pregnancies is unknown. We assessed whether EASL group classification in an index pregnancy could predict the risk of ICP recurrence and disease severity in later pregnancies.
Method: We conducted a retrospective cohort study at a large U.S. health system (2009–2024). Groups were assigned per the 2023 EASL guidelines for suspected ICP: A (bile acids (BA) < 19 µmol/L, normal ALT/AST), B (BA < 19 µmol/L, elevated ALT/AST), or C (BA ≥ 19 µmol/L). Confirmed ICP was defined as BA ≥10 µmol/L. Recurrent ICP was defined as peak BA ≥10 µmol/L in a subsequent pregnancy among those with confirmed ICP in the index pregnancy. Regression models estimated risk ratios (RRs) for predictors of ICP recurrence and progression between EASL groups.
Results: Among 4,386 patients with suspected ICP in an index pregnancy (median age: 32 years, 45% Hispanic), we identified 265 with a subsequent pregnancy with BAs ordered: 158 in Group A (7% with confirmed ICP), 64 in B (29% with confirmed ICP), and 43 in C. Confirmed ICP recurred in 46% (66/145; 95% CI 37–54%). Recurrent ICP was associated with symptom onset before 28 weeks in the index pregnancy (27% vs 10%), Hispanic ethnicity (62% vs 38%), and gallstones (27% vs 9%), all p < 0.01. Index pregnancy BAs ≥ 40 (n = 44, 30%) or ≥ 100 µmol/L (n = 14, 10%) were not significantly associated with ICP recurrence, whereas index pregnancy EASL group classification significantly stratified recurrence risk (51% in C, 49% in B, 20% in A; p = 0.020). Among those with confirmed ICP in the index pregnancy, both Group B (aRR 2.5, 95% CI 1.1–5.6) and C (aRR, 2.4 95% CI 1.1–5.2) had higher risk of recurrence compared to A. EASL group agreement across pregnancies was fair: 53% remained in the same group, 35% shifted to a lower-risk group, and 12% moved to a higher-risk group. Among suspected ICP patients initially in A or B, peak BAs ≥ 10 µmol/L in the index pregnancy was associated with higher risk of progressing to C (RR 3.9, 95% CI 1.4–11.0). Adverse obstetric outcomes did not differ significantly between those with and without ICP recurrence.
Conclusion: ICP recurs frequently, yet BA levels in the index pregnancy alone were not associated with recurrence. EASL-defined groups meaningfully stratified future risk, highlighting heterogeneity within suspected ICP and the value of this framework for longitudinal risk assessment.

OS-060

Incidence, clinical characteristics and outcomes of checkpoint inhibitor-induced liver injury (ChILI): a multicentre UK-wide retrospective cohort study

Edmond Atallah[1], Thomas Moore[1], Hester Franks[1,2] and The UK National Oncology Trainee Collaboration for Healthcare Research (NOTCH)[3]. [1]*Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom;* [2]*University of Nottingham, Division of Cancer and Stem Cells, BioDiscovery Institute, Nottingham, United Kingdom;* [3]*The UK National Oncology Trainee Collaboration for Healthcare Research (NOTCH), Clatterbridge, United Kingdom*
Email: edmond.atallah@gmail.com

Background and aims: Immune checkpoint inhibitors (CPI) have become the leading cause of drug-induced liver injury (DILI) cases in national registries. Current evidence on the incidence and outcomes of checkpoint inhibitor-induced liver injury (ChILI) is derived from studies with small sample sizes and lacks systematic evaluation. Here, we present a national real-world analysis of the incidence, clinical characteristics, and outcomes of ChILI in all patients who received CPI over 5 years.
Method: Using the prospective electronic prescribing and management system for Systemic Anti-Cancer Therapy (SACT) in the UK, all adult patients who received CPI for melanoma or renal cell carcinoma with or without concurrent targeted therapy between January 2018 and December 2022 at 20 centres were identified. Patients were systematically screened for acute liver injury ≥ Grade 2 by the Common Terminology Criteria for Adverse Events (CTCAE v5). Detailed clinical data, including CPI, investigations, treatment and outcomes, were collected. Causality assessment and formal adjudication were performed centrally. ChILI pattern and severity grading were assessed using the international expert working group criteria and CTCAE.
Results: Out of 8080 patients who received CPI, 724 had acute liver injury and were included (9%). ChILI occurred in 535 patients (7% of all who received CPI). Hepatocellular was the most common pattern of injury occurring in 220 patients (41%). Three-quarters of ChILI patients (404) developed Grade 3/4 liver injury, 82 developed jaundice (15%), and 13 met severe DILI criteria (2%). 10 ChILI patients developed cholangiopathy (2%), and 2 had sinusoidal obstruction syndrome (SOS) (0.4%). None of the patients progressed to acute liver failure (ALF) or died due to ChILI. 46 out of 535 ChILI patients improved without receiving steroids (9%). Among the 489 who received steroids, 143 had over 3 months of treatment (29%), 122 received additional immunosuppression (25%), and 89 had significant steroid-related side effects (18%). Among the 250 patients who were challenged with CPI (47%), ChILI recurred in 68 patients (27%).
Conclusion: In this largest real-world cohort of ChILI to date, no patients developed ALF or died due to ChILI. Distinctive ChILI subtypes, cholangiopathy and SOS, are rare but require clinical suspicion and early investigations. There is significant heterogeneity in ChILI management and prolonged steroid use in >25% of patients; a prospective clinical trial is needed to inform clinical practice.

Regeneration and gut communication

Microbial pathways differentiate between patients with cirrhosis who are hospitalized withis 90 days in a multi-national cohort

Jasmohan Bajaj[1], Darja Nikitina[2], Masoumeh Sikaroodi[3], Mario Álvares-da-Silva[4], Aldo Torre[5], Ramazan Idilman[6], Ki Tae Suk[7], Mette Lauridsen[8], Elise Jonasson[8], Matheus Truccolo Michalczuk[4], Hye Won Lee[7], Satya Priya Sharma[7], Jesus Alejandro Ruiz Manríquez[5], Edita Kiudeliene[2], Dilara Turan Gökçe[6], Sai Bojja[3], Juozas Kupcinskas[2], Patrick Gillevet[3]. [1]*Virginia Commonwealth University, Richmond, United States;* [2]*Lithuanian University of Health Sciences, Kaunas, Lithuania;* [3]*George Mason University, Manassas, United States;* [4]*Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil;* [5]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, San José del Rincón, Mexico;* [6]*Ankara Bilim Üniversitesi, Ankara, Türkiye;* [7]*Hallym University College of Medicine, Chuncheon, Korea, Rep. of South;* [8]*Sdu University Of Southern Denmark, Ejsberg, Denmark*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Prediction of hospitalizations is important in cirrhosis to ensure timely prevention. Microbial composition is altered in cirrhosis but functionality, which is the host-bacterial interface, needs further evaluation. Aim: define microbial pathways linked with 90-day hospitalization in a multi-national cirrhosis cohort.
Method: Cirrhosis outpatients were recruited from 7 countries (USA, Türkiye, Korea, Denmark, Lithuania, Brazil & Mexico). Demographics, cirrhosis severity (MELD, complications, medications), diet, were recorded, stool collected & pts followed for 90 days for hospitalizations. Metagenomics & pathway analysis using HUMAnN were performed. PERMANOVA & regression analysis was performed using Maaslin2 for 90-day hospitalizations prediction.
Results: 682 patients with cirrhosis (170 US, 90 Brazil, 99 Korea, 93 each Lithuania & Mexico, 84 Türkiye, & 53 Denmark) were enrolled. 60% were men, MELD 12 ± 5, albumin3.5 ± 0.70, Na 138 ± 7. Most common etiology was alcohol (35%) then viral (31%) & MASLD (17%). 56% were decompensated (35% on lactulose, 19% on rifaximin, 44% prior ascites, 19% prior variceal bleed, 31% on NS βblockers). Diet varied (most with yogurt & coffee). 90-day Hospitalizations: Seen in 169 (25%), most of which 133(79%) were liver-related. Country-wise rate differed with lowest in Brazil & Türkiye & highest in Lithuania & Korea. Bacterial pathway analysis: PERMANOVA adjusted for country showed differences between hospitalized versus not ($p = 0.001$). There were differences in pathway diversity ($p = 0.004$) but not richness. Maaslin2: Pathways ↓ in hospitalized: All had $p < 0.01$, carbohydrate storage and biosynthesis (sucrose synthesis II, glycogen degradation II), amino acid biosynthesis (L-ornithine & L-methionine synthesis), nucleotide & aromatic compound degradation Pathways ↑ in hospitalized fermentation, alternative substrate utilization, *de novo* nucleotide biosynthesis, cell wall recycling, lipid metabolism, and Enterobacteriaceae-associated functions (heterolactic fermentation, ethanolamine utilization, glycerol and hexitol fermentation, pyrimidine biosynthesis, & enterobacterial common antigen biosynthesis).
Conclusion: In a multinational outpatient cirrhosis cohort, gut microbial functional pathways focused on urea cycle and bioenergetics intermediates were lower, while ammoniagenic and Enterobacterial pathways were higher in those who were hospitalized within 90 days. Microbial pathway profiling could improve risk prediction in cirrhosis beyond single center studies.

Background and aims: The diminished regenerative capacity of the liver in aging individuals represents a major clinical obstacle. Although liver sinusoidal endothelial cells (LSECs) are essential regulators of the hepatic regenerative niche, the molecular basis for their functional decline with age remains largely undefined. This study investigates the mechanistic role of CD36 upregulation in aged LSECs and its contribution to impaired liver regeneration via metabolic and signaling dysregulation.
Method: Partial hepatectomy (PHx) was conducted in young and aged mice, with subsequent single-cell RNA sequencing of the liver. Aged mice with endothelial-specific CD36 knockout (CD36-/-) were generated to evaluate liver regeneration. In vitro, CD36-overexpressing endothelial SK-HEP1 cells were subjected to etoposide-induced senescence, followed by assessment of senescence markers and functional assays. 2D(transwell) and 3D(assembloids) co-culture systems were employed to examine the paracrine effects of endothelial cells on hepatocyte proliferation. Transcriptional regulation of CD36 by IRF1 was validated using chromatin immunoprecipitation (ChIP) and dual-luciferase reporter assays.
Results: Single-cell transcriptomics identified CD36 as markedly upregulated in aged liver endothelial cells, correlating with enhanced lipid metabolism pathways and suppression of cell-cycle expression. Conditional ablation of CD36 in endothelium significantly enhanced hepatocyte proliferation and restored regenerative capacity in aged mice post-PHx. Mechanistically, CD36 overexpression amplified palmitate uptake, driving metabolic reprogramming and activating the TGF-β1 signaling. This led to endothelial dysfunction via induction of endothelial-to-mesenchymal transition, coupled with potent cell-cycle arrest in hepatocytes. Mechanistically, we found that CD36 expression is directly driven by the transcription factor IRF1, whose levels were higher in aged LSECs.
Conclusion: Our findings unveil a previously unrecognized regulatory axis—IRF1/CD36/TGF-β1—in aged LSECs that disrupts liver regeneration through integrated metabolic reprogramming and inhibitory paracrine signaling. This axis represents a key mechanism underlying age-related liver regenerative failure and highlights potential therapeutic targets for improving postoperative recovery in elderly patients.

Email: hexin.yan@celliver.com

Background and aims: Liver transplantation demand is constrained by donor scarcity and surgical risks, creating an urgent need for novel therapies targeting cirrhosis' core pathophysiology: hepatic stellate cell (HSC) activation, excessive type I collagen (Col1a1) deposition (fibrosis), and hepatocyte apoptosis/impaired regeneration. This study evaluated the safety and therapeutic potential of hepatocyte-derived liver progenitor-like cells (HepLPCs) for cirrhosis, validating its mechanism against these pathophysiological defects.
Method: We developed expandable hepatocyte-derived liver progenitor-like cells (HepLPCs) from primary human hepatocytes, defined their antifibrotic and pro-regenerative mechanisms, also validated efficacy in a TAA-induced rat cirrhosis model. Biodistribution studies tracked the in vivo clearance of xenogeneic HepLPCs, and preclinical safety was evaluated in 36 cynomolgus monkeys. Based on these data, a first-in-human trial was conducted in nine cirrhosis patients, who received HepLPCs via transhepatic arterial infusion without immunosuppression.
Results: HepLPCs secreted high levels of MMP-1/-3 (key antifibrotic MMP subtypes) and HGF. MMP-1/-3 specifically degraded Col1a1 from activated HSCs. HGF bound its receptor c-MET to promote hepatocyte proliferation and inhibit apoptosis. In TAA rats, HepLPCs reduced α-SMA expression and Col1a1 deposition, while increasing Ki67-positive hepatocytes. Biodistribution showed HepLPCs clearance within 1 week; fluorescence tracking + immunohistochemistry confirmed no long-term engraftment in liver or other organs. Preclinical studies in monkeys showed no dose-limiting toxicities. In the clinical trial, no serious adverse events occurred; minor events were cirrhosis-related. Treatment was well-tolerated without transfusion reactions. While Child-Pugh and MELD scores did not change significantly, some patients showed improved liver biochemistry (increased albumin synthesis), coagulation profiles (increased prothrombin activity), and portal hypertension indicators (decreased portal vein pressure) over 6 months.
Conclusion: HepLPCs transplantation exhibits promising safety and potential efficacy in cirrhosis, with mechanisms precisely targeting fibrosis and impaired hepatocyte regeneration. The available evidence supports a predominantly paracrine mechanism underlying these therapeutic effects. These data support further clinical investigation, particularly in decompensated cirrhosis and acute-on-chronic liver failure.

OS-064-YI
Intestinal sirtuin 1 controls liver regeneration by altering hepatocyte priming and promoting metabolic remodelling

Vinicius Dias Nirello[1], Sian Seaman[1], Paula Ruiz[1], Mark Philo[1], Mar Moreno-Gonzalez[1], Patrick Varga-Weisz[2], Naiara Beraza[1]. *[1]Quadram Institute, Norwich, Northern Ireland; [2]University of Essex, Colchester, Northern Ireland*
Email: mark.philo@quadram.ac.uk

Background and aims: The liver rapidly restores its mass after injury, yet how the gut–liver axis contributes to this process remains unclear. Bile acids (BA) and their metabolism are key regulators of liver regeneration. Previous work highlighted the role of both liver- and intestinal-specific FXR in this process. SIRT1 regulates FXR signalling and BA metabolism, but the role of intestinal-specific SIRT1 in modulate the liver regenerative response remains undefined. Here, we aimed to define how intestinal SIRT1 shapes early signalling and metabolic reorganisation after partial hepatectomy (PHx).
Method: Intestinal-specific SIRT1-deficient mice (SIRT1^int-KO) and wildtype littermates underwent PHx. Liver tissue collected at 0, 6 and 24 h was analysed by bulk RNA-seq. STAT3 activation, hepatic BA and progenitor cell expansion was evaluated by immunoblotting, targeted metabolite profiling and immunohistochemistry.
Results: At 6 h post-PHx, both genotypes suppressed metabolic regulators (e.g., *Srebf1*, *Ppard*, *Mlxipl*) and activated a core inflammatory programme. However, SIRT1^int-KO livers displayed a distinct signature marked by (i) reduced STAT-associated genes (*Jak3*, *Osmr*, *Il15*, *Ccl5*), (ii) induction of interferon-stimulated genes (*Ifi*, *Gbp*, Oas families), and (iii) activation of stress pathways including *Atf3* and *Eif2ak3*/PERK. Correspondingly, STAT3 phosphorylation was markedly reduced in SIRT1^int-KO mice despite comparable TNF-α and IL-6 levels, indicating defective hepatocyte priming. By 24 h, transcriptomic divergence intensified. WT livers initiated broad metabolic reprogramming—fatty-acid oxidation, amino-acid metabolism and organic-acid catabolism—whereas SIRT1^int-KO livers failed to engage these pathways and instead sustained chemokine expression (*Ccl2*, *Ccl3*, *Cxcl10*), extracellular-matrix genes (*Col1a1*, *Loxl1*, *Adamts2*) and senescence regulators (*Cdkn1a*/*p21*). These molecular features aligned with pronounced parenchymal injury, hepatic BA accumulation and expansion of liver progenitor cells. Mechanistically, impaired intestinal FXR–FGF15 signalling was strongly associated with these defects, and targeted intestinal FXR agonism with Fexaramine restored liver regeneration in SIRT1^int-KO mice.
Conclusion: Intestinal SIRT1 is required for the transcriptional and metabolic transitions that support liver regeneration, including cell priming and the reactivation of lipid and amino-acid metabolic networks, protecting from a BA–driven inflammatory and senescent state.

OS-065
Evidence for bile acid-mediated ileal barrier function deficits in primary sclerosing cholangitis

Nicholas Ilott[1], Nicholas Provine[1], Matthias Friedrich[1], Claire Pearson[1], Kyla Dooley[1], Amelia Heslington[2], Miriam Tomczak[3], Kate Coldwell[1], Elizete Araujo Batista Neves[1], Anna Hoyle[1], Yukari Kimura[1], Megan Perry[1], Shana-Lee Bownes[1], Kaye Eve-Rowe[1], Calliope Dendrou[1], Charlotte Rich-Griffin[4], Iolanda Vendrell[1], Lisa Gartner[5], Ida Parisi[1], Oyindamola Ajisegiri[1], Amy Cross[1], Joanna Hester[1], Roman Fischer[1], Fadi Issa[1], Fiona Powrie[1], Holm Uhlig[1], Emma Culver[1], Paul Klenerman[1]. *[1]University of Oxford, Oxford, United Kingdom; [2]University of Newcastle, Newcastle, United Kingdom; [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Nonacus, Birmingham, United Kingdom; [5]The Francis Crick Institute, London, United Kingdom*
Email: nicholas.ilott@kennedy.ox.ac.uk

Background and aims: Primary sclerosing cholangitis (PSC) is a rare progressive disease of the bile ducts and liver. Primary causes and factors influencing progression remain unknown although likely involve autoimmune-related damage to cells of the biliary tree and pathologic gut-liver communication. Given a high prevalence of ulcerative colitis in PSC, research into pathological intestinal involvement in liver disease has largely focussed on the large intestine. However, reduced bile flow from the liver has the potential to impact on homeostatic barrier-protective functions of the small intestine, including the main site of bile acid reuptake – the terminal ileum (TI). This could lead to disease progression through pathobiont-induced damage to the liver, as well as dysbiosis-associated right-sided colonic inflammation.
Method: Using a combination of scRNA-seq, spatial transcriptomics and proteomics of TI biopsies from patients with PSC-UC, UC and healthy controls we demonstrate changes across multiple cell types in PSC-UC.
Results: In both CD4 and CD8 memory T cells, we show evidence of decreased expression of genes involved in oxidative phosphorylation (OXPHOS) in the TI of patients with PSC-UC, supporting altered barrier immunity. We also show that mature enterocytes of the TI can be characterised by spatially organised cell states. The phase II detoxification gene, *Glutathione-S-transferase alpha 1* (*GSTA1*) marks one enterocyte state that is enriched at the base of villi and is co-expressed with multiple other detoxification enzymes. Genes within this co-expression module are downregulated in ileal samples from patients with PSC-UC, supporting altered detoxification capacity in ileal enterocytes in patients with PSC. Inverse correlations between GSTA1 protein abundance and alkaline phosphatase (ALP) levels in patients with PSC, and reduced *Gsta1* mRNA expression in a mouse model of cholestatic liver disease, support a direct role for reduced bile flow in downregulating GSTA1 and related detoxification proteins. Results from gnotobiotic mouse models suggests that *Gsta1* expression is tuneable through microbiome manipulation, with evidence that the presence of microbes that can deconjugate conjugated primary bile acids contribute to reduced expression of *Gsta*1.
Conclusion: We have identified new pathways that are disrupted in the small intestine of patients with PSC. These pathways represent potential new targets for treatment that can be tuned by microbiome intervention.

Email: elisabetta.degasperi@policlinico.mi.it

Background and aims: Bulevirtide (BLV) is approved by EMA for treatment of chronic hepatitis Delta (CHD), however data about long-term outcomes in patients with cirrhosis are limited.
Method: CHD patients with cirrhosis treated with BLV 2 mg/day in the SAVE-D study (51 centers) were included. Virological (HDV RNA undetectable or ≥2 Log_{10} decline *vs.* baseline), biochemical (ALT<40 U/L), combined response, viral breakthroughs (VBK: 1 Log_{10} HDV RNA increase *vs.* previous timepoint) and liver-related events (LREs) were assessed. Clinically significant portal hypertension (CSPH) was defined according to Baveno VII criteria.
Results: 424 patients treated with BLV up to 192 weeks (W) were included: age 50 (IQR 40–58) years, 61% men, ALT 78 (51–128) U/L, liver stiffness measurement (LSM) 16.5 (12.6–25.3) kPa, platelets 101 (68–149) x10^9/L, 96% CPT score A, 51% with varices, 9% with previous decompensation, 90% on NUC. Baseline HDV-RNA was 5.4 (4.2–6.3) Log_{10}IU/mL and qHBsAg 3.7 (3.2–4.1) Log_{10}IU/mL. After W144 of BLV, 70%, 67%, 51% and 34% of patients achieved virological, biochemical, combined response, and HDV RNA undetectability, respectively. In 42 patients with available W192 data, the corresponding figures were 76%, 60%, 52% and 33%. Patients with <1 Log_{10} HDV RNA decline *vs.* baseline decreased from 20% (W48) to 14% (W144). VBK occurred in 8% between W48-W96 (75% normal ALT)) and 10% between W96-W144 (70% normal ALT). 26 patients developed a LRE, 9 decompensation and 17 HCC: the 3-year cumulative incidences were 2.7% (95% CI 1–4%) and 5.3% (95% CI 2–7%), respectively. The corresponding figures in patients with *vs.* without baseline CSPH were 5.9% *vs.* 0.5%

for decompensation (p = 0.004) and 8.4% *vs.* 2.5% for HCC (p = 0.01), respectively. Lower baseline albumin independently predicted LREs (HR 0.13, p = 0.0003). The 3-year liver transplantation (LT)/death-free survival was 88.8% (95% CI 85–92%): 29 patients underwent LT (22 HCC, 7 decompensation) and 13 patients died, 8 of LREs. Persistence on-treatment was maintained by 94% of patients, 20 discontinued BLV monotherapy (7 add-on IFN, 2 skin allergy, 2 decompensation, 3 undetectable HDV RNA, 3 non-compliance, 2 non-response, 1 clinical trial entry), 7 were lost to follow-up.
Conclusion: Most CHD patients with cirrhosis treated for up to 4 years with BLV 2 mg/day monotherapy achieved a virological and/or biochemical response. The incidence of LREs remained low and was associated with lower baseline albumin and CSPH.

OS-067
Is undetectability of HDV RNA for 96 weeks on Bulevirtide associated with a sustained virological response off-treatment in the real life? Results from the French ANRS HD EP01 HEPDELTA cohort

Email: helene.fontaine@aphp.fr

Background and aims: In the phase 3 study (Myr301), HDV RNA remained undetectable (Robogene 2.0 assay: LL0D 6 IU/ml) 2 years after discontinuation of Bulevirtide (BLV) 2 or 10 mg/day for 96 to 144 weeks, in 23/148 (15.5%) patients of the total population and in 90% patients with undetectable HDV RNA for 96 weeks on BLV, suggesting a finite duration of treatment in these patients. The aim of this sub-study of HEPDELTA cohort, aiming to study the natural history of HDV infection according different treatment modalities, was to analyse this result in the real life.
Method: 344 patients were treated (161 with BLV 2 mg alone, 154 with BLV + Pegylated Interferon (PegIFN), 29 with BLV for at least six months then BLV + PegIFN): 42.4 ± 11.3 years, 67% males, 41% sub-Saharan origin, 7125% with cirrhosis, HDV RNA 5.9 + 1.4 $\log_{10}$ IU/ml, 83.3% genotype 1 and 12.5% of genotype 5. The HDV RNA undectectability (less sensitive test), during treatment, was 38.5, 59.3 and 53.3% at W96, 38.5, 44 and 50% at W144 and 46.2, 72.7 and 20% of patients at W192, in the 3 groups, respectively.
Results: The virological response was 26.2, 43.2 and 30% at FU 24, 38.5, 29.7 and 22.2% at FU 48, 35.7, 44.0 and 25.0% at FU 96 and 42.9, 70.00 and 0% at FU 144, respectively. Among the 161 patients receiving BLV alone, 79 (49%) discontinued treatment, including 23 with undetectable HDV RNA at the end of treatment (EOT) (mean duration 103.3 ± 56.4 weeks): 9 patients (39.1%) relapsed during follow-up ≥ 48 weeks off-treatment. In 13 with undetectable HDV RNA for ≥96 weeks, 5 discontinued treatment: 1 (20%) relapsed after >48 weeks of follow-up. Among the 154 treated with BLV + PegIFN, 92 (59.7%) discontinued treatment, including 42 with undetectable HDV RNA at EOT (mean BLV and PegIFN duration of 109.4 ± 77.5 and 72.9 ± 52 weeks, respectively): 18 (42.8%) relapsed. In 25 of them, with undetectable HDV RNA for ≥ 96weeks on treatment, 11 discontinued treatments: 4 (36.4%) relapsed within 48 weeks off treatment. Among 29 receiving BLV for > 6 months then BLV + Peg IFN, one patient with undetectable HDV RNA for ≥96 weeks discontinued treatments with HBsAg loss and remained responder after 48 weeks off-treatment.
Conclusion: In the real life HEPDELTA cohort as in MYR 301, the sustained virological response at 48 weeks off treatment remains high in patients with HDV RNA undetectability for > 96 weeks during BLV (80%) or BLV + peg IFN (67%) treatment.

OS-068-YI
The new EASL treatment indications for HBeAg-negative chronic hepatitis B virus infection reduce grey-zone patients and reflect better routine clinical practice

Margarita Papatheodoridi[1], Sofia Paraskevopoulou[1], Panagiota Ioannidou[1], Paraskevi Fytili[1], Alkistis Maria Papatheodoridi[1], Stratigoula Sakellariou[2], Evangelos Cholongitas[1], Ioannis Vlachogiannakos[1], George Papatheodoridis[1]. *[1]1st Academic Department of Gastroenterology, General Hospital of Athens "Laiko", Medical School of National & Kapodistrian University of Athens, Athens, Greece; [2]1st Department of Pathology, Medical School of National & Kapodistrian University of Athens, General Hospital of Athens "Laiko", Athens, Greece*
Email: gepapath@med.uoa.gr

Background and aims: The 2025 EASL HBV clinical practice guidelines (CPGs) expand treatment indications (TxI) for HBeAg-negative chronic HBV (CHBVe-) patients (pts) promoting earlier treatment initiation in grey-zone (GZ) cases, but their real life implementation is unknown. We assessed how the 2025 TxI compared to the 2017 EASL TxI apply in our GZ CHBVe- pts and how they are associated with

treatment initiation in CHBVe- in clinical practice over the recent years (yrs).
Method: All CHBVe- pts with ≥1 visit between 2010 and 2019 were included if they had no TxI by the 2017 CPGs based on baseline ALT/HBV DNA defined as HBV DNA >20,000 IU/ml and ALT >2 × ULN. Pts with coinfection, immunosuppression, decompensation or HCC, alcohol abuse or other liver injury were excluded. Parameters based on a predefined CRF were collected. Among pts without TxI during yr-1, typical HBeAg-negative chronic infection (CIe-) pts were defined those with persistently ALT ≤ULN and HBV DNA <2000 and GZ pts were considered those who did not fulfill the typical CHBVe- definition. Former (2017) TxI were: a) HBV DNA >20,000 and ALT >2 × ULN, b) HBV DNA ≥2000 and Ishak-stage (F) 3–4 or liver stiffness (LS) 9.1–12/12.1–15 kPa in case of ALT ≤/>ULN or c) detectable HBV DNA and F5–6 or LS>12/>15 kPa in case of ALT≤/>ULN. New (2025) TxI were: A) detectable HBVDNA and LS >8 Kpa or F≥4 or B) HBV DNA ≥2000 and ALT >ULN or LS 7.1–8 kPa or F3.
Results: Of 2012 chronic HBV pts, 1501 (75%) (males 60%, mean age 44 ± 15 yrs, BMI 26 ± 4 kg/m^2, follow-up 6.0 ± 4.6 yrs) were included. Using 2017 vs 2025 EASL CPGs, 679 (45%) vs 660 (44%) were CIe-, 577 (38%) vs 297 (20%) were GZ and 245 (16%) vs 544 (36%) were pts with TxI (A: 259, B: 285), respectively. New (2025) TxI during yr-1 were met by 19 (2.8%) former CIe-, 280 (48.5%) former GZ and all 145 pts with 2017 TxI. Of 297 former GZ pts without new TxI, 238 (80%) had HBV DNA ≥2000 but ALT ≤ULN and 59 (20%) had ALT >ULN but HBV DNA <2000 (all LS ≤7 kPa). Therapy during yr-1 was initiated in 366/544 (67%) pts with new TxI, 34/297 (11.4%) new GZ and 9/660 (1.4%) new CIe- pts ($p < 0.001$). The 1-/3-/5-yr treatment initiation rates were 67/77/85% in pts with as well as 4.5/9/16% in pts without new TxI within yr-1 (log-rank, $p < 0.001$).
Conclusion: The EASL 2025 TxI reduce by half the GZ CHBVe- pts and reflect better treatment policies in routine clinical practice over the last 15 years identifying the majority of pts clinicians are already more likely to treat.

OS-069
Efficacy and safety of interferon combined with antiretroviral therapy in people with HIV/HBV co-infection: a prospective observational study

Yaozu He[1], Weiyin Lin[1], Hong Li[1], Fei Gu[1], Peishan Du[1], Shaozhen Chen[1], Xiaoping Tang[2], Linghua Li[1]. [1]*Infectious Disease Center, Guangzhou Eighth People's Hospital, Guangzhou Medical University Guangzhou, Guangzhou, China;* [2]*Institute of Infectious Disease, Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China*
Email: llheliza@126.com

Background and aims: To evaluate the efficacy and safety of interferon combined with antiretroviral therapy (ART) for achieving HBV functional cure (HBsAg seroclearance) in HBV/HIV co-infected individuals.
Method: In this prospective observational study, we enrolled HBV/HIV co-infected adults on stable ART (>1 year) with HBeAg-negative status, HBsAg <1500 IU/mL, HIV RNA <20 copies/mL, and HBV DNA <100 IU/mL. Participants were allocated to two groups according to patient preference and physician recommendation: pegylated interferon α-2b (PEG-IFN α-2b) weekly for 48 weeks added to ongoing ART (n = 30) or continued ART alone (n = 90). All ART regimens contained two drugs with anti-HBV activity (3TC or FTC plus TDF or TAF). Primary endpoint was HBsAg seroclearance (quantitative HBsAg <0.05 IU/mL) at weeks 24 and 48. Secondary endpoints included early interferon response by week 24 (HBsAg decline >1 $\log_{10}$ IU/mL from baseline or seroclearance) and safety.
Results: Of the 2045 screened individuals with HBV/HIV co-infection, 409 met the preliminary criteria. Thirty entered the PEG-IFN α-2b plus ART group, and 90 entered the ART-alone group. Baseline features were balanced, except for a younger age in the PEG-IFN group (mean 41.8 ± 6.9 vs 45.7 ± 7.4 years; P = 0.011). Gender, ART duration, baseline HBsAg levels, and CD4 count were comparable between the groups (all P > 0.05). At week 24, 27 participants in the PEG-IFN group and 87 in the ART-alone group completed follow-up. HBsAg seroclearance was observed in 4/27 (14.8%) of those receiving PEG-IFN α-2b plus ART, versus none in the ART-alone group. Early interferon response occurred in 15/27 (55.6%) of the PEG-IFN group. As the study is still ongoing, only a subset of participants has completed the 48-week follow-up. At 48 weeks, 18 patients in the PEG-IFN α-2b plus ART group completed follow-up, with 7 (38.8%) achieving HBsAg seroclearance. In the ART-alone group, 54 patients completed 48 weeks of follow-up, with only 1 (1.9%) achieving HBsAg seroclearance. The difference in seroclearance rates between the two groups was statistically significant (P < 0.001). Adverse events in the PEG-IFN group were frequent but manageable, with no severe interferon-related adverse events leading to discontinuation.
Conclusion: PEG-IFN α-2b added to ART shows potential for HBsAg seroclearance in selected individuals with HIV/HBV co-infection, with acceptable tolerability.

OS-070-YI
Peg-IFN add-on versus nucleos(t)ide analogue withdrawal in patients with chronic hepatitis B – a pooled analysis of two global cohorts (RETRACT-B and PROSPER studies)

Email: e.dongelmans@erasmusmc.nl

Background and aims: Both nucleo(s)tide analogue (NA) withdrawal and pegylated-interferon (peg-IFN) add-on are strategies to increase HBsAg loss rates in chronic hepatitis B patients on long-term NA therapy. It remains unclear which strategy is superior.
Method: We compared HBsAg loss rates in HBeAg negative patients who stopped NA therapy with patients who received peg-IFN add-on using individual participant data from two global cohorts: (1) RETRACT-B, including patients who withdrew NA therapy and, (2) PROSPER, which studied NA-treated patients allocated to 48 weeks of peg-IFN add-on. The primary outcome was the cumulative HBsAg loss rate at 2-years after NA-stop or start of peg-IFN add-on (Kaplan-Meier method). Secondary outcome included ALT-flares (5≥×ULN). Robustness of the findings was subsequently confirmed after IPTW balancing. Analyses were performed in the overall population and stratified by ethnicity.
Results: In total, 2,095 patients were included (NA-stop: n = 1,772; peg-IFN add-on: n = 323). In comparison to NA-stop, peg-IFN treated patients were younger (48 vs. 52 years, p < 0.001), more often male (83 vs. 72%, p < 0.001), non-Asian (38 vs. 19%, p < 0.001), and had higher baseline ALT (26 vs. 23, p = 0.002). Baseline HBsAg (2.8 vs. 2.7 log10 IU/mL, p = 0.30), duration of NA therapy (4.3 vs. 3.1 years, p = 0.97) and patients with cirrhosis (8 vs. 11%, p = 0.10) were similar. The cumulative 2-year HBsAg loss rate was higher for patients treated with peg-IFN add-on vs. NA-stop (16 vs. 5%, p < 0.001; IPTW: 13 vs. 5%, p < 0.001). Importantly, the superiority of peg-IFN add-on was apparent in Asians (20 vs. 3%, p < 0.001; IPTW: 13 vs. 3%, p < 0.001), but not in non-Asians (9 vs. 13%, p = 0.37; IPTW: 8 vs. 12%, p = 0.54). Results were consistent for patients with baseline HBsAg <1,000 IU/mL, with higher HBsAg loss rates observed with peg-IFN add-on vs. NA-stop in Asians (30 vs. 5%, p < 0.001; IPTW: 20 vs. 5%, p < 0.001), but not in non-Asians (19 vs. 33%, p = 0.13; IPTW: 27 vs. 35%, p = 0.68). ALT-flares were more common after NA-stop (24 vs. 6%, p < 0.001; IPTW: 23 vs. 5%, p < 0.001), being consistent in Asian (24 vs. 7%, p < 0.001; IPTW: 24 vs. 5%,p < 0.001) and non-Asian patients (22 vs. 6%, p < 0.001, IPTW: 21 vs. 3%, p = 0.016).
Conclusion: Peg-IFN add-on resulted in higher HBsAg loss rates when compared to NA withdrawal in Asian patients, while responses were similar in non-Asians. These findings pave the way for personalised decision-making on the optimal strategy to increase HBsAg loss rates in patients on NA therapy.

Viral hepatitis B/D – New therapies

PD-1 inhibitor plus Peg-IFNα therapy: efficacy and predictors of HBsAg clearance in CHB patients with a suboptimal early response to Interferon

Chenrui Liu[1], Yaping Li[1], Meng Zhang[1], Guoe Gou[1], Miao Hao[1], Muqi Wang[1], Yikai Wang[1], Shuangsuo Dang[1]. *[1]The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: dang212@126.com

Background and aims: Despite being a cornerstone HBsAg clearance therapy, interferon often yields poor responses and risks T-cell exhaustion. PD-1 inhibitors offer a potential strategy but are limited as monotherapy. This study followed HBsAg outcomes in CHB patients over 24 weeks of PD-1 inhibitor plus Peg-IFNα treatment and a 24-week off-treatment period to identify characteristics of responders.
Method: This study enrolled interferon-experienced CHB patients (prior interferon ≥24 weeks with HBsAg decline <0.5 $\log_{10}$ IU/mL at week 24, HBsAg <1500 IU/mL, HBeAg-negative, HBV DNA <5 IU/mL) without PD-1 inhibitor contraindications. Patients received 24 weeks of PD-1 inhibitor (1 mg/kg, Q8–12W) plus Peg-IFNα (180 μg/week), followed by 24 weeks off-treatment. HBsAg status at end of follow-up (EOF) defined clearance and non-clearance groups. Baseline predictors were analyzed via univariate and binary logistic regression.
Results: Of 91 enrolled patients (69 male, 22 female), 26 (28.5%; 22M, 4F) achieved HBsAg clearance at EOF, with no unexpected safety signals. Baseline levels differed significantly between clearance and non-clearance groups for globulin (25.2 [23.2–29.0] vs. 27.65 [25.55–30.725] g/L, P = 0.013), albumin-to-globulin ratio (1.73 [1.485–1.9275] vs. 1.565 [1.3825–1.7925], P = 0.04), HBsAg (2.8 [0.6925–5.62] vs. 51.115 [4.025–294.925] IU/mL, P < 0.001), and HBsAb (2.645 [1.575–9.04] vs. 0.88 [0.4275–1.6975] IU/mL, P < 0.001). Based on a week-4 HBsAg decline >0.5 $\log_{10}$ IU/mL, patients were classified as early (n = 33) or poor early responders (n = 58). HBsAg clearance rates were 54.5% (18/33) and 13.7% (8/58), respectively. In binary logistic regression, only baseline HBsAg (OR 0.991, 95% CI 0.984–0.999, P = 0.017) and a week-4 HBsAg decline >0.5 $\log_{10}$ IU/mL (OR 10.233, 95% CI 2.706–38.699, P < 0.001) were independent predictors of week-48 clearance. ROC analysis for week-4 HBsAg decline yielded an AUC of 0.808 (0.700–0.917, P < 0.001), with an optimal cutoff of 0.418 $\log_{10}$ IU/mL (Se = 0.769, Sp = 0.754). Baseline HBsAg had an AUC of 0.790 (0.691–0.889, P < 0.001), with an optimal cutoff of 10.165 IU/mL (Se = 0.677, Sp = 0.846).
Conclusion: PD-1 inhibitor combined with Peg-IFNα achieved an HBsAg clearance rate of approximately 28.5% in interferon-experienced CHB patients with a suboptimal early response, supporting its potential as a viable clinical cure strategy. Baseline HBsAg <10 IU/mL and week-4 HBsAg decline ≥0.418 $\log_{10}$ IU/mL were predictive of HBsAg clearance at week 48.

Email: martin.r.leivers@gsk.com

Background and aims: GSK3965193 (GSK193) is a novel, orally bioavailable, small molecule inhibitor of the human non-canonical poly(A) polymerases PAPD5/7, designed to reduce the HBV antigen HBsAg through destabilization of HBV RNA. This first-in-patient study aimed to assess the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of GSK193 in patients with chronic hepatitis B (CHB).
Method: This was a multicenter, randomized, double-blind, placebo-controlled phase 1 study (ClinicalTrials.gov: NCT05330455). In Part 3 of the study, HBeAg positive and negative patients on nucleoside analogs were randomized to GSK193 (0.5 mg, QD; n = 14) or placebo (QD; n = 4) for 28 days. PK, PD (HBV biomarkers) and safety monitoring, including nerve conduction assessments at baseline, days 15 and 29, were assessed.
Results: GSK193 had an acceptable safety profile and was well tolerated in CHB patients at the tested dose and duration. In part 3, no serious treatment-emergent adverse events (TEAEs) or TEAEs > Grade 2 occurred. The most common TEAEs were dizziness, fatigue, dysgeusia, and headache, all of which occurred more frequently with GSK193 than placebo. No significant changes were observed in nerve conduction assessments. Following administration, GSK193 was rapidly absorbed, with a median T_{max} of 3.0 h and median $t_{1/2}$ of 7.9 h. No accumulation was observed after 28 daily doses. A plasma target concentration corresponding to the protein-binding–adjusted preclinical liver EC90 was exceeded for 24 hours following the 0.5 mg dose, confirming PK model-based predictions. GSK193 treatment resulted in a posterior mean for the maximum HBsAg reduction from baseline of 0.50 log10 IU/mL (95% credible interval [CrI]: 0.3, 0.7) which was higher than in the placebo group (0.08 log10 IU/mL; 95% CrI: 0.05, 0.09). Individually, the highest observed maximum reduction of HBsAg levels with GSK193 was 1.66 log10 IU/mL compared to 0.10 log10 IU/mL with placebo. On average, this maximum reduction was achieved within 24 days with GSK193. Upon cessation of GSK193 administration, HBsAg levels generally rebounded to baseline within 2 weeks.
Conclusion: GSK193 at the tested dose was tolerated, showed favorable safety and pharmacokinetic profile, and demonstrated preliminary evidence of antiviral activity through HBsAg reduction, supporting further clinical development of GSK193 as part of a regimen for treating CHB.
Funding: GSK (study 214760).

OS-073

A single VRON-0200 prime dose, followed by a monthly antiviral combination regimen, resulted in rapid, profound, and durable HBsAg declines in chronically hepatitis B-infected patients

Edward J. Gane[1], Sue Currie, Tien Huey Lim[2], Andrew Luber[3], Marie Bonhomme[4], Grace Wong[5]. *[1]Auckland City Hospital, Auckland, New Zealand; [2]Middlemore Hospital, Auckland, New Zealand; [3]Virion Therapeutics, LLC, Philadelphia, United States; [4]PPD, Part of Thermo Fisher Scientific, Richmond, United States; [5]The Chinese University of Hong Kong, Hong Kong, Hong Kong*
Email: scurrie@viriontx.com

Background and aims: VRON-0200 is an immune-modulator containing a checkpoint modifier targeting HBV core and pol (but not S) antigens, designed to enhance, broaden, and prolong T cell responses. The Phase 1b study demonstrated that VRON-0200 induces anti-HBV immune activation/restoration, with durable HBsAg declines after a single dose. This study report evaluates the safety,immunogenicity,and HBsAg data from chronically-HBV(CHB) infected patients(pts), on NUCs, that received VRON-0200, alone, or in combination with investigational antivirals.
Method: CHB pts, NUC-suppressed with HBsAg <500 IU/mL (Cohorts 1 and 2;C1/2), or <1,000 IU/mL (Cohort 3;C3), were randomized to receive i.m. VRON-0200 prime on D1, w/wo VRON-0200 boost on D91;C3 receive VRON-0200 prime, followed by 6 monthly doses of elebsiran plus tobevibart (E+T) starting on D28, alone, or with a VRON-0200 boost on D196. Safety, virologic, and immunologic assessments were performed. HBsAg (ELISA; LLOD:0.05 IU/mL),and T cell frequencies (IFNɣ ELISpot) were measured.
Results: As of December 19, 2025, 35 pts were included: 28 (80%) male, 30 (86%) Asian, median age:46 yrs, and median BL HBsAg,179 IU/mL(range:10–1169). In 12,073 pt safety days, 38 TRAEs were reported: 4-GR2,34-GR1, with no treatment-related SAEs or D/Cs. In C1/2, all 27 reached EOS(D360); at D360, 359 days post VRON-0200 prime dose, 23/27(85%) had sustained and/or continued HBsAg declines;12/23(52%) had >50% declines, and 4 pts had $\geq 1 \log_{10}$IU/mL reduction from baseline. A boost dose did not enhance responses, and HBsAg declines were independent of BL HBsAg levels. IFNɣ ELISpot responses did not appear to be associated with HBsAg declines. In C3, within 7 days of first E+T dose, rapid and profound HBsAg declines were observed (100% ≤2 IU/mL; 1 below LLOD) and were independent of BL HBsAg levels. At Day 196 (28 days post last E+T dose), 100% were ≤1 IU/mL; 3 of 7 below LLOD. C3 results, at least 3 months post last E+T dose, to be reported.
Conclusion: In this Phase 1b study, VRON-0200 alone, or in combination, had no observed safety concerns, and was well tolerated. VRON-0200-induced anti-HBV activity was enhanced in combination with antivirals and produced rapid and profound HBsAg declines in all patients. This novel approach, where anti-HBV immunity is "sparked" (i.e. primed) with VRON-0200, and then "fanned" (i.e. boosted) by HBV removal, supports the potential of VRON-0200 as a foundational backbone agent for future HBV Functional Cure regimens. A Phase 2b study (SPARK-B) is in planning.

Marked sensitivity to an entry inhibitor in Mongolian patients with chronic hepatitis delta: 24-week results from a phase IIb multicentre randomised controlled trial of Hepalatide

Janchiv Oyunbileg[1], Xiaolu Tang[2], Shirnin Tamir[3], Batjargal Azjargal[4], Munkhzaya Chogsom[5], Otgonjargal Nomingerel[3], Batzorig Orgil[3], Xian Gao[2], Fei Cai[2], Wenhui Liu[2], Hanzhi Fang[2], Hongli Liu[2]. *[1]National Center for Public Health, Ulaanbaatar, Mongolia; [2]Shanghai HEP Pharma Co., Ltd., Shanghai, China; [3]SFCS Site Management LLC, Ulaanbaatar, Mongolia; [4]National Center for Communicable Diseases, Ulaanbaatar, Mongolia; [5]National Cancer Center of Mongolia, Ulaanbaatar, Mongolia*
Email: jobileg@gmail.com

Background and aims: HBV/HDV entry inhibitors represent a major advance in the direct antiviral treatment for chronic hepatitis delta (CHD). Bulevirtide is the first approved therapy for CHD in Europe as an orphan drug. In the phase II MYR202 trial, 24 weeks of bulevirtide 2 mg achieved a combined response rate of 21%. However, efficacy and safety data from hyperendemic regions remain limited, where entry inhibitors are urgently needed. Mongolia is among the countries with the highest reported prevalence of CHD worldwide.

This study reports a phase IIb trial of the entry inhibitor hepalatide in Mongolian CHD patients.
Method: This multicentre, randomised, open-label, delayed-treatment–controlled trial enrolled adults aged 18–65 years with compensated CHD and quantifiable HDV RNA in Mongolia (NCT06505928). Participants were randomised 1:1:1 to once-daily subcutaneous hepalatide 2.1 mg, hepalatide 4.2 mg, or delayed treatment for 48 weeks, followed by a 96-week extension with hepalatide 2.1 mg. Virological response was defined as undetectable HDV RNA or a ≥ 2 $\log_{10}$ decline, and biochemical response as alanine aminotransferase normalisation. Combined response and safety were assessed at the 24-week interim analysis.
Results: Ninety subjects (81 Mongolian, 1 Kazakh, and 8 of other ethnicities) were randomised to the 2.1 mg, 4.2 mg, or delayed treatment groups (n = 31, 29, and 30). Eighty-nine participants completed the 24-week period, with one discontinuation in the 2.1 mg group. Hepalatide was generally well tolerated, with no grade ≥ 3 treatment-related adverse events. At week 24, virological response rates were 51.6%, 62.1%, and 0.0%, with mean HDV RNA changes of −1.96, −2.30, and + 0.04 $\log_{10}$ IU/mL. Biochemical response occurred in 77.4%, 65.6%, and 13.3% of patients, while combined response rates were 48.4%, 41.4%, and 0.0%. All virological, biochemical, and combined responses in both hepalatide groups were significantly higher than in the delayed treatment group ($p < 0.001$ for each comparison).
Conclusion: Hepalatide demonstrated significant virological, biochemical, and combined responses with good tolerability in Mongolian patients with CHD. Relative to historical bulevirtide data predominantly from Caucasian cohorts, the high combined response rates observed in the study may indicate heightened sensitivity to entry inhibitors in this highly endemic Mongolian population. These findings may suggest long-term clinical relevance of entry inhibitors in Mongolian CHD patients.

OS-075
Lonafarnib/ritonavir and peg-Interferon alfa drive histological improvement and inflammation resolution in chronic hepatitis D: results of the multicenter phase 3 D-LIVR study

Email: jeffrey.glenn@eitpharma.com

Background and aims: Lonafarnib (LNF) boosted with ritonavir (LNF/RTV) is an oral therapy for chronic hepatitis D (CHD) that may be combined with peg-interferon-alfa (Peg). LNF has a dual mechanism, inhibiting the host farnesyltransferase to disrupt HDV virion assembly, and inducing interferon-stimulated gene expression. Improvement of liver histology in CHD is a key predictor of long-term clinical benefit, and reducing hepatic inflammation is a necessary precursor to hepatic histology improvement. Therefore, we evaluated the impact of LNF/RTV with and without Peg on inflammatory and histological outcomes in D-LIVR, the largest phase 3 randomized placebo-controlled CHD trial to date.
Method: Oral LNF/RTV with or without PEG was evaluated in placebo controlled 407 patients with CHD, largest number of histology biopsies for CHD in a single study. The primary endpoint was a composite score of ≥ 2 log HDV RNA reduction and ALT normalization compared to baseline at week 48 on-treatment, with improvement in liver histology as a secondary endpoint. Histological response was defined as a ≥2-point improvement in modified Ishak Histologic Activity Index (HAI) without worsening of fibrosis. This study examines the relationship between ALT normalization and histological improvement.
Results: Both LNF/RTV monotherapy and LNF/RTV+Peg met the primary composite endpoint with significant improvement over placebo (LNF/RTV: 10%, $p = 0.004$, LNF/RTV+ Peg: 19% $p < 0.0001$). Peg monotherapy had limited composite response rate (9%, $p = 0.09$ vs placebo) at 48 weeks on treatment driven by limited ALT normalization. In contrast, ALT was significantly normalized in both LNF/RTV (25%, $p = 0.0003$ vs placebo) and LNF/RTV+Peg (34%, $p < 0.0001$ vs placebo) arms. Importantly, LNF/RTV+Peg resulted in a statistically significant histological improvement at 48-weeks on-treatment ($p = 0.01$) and LNF/RTV monotherapy directionally improved histological endpoints.
Conclusion: In patients with chronic hepatitis D, reduction of hepatic inflammation is a critical step toward histological improvement and long-term clinical benefit. LNF/RTV, a first-in-class oral CHD therapy, alone and in combination with peg-interferon alfa, significantly reduces HDV viral load and normalizes ALT, and combination treatment translates into meaningful improvements in liver histology after only 48 weeks of treatment. These findings support LNF/RTV-based regimens as disease-modifying therapies for CHD and highlight the added histological benefit of combination therapy.

Email: stefanodanna26@gmail.com

Background and aims: HDV relies on HBsAg for its infectivity. HBsAg transcripts originate from cccDNA via the conventional poly-A signal and from integrated double-stranded linear HBV-DNA via the cryptic poly-A signal. Here, we evaluated intrahepatic HBV/HDV reservoir and the contribution of HBsAg production from linear HBV-DNA integration in sustaining HDV activity and pathogenetic potential.
Method: 70 liver biopsies from eAg- patients (pts) (74% NUC-treated) were included: 35 with chronic hepatitis delta (CHD) and 35 with chronic hepatitis B (CHB). Droplet-digital PCR quantified cccDNA, pgRNA, HDV-RNA and HBsAg transcripts from cccDNA and integrated HBV-DNA. In 19 CHD pts, long-read Nanopore sequencing assessed HBV-DNA integrations including those containing at least the entire ORF-S up to the cryptic poly-A signal (S-integrants). RNA-seq evaluated viral gene expression.
Results: In CHD pts, median (IQR) cccDNA, pgRNA and cccDNA-derived HBsAg transcripts were 1 (0.02–12), 8 (1–147) and 1 (0.2–41) copies/1000cells, all >1 log lower than in CHB pts ($p < 0.001$). HDV-RNA was 787 (1–7596) copies/1000cells. cccDNA strongly correlated with pgRNA and cccDNA-derived HBsAg transcripts ($p < 0.001$) but not with HDV-RNA ($P = 0.60$). Despite limited intrahepatic HBV reservoir, >1 HBV-DNA integrant was detected in 73.7% (14/19) of CHD pts (5 [2–6] number of unique events per pt). Notably, 10/14 (71.4%) CHD pts carried S-integrants. S-integrant carriers had high levels of integrated-derived HBsAg transcripts (32410 [16733–53180] cps/1000cells), which were absent in pts without HBV-DNA integrants, as confirmed by RNA-seq. S-integrant carriers had higher cccDNA and pgRNA ($p < 0.005$ for both), supporting that an active cccDNA fuels HBV-DNA integration, while HDV-RNA was similar regardless of S-integrants ($p = 0.5$). Moreover, S-integrant carriers had higher serum HBsAg (4.3 [4.0–4.4] vs 3.7 [3.5–3.9] logIU/ml, $p = 0.04$). By AUROC, HBsAg >4logIU/ml predicted the occurrence of S-integrants with the best accuracy (75% sensitivity and 75% specificity). Finally, in 7/10 pts, S-integrants localised in 26 human genes regulating cell proliferation, most of which ($N = 21$) are known to dysregulate hepatocytes proliferation.
Conclusion: This study provides the first direct evidence that S-integrants sustain massive HBsAg production, supporting HDV persistence. High serum HBsAg (>4 logIU/ml) may reflect an enrichment of HBV-DNA integration. Localization of integrants in proliferation-related genes suggests a role in paving the way to hepatocarcinogenesis.

OS-077
Clinical efficacy of BRII-179 therapeutic vaccine provided by a mismatched T cell epitope of prehistoric origin

Nina Le Bert[1], Akshay Binayke[1], Shubhankar Ambike[1], Previtha Dawn[1], Ying Tan[2], Anthony Tan[1], Yazhini Avaiarasi[1], Shoukit Hang[3], Yun Ji[4], Qing Zhu[4], Antonio Bertoletti[1]. *[1]Duke-Nus Medical School, Singapore, Singapore; [2]Brii Biosciences Inc, Beijing, China; [3]T Cell Diagnostic Pte Ltd, Singapore, Singapore; [4]Brii Biosciences Inc, Durham, United States*
Email: antonio@duke-nus.edu.sg

Background and aims: Therapeutic vaccines for HBV cure aim to restore dysfunctional HBV-specific T and B cells. BRII-179 is a therapeutic vaccine composed of recombinant HBV envelope proteins. Clinical trials combining siRNA, BRII-179, and PegIFN-alpha demonstrated that BRII-179 modulates HBV-specific immunity and increases rates of HBsAg loss (Wong, G. L.-H. *et al*. Elebsiran and PEG-IFNα for chronic hepatitis B infection: a partially randomized, open-label, phase 2 trial. *Nat. Med.* (2025) doi:10.1038/s41591-025-04049-z).
Method: We studied CHB patients on nucleo(t)side analogue therapy who received BRII-179 plus siRNA ($n = 77$), with a subset subsequently treated with siRNA and PegIFN-alpha ($n = 31$). We performed T cell epitope mapping, functional characterization and longitudinal tracking of vaccine-induced T cells, quantification and phenotyping of HBs-specific B cells, and sequence analysis comparing vaccine and infecting HBV strains.
Results: Anti-HBs titers after BRII-179 treatment correlated not with pre-existing PreS1/PreS2/S-specific T cells, but with expansion of IL-2-producing CD4T cells targeting two adjacent epitopes in the PreS1 N-terminal domain. These epitopes, mismatched with patients' infecting genotypes (B and C), were induced by a PreS1 sequence of a rare genotype G considered a remnant of prehistoric HBV lineages. The vaccine-induced CD4T cells produced predominantly IL-2 and were detected in most vaccinated patients across diverse HLA-class II backgrounds. They remained functionally stable for over two years, and persisted during subsequent PegIFN-alpha/siRNA treatment. Despite lacking cross-reactivity with contemporary HBV genotypes, patients with these epitope-mismatched CD4T cells showed marked progressive maturation of HBs-specific B cells, suggesting intramolecular help between vaccine-specific T cells and HBs-specific B cells.
Conclusion: Enhanced HBsAg loss rates following siRNA and PegIFN-alpha treatment are associated with the expansion of epitope-mismatched vaccine-specific CD4T cells and HBs-specific B cell maturation. These findings underscore the role of HBs-specific B cells in achieving HBsAg loss. The notable immunogenicity of this ancient HBV sequence raises the possibility that viral epitopes lost during evolution may hold the key to eliciting therapeutically effective antiviral immunity.

OS-078
Metabolic dysfunction-associated steatotic liver disease induces hepatocellular ferroptosis and activates intrahepatic macrophages by upregulating lipocalin-2 to accelerate the clearance of Hepatitis B surface antigen

Yan Han[1], Jing Tang[1], ZhiWei Chen[1], Hong Ren[1]. *[1]Department of infectious diseases, The second affiliated hospital of Chongqing Medical University., Chongqing, China*
Email: renhong0531@cqmu.edu.cn

Background and aims: To date, it remains challenging to cure chronic hepatitis B (CHB). Intriguingly, recent cohort studies have revealed that metabolic dysfunction-associated steatotic liver disease (MASLD) can promote the spontaneous clearance of HBsAg in CHB patients. This study aims to uncover the underlying mechanism.
Method: C57BL/6J mice were administered rAAV8-1.3HBV via tail-vein injection to establish chronic HBV infection. Subsequently, either a Methionine-Choline Deficient (MCD) or a Choline-Deficient, L-Amino Acid-defined, High-Fat Diet (CDAHFD) regimen was fed to the mice to induce a CHB concurrent with MASLD model. Bulk RNA-seq of liver tissue and single-cell RNA sequencing (scRNA-seq) of hepatocytes and immune cells were conducted to investigate the mechanism. In vitro, the conditioned medium from lipocalin-2 (Lcn2)-overexpressing or ferroptosis-induced hepatocytes was co-cultured with macrophages to mimic cell-cell crosstalk.
Results: In the MASLD/CHB co-diseased group, both mouse models exhibited markedly reduced serum HBsAg levels compared to baseline. ScRNA-seq of hepatocytes revealed a substantial decrease in HBV mRNA-positive cells in the co-diseased group. Bulk RNA-seq indicated significant upregulation of the hepatic ferroptosis pathway, which was further corroborated by iron overload and elevated malondialdehyde (a lipid peroxidation product). Treatment with Liproxstatin-1, a ferroptosis inhibitor, increased serum HBsAg levels. To assess whether hepatic ferroptosis triggers an immune response, we analyzed intrahepatic immune cells via scRNA-seq and found significant macrophage activation. In vitro studies demonstrated that

this activation was characterized by the upregulation of M1 markers and, importantly, the phosphorylation and nuclear translocation of key proteins in the TLR4/NF-κB/IRF3 axis. Following macrophage depletion with Gacl3, serum HBsAg levels elevated. Notably, Liproxstatin-1 treatment could also attenuate macrophage activation. At Last, we found that Lcn2, a key metabolic gene in MASLD, was markedly upregulated. Inhibition of Lcn2 significantly alleviated hepatic ferroptosis and reduced macrophage infiltration, leading to a significant rebound in the serum HBsAg level.
Conclusion: Our study demonstrated that MASLD can induce hepatocellular ferroptosis and activate intrahepatic macrophages via Lcn2 upregulation, thereby accelerating HBsAg clearance. This finding provides new insights into the MASLD-HBV interplay.

SR-1891, a first long-acting capsid assembly modulator, induces safe, profound and durable antiviral suppression after a single subcutaneous dose in mouse models of chronic hepatitis B
Romano Di Fabio[1], Marco Manenti[1], Alessandro Grillo[1], Pietro Di Lucia[1], Elisa Bono[2], Leonardo Giustini[2], Lorena Donnici[3], Katherine Squires[4], Gaston Picchio[2], Raffaele De Francesco[3,5], Matteo Iannacone[1,2], Micol Ravà[1], Luca G. Guidotti[1,2]. *[1]Vita-Salute San Raffaele University, Milan, Italy; [2]IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]INGM, National Institute of Molecular Genetics "Romeo ed Enrica Invernizzi," Milan, Italy; [4]Former Antios Therapeutics, Mendham, NJ, USA, Mendham, NJ, United States; [5]Department of Pharmacological and Biomolecular Sciences, Università degli Studi di Milano, Milan, Italy*
Email: guidotti.luca@hsr.it

Background and aims: Novel suppressive therapies that improve both antiviral potency and adherence over current nucleos(t)ide analogues are likely to be needed to curb the global burden of chronic HBV infection in the foreseeable future. Here, we report the discovery and initial preclinical characterization of SR-1891, a highly potent capsid assembly modulator (CAM) that leverages intrinsic long-acting properties following subcutaneous administration.
Method: SR-1891 was administered as a single subcutaneous dose (150 mg/kg) to HBV-replicating immunocompetent transgenic mice (HBV Tg, baseline viremia 10^7–10^8 copies/mL) or HBV-infected immunodeficient liver-humanized mice (HBV Hu, baseline viremia 8 × 10^8–4 × 10^9 copies/mL). This dose is comparable to those used in the preclinical development of lenacapavir, a long-acting CAM approved for HIV treatment. At abstract submission, HBV Tg and HBV Hu cohorts had been followed through days 14 and 28, respectively. Control animals received continuous oral entecavir (ETV; 0.1 mg/kg/day in drinking water), a regimen commonly used in mouse studies to approximate human clinical exposure. Serum HBV DNA, HBV RNA and ALT were measured at multiple time points before and after dosing. In selected HBV Tg mice, liver injury and hepatocellular capsid distribution were assessed histologically on day 14.
Results: Relative to pre-dose serum HBV DNA, ETV produced progressive multi-log10 declines after 14 days in HBV Tg (−3.4 log10) and HBV Hu (−1.9 log10) mice, and after 28 days in HBV Hu mice (−2.8 log10), without reducing serum HBV RNA. In contrast, SR-1891 achieved ≈10-fold greater decreases in serum HBV DNA than ETV at all assessed time points, reaching −4.3 log10 at day 14 in HBV Tg mice and −3.0 log10 at day 14 in HBV Hu mice, with an ≈8-fold difference still evident at day 28 in HBV Hu mice (−3.7 log10). SR-1891 also induced progressive declines in serum HBV RNA, reaching ≥2 log10 reductions versus baseline and ETV by day 14 (last assessment) in both models. No ALT elevations were detected in HBV Tg mice, and day-14 histology showed no liver injury or aberrant hepatocellular capsid accumulation.
Conclusion: SR-1891 is a first long-acting CAM that, after a single subcutaneous dose, achieves greater and more durable antiviral effects than daily oral ETV. Ongoing studies of serum and hepatic viral markers, including HBeAg, HBsAg and cccDNA before and after days 14–28, as well as ADME profiling and PK/PD analyses, will be reported at the meeting.

OS-080-YI
The spatial single-cell landscape in the hepatitis B virus/hepatitis D virus-coinfected human liver reveals spatially confined immunosuppressive virus-immune niches
Yuan Suo[1], Shirin Nkongolo[2,3,4], Carolin Mogler[5], Ira Godbole[1], Günter Päth[1], Stephan Urban[3], Robert Thimme[1], Bertram Bengsch[1,6,7]. *[1]Clinic for Internal Medicine II, University Medical Center Freiburg, Freiburg, Germany; [2]Internal Medicine IV (Gastroenterology, Hepatology, Infectious Diseases), University Hospital Heidelberg, Heidelberg, Germany; [3]Molecular Virology, Department of Infectious Diseases, University Hospital Heidelberg, Heidelberg, Germany; [4]German Center for Infection Research, partner site Heidelberg, Heidelberg, Germany; [5]Institute of Pathology, School of Medicine & Health, Technical University of Munich, Munich, Germany; [6]Signaling Research Centres BIOSS and CIBSS, Freiburg, Germany; [7]German Cancer Consortium (DKTK), Heidelberg, Germany, Partner Site Freiburg, Freiburg, Germany*
Email: yuan.suo@uniklinik-freiburg.de

Background and aims: Chronic hepatitis B virus (HBV) and hepatitis D virus (HDV) infection can lead to severe viral hepatitis and progression to liver cirrhosis and liver failure. The mechanisms underlying the failure of the immune system to clear HDV remain poorly understood. This study aimed to comprehensively characterize virus-host interactions in the spatial microenvironment in the HDV-infected human liver at single-cell resolution.
Method: Liver samples from 21 chronic HBV/HDV-infected patients were analyzed using MIBI-TOF imaging. The imaging panel comprised 40 markers for liver parenchymal cells and liver architecture, immune lineages and functional markers. Virus-infected cells were identified by hepatitis D antigen (HDAg) and hepatitis B virus core and surface antigens (HBsAg, HBcAg).
Results: We identified 18 different cell types, with hepatocytes accounting for the majority of cells, as expected. 4.3% of hepatocytes stained positive for the viral antigens HDAg, HBsAg, and/or HBcAg. Virus antigen-positive hepatocytes were biased towards either a dominant $HBsAg^+$ or $HDAg^+$ population. $HDAg^+$ hepatocyte density correlated with serum HDV RNA levels ($R^2 = 0.9212$, $P < 0.0001$) and the density of virus marker-positive hepatocytes was associated with immune cell infiltration ($R^2 = 0.2013$, $P = 0.0413$). Macrophages and CD8T cells were the most abundant immune cells (8.95% and 8.59%). Zonation analysis identified hepatic zones 1–3, and predominant stromal regions. Zone 3 exhibited the highest density of virus antigen-positive hepatocytes, whereas immune cells were most densely localized in Zone 1 and the stromal region. Spatial interactions between immune and virus-positive cells were further analyzed by distance analysis. Macrophages were significantly enriched within viral regions ($P = 0.011$), and showed higher immunosuppressive PD-L1 and CD204 expression in close proximity to hepatocytes with viral antigens. Cellular interaction analysis revealed those hepatocytes to interact more with macrophages, which in turn displayed enriched interactions with exhausted and progenitor exhausted CD8T cells.
Conclusion: Intrahepatic analysis of HDV patients identifies distinct spatial virus-immune niches in HBV/HDV infection. Phenotypic gradients around virus marker-positive hepatocytes suggest prominent interactions between HDV-infected hepatocytes and M2-like macrophages, suggesting the establishment of an immunosuppressive niche involved in regulating adaptive immunity.

Cirrhosis – Clinical and experimental III

Email: laurarturco.md@gmail.com

Background and aims: TIPS is well-established for portal hypertension (PH) in cirrhosis, but knowledge in PSVD is limited. This study evaluated TIPS efficacy and outcomes in PSVD.

Method: Retrospective, multicenter study in patients with histologically confirmed PSVD undergoing TIPS across 31 centers. Time-to-event outcomes were analyzed using Cox proportional hazards models and competing-risks event analysis.

Results: The cohort comprised 300 patients, 63% male, with a median age of 51 years (36–62). 51% had associated conditions, predominantly drug exposure (27%), hematological (22%) or immunological disorders (19%). Pre-TIPS portal vein thrombosis (PVT) was present in 45%, occlusive in 12%. 28% patients were on anticoagulation treatment before TIPS. All received covered stents dilated to < 8 (20%), 8–10 (56%), or 10 mm (16%); dilation was not documented in 8% of cases. Median portal pressure gradient (PPG) decreased from 19 (15–23) to 8 mmHg (5–11). The primary indication for TIPS placement was variceal bleeding (66%), followed by recurrent/refractory ascites (19%) and PVT (13%). After TIPS, 91% did not rebleed, ascites was controlled in 62%, and 22% discontinued diuretics. Stent dysfunction occurred in 22% and was independently correlated with the presence of complete PVT before TIPS (HR: 3.15, 95% CI 1.58–6.25; p = 0.0011). Cardiac failure occurred in 6%, liver failure in 2%. Overt hepatic encephalopathy (oHE) occurred in 18% at 1 and 21% at 3 years, with pre-TIPS ascites as an independent risk factor (HR: 3.43, 95% CI 1.70–6.92; p = 0.0006). During follow-up [27 months (12–60)], 6% underwent transplant, 17% died (11 liver-related). Transplant-free survival was 90% at 1 year, 69% at 5 years. Ascites control (HR: 0.32, 95% CI 0.15–0.68; p = 0.0032), immunological disorders (HR: 3.56, 95% CI 1.30–9.76; p = 0.013), bacterial infection after TIPS (HR: 1.93, 95% CI 1.06–3.52; p = 0.031 and oHE (HR: 2.10, 95% CI 1.02–4.29; p = 0.043) predicted transplant/death. For non-liver related deaths, chronic kidney disease (HR: 3.57, 95% CI 1.49–8.58; p = 0.0045), bacterial infection (HR: 2.93, 95% CI 1.61–5.34; p = 0.0004), and hematological disorders (HR: 2.61, 95% CI 1.11–4.85; p = 0.0261) were independent factors.

Conclusion: TIPS effectively manages PH complications in PSVD despite high stent dysfunction. Multidisciplinary evaluation remains essential given the influence of associated conditions on survival.

Background and aims: TIPS is an effective treatment for complications of portal hypertension but carries a relevant risk of heart failure (HF) occurring in 10–20% of cases. The previously published Toulouse algorithm (TA), based on baseline BNP/NT-proBNP levels and simple echocardiographic parameters, suggested a negligible risk of post-TIPS HF in patients with BNP < 40 pg/mL or NT-proBNP <125 pg/mL, and a high risk (> 50%) in those with elevated NT-proBNP and signs of diastolic dysfunction. This algorithm has only been validated in a small cohort of patients with refractory ascites. The aim of the present study was 1) to assess the external validity of the Toulouse algorithm and 2) to further refine prediction strategies.

Method: Retrospective multicenter study within the EuroTIPS registry. Consecutive patients with cirrhosis treated with TIPS were included if baseline BNP or NT-proBNP, echocardiography and 12-month follow-up were available. Patients were included between 2015 and 2024. HF was defined by typical CF symptoms, objective evidence of pulmonary congestion and need for new-onset or intensified diuretic therapy.

Results: A total of 255 patients were included (76% men, median age of 59 years). Most common etiologes were alcohol-related in 45% and MASLD in 30%; TIPS indication was refractory ascites in 50% and secondary prevention of bleeding in 31%. Prior history of ischemic heart disease and valvular disease was present in 6% and 4% of patients, respectively. Post-TIPS HF occurred in 28 patients (11%). Seven of the 117 (6%) patients classified as negligible HF risk by TA developed CF. Conversely, only 12 of 84 patients (14%) classified as high risk by TA developed CF, compared with a previously reported incidence of 51% in this group. The AUC of TA for predicting CF was 0.62, without relevant improvement according to TIPS indication. Subsequently, based on univariable and multivariable analysis, a new predictive model including baseline NT-proBNP, serum sodium and metabolic syndrome was developed. The model was internally validated using bootstrap resampling and showed a concordance statistic of 0.78, with a time-dependent AUC of 0.83 at 1 year. Echocardiographic parameters were not associated with post-TIPS HF.

Conclusion: In this large international cohort, the Toulouse algorithm showed limited accuracy to predict post-TIPS HF. A new model based on NT-proBNP, metabolic syndrome and sodium levels may better identify patients at risk of HF after TIPS.

Background and aims: Definition of porto-sinusoidal vascular disease (PSVD) currently relies on specific and non-specific histological lesions, based on expert opinion. The aim of this study was to establish evidence-based histological criteria for diagnosing PSVD.
Method: We used a four-step strategy (1) Definition of normal liver vasculature by morphometric analysis of 10 normal surgical liver samples measuring area, axis, and number of vascular structures. (2) Definition of elementary histological lesions of PSVD based on literature data and results of step #1, and their reproducibility between 9 European pathologists. Inter-reader reproducibility was established by analyzing 58 liver biopsies (42 PSVD patients and 16 normal liver biopsies), using intra-class correlation (ICC) and Fleiss' kappa. (3) Identification of histological lesions associated with PSVD diagnosis: review of another cohort of 218 liver biopsies from 88 patients with PSVD and portal hypertension, 89 patients with chronic liver disease without cirrhosis and 41 living liver donors. Patients with venous outflow obstruction were excluded. Major histological criteria were defined as having a specificity > 95% and a sensitivity > 10% for PSVD. Minor histological criteria were defined as having a specificity between 80 and 95% and a sensitivity > 10% for PSVD. (4) External validation of these major and minor criteria was done by 9 independent pathologists from USA, Brazil, India and Japan.
Results: (1) and (2) resulted in an atlas of 15 histological lesions previously associated with PSVD including their precise definition, based on morphometry and expert consensus. Portal venule stenosis (PVS) had the highest ICC across the 9 raters (0.51), while nodular regenerative hyperplasia (NRH) had a Fleiss' kappa at 0.26, with pairwise kappa ranging from 0.12 to 0.67. (3) Three major histological criteria were identified: PVS in ≥ 50% of portal tracts; muscularized portal veins and NRH. Three minor criteria were identified: PVS in 25 to 50% of portal tracts; regenerative changes and abnormal distribution of vascular structures. Presence of these 3 minor features in the same biopsy reached the definition of a major criterion (specificity 98%, sensitivity 17%). (4) Results were validated by the external group of pathologists.
Conclusion: This study, by identifying major and minor histological lesions associated with PSVD, represents a turning point in the revised 2026 definition of this disease.

Background and aims: In patients with cirrhosis and refractory acute variceal bleeding, salvage/rescue transjugular intrahepatic portosystemic shunt (TIPS) placement is associated with a 6-week mortality rate of 30–50%. International guidelines raise the question of placing a TIPS in patients with 6-week mortality > 90%, i.e. in patients with a Child-Pugh score ≥ 14, or in patients with lactate ≥ 12 mM and/or a MELD score ≥ 30, especially if they are not candidate for liver transplantation (LT). The aim of this study was to prospectively validate these futility criteria.
Method: This was an ancillary multicenter study within the EuroTIPS registry, which included all consecutive patients with cirrhosis and treated with salvage/rescue TIPS between 2020 and 2024 in 19

centers in Europe. Patients were followed up at 1, 3, 6, 9 and 12 months, or until death or LT. The primary endpoint was 42-day mortality (LT as a competing event). We also aimed to develop a futility score for TIPS placement, and to validate it in a previously published retrospective multicenter European cohort.
Results: Overall, 177 pts were included (73.4% men, age 54 years, alcohol-related cirrhosis 76%, Child-Pugh score 9, MELD score 16, ACLF 23%, salvage/rescue TIPS 78.5%/21.5%). Forty-two-day mortality was 24.3%, with no significant difference between salvage and rescue TIPS ($p = 0.14$). In multivariate analysis, factors independently associated with 42-day mortality were higher age, ascites, higher bilirubin, INR and creatinine and vasopressors at TIPS placement. Only one patient had a Child-Pugh score ≥ 14, precluding validation of this criterion. Among the 27 patients with a MELD score ≥ 30 and/or lactate ≥ 12 mM, the 42-day transplant-free survival rate was 37%. A futility score was developed using the previously listed factors associated with 42-day mortality: the AUROC for the prediction of 42-day mortality was 0.808 and 42-day mortality was 100% in patients with a score ≥ 90 in our derivation cohort. In the validation cohort of 164 patients, 29 patients (17.7%) had a score ≥ 90, with a 42-day mortality rate of 93.1%.
Conclusion: In this prospective series, rescue/salvage TIPS was associated with a better prognosis than previously reported, possibly due to patient's selection. Previously described futility criteria were not validated. A new score should be used to discuss rescue/salvage TIPS on a case-by-case basis in patients who are not candidate for LT.

Background and aims: Data on the natural history of patients with histological lesions of porto-sinusoidal vascular disorder (PSVD) who do not show signs of portal hypertension (PH) are scarce. We aimed to describe the natural history of these patients and identify risk factors for progression.
Method: A retrospective study was conducted to collect health-related data on patients with a histopathological diagnosis of PSVD and no sign of PH. Patients with any sign of PH were excluded and a liver biopsy of at least 15 mm was required. Associated conditions were defined as the use of any medication or the presence of any disease that could be associated with PSVD. They were considered severe if they were potentially associated with reduced life expectancy. Main endpoints were the development of signs or complications of PH and death.
Results: 227 patients from 18 centers were included (92 men [41%], median age 46 years). Indication for liver biopsy was abnormal liver tests in 186 patients (82%). Histological findings were nodular regenerative hyperplasia, obliterative portal venopathy, incomplete septal cirrhosis, a combination of these histological lesions, or sinusoidal dilatation with or without other signs indicative of PSVD, in 126 (56%), 41 (18%), 2 (1%), 14 (6%) and 44 (19%) patients, respectively. Associated conditions were observed in 100 patients (46%), of which 55 (24%) were considered as severe. During a median follow-up of 37 months (95% CI: 27–46), 3 patients (1.3%) developed PH-related manifestations (ascites in 2 patients, esophageal varices in 1 patient). The cumulative incidence of PH-related manifestations at 10 years was 6% (95% CI: 2–20%). Nineteen patients (8%) died, 17 from non-hepatic causes and 2 from complications related to preexisting cholangiocarcinoma. No patient died from PH-related complications. Independent predictors of death were age (relative risk [RR]: 1.07, 95% CI: 1.03, 1.11, $p < 0.001$) and presence of a severe associated condition (RR: 4.76, 95% CI: 1.55–14.65, $p = 0.006$). The 10-year survival rate was 84% (95% CI: 77–92%): 95% (95% CI: 89–100) in patients without an associated condition, 100% in patients with a non-severe associated condition, and 58% (95% CI: 41–76) in patients with a severe associated condition ($p < 0.001$).
Conclusion: Most patients with PSVD without PH will not develop it. Sixteen percent of patients die within 10 years, mostly from non-hepatic causes, and the risk of death is independently associated with the severity of the associated condition.

Background and aims: Progressive Familial Intrahepatic Cholestasis (PFIC) is a group of hepatocellular bile acid transport disorders that lead to pruritus, growth failure, lipid-soluble vitamin deficiency, and liver failure. Maralixibat, an ileal bile acid transporter inhibitor, is approved for PFIC-related cholestatic pruritus in patients ≥12 months of age in the US and treatment of PFIC ≥3 months of age in Europe. We compared event-free survival (EFS), time to surgical biliary diversion (SBD), liver transplant (LT), or death in maralixibat-treated patients from the MARCH, MARCH-ON, and RISE trials with aligned real-world data of untreated patients from the NAPPED study.
Method: We randomly selected NAPPED eligible untreated patients with genetically confirmed biallelic non-truncating bile salt export pump (nt-BSEP) or FIC1 deficiencies. To balance baseline characteristics, inverse probability of treatment weights (IPTW) were applied derived from propensity scores for receiving maralixibat (vs. being in NAPPED) estimated from age, sex, PFIC type, total bilirubin, alanine aminotransferase, and aspartate aminotransferase. EFS and SBD-free were compared using IPTW-adjusted Kaplan-Meier curves and Cox models.
Results: Among patients ≥1 year old, 41 maralixibat-treated patients (nt-BSEP, N = 28; FIC1, N = 13) were compared with 256 untreated NAPPED patients (nt-BSEP, N = 201; FIC1, N = 55). At 3 years, EFS was 0.74 (95%CI, 0.59–0.92) in the maralixibat cohort versus 0.42 (95%CI, 0.35–0.51) in NAPPED; the corresponding SBD-free survival probabilities were 0.98 (95%CI, 0.94–1.00) and 0.67 (95%CI, 0.6–0.76), respectively. EFS was significantly better with maralixibat (hazard ratio [HR], 0.29; 95%CI, 0.16–0.54; $p < 0.0001$). The HR for SBD-free probability was 0.05 (95%CI, 0.01–0.39, $p = 0.0036$). In a sensitivity analysis restricted to patients who remained event-free during the first 6 months, the HRs were 0.46 (95%CI, 0.23–0.91; $p = 0.0252$) for EFS and 0.08 (95%CI, 0.01–0.57, $p = 0.0125$) for SBD-free probability.
Conclusion: Maralixibat treatment was associated with improved event free survival in nt-BSEP and FIC1 patients.

OS-087-YI
Enhanced liver fibrosis test and vibration controlled transient elastography as surrogate endpoints in primary sclerosing cholangitis

Tim Middelburg[1,2], Jutta van Crevel[1,2], Bregje Mol[1,2], Liesbeth de Vries[3], Johannes Bogaards[4], Cyriel Ponsioen[1,2].

Email: t.e.middelburg@amsterdamumc.nl

Background and aims: Enhanced Liver Fibrosis (ELF) and Vibration Controlled Transient Elastography (VCTE) have shown promising results for prediction of transplant-free survival in primary sclerosing cholangitis (PSC). However, the individual risk associated with their changes over time and the variability therein are unknown.
Method: This prospective study included annual ELF and VCTE data of PSC patients. Joint models were used to assess overall and risk-group–specific changes over time and the overall association with PSC-related death or liver transplantation, reported as longitudinal hazard ratios (HR). Risk groups at baseline were defined using recommended cut-offs for ELF (<7.7, 7.7–10.6, >10.6) and VCTE (<6.5, 6.5–9.9, >9.9 kilopascal). VCTE was log-transformed to account for right skewness. Linearity of longitudinal trajectories was assessed using likelihood ratio tests, comparing linear and quadratic trendlines. Overall variability was evaluated with random slope effects and residual variance, and expressed as the overall coefficient of variation (CV).
Results: Joint model analysis of ELF included 118 participants (10 events) with 446 measurements over a median follow-up of 5.0 years [Q1-Q3: 3.9–5.5], whereas VCTE analysis included 198 participants (26 events) and 787 measurements over a median 5.8 years [Q1-Q3: 3.8–7.3]. Median baseline ELF was 9.29 [Q1-Q3: 8.55–10.18), with an estimated annual increase of 0.16 (95% CI: 0.12–0.21), associated with a 22% (95% CI: 10–35) higher hazard per year. Median baseline VCTE was 7.1 kPa (Q1-Q3: 5.1–10.1), with an estimated annual increase of 0.04 (95% CI: 0.03–0.06) on the log-scale, associated with a 6% (95% CI: 3–9) higher hazard per year. Risk-group-specific slopes showed no significant differences for both ELF and VCTE. ELF followed a linear trajectory ($p = 0.31$ for non-linearity), whereas VCTE demonstrated a significantly increased slope over time, even on the log-scale ($p = 0.02$ for non-linearity). The overall CV was 13.7% for ELF and 32.3% for VCTE.
Conclusion: Both ELF and VCTE increase over time in PSC patients, which is associated with an increased individual risk for PSC-related death or liver transplantation. However, the longitudinal trajectory for ELF is more stable and predictable than that for VCTE, and annual increases in ELF are associated with a greater increase in hazard compared with the average annual increase in VCTE. These findings support ELF as a candidate surrogate endpoint of transplantation-free survival in PSC.

OS-088
Portal endothelial–biliary epithelial crosstalk shapes early primary sclerosing cholangitis

Email: lauraanne.liebig@mdc-berlin.de

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic immune-mediated cholestatic liver disease likely driven by dysregulated hepatic cell interactions. Its association with inflammatory bowel disease and reported intestinal and biliary dysbiosis suggest microbial influences on early disease development. Here, we aimed to define stage-specific transcriptional cell states and intercellular signaling pathways in PSC with a focus on early-stage disease.
Method: Single-nucleus RNA sequencing of fresh-frozen human liver samples ($n_{TOTAL} = 63$) included PSC spanning early, intermediate, and advanced disease stages ($n_{PSC} = 20$), as well as autoimmune hepatitis, other chronic liver diseases, and controls; spatial transcriptomics covered PSC across stages and controls ($n_{TOTAL} = 22$). Data were analyzed using unsupervised clustering, differential gene expression, and interactome analysis.

Results: From early PSC onward, biliary epithelial cells (BECs) exhibited prominent disease-associated cell states and transcriptional changes, with reduced progenitor-like BECs and progressive expansion of reactive ductular cells. Early PSC was marked by altered epithelial barrier function, extracellular matrix and basement membrane reorganization, as well as microbial sensing and inflammatory signaling, which intensified with disease progression. Interactome and spatial transcriptomic analyses identified early activation of portal vein–associated endothelial cells with increased IL6 expression and predicted IL6–IL6R signaling toward BECs in the portal tracts, accompanied by sustained downstream IL6 signaling and persistent BEC activation across disease stages. Early immune and stromal involvement included TNF-expressing Kupffer cells, IFNG signaling from $CD8^+$ T cells toward BECs, CCL2-mediated $CD4^+$ T cell–BEC interactions, and expansion of activated fibroblasts engaging with BECs, consistent with early periductal matrix remodeling.
Conclusion: Our data show that early PSC involves disease-specific remodeling of biliary epithelial cell states. A newly described epithelial–vascular interaction may explain the close link between PSC and intestinal inflammation. Disrupted epithelial function and portal endothelial IL-6 signaling, together with immune and fibroblast interactions, place BECs at the center of intestinal and portal inflammatory signaling. Ongoing functional validation will further define the contribution of endothelial activation to PSC pathogenesis.

Email: mfrey@courpharma.com

Background and aims: Primary biliary cholangitis (PBC) is a progressive autoimmune liver disease with significant unmet needs. Increasing evidence supports using liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) as a predictor of clinical outcomes independent of liver biochemistries. CNP-104 is a novel tolerogenic nanoparticle encapsulating PDC-E2, previously shown to impact the underlying autoimmunity of PBC via antigen-specific decreases in pathogenic Th17T cells and expansion of tolerogenic T cells. Here we present the first-in-human results of CNP-104 on LSM in adults with PBC.
Method: This randomized, double-blind, placebo-controlled trial enrolled 42 patients with PBC with an incomplete biochemical response to ursodeoxycholic acid. Two doses of CNP-104 or placebo were administered IV one week apart, randomized 2:1 (CNP-104: n = 25; placebo: n = 16). The study included safety monitoring, exploratory clinical endpoints including liver stiffness via FibroScan®, and mechanistic immune endpoints including antigen-specific Th17 T cells with a pre-specified analysis through Day 120.
Results: Baseline LSM for CNP-104 and placebo were 9.60 ± 11.35 kPa and 10.45 ± 11.35 kPa, (p = 0.87) respectively. LSM increased in the placebo arm and remained stable in the CNP-104 arm through Day 180 (p = 0.0005). Fewer CNP-104 treated participants had a ≥ 2 kPa increase from baseline compared to placebo at Day 120 (17% vs. 40%, respectively) and Day 180 (25% vs. 47%, respectively). Response rates across increasing percent change thresholds at Day 120 and 180 demonstrated a consistently higher LSM response rate in the CNP-104 arm compared to placebo (decrease ≥ 0% at Day 120: 65% vs. 18%, respectively; p = 0.0026). The separation seen in this analysis suggests a CNP-104 treatment effect across a range of progressor definitions. Among all patients who had a reduction in PDC-E2-specific Th17 cells, LSM decreased significantly compared to those who had an increase in this pathogenic immune population through Day 180 (p = 0.001), suggesting a mechanistic link. CNP-104 had a favorable safety profile.
Conclusion: CNP-104 treatment stabilized LSM compared to placebo across multiple definitions of progression. The correlation between modulation of PDC-E2-specific Th17 cells and lower LSM suggests an effect mediated by restoring antigen-specific immune tolerance. These findings support further investigation of CNP-104 as a novel therapy for PBC.

OS-090

Increased risk of major adverse cardiovascular events in patients with primary biliary cholangitis, a population-based national cohort study in Sweden

Ida Henriksson[1], Carl Eriksson[2], Linnea Widman[3], Axel Wester[3], Nils Nyhlin[1], Hannes Hagström[4]. *[1]Department of Gastroenterology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden; [2]Department of Gastroenterology, Faculty of Medicine and Health, Clinical Epidemiology Division, Department of Medicine Solna, Karolinska Institutet, Stockholm, Örebro, Sweden; [3]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden; [4]Department of Medicine, Huddinge, Karolinska Institutet, Division of Hepatology, Department of Upper GI, Karolinska University Hospital, Stockholm, Sweden*
Email: ida.henriksson@regionorebrolan.se

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease, where previous studies have shown conflicting results regarding cardiovascular morbidity and mortality. The aims of this study are to assess the risk of Major Adverse Cardiovascular Events (MACE) in PBC and to explore the influence of disease severity.
Method: Nationwide register-based study on all patients with PBC diagnosed in Sweden between 2002 and 2022, matched with up to ten controls from the general population on age, sex, year of diagnosis and municipality. The primary outcome was incident MACE, adjusted for cardiovascular risk factors in a Cox regression model. Patients with cirrhosis were analyzed separately.
Results: We identified 3 332 patients and 28 076 matched controls. Of patients with PBC, 743 (22%) experienced MACE, with an incidence rate of 30.5/1000 person-years (PY), compared to 18.9/1000 PY in controls. This corresponds to 12 additional MACE events per 100 persons with PBC over 10 years. The association was strongest for cardiovascular death, (aHR = 2.19, 95%CI = 1.95–2.46) and congestive

heart failure (aHR = 1.73, 95%CI = 1.50–2.00). Among patients with PBC and cirrhosis, the incidence rate of total MACE was 87/1000 PY:s compared to 27/1000 PY:s in those without cirrhosis.
Conclusion: PBC is associated with an increased risk of MACE compared to matched controls. The highest rates are seen in patients with cirrhosis. Efforts to reduce cardiovascular risk is needed in patients with PBC.

Liver transplantation

Email: ropeml@hotmail.com

Background and aims: Immunosuppression withdrawal after liver transplantation (LT) is feasible in selected individuals but the risk of chronic graft damage is unknown. We aimed to describe the clinical characteristics and long-term outcomes of patients with successful immunosuppression withdrawal after LT.
Method: Retrospective cohort study involving 31 LT centers in 15 countries. Adult and pediatric patients with complete immunosuppression withdrawal for ≥12 months following LT were eligible. Patients receiving multi-organ or re-transplants were excluded. We evaluated long-term outcomes, including evidence of histological graft injury, rejection, and mortality.
Results: A total of 287 patients (223 adults and 64 children) were included, representing 0.46% of the reference LT population. The prevalence of complete immunosuppression withdrawal ranged from 0% to 4.4% in adults and from 0% to 13.3% in children. The median time from LT to immunosuppression withdrawal was 9.4 years, followed by 7.8 years of post-withdrawal follow-up. The most common reasons for immunosuppression withdrawal were participation in a clinical trial (53%), patient decision (25.1%), and immunosuppression-related side effects (16.7%). Immunosuppression withdrawal was associated with a metabolic improvement including reductions in diabetes (34.1% to 19.7%) and hypertension (58.7% to 31.4%). Paired liver biopsies before and after immunosuppression withdrawal were available in 108 patients (37.6%) and among them 43.5% achieved operational tolerance. Worsening fibrosis (≥1 Ishak's stage) and new-onset inflammation occurred in 30.5% and 22.2% of patients, respectively. Five-year overall survival after immunosuppression withdrawal was 93%, and no patient experienced immunologically mediated graft loss. Neither worsening fibrosis nor inflammation had an impact on mortality (HR = 1.77 [95%CI 0.63–4.96] and HR = 1.46 [95%CI 0.39–5.49], respectively).
Conclusion: Immunosuppression withdrawal is seldom attempted after LT and mostly within clinical trials. Although some patients may experience mild histological changes during follow-up, the risk of immunologically mediated graft loss is negligible. Patients showed excellent overall survival rates with fewer metabolic comorbidities. Future studies should focus on safely expanding immunosuppression withdrawal to a broader subset of LT patients.

OS-092-YI
Eurotransplant experience with model for end-stage liver disease standard exceptions for hepatopulmonary syndrome and portopulmonary hypertension

Maïté Verstraeten[1,2], Axel J. T. Jens[3], Gabriela Berlakovich[4], Martina Sterneck[5], Felix Braun[6], Caroline den Hoed[7], Blaž Trotovšek[8,9], Danko Mikulic[10], Tamas Benkoe[11,12], Anja Geerts[1,2], Xavier Verhelst[1,2], Hans Van Vlierberghe[1,2], Sarah Raevens[1,2]. *[1]Hepatology Research Unit, Department of Internal Medicine and Paediatrics, Ghent University, Ghent, Belgium; [2]Department of Gastroenterology and Hepatology, Ghent University Hospital, Ghent, Belgium; [3]Eurotransplant International Foundation, Leiden, Netherlands; [4]Division of Transplantation, Medical University of Vienna, Vienna, Austria; [5]Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [6]Sektion für Klinische Transplantationsmedizin, Klinik für Allgemeine, Viszeral-, Thorax-, Transplantations- und Kinderchirurgie, Universitätsklinikum Schleswig-Holstein (UKSH), Campus Kiel, Kiel, Germany; [7]Erasmus MC Transplant Institute, University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [8]Department of Abdominal Surgery, University Medical Center Ljubljana, Ljubljana, Slovenia; [9]Medical Faculty Ljubljana, University of Ljubljana, Ljubljana, Slovenia; [10]Center for Solid Organ Transplantation, University Hospital Merkur, Zagreb, Croatia; [11]Department of Surgery, Transplantation and Gastroenterology, Semmelweis University, Budapest, Hungary; [12]Department of General-, Visceral-, Transplantation-, and Thoracic Surgery, University Hospital Frankfurt, Frankfurt, Germany*
Email: maite.verstraeten@ugent.be

Background and aims: Hepatopulmonary syndrome (HPS) and portopulmonary hypertension (PoPH) are severe pulmonary vascular

complications of end-stage liver disease (ESLD) and portal hypertension. Some patients are eligible for Model for End-Stage Liver Disease (MELD) standard exception (SE) liver transplantation (LT) prioritization in Eurotransplant. Data on waitlist and post-transplant outcomes under current SE policies remain limited.

Method: We analysed Eurotransplant registry data (2006–2022) for adult LT candidates with approved SE for HPS (n = 117) or PoPH (n = 25), compared with 710 matched controls (matching based on age, sex, MELD score, and liver disease etiology) without SE. Outcomes included overall survival, waitlist outcomes, and post-LT survival. Survival analyses were performed using Kaplan-Meier, Cox proportional hazards, and Fine and Gray competing risks models.

Results: Overall mortality was similar between HPS and controls (HR 1.23, 95% CI 0.93–1.63, p = 0.16), but higher in PoPH (HR 1.79, 95% CI 1.06–3.00, p = 0.028). Pre-transplant mortality was comparable across groups (for HPS: HR 1.02, 95% CI 0.68–1.53, p = 0.92; for PoPH: HR 1.22, 95% CI 0.55–2.72, p = 0.62). Post-LT survival was similar for HPS and controls (HR 1.11, 95% CI 0.73–1.67, p = 0.63), but significantly poorer for PoPH (HR 2.39, 95% CI 1.17–4.89, p = 0.017). At 6 months, survival rates were 88.1% (95% CI 84.7% - 91.6%) for control patients, 92.3% (95% CI 86.6% - 98.4%) for HPS and 57.1% (95% CI 36.3% - 89.9%) for PoPH; and at 1 year 84.7% (95% CI 81% - 88.7%), 87% (95% CI 79.7% - 94.8%), and 57.1% (95% CI 36.3% - 89.9%) respectively. Infection was the leading cause of post-LT mortality; cardiovascular events were more frequent in PoPH recipients.

Conclusion: LT candidates with SE for severe HPS achieve comparable overall and post-LT survival to non-SE recipients, supporting the appropriateness of current SE policy. Conversely, PoPH patients demonstrate markedly poorer post-LT outcomes, highlighting the need for careful candidate selection, optimized pre-transplant management, and perioperative strategies to improve survival.

Cell-free chromatin for identifying T cell-mediated liver rejection

Abed Khakayla[1], Achraf Imam[1], Gavriel Fialkoff[2], Israa Sharkia[2], Ronen Sadeh[2], Omri Or[2], Jenia Gutin[2], Rifaat Safadi[1,3], Yael Milgrom[3], Orit Pappo[4], Severin Jacobi[5], Bastian Engel[6], Richard Taubert[6], Jonathan Frederik Brozat[7], Frank Tacke[7], Cornelius Engelmann[7], Esther Harpenas[8], Nofar Rosenberg[9], Ophir Hay[9], Eithan Galun[9], Nir Friedman[8]. *[1]Hadassah-Hebrew University Medical Center, Department of General surgery and Transplantation Unit, Jerusalem, Israel; [2]Senseera LTD, Jerusalem, Israel; [3]Hadassah-Hebrew University Medical Center, The Liver Unit Institute of Gastroenterology and Liver Diseases, Jerusalem, Israel; [4]Hadassah-Hebrew University Medical Center, Department of Pathology, Jerusalem, Israel; [5]Ludwig-Maximilians-Universität München, Munich, Germany; [6]Hannover Medical School, Department of Gastroenterology, Hepatology, Hannover, Germany; [7]Charité - Universitaetsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [8]Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel; [9]Hadassah-Hebrew University Medical Center, The Goldyne Savad Institute for Gene Therapy, Jerusalem, Israel*
Email: nir.friedman@mail.huji.ac.il

Background and aims: T cell-mediated rejection (TCMR) complicates up to 30% of liver transplant recipients, predominantly within the first post-transplant year, and requires timely immunosuppressive intervention. Current diagnosis relies on invasive liver biopsy, which is unsuitable for frequent monitoring and delays the diagnosis. Emerging evidence supports the use of liquid biopsies as minimally invasive tools for real-time assessment of tissue injury and immune activity.

Method: Cell-free chromatin immunoprecipitation followed by sequencing (cfChIP-seq) targeting H3K4me3 - a histone mark associated with active or poised promoters - is a non-invasive method that provides a genome-wide scale readout of transcriptional activity and cell-state in the tissues of origin. A Chromatin Rejection Score (CRS), reflecting TCMR-specific signals, was developed in an exploratory cohort of cfChIP-seq plasma samples (n = 4,988) and evaluated in an independent cohort of liver transplant recipients (Jerusalem) who underwent a for-cause biopsy (TCMR, n = 17; non-TCMR, n = 23). Additional validation was performed on n = 50 samples with biopsy-verified TCMR status from a multicenter German cohort.

Results: CRS robustly discriminated biopsy-confirmed TCMR from other causes of post-transplant liver injury, achieving an area under the receiver operating characteristic curve (AUC) of 0.99 (95% CI 0.98–1), outperforming conventional transaminase markers ALT and AST (AUC 0.76, 0.68, resp.). This performance was reproduced on the external validation cohort. In longitudinal analyses, increases in CRS often preceded histopathological confirmation of TCMR and decreased rapidly following initiation of corticosteroid therapy, preceding the normalization of transaminase levels. Finally, we show that the same results can be obtained using a rapid-turnaround digital PCR method for CRS readout, demonstrating the feasibility of a quick and cost-effective assay at the medical center.

Conclusion: cfChIP-seq is an accurate, reproducible, and reliable biomarker for diagnosing and monitoring TCMR through minimally invasive molecular profiling of liver allograft injury. cfChIP-seq has the potential to enable early diagnosis, reduce the need for liver biopsies and guide effective immunosuppressive management in liver transplant recipients. By incorporating the digital PCR method it can provide real-time indication of rejection onset and rapid assessment of treatment responses.

Liver transplantation for hepatocellular carcinoma: prognostic impact of complete pathologic response and influence of treatment modality- a U.S. national database study

Benjamin Tran[1], Rebecca Marino[1], Justine Aziz[2], Joseph DiNorcia[1], Julia Torabi[1], Myron Schwartz[1], Sander Florman[1], Kirema Garcia-Reyes[2], Rahul Patel[2], Edward Kim[2], Parissa Tabrizian[1]. *[1]Liver Transplant and Hepatobiliary Surgery, Recanati/Miller Transplantation Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [2]Department of Diagnostic, Molecular and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York, United States*
Email: benjamin.tran2@mountsinai.org

Background and aims: Complete pathologic response (cPR) in hepatocellular carcinoma (HCC) is associated with improved post-liver transplant (LT) outcomes. However, national cPR rates, modality-specific differences, and predictors remain undefined. We evaluated the significance of cPR in a large national U.S. cohort.

Method: A retrospective study was performed using the UNOS database of adult LT recipients with HCC (2012–2024). cPR was defined as absence of viable tumor on explant pathology. Predictors of cPR were assessed using logistic regression. Cumulative incidence of cPR was estimated using Fine–Gray competing risk models. Overall (OS) and recurrence-free survival (RFS) were analyzed using Kaplan–Meier estimates.

Results: Among 7,398 LT recipients, 2,167 (29.3%) achieved cPR with poor imaging–pathology concordance (30.5%), with imaging demonstrating fewer lesions than pathology (thus overestimating response) in 42.6% of cases ($\kappa = 0.17$, $p < 0.001$). At listing, patients with cPR had smaller tumors (max size 2.3 vs 2.7 cm), lower total tumor diameter (2.7 vs 3.2 cm), and lower AFP levels (10 vs 11 ng/mL; all $p < 0.001$). These significant differences persisted at LT. Higher cPR rates were associated with patients achieving a longer waitlist period prior to LT (>18 months vs <6 months; OR 1.94, 95% CI 1.57–2.40). cPR rates were higher after Y-90 radioembolization (41.2%) and ablation (36.4%) than TACE (24.0%; p <0.001). On multivariable analysis, cPR likelihood increased with Y-90 (adjusted OR 1.89, 95% CI 1.46–2.05) and ablation (adjusted OR 1.23, 95% CI 1.08–1.39) compared to TACE. Increasing tumor burden (TTB ≥13 vs ≤3: OR 0.33,95% CI 0.13–0.86) and elevated AFP (≥100 ng/mL: OR 0.92, 95% CI 0.86–1.05) were independently associated with reduced cPR. Interaction analyses

showed that Y-90 benefit was greatest when administered within 6 months of waitlisting (OR 2.40, 95% CI 1.59–3.61) and among all-comer patients (OR 1.58, 95% CI 1.17–3.26). Competing risk analyses confirmed that Y-90 achieved the highest cumulative incidence of cPR across transplant eligibility regardless of the extent of disease. Patients with cPR had superior OS (5-year: 86.6% vs.77.4%) and RFS (76.9% vs 63.1%) compared with patients not achieving cPR ($p < 0.001$).

Conclusion: In this cohort, nearly one-third of LT recipients with HCC achieved cPR, associated with greater OS and RFS. Y-90 radioembolization was independently associated with higher cPR rates, with greatest benefit when administered early and among patients with higher tumor burden.

OS-095-YI

Non-vascular, non-cirrhotic portal hypertension following liver transplantation is largely caused by combination of portosinusoidal injury and allograft rejection

Iulia Minciuna[1,2,3], Michail Doukas[4], Valérie Paradis[5], Raoel Maan[6,7], Caroline den Hoed[1,7], Anne Van Eldere[1,7], Sandra Coenen[1,7], Wojciech Polak[7,8], Jeroen de Jonge[7,8], Bogdan Procopet[2,3], Sarwa Darwish Murad[1,7]. *[1]Department of Gastroenterology and Hepatology, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands; [2]University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania; [3]Regional Institute of Gastroenterology and Hepatology "O. Fodor", Cluj-Napoca, Romania; [4]Department of Pathology, Erasmus University Medical Center, Rotterdam, Netherlands; [5]Department of Pathology, AP-HP Hôpital Beaujon, Clichy, Paris, France; [6]Department of Gastroenterology and Hepatology, Erasmus University Medical Center, Rotterdam, Netherlands; [7]Erasmus MC Transplant Institute, Erasmus University Medical Center, Rotterdam, Netherlands; [8]Department of Surgery, Division of HPB and Transplant Surgery, Erasmus MC Transplant Institute, Erasmus University Medical Center, Rotterdam, Netherlands*
Email: Iuliabreaban@yahoo.com

Background and aims: Portal hypertension (PH) may develop after liver transplantation (LT) due to vascular complications or recurrence of cirrhosis. However, in rare cases, post-transplant PH (PTPH) occurs outside this setting which has been associated to a variety of histological entities, including sinusoidal obstruction syndrome (SOS), nodular regenerative hyperplasia (NRH) and several allograft rejection forms. In this study, we hypothesize that there is a considerable degree of overlap between these entities that contribute PTPH.

Method: From 2007–2022, 1004 adults underwent LT in our institution. Patients with non-cirrhotic, non-vascular PTPH (i.e. new-onset ascites, varices, portal hypertensive bleeding or newly detected portosystemic collaterals), who underwent liver biopsy for this indication were compared to matched LT patients with liver test abnormalities. Two independent pathologists, blinded to the cases, reviewed all biopsies systematically using internationally accepted criteria for acute and chronic T-cell mediated rejection (TCMR), acute and chronic antibody mediated rejection (AMR), portosinusoidal vascular disorder and SOS.

Results: Overall, 19 patients developed PTPH without vascular cause or recurrent liver disease. Upon systematic assessment, all patients (100%) with PTPH met histological criteria for PSVD, 63% for acute and 63% for chronic TCMR, 47% for SOS, 26% for cAMR and 16% for AMR. Global inter-pathologist agreement was 84%. Interestingly, 74% showed both features of rejection and PSVD. However, only 26% had isolated microvascular injury at the portosinusoidal (PSVD only, $n = 2$) and/or centrilobulair (PSVD and SOS, $n = 3$) level. Compared to matched controls, PTPH was significantly more frequently associated with PSVD (100% vs 5%, $p < 0.001$), SOS (47% vs 16%; $p = 0.03$) and chronic TCMR (63% vs 16%, $p = 0.03$). There were no differences in acute TCMR (63% vs 79%), acute AMR (16% vs 16%) and chronic AMR (26% vs 16%). Outcome was dismal in PTPH, with poor response to therapy and significantly lower 10-year patient (26% vs 76%, $p = 0.01$) and graft survival (18% vs 76%, $p = 0.001$).

Conclusion: Non-cirrhotic, non-vascular PTPH is a rare but serious complication, which is most often caused by a combination of allograft rejection and portosinusoidal injury. Increased vigilance and a systematic, unbiased approach by pathologists are needed to identify these overlapping features, since this may guide targeted treatment and enhance response.

Home-based exercise and motivational programme before and after liver transplantation (EXALT): a multicentre randomised, controlled trial

Matthew Armstrong[1], Samir Mehta[2], Joan Duda[3], Sally Fenton[3], Chiemelie Ngonadi[1], Alice Freer[1], Ashlea Hargreaves[1], Nigel Cope[4], Dawn Brant[2], Yongzhong Sun[2], Dr. Clare Melikian[4], Dan Martin[5], Felicity Williams[1]. *[1]Liver Unit, Queen Elizabeth University Hospital Birmingham, UK, NIHR Birmingham Biomedical Research Centre, University of Birmingham, UK, Birmingham, United Kingdom; [2]Birmingham Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom; [3]School of Sports, Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham, United Kingdom; [4]Hepatobiliary and Liver transplant Anaesthesia Department, Royal Free Hospital, London, United Kingdom; [5]Peninsula Medical School, University of Plymouth, Plymouth, United Kingdom*
Email: mattyarm2010@googlemail.com

Background and aims: Physical frailty is associated with mortality and reduced health-related quality of life (HRQoL) after liver transplantation. Exercise interventions may improve transplantation outcomes, but data from clinical trials are limited and adherence strategies are lacking. We evaluated the efficacy of a personalised home-based exercise and motivational programme in patients undergoing liver transplantation.

Method: EXALT trial was a multicentre, randomised-controlled trial in two supra-regional UK transplant centres. Patients awaiting liver transplantation were randomly assigned (1:1) to a remotely monitored, physiotherapist-delivered, home-based exercise and motivational programme (Exercise group) or a patient advice leaflet (Control group) up to 52 weeks pre- and 24 weeks post-transplantation. The primary outcome was the physical component summary (PCS) of the short form-36v2.0 HRQoL questionnaire 24 weeks post-transplantation. We used a repeated-measures, mixed-effects linear regression model (adjusted for age, sex, site, and disease severity) in patients who underwent transplantation within 52 weeks of randomisation.

Results: Between May 2022 and May 2024, 269 patients were enrolled (134 exercise group, 135 control group). 180 (67%) were male and mean age was 51.8 years (SD 12.3). 85 (63%) patients underwent transplantation in each group. At 24 weeks post-transplantation, the improvement in PCS score was greater in the exercise group compared to the control group (least-squares mean difference +4.7, 95% CI 1.7 to 7.8; $p < 0.01$). The exercise group had greater improvements compared to control group in physical frailty (liver frailty index; least-squares mean difference -0.3, 95%CI -0.6 to -0.1; $p < 0.01$), aerobic exercise capacity (duke activity status index; least-squares mean difference +5.6, 95%CI 1.7 to 9.5; $p < 0.01$) and autonomous motivation towards exercise (Behavioural Regulation in Exercise Questionaire-2 least-squares mean difference +0.6, 95%CI 0.1 to 0.9; $p = 0.01$) at 24 weeks post-transplantation. There were similar rates of surgical complications and adverse events between groups. 90-day and 1-year post-transplant survival was 100% and 98% in the exercise group compared to 94% and 92% in the control group.

Conclusion: This personalised home-based exercise and motivational programme significantly improved physical health-related quality of life, frailty and physical fitness after liver transplantation, and enhanced patient's autonomous motivation for long-term engagement in exercise.

MASLD: Clinical and therapeutical aspects II

Belapectin reduces varices development in high-risk MASH cirrhosis by modulating fibrogenesis balance as reflected by Pro-C3/CTX-III ratio

Mazen Noureddin[1], Naim Alkhouri[2], Mitchell Shiffman[3], Raj Vuppalanchi[4], Nadege Gunn[5], Khurram Jamil[6], Seth Zuckerman[6], Andrew Volosov[6], Naga Chalasani[4]. [1]*Houston Methodist Hospital, Houston, TX, United States;* [2]*Summit Clinical Research, Clinical Research Institute of Ohio, San Antonio, TX, United States;* [3]*Liver Institute of Virginia, Richmond, VA, United States;* [4]*Indiana university school of medicine, Indianapolis, United States;* [5]*Impact Research Institute, Waco, TX, United States;* [6]*Galectin Therapeutics, Norcross, GA, United States*
Email: khurramjamil@yahoo.com

Background and aims: Belapectin, a galectin-3 inhibitor, reduced new varices development in the per-protocol population of the Phase 2b/3 NAVIGATE trial. As variceal formation reflects fibrosis progression and portal hypertension, we evaluated whether belapectin 2 mg/kg's clinical benefit is linked to attenuation of active fibrogenesis, using the Pro-C3/CTX-III ratio, a marker of collagen formation versus degradation.
Method: NAVIGATE (NCT04365868) randomized patients with compensated MASH cirrhosis, portal hypertension, and no baseline varices to belapectin 2 mg/kg, 4 mg/kg, or placebo every 2 weeks for 18 months, stratified by T2DM. Of 357 randomized (119 per group), 287 completed 18 months with both baseline and end-of-treatment endoscopy, forming the per-protocol population. Baseline characteristics were balanced (mean age 60 years; 65% female; platelets 131 × 10^9/L; LSM 24.8 kPa; 67% T2DM). This study examined new varices and changes in Pro-C3/CTX-III at week 78 in subjects at high risk of progression, including those with baseline ELF >11.3, an ELF increase ≥0.5, or a Pro-C3/CTX-III ratio above median at baseline.
Results: Belapectin consistently lowered varices incidence across all ELF categories, with the largest effect in patients with baseline ELF >11.3 (22.7% vs. 42.9% with placebo). In this subgroup, Pro-C3/CTX-III worsened by 4.3% with placebo but improved by 13.6% with belapectin. Among patients with baseline Pro-C3/CTX-III above the median, placebo worsened by 2.2% versus a 9.3% improvement with belapectin. In all subjects with ELF increases ≥0.5 subjects receiving belapectin experienced markedly less progression in Pro-C3/CTX-III relative to placebo (15.9% vs 40.4%, p = 0.004), reflecting reduced collagen formation and enhanced degradation with belapectin.
Conclusion: In advanced MASH cirrhosis, belapectin 2 mg/kg reduces new varices and attenuates active fibrogenesis, as evidenced by favorable shifts in the Pro-C3/CTX-III ratio in high-risk ELF subgroups. These data suggest that belapectin's anti-fibrotic effects may contribute to reducing the risk of portal hypertension–associated complications.

OS-097

Liver fibrosis is the only predictor of adverse outcomes: time to remove metabolic dysfunction associated steatohepatitis (MASH) resolution as a clinical trial endpoint

Background and aims: MASH pathologic diagnosis requires steatosis, lobular inflammation, and hepatocyte ballooning with significant inter- and intra-observer variability leading to large screen failures in clinical trials. Nevertheless, "MASH resolution" has been an endpoint in most recent clinical trials. Also, most non-invasive tests (NITs) are being developed as surrogates of fibrosis rather than MASH. We evaluated associations between histological features of MASH, fibrosis stage, and clinical outcomes.
Method: Adults with MASLD from 41 countries (G-MASLD) were included if they had liver biopsy with MASLD Activity Score (steatosis 0–3, inflammation 0–3, ballooning 0–2), fibrosis stage (0–4), and longitudinal follow-up for mortality and clinical events (decompensation, HCC, transplant, death).
Results: 9,712 MASLD patients were included [age 51 ± 13 years; 49% male; 66% obesity; 51% type 2 diabetes (T2D); 54% hypertension (HTN)]. Advanced fibrosis (AF, F3–F4) was present in 42%, and 15% had significant fibrosis (SF, F2). Patients with AF were older, more often female, and had more T2D and HTN (all $p < 0.001$). NAS scores were higher in AF (mean 4.9 ± 1.4 vs. 3.8 ± 1.6), with greater frequency of NAS≥5 (64% vs. 35%), grade 3 lobular inflammation (30% vs. 3%), and grade 2 hepatocyte ballooning (57% vs. 19%) (all $p < 0.0001$). Higher NAS was associated with AF (OR per 1-point increase 1.64, 95% CI 1.58–1.70; NAS ≥5 vs <5: OR 3.32, 3.00–3.68; all $p < 0.0001$). Lobular inflammation (grade 2: OR 2.23; grade 3: OR 8.02) and hepatocyte ballooning (grade 1: OR 3.42; grade 2: OR 7.87) were independently associated with AF (all $p < 0.0001$). However, predicting long-term outcomes using Cox models (adjusted for country, age, sex, obesity, T2D, and HTN) showed that only AF predicted all-cause mortality (aHR 2.10, 1.65–2.68) and clinical events (aHR 3.73, 3.07–4.53; both $p < 0.0001$). After adjustment for AF or AF+SF, neither NAS nor its components (including hepatocyte ballooning) were associated with adverse outcomes (all $p > 0.05$), a pattern unchanged in fibrosis subgroups (no SF/AF, SF, AF) or when adjusting for liver stiffness ≥10 kPa.
Conclusion: MASH features are associated with AF but not with adverse outcomes after adjustment for fibrosis. Although inflammatory pathways remain important therapeutic targets, variability in pathologic assessment of MASH and its inability to predict clinically relevant outcomes make MASH resolution a suboptimal primary endpoint; fibrosis-related NITs should instead be prioritized as the key endpoint.

OS-098-YI

Distinguishing persistent from transient liver stiffness elevation using blood-based non-invasive tests: Longitudinal results from the European LiverScreen consortium

Background and aims: Liver stiffness measurements (LSM) have a well-established role in liver disease screening, but high regression rates among initial elevated values have been reported. Blood-based non-invasive tests (NITs) may help distinguish transient from persistent LSM elevation over long-term follow-up in a general population-based setting.
Method: This prospective, longitudinal study, conducted at three European centres (Barcelona, Rotterdam, Odense), was part of the LiverScreen consortium. We assessed LSM over a four-year interval. Persistent LSM elevation was defined as LSM ≥8 kPa at both baseline and follow-up, and transient elevation as a decrease to <8 kPa at follow-up. First, we stratified the prevalence of follow-up LSM elevation according to baseline LSM and NIT-scores (FIB-4, MAF-5, LiverRisk Score [LRS], and LiverPRO). Next, we evaluated the ability of NITs to detect persistent LSM elevation using area under the curve (AUC) analyses Finally, we analyzed transitions in NIT-score categories over follow-up and subsequent LSM elevation.
Results: Among 4536 participants (median follow-up 4.3 years [IQR 4.1–8.2]; median age 62 years [56–68]; 52% female), 5.5% (n = 251) had baseline LSM ≥8 kPa. Of these, 38% had persistent LSM elevation at follow-up. Among individuals with elevated baseline LSM but low NIT-scores, transient LSM elevation rates were high, ranging from 81% (LiverPRO) to 74% (FIB-4). Conversely, when baseline NIT-scores were high, persistent LSM elevation rates ranged from 43% (LiverPRO) to 47% (MAF-5). A sequential high NIT-score at follow-up further increased persistent elevated LSM prevalence ranging from 45% (LiverPRO) to 54% (FIB-4). Baseline NITs scores demonstrated moderate to excellent ability to predict persistent LSM elevation (AUC: MAF-5: 0.872; LRS: 0.852; LiverPRO: 0.845; FIB-4: 0.700). In individuals with a low baseline LSM and serial low NIT-scores, elevation at follow-up occurred in 1.4% (MAF-5) to 2.2% (FIB-4), compared to 5.3% (FIB-4) and 12.9% (MAF-5) when NIT-scores remained high during follow-up.
Conclusion: During long-term follow-up, transient LSM elevations were more frequent than persistent elevations. MAF-5, LRS, and LiverPRO provide excellent predictive value for long-term persistent LSM elevation. Low baseline NIT-scores can reduce the likelihood of persistent elevation to 19%, while repeated high NIT-scores can increase this likelihood to 54%.

Email: soheil@hepta.bio

Background and aims: With the approval of resmetirom and semaglutide for the treatment of MASH with moderate-to-advanced fibrosis (F2-F3), accurate identification of treatment-eligible patients has become a critical clinical need. Current non-invasive tests (NITs) result in missing almost a third of the treatment-eligible patients as they were predominantly developed for detecting advanced fibrosis (F3-F4). We developed and validated an AI-powered cell-free DNA (cfDNA) methylation platform optimized for detecting MASH with F2-F3 to address this diagnostic gap.
Method: This multi-cohort study includes 553 biopsy-confirmed MASLD patients from 3 independent cohorts across the US and Europe: (1) Duke MASLD Biobank (n = 276), (2) University Medical Center Mainz Biobank (n = 73), and (3) Akero Therapeutics' SYNCHRONY Phase 3 screening population (n = 204). Deep methylation sequencing of plasma cfDNA was performed, generating 112 terabytes of genomic data. A novel transformer architecture (LiquidTransformer 89 million parameters), trained on a 20,000 core cluster, was developed to identify clinically significant fibrosis. Test performance was evaluated for the detection of: (1) significant fibrosis (F2-F3) in non-cirrhotic patients and (2) cirrhosis (F4). Performance was compared head-to-head against Fib4, VCTE and ELF on matched samples. All performance results were measured on the validation set.
Results: For detection of treatment-eligible fibrosis, F2-F3, and cirrhosis detection the test achieved AUC of 0.83 and 0.80 respectively. In direct comparison on matched subsets of samples, cfDNA methylation test outperformed Fib4 (AUC 0.82 vs 0.71) across all datasets with delta AUC 0.07, 0.07 and 0.13 for Duke, Mainz and Akero respectively. On a subset of Akero samples n = 201 where other comparators were available the test (AUC = 0.82) outperformed ELF (AUC = 0.69), VCTE (AUC = 0.67) and Fib4 (AUC = 0.64). Notably, the Akero cohort represents a clinically pre-selected population yet the model maintained robust performance. Performance was consistent across sex and diabetes status.
Conclusion: This AI-powered cfDNA methylation platform accurately identifies MASLD patients eligible for treatment while excluding cirrhosis, directly addressing a diagnostic gap in current guideline-recommended NIT pathways. The technology demonstrates consistent performance across independent international cohorts including a clinical trial screening population, uniquely positioning it to be considered for integration into treatment decision algorithms.

Background and aims: The semi-synthetic bile acid homologue norucholic acid (NCA) was shown in a prior phase 2a trial to improve liver enzymes in metabolic dysfunction-associated steatotic liver disease. Here, we report the results of a phase 2b trial of NCA on liver

histology in metabolic dysfunction-associated steatohepatitis (MASH).
Method: In this placebo-controlled, randomized clinical trial, MASH patients with a NAFLD activity score (NAS) ≥4 and fibrosis stage of F2 or F3 were randomized to treatment with 1,500 mg NCA, 1,000 mg NCA, or placebo once daily for 72 weeks. The primary endpoint was resolution of MASH with no worsening of fibrosis, or improvement of fibrosis with no worsening of MASH, from baseline visit to week 72. Secondary endpoints included components of the primary endpoint as well as change in NAS, change in the histologic Steatosis, Activity, and Fibrosis (SAF) score, changes in liver biochemistry, and safety outcomes.
Results: The trial enrolled 83, 70 and 63 patients in the 1,500 mg NCA, 1,000 mg NCA, and placebo arms, respectively. At week 72, 33.7% of patients in the 1,500 mg NCA arm, 20.0% in the 1,000 mg NCA arm, and 30.2% in the placebo arm achieved the primary endpoint (1,500 mg NCA vs placebo: p = 0.30, 1,000 mg NCA vs placebo: p = 0.92). Resolution of MASH with no worsening of fibrosis was observed in 27.7% of 1,500 mg NCA patients vs. 19.0% of placebo patients (p = 0.18), while improvement of fibrosis with no worsening of MASH was reported for 18.1% of 1,500 mg NCA patients vs. 20.6% of placebo patients. The absolute change in total NAS was −1.7 for 1,500 mg NCA vs. −0.9 for placebo (p = 0.005), with changes of −0.5 vs. − 0.1, respectively, in the inflammation subscore (p = 0.002). Improvement in the SAF inflammation subscore was also significantly greater with 1,500 mg NCA (−0.4 vs. −0.2, p = 0.02). NCA led to significantly higher rates of ALT normalization (1,500 mg NCA: 29.0%, placebo: 10.5%, p = 0.01) and significantly greater reduction in gamma-glutamyltransferase than placebo. The pooled rates of patients with adverse events were 92.8% for NCA and 87.3% with placebo, with serious adverse events reported for 15.7% of NCA patients and 9.5% of placebo patients.
Conclusion: NCA was not superior to placebo in the composite primary endpoint. Statistical superiority was observed in multiple histologic and biochemical parameters of inflammation. The known favorable safety profile of NCA was confirmed.

Viral hepatitis – Clinical aspects

Email: fleur.ballet@uantwerpen.be

Background and aims: Hepatitis B core-related antigen (HBcrAg), hepatitis B core IgG antibodies (anti-HBc) and HBV RNA are emerging biomarkers in chronic hepatitis B, and bear potential for predicting severe biochemical flares (SBFs; ALT >10xULN) after nucleos(t)ide analogue (NUC) cessation. Recently, hepatitis B virus (HBV) genotype (gt) A was identified as a protective factor against SBFs. We aimed to investigate the relationship between these biomarkers and HBV genotype to provide more insight into the mechanisms behind this effect and guide future treatment strategies.
Method: Individual patient-level data from five international prospective NUC-stop studies within the PROSTOP consortium were pooled. All patients were HBeAg negative, long-term virologically suppressed, and none had advanced liver fibrosis. Multivariate mixed linear and logistic regression models were used to assess associations between biomarkers and gt, with study included as a random effect. Models were adjusted for age, sex, and log-transformed HBsAg levels. HBcrAg and anti-HBc were analysed as continuous log-transformed variables while HBV RNA was analysed as undetectable versus detectable.
Results: A total of 343 patients with available gt (A: 58 (16.9%), B: 70 (20.4%), C: 59 (17.2%), D: 131 (38.2%), E: 23 (6.7%), F: 2 (0.6%)) were included. HBcrAg, anti-HBc and HBV RNA were available for 320, 338 and 153 patients, respectively. Combined HBcrAg and anti-HBc data were available for 296 patients, and all three biomarkers for 140 patients. Anti-HBc levels were significantly higher in gt A compared to C, D and E (log_{10} units difference 0.52, 0.45 and 0.64 respectively, all p < 0.001). Conversely, HBcrAg levels were significantly lower in gt A compared to B and C (log_{10} units difference −1.09 and −1.07 respectively, all p < 0.001). Compared with gt A, gt D was associated with lower odds of having detectable HBV RNA (OR 0.23, 95% CI 0.06–0.83, p = 0.03).
Conclusion: In this large, pooled analysis of five prospective NUC cessation studies, genotype A was significantly associated with higher anti-HBc and lower HBcrAg levels, both known protective factors for SBFs. This relation could partially explain the low number of post-cessation severe flares observed in patients with HBV gt A and provide mechanistic insight to inform biomarker-guided individualized NUC cessation strategies.

OS-102
Long term survival benefits of DAA in HCV related HCC patients: results from England National HCV registry

Maria Guerra Veloz[1], Rathiga Rudra[2], Simon Hume[3], Daniel Clayton-Chubb[3], Renita George[1], Sarah Selemani[1], Paul Ross[1], Janet Dearden[2], Aileen Marshall[3], Peter Sandwith[2], Matthew Foxton[4], Kosh Agarwal[1], Douglas Macdonald[3]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Department of Hepatology, Barts Health NHS Trust, London, United Kingdom; [3]Royal Free Hospital, London, United Kingdom; [4]Chelsea & Westminster NHS Foundation Trust, London, United Kingdom*
Email: maria.guerraveloz@nhs.net

Background and aims: Patients with Hepatitis C virus (HCV) related hepatocellular carcinoma (HCC) have largely been excluded from European HCV National treatment registries and so the survival benefits in this cohort are unclear. Since 2015, NHS England has approved direct acting antiviral (DAA) therapies for all viraemic patients, including those with HCC. The aim of this study is to assess

the HCV care cascade and overall survival (OS) benefits in those with HCC.
Method: Patients with HCV related HCC from the National Hepatitis C registry in Greater London between 2015 and 2025 were included. Patients' data was cross referenced with their local multidisciplinary HCC team records. Two cohorts were compared (DAA therapy initiation vs non initiation).
Results: 343 patients with complete records were included. The majority were male (79%) with compensated cirrhosis (62.7%) and genotype 3 (45.5%). DAA therapies were started in 78.7% (270) and 88.5% (239) had an outcome reported. SVR was achieved in 88.7% (212/239) of patients. In those patients who started DAA therapies, the cancer stage distribution was BCLC 0/A 64.4%, B 16.7%, C 10% and D 4.4%, whereas in those who did not it was 45.7%, 5.7%, 18.6% and 30% respectively ($p < 0.005$). Almost 80% had untreated HCC at the time of DAA therapy initiation. The median OS was longer in patients who received DAA therapies (68 (95% IC 48–87) months)) in comparison with those who did not (15 (95% CI 7–23) months)) (Log Rank $p < 0.001$). Moreover, OS was longer in those with BCLC stage 0/A who achieved SVR (128 months; 95% CI 112–144) in comparison with those BCLC stage 0/A who did not receive DAA therapies (25 (95% CI 12–37) months)). The median OS for those with BCLC stage B/C who achieved SVR was 35 (95% IC 26–44) months in comparison with those who did not receive DAA therapies, which was 9 (95% IC 0–19) months. In the multivariate Cox regression model, [adjusted by sex, age, BCLC stage, liver function (ALBI grade)], non-DAA therapy initiation (HR 7; 95%CI 3.8–13, $p < 0.001$), non-SVR (HR 2.3, $p < 0.001$,) BCLC stage C/D (HR 1.43, $p < 0.001$) and non-curative cancer treatments (HR 1.95) were the risk factors associated with mortality.
Conclusion: In this cohort, more than two thirds of patients with HCV-related HCC initiated DAA therapies leading to a higher rate of SVR. DAA therapies along with SVR are associated with improvement in overall survival independent of BCLC stage and so treatment should be started in eligible patients.

OS-103-YI
Identifying individuals for hepatocellular carcinoma (HCC) surveillance after hepatitis B surface antigen (HBsAg) seroclearance: refining risk thresholds by age, sex, cirrhosis, diabetes and risk scores

Terry Cheuk-Fung Yip[1], Vincent Wai-Sun Wong[2], Mandy Sze-Man Lai[3], Jimmy Che-To Lai[1], Vicki Wing-Ki Hui[3], Lilian Liang[3], Yee-Kit Tse[2], Henry L.Y. Email: tcfyip@cuhk.edu.hk

Background and aims: Current European and American guidelines provide no specific HCC surveillance recommendations for patients with HBsAg loss, despite a lower HCC incidence than patients with chronic hepatitis B (CHB); target groups remain those with cirrhosis, men > 40 years, women > 50 years, and PAGE-B ≥ 10. We evaluated HCC risk after HBsAg loss by age, sex, cirrhosis, and diabetes, and evaluated PAGE-B and modified PAGE-B (mPAGE-B) scores.
Method: Using a territory-wide database in Hong Kong, we included adults with monoinfected CHB who cleared HBsAg from Jan 2000 to Dec 2020, followed until Mar 2025. Exclusions were liver transplantation or HCC before HBsAg loss and follow-up < 6 months. Annual HCC incidence was estimated with death as a competing risk. Subgroups potentially met surveillance threshold if the upper 95% CI of annual incidence was ≥ 0.2%. We calculated the 5-year integrated time-dependent area under the receiver operating characteristic curve (iAUC) for PAGE-B and mPAGE-B. Cirrhosis was defined by diagnosis codes, fibrosis-4 index > 3.25, and/or aspartate aminotransferase to platelet ratio index > 2.
Results: Of 9,733 patients included (mean age 57.4 ± 13.8 years, 40.0% female, 13.1% cirrhosis, 21.4% diabetes), 181 (1.9%) developed HCC at a median (IQR) follow-up of 9.2 (6.5–13.1) years. Annual HCC incidence was 0.47% (0.37%–0.58%) with cirrhosis and 0.11% (95% CI 0.09%–0.14%) without cirrhosis. In men without cirrhosis, the annual HCC incidence was 0.01% (95% CI 0.001%–0.08%) for HBsAg loss ≤ 40 years, 0.08% (0.03%–0.17%) for 41–50 years, and 0.18% (0.14%–0.23%) for > 50 years. In women without cirrhosis, the annual HCC incidence was 0.01% (95% CI 0.001%–0.04%) for HBsAg loss ≤ 50 years, 0.06% (0.02%–0.13%) for 51–60 years, and 0.13% (0.07%–0.23%) for > 60 years. In patients without cirrhosis, the 5-year iAUC was 0.749 (95% CI 0.695–0.801) for PAGE-B and 0.768 (0.716–0.814) for mPAGE-B. Annual HCC incidence was 0.17% (95% CI 0.13%–0.21%) for PAGE-B ≥ 12, and 0.17% (0.14%–0.22%) for mPAGE-B ≥ 11. In the absence of cirrhosis, the annual HCC incidence was 0.17% (95% CI 0.12%–0.25%) with diabetes and 0.09% (0.07%–0.12%) without diabetes.
Conclusion: Patients with HBsAg loss who have cirrhosis warrant HCC surveillance. When cirrhosis is absent, thresholds are met by men > 50 years and women > 60 years at HBsAg loss, and by those with diabetes. PAGE-B and mPAGE-B accurately stratify HCC risk; cut-offs after HBsAg loss should be higher than those used in CHB.

Rolling FIB-4 as a dynamic predictor of liver disease progression in HCV patients: insights from the french HEPATHER cohort

Lucia Parlati[1], Clovis Lusivka-Nzinga[2], Marc Bourliere[3], Fabrice Carrat[2], Pierre Nahon[4], Vincent Mallet[1,5]. *[1]Cochin Hospital, Hepatology Departement, Paris, France; [2]Sorbonne Université, Inserm, iPLesp, Paris, France, Paris, France; [3]Hopital Saint Joseph, Marseille, France; [4]Hôpital Avicenne, Bobigny, France; [5]AP-HP, Paris, France*
Email: lucia.parlati@aphp.fr

Background and aims: Single FIB-4 measurements may inadequately capture liver-related risk. Rolling FIB-4, defined as the cumulative area under consecutive FIB-4 measurements anchored to baseline, reflects longitudinal hepatic risk. We assessed its ability to predict 5-year liver disease progression in adults with hepatitis C (HCV).
Method: Patients with HCV enrolled in the prospective French ANRS CO22 HEPATHER cohort (2006–2015) were analyzed. Liver disease progression was defined as hepatocellular carcinoma (HCC) or decompensated cirrhosis, with death or liver transplantation treated as competing events. Fine–Gray competing-risk models estimated 5-year cumulative incidence. The cohort was split into training (2/3) and independent test (1/3) sets. Predictive performance of baseline FIB-4, rolling FIB-4, and their combination was evaluated. Discrimination was assessed using ROC curves at a fixed 5-year horizon, with AUC comparisons by the DeLong test. Calibration was assessed on the test set and corrected using logistic recalibration.
Results: Among 8,436 patients, 52% were men and the median age was 56 years (Q1–Q3: 50–64), 34% had cirrhosis. Overall, 93.6% received direct-acting antivirals, of whom 95.6% achieved SVR. Over a median follow-up of 5.96 years (IQR: 4.20–7.67), 353 patients (4.2%) experienced liver disease progression, 438 (5.2%) experienced a competing event, and 7,645 (90.6%) were censored. Baseline FIB-4 and rolling FIB-4 showed good discrimination for 5-year progression (AUC = 82.3% [79.8–84.8] and 83.7% [81.2–86.2], respectively). In multivariable Fine–Gray models including both indices, rolling FIB-4 remained independently associated with progression ($p < 0.0001$), whereas baseline FIB-4 was no longer significant ($p = 0.44$). Adding

rolling FIB-4 to a clinically adjusted Fine–Gray competing-risk model significantly improved 5-year risk prediction compared with baseline FIB-4 alone (ΔAUC = 0.0378; p = 0.006), achieving excellent predictive performance (AUC ≈ 0.90). Direct comparison of multivariable models confirmed a significant gain with rolling FIB-4 (ΔAUC = 0.0259; p < 0.0001). Recalibration improved agreement between predicted and observed risks without altering discrimination (AUC = 0.902).
Conclusion: Rolling FIB-4 improves 5-year prediction of liver disease progression beyond baseline FIB-4 in HCV patients, providing dominant prognostic information when integrated into clinically adjusted competing-risk models, with robust discrimination and calibration after validation.

Email: mdcleegh@nus.edu.sg

Background and aims: Hepatitis E virus (HEV) is a leading cause of acute viral hepatitis, but its prognostic impact in acute-on-chronic liver failure (ACLF) is unclear. We evaluated organ-failure trajectories and survival in ACLF patients with acute HEV infection within the APASL ACLF Research Consortium (AARC).
Method: We analysed 5,612 prospectively enrolled ACLF admissions from 25 countries (2004–2021). Acute HEV was defined by HEV IgM positivity. Organ failures (day 0/4/7) and survival were compared between HEV and non-HEV; multivariable Cox regression was performed in patients with complete covariate data.
Results: Acute HEV was present in 340/5,612 patients (6.1%). At admission, HEV patients had higher platelet counts, higher bilirubin levels, and lower albumin levels (all p < 0.05). HEV was associated with a higher organ-failure burden at presentation: any organ failure (95.0% vs 91.7%; p = 0.032), ≥3 organ failures (41.2% vs 31.7%; p < 0.001), and renal failure (37.4% vs 29.2%; p = 0.001). Among those with day-4 assessments, persistent organ failure remained higher (87.6% vs 77.7%, p < 0.001), and organ-failure distribution was worse (p < 0.001). By day 7, liver failure (66.0% vs 58.2%, p = 0.028), renal failure (21.4% vs 16.1%, p = 0.046), and ≥3 organ failures (24.3% vs 14.6%, p < 0.001) remained higher. Kaplan–Meier survival was worse (median 12 vs 18 days; log-rank p < 0.001), but HEV was not independently associated with mortality in Cox regression (n = 3,409; HR 1.09, 95% CI 0.93–1.28; p = 0.299). Fewer HEV patients received liver transplantations (2.9% vs. 5.7%), and among those who did, 90 day survival rates were significantly lower compared to non-HEV transplant recipients (0% vs 5.5%, p = 0.003).
Conclusion: Acute HEV-associated ACLF is characterised by greater renal and multi-organ failure and delayed early recovery with poorer unadjusted survival; however, HEV is not an independent mortality determinant after adjustment, suggesting baseline organ-failure burden largely explains the excess risk.

OS-106
Safety and efficacy of pemafibrate (K-808), a selective peroxisome proliferator-activated receptor alpha modulator, in patients with primary biliary cholangitis: twelve-week data from the randomized, placebo-controlled, PEMA-PBC dose-finding study
Gideon M. Hirschfield[1], Kris V. Kowdley[2], Marco Carbone[3], David E. Jones[4], Albert Parés[5], Cynthia Levy[6], Shinji Shimoda[7], Andrey Belous[8], Ryohei Tanigawa[9], Hideki Suganami[9], Atsushi Tanaka[10]. *[1]The Autoimmune and Rare Liver Disease Programme, Toronto General Hospital, Toronto, Canada; [2]Washington State University, Liver Institute Northwest, Velocity Clinical Research, Seattle, United States; [3]University of Milano-Bicocca, Milan, Italy; [4]Newcastle University, Clinical and Translational Research Institute, Newcastle, United Kingdom; [5]University of Barcelona, Hospital Clinic, Barcelona, Spain; [6]University of Miami, Milan, United States; [7]Kansai Medical University, Osaka, Japan; [8]Kowa Pharma Development, Boston, United States; [9]Kowa Company, Tokyo, Japan; [10]Teikyo University, Tokyo, Japan*
Email: gideon.hirschfield@uhn.ca

Background and aims: Treatment goals for patients living with primary biliary cholangitis (PBC) include improving alkaline phosphatase levels (ALP), with normalization increasingly recognized as the ideal response to therapy. We report 12-week data from the Phase 2, double-blind, randomized, placebo-controlled, multicenter trial of extended-release pemafibrate (K-808), a highly selective peroxisome proliferator-activated receptor (PPAR) alpha modulator, in patients with inadequate response or intolerance to ursodeoxycholic acid (UDCA); NCT06247735.
Method: Eligible non-cirrhotic patients with ALP >1.5× upper limit of normal (ULN, 116 U/L) after at least 1 year of treatment with, or intolerance to, UDCA were randomized to receive either K-808 0.2 mg/day, 0.4 mg/day or placebo for 12 weeks, followed by a 52-week extension. The primary endpoint was percentage change from baseline in ALP. The key secondary endpoint was ALP normalization.

Additional endpoints included achievement of POISE criteria (ALP <1.67× ULN, with a reduction from baseline ≥ 15%, and total bilirubin ≤1× ULN), patient-reported outcomes with PBC-40, 5-D Pruritus Scale, Pruritus and Fatigue Numerical Rating Scale (NRS). Safety endpoints included adverse events (AEs).
Results: In total, 46 patients were randomized, with 15, 15 and 16 receiving K-808 0.2 mg, 0.4 mg and placebo, respectively. Mean (SD) age was 60.0 (12.3) years; 80.4% were female; 52.2% were from North America and 47.8% from Japan; BMI was 26.7 (7.5) kg/m^2. Baseline ALP levels were 216.5 (49.8), 263.8 (124.9) and 271.5 (172.4) U/L, and 1, 3 and 2 patients had ALP >3× ULN in K-808 0.2 mg, 0.4 mg and placebo groups, respectively. At week 12, least-squares mean changes in ALP were −47.7%, −48.5% and −1.3%; ALP normalized in 66.7%, 60.0% and 0% of patients. In the subpopulation with baseline ALP >1.67× ULN (n = 32), ALP normalized in 44.4%, 60.0% and 0%, and POISE criteria were achieved in 88.9%, 70.0% and 0%. There were numerically greater improvements in endpoints of fatigue and pruritus with K-808. No serious AEs or safety concerns were identified during the 12-week treatment period.
Conclusion: In patients with PBC who have insufficient response or intolerance to UDCA, addition of pemafibrate (K-808), a highly selective PPAR alpha modulator, for 12 weeks, led to clinically meaningful, and statistically significant, biochemical improvements in ALP, including normalization in ≥60% of participants. There were no safety concerns.

Background and aims: Up to 40% of patients with primary biliary cholangitis (PBC) have an inadequate response to ursodeoxycholic acid (UDCA), highlighting an unmet medical need. Linafexor is a novel pulsatile farnesoid X receptor (FXR) agonist with an ultra-short half-life (approximately 1 hour), designed to deliver choleretic and anti-inflammatory effects while minimizing the toxicity associated with continuous FXR occupancy. We evaluated the efficacy and safety of linafexor in patients with PBC and an inadequate response to UDCA.
Method: In this multicenter, double-blind, phase 2 trial, patients with PBC and an inadequate response to UDCA (alkaline phosphatase [ALP] >1.67× upper limit of normal [ULN] after ≥6 months of UDCA) or UDCA intolerance were randomized 1:1:1 to linafexor 2 mg, linafexor 4 mg, or placebo once daily for 12 weeks, followed by a 40-week open-label extension (OLE). The primary endpoint was percent change in ALP from baseline to week 12. Secondary endpoints included composite biochemical response (ALP <1.67×ULN, ≥15% ALP reduction, and normal total bilirubin), changes in other liver biochemistries, and safety.
Results: Among 74 randomized patients, the mean percent change in ALP from baseline to week 12 was −18.1% (95% CI, −28.1 to −8.1) with linafexor 2 mg and −20.6% (95% CI, −30.9 to −10.4) with linafexor 4 mg, compared with +5.6% (95% CI, −3.9 to 15.2) with placebo (P < 0.001 for both comparisons). Composite biochemical response was achieved in 20.8% (2 mg), 33.3% (4 mg), and 3.8% (placebo). Significant reductions were also observed in gamma-glutamyl transferase, aminotransferases, and immunoglobulin M levels. Improvements in biochemical markers were sustained throughout the OLE, and placebo crossover participants exhibited significant improvements upon initiating linafexor. Cumulative composite response rates reached 39.6% (original linafexor) and 30.8% (crossover). During the double-blind phase, pruritus was the most common treatment-related adverse event; nearly all cases were mild to moderate (only one Grade 3 CTCAE event). Throughout the study period, no new safety signals emerged during the OLE, and no cases of drug-induced liver injury (DILI) were reported.
Conclusion: Linafexor, a novel pulsatile FXR agonist, demonstrated significant and durable improvements in biochemical markers with a manageable safety profile in patients with PBC. Based on these phase 2 findings, phase 3 clinical trials are now underway.

Primary care liver fibrosis detection pathway in people with type 2 diabetes: results from the PRELUDE1 prospective, pragmatic, electronic health record-embedded, parallel-arm cohort study

Kushala Abeysekera[1], Michael James[2], Stuart Rison[3], Huei-Tyng (Philippe) Huang[2], John Moore[4], Ann Archer[1], Gillian Hood[2], Imogen Salisbury[2], Matthew Hickman[1], James Brindley[2], William Alazawi[2]. *[1]Bristol University, Bristol, United Kingdom; [2]Barts Liver Centre, Blizard Institute, Queen Mary University of London, London, United Kingdom; [3]Wolfson Institute of Population Health, Queen Mary University of London, London, United Kingdom; [4]Charlotte Keel Medical Practice, Bristol, United Kingdom*
Email: w.alazawi@qmul.ac.uk

Background and aims: People with type 2 diabetes mellitus (T2DM) are at increased risk of steatotic liver disease. Guidelines recommend calculated scores (e.g. Fib-4) followed by second-tier (e.g. vibration controlled transient elastography (VCTE)) to risk-stratify patients, inform specialist referral and treatment eligibility. Adoption of these guidelines in primary care practices (PCPs) remains low (~5%). PRELUDE1 was a large, prospective pragmatic, electronic health record (EHR)-embedded parallel-arm cohort study in UK PCPs. We assessed adding Fib-4 to T2DM annual reviews followed by VCTE in community versus hospital settings.
Method: Ten PCPs (in London and Bristol) were included and allocated at start of study to community or hospital scanning arms. Fib-4 was included by requesting a specific T2DM annual review set or adding a Fib-4 order set to routine bloods. People with Fib-4≥1.3 were referred for VCTE (LSM≥8.0 referred to specialist care). Clinical, demographic and laboratory data were extracted from EHR.
Results: Total study population (n = 8705) was balanced across community (n = 4599) and hospital (n = 4106) arms with no clinically-meaningful differences in demographic or metabolic parameters. Mean age was 61 years, 55% male, 41% South Asian ethnicity and 67% in the two most-deprived national quintiles. At baseline, 294 (3.4%) people had Fib-4 scores which increased to 2999 (34.3%) by study-end (community 32.3%; hospital 36.8%) of whom 1115 (37.2%) had Fib-4≥1.3. Significantly more patients attended VCTE in community than hospital settings (78.3% vs 71.7%, p = 0.007), driven by differences in London PCPs: 81.6% in community, 56.9% in hospital (p < 0.001), but not between cities themselves. Of all scans performed, 25.5% (n = 168) had LSM≥8.0 and 15.5% (n = 102) LSM≥10 with no statistically significant differences between settings or cities. Increasing Fib-4 threshold to 2.0 for VCTE referral in people aged >65 would have reduced referrals by 45.5% to n = 608, increased rates of LSM≥8.0 and LSM≥10 to 31.0% and 20.0% respectively but not identified 32.3% (n = 55) of all people with LSM≥8.0 kPa, over half of whom had LSM≥10 kPa.
Conclusion: In this EHR-embedded pragmatic study conducted in socioeconomically diverse populations, adding Fib-4 testing to T2DM annual reviews markedly increased availability of scores from baseline. Patient attrition through second-tier testing was more pronounced in hospital-referring PCPs. Fibrosis testing in T2DM is feasible and should be tailored to local population needs. ISRCTN14585543.

Background and aims: Ursodeoxycholic acid (UDCA) represents the first-line therapy in patients with Primary Biliary Cholangitis (PBC), although up to 40% of patients respond inadequately. Elafibranor, a PPAR agonist, is an emerging alternative that reduces ALP with a favourable safety profile. The ELEVATE-PBC study evaluated real-world efficacy and safety of elafibranor in patients with inadequate response or intolerance to prior therapy or naïve to other second-line therapies.
Method: In this multicentre study, we included adult patients from the *Italian PBC Registry* treated with elafibranor since October 2024. Biochemical response (BR) was defined as ALP <1.67×ULN with normal bilirubin; complete BR as normal ALP and bilirubin. Longitudinal data at baseline, 3- and 6-month after elafibranor initiation were analysed descriptively and reported as median and interquartile range (IQR) for continuous variables and proportions for categorical variables.
Results: We included 281 patients, predominantly females (n = 244, 86.8%), with a median age of 61 years (IQR 54–67). The median disease duration was 8.9 years. Cirrhosis was present in 77 patients (27.4%). Autoimmune hepatitis overlap was present in 20 patients (7.1%). Median liver stiffness (LS) was 7.2 kPa. Prior fibrate use was reported in 80 (28.5%) patients, whereas 193 (68.7%) were on obeticholic acid. Median washout intervals from the last obeticholic acid and fibrate courses to elafibranor initiation were 7.5 (3.7–10.3) and 0.11 (0.0–9.5) months, respectively. 71 patients (25.3%) were on statins. Median baseline values of ALP were 1.72×ULN, total bilirubin 0.67 mg/dl and ALT 0.9×ULN. At baseline, 131 patients (47%) presented BR and 24 (8.6%) complete BR. Follow-up data were available for 78 patients at 3-month and 39 patients at 6-month. At 3-month, BR was reached by 64 patients (84.2%) and complete BR by 40 patients (41.0%), while at 6-month these endpoints were achieved by 32 (82.1%) and 16 (41%) patients, respectively. No increase in serum creatinine values or total bilirubin were observed at 6-month. Responses were similar regardless of prior second-line therapies. Treatment was discontinued in 15 patients, mainly due to gastro-intestinal intolerance (7 cases; 46.6%). Longer follow-up data will be available at the time of presentation.
Conclusion: Preliminary real-world data from the ELEVATE-PBC study confirm trial findings — elafibranor is effective and safe in a large cohort of UDCA non-responsive patients previously treated with OCA or fibrates.

Treatment of hepatitis C in pregnancy with Sofosbuvir/Velpatasvir: interim results from the STORC study

Catherine Chappell[1], Jasmin Charles[2], Marcela Smid[2], Kara Rood[3], Tatyana Kushner[4], Mia Biondi[5], Jordan J. Feld[6], Mark Yudin[7], Genevieve Eastabrook[8], Sarah Osmundson[9], Todd Davies[10], John Cafardi[11], Leslie Meyn[1], Stacey Scherbakovsky[12], Kyung Min Kwon[12], Cathleen Letterio[12], Sharon Hillier[1]. *[1]University of Pittsburgh, Pittsburgh, United States; [2]University of Utah Health, Salt Lake City, United States; [3]The Ohio State University, Columbus, United States; [4]Weill Cornell Medical College, New York, United States; [5]York University, Toronto, Canada; [6]University Health Network, Toronto, Canada; [7]Unity Health Toronto, Toronto, Canada; [8]London Health Sciences Centre, London, Canada; [9]Vanderbilt University, Nashville, United States; [10]Marshall University, Huntington, United States; [11]University of Cincinnati, Cincinnati, United States; [12]Gilead Sciences, Foster City, United States*
Email: chappellca@upmc.edu

Background and aims: Pregnancy presents a key opportunity to treat hepatitis C virus (HCV) infection, improving maternal outcomes and reducing perinatal transmission. However, safety data for direct-acting antivirals in pregnancy remain limited. The STORC study is an international, multi-center study evaluating sofosbuvir/velpatasvir (SOF/VEL) in pregnant people with HCV.
Method: In this open-label, single-arm study, pregnant people with HCV infection were enrolled between 20 and 30 weeks' gestation and treated with a 12-week course of SOF/VEL. HCV RNA testing was performed at screening, enrollment, delivery and 12 weeks after SOF/VEL completion (SVR12). The primary outcomes were gestational age at delivery and SVR12. Infants were followed for 12 months.
Results: Between July 2022 and March 2026, 100 pregnant people with HCV were screened and 83 enrolled. Participants had a median age of 33 (range 18–44). 79 (95.2%) participants had FIB-4 scores <1.45; 4 (4.8%) had scores 1.45 to <3.25, including two with elevated AST/ALT and two with low platelets. None of the participants had decompensated cirrhosis. At enrollment, participants had a median HCV RNA of 4.59 (range 2.61, 6.18) log copies/mL. Three participants discontinued treatment after one dose due to vomiting (n = 2) and declining further treatment (n = 1). After initiation of SOF/VEL, 51/52 (98.0%) had an undetectable HCV RNA at time of delivery. To date, 61 participants have completed the SVR12 visit and of those 59 (96.7%)

were cured. Of the two participants with treatment failure, one missed 20 doses and had HCV re-exposure via her sexual partner and the other missed 28 doses and had HCV re-exposure due to return to injection drug use. Among 52 participants with HCV RNA results at delivery, 12 were within the SVR4 window; 11 (91.7%) had concordant SVR12 results, and the discordant case was treatment failure with HCV re-exposure. Of the 73 participants who have delivered, median gestational age was 38+5 weeks (range 30+1, 42+0), 8 (10.9%) had preterm delivery at less than 37 weeks, and none had cholestasis of pregnancy. All adverse events related to SOF/VEL were less than grade 2, except one participant had grade 3 nausea. Of 59 infants tested for HCV RNA, all were undetectable within 2–12 months of age.
Conclusion: Interim STORC data support the safety of SOF/VEL after 20 weeks' gestation, with high HCV cure rates and possible prevention of cholestasis and perinatal HCV transmission.

LBP-007
Comparative study of the efficacy and safety of systemic glucocorticosteroids on liver enzyme activity in patients with autoimmune hepatitis without liver cirrhosis
Volodymyr Cherniavskyi[1], Leonid Pavlovskyi[1], Liudmyla Onyshchuk[1].
[1]*Bogomolets National Medical University, Kyiv, Ukraine*
Email: onishluda@gmail.com

Background and aims: Autoimmune hepatitis (AH) is a chronic progressive disease that leads to the early development of liver fibrosis and cirrhosis. To prevent these complications, timely appointment of effective and safe treatment is necessary. The key drugs in the treatment of AH remain glucocorticosteroids. However, whether they are all equally effective and safe remains a subject of discussion and the interest of this work.
Aim: To compare the effects of methylprednisolone, prednisolone, and budesonide on reducing liver enzyme activity in patients with AH without liver cirrhosis.
Method: We conducted a prospective randomized cohort study of 70 patients with AH. All patients were equally divided into three groups. Patients in the first group received methylprednisolone 24 mg per day. Patients in the second group received prednisolone 30 mg per day. The third group of patients received budesonide 9 mg per day. Assessment of ALT and AST activity, as well as side effects, was carried out at 4, 8 and 12 weeks. All patients were prescribed azathioprine 50 mg per day according to the standard of treatment at the end of the second week with subsequent dose titration to 100 mg per day.
Results: In patients of the three groups at the beginning of treatment, the average values of ALT activity were 95 ± 14.8, 98 ± 15.3, 99 ± 14.8, AST 65 ± 9.1, 59 ± 8.7, 55 ± 8.7 (p = 0.870 for ALT and p = 0.177 for AST). After 4 weeks, ALT activity in patients of the three groups did not differ significantly and was 58 ± 13.1, 62 ± 9.7 and 67.5 ± 8.5 (p = 0.064). After 8 weeks, ALT activity in patients of the three groups was 37 ± 5.8, 39 ± 7.7, 44 ± 6.9 and did not differ significantly (p = 0.0820). At the end of week 12, ALT activity in patients of the three groups was within the reference values (p = 0.065). AST activity in patients of the three groups at 4, 8 and 12 weeks was within normal limits and did not differ significantly (p = 0.269 after 4 weeks, p = 0.652 after 8 weeks, p = 0.139 after 12 weeks). The frequency of side effects after 4, 8 and 12 weeks was the lowest in patients of the first and third groups 20 and 15% respectively (p = 0.001). At the same time, in patients who took prednisolone, the frequency of side effects was observed in 30% of cases.
Conclusion: The administration of methylprednisolone, prednisolone, or budesonide to patients with AH without cirrhosis is equally effective in improving liver enzyme. Methylprednisolone and budesonide are safer than prednisolone in patients with AH without cirrhosis.

Background and aims: Animal models using partial hepatectomy (PH) have established our understanding of how liver regeneration could possibly occur in humans. This has considerable implications for regenerative medicine, such as prediction of post-hepatectomy liver failure (PHLF) upon major resections. As translation to humans has been limited and challenging, we aimed to provide both basic knowledge and proof-of-concept insights for clinical applications in the human setting.
Method: Two-stage hepatectomy combined with longitudinal multi-omics was used as the human model at the Karolinska University Hospital. The study included 21 patients subjected to Associating Liver Partition and Portal Vein Ligation for Staged Hepatectomy (ALPPS). Serial liver biopsies (segments 3 and 5), peripheral blood mononuclear cells, and plasma were collected. Separately, preoperative plasma samples from 120 patients subjected to major hepatectomy from which 60 developed PHLF was analyzed (3 cohorts of 40 patients, ISGLS grade B or C, including metastatic colorectal cancer, hepatocellular carcinoma, klatskin, cholangiocarcinoma and gallbladder cancers).
Results: Analysis of longitudinal matched liver biopsies during the proliferative phase (stage 2) identified transcriptomic and epigenetic modules preferentially mobilized in the regenerating future liver remnant (FLR) rather than the matched deportalized tissue. Integration of these modules revealed the main pathways, transcription factors, cytokines, and oncogenes involved. To study the initiation phase, we performed serum profiling the days prior and following Stage 1 and identified the main pathways active during the metabolic remodeling, including evidence for nucleotide salvage and lipolysis. Finally, using machine learning techniques, we revealed a proteomic signature capturing the regenerative potential of human liver. This plasma signature predicted efficient regeneration or liver failure after major hepatectomy in three independent cohorts, even in patients with sFLR below 20%. Deconvolution of this signature identified HNF4 as master regulator and potential therapeutic target.
Conclusion: Overall, we validate key knowledge from experimental PH models and provide novel insights into human liver regeneration with clinical implication for prediction of PHLF.

Email: pietro.lampertico@unimi.it

Background and aims: Bulevirtide (BLV) monotherapy induces virological and biochemical responses in patients with CHD, but the possibility to evaluate its impact on clinical outcomes is currently limited by unavailability of comparable untreated controls. Synthetic data (SD) mimic real-patient statistical and clinical properties, potentially overcoming these limitations. We aimed to generate and validate high-fidelity SD evaluating disease outcomes in BLV-treated versus untreated CHD patients with cirrhosis.
Method: Clinical data from 344 CHD patients with cirrhosis treated with BLV in the SAVE-D study and two historical BLV-untreated cohorts from Italy and France (n = 298) were used to train models. Two settings were defined: A) 1:1 generation of both cohorts assessing clinical fidelity and privacy standards; B) generation of balanced, augmented cohorts (n = 3000/group), reproducing clinical endpoints and addressing matching challenges. SD were evaluated using SAFE framework (PMID: 41197110) against a real data pool excluded from the training phase. Fidelity and privacy were evaluated by Clinical Synthetic Fidelity (CSF) score (average of statistical metrics) and Nearest Neighbour Distance Ration (NNDR) (optimal 0.65–0.85). Propensity score matching (logistic regression) aligned clinical and demographic covariates (SMD <0.1). Primary endpoint compared three-year incidences of liver-related events (hepatocellular carcinoma [HCC] and decompensation).
Results: In setting A, synthetic cohorts of BLV-treated and untreated patients showed high fidelity and privacy (CSF 90%/94%, NNDR 0.71/0.85). In setting B, propensity score matching identified 624 pairs from 3,000 SD samples per group with consistent SAFE metrics. 3-year cumulative incidences of decompensation and HCC were similar across real *vs.* synthetic BLV-treated and untreated patients: decompensation 2.7% *vs.* 4.2% (BLV-treated) and 11.3% *vs.* 10.0% (untreated), HCC 6.6% *vs.* 8.5% (BLV-treated) and 3.6% *vs.* 4.8% (untreated), respectively. Compared to real patients, the synthetic cohort significantly improved statistical robustness, due to the larger pool of matched individuals with perfectly comparable characteristics (real: p = 0.054 and p = 0.378 *vs.* synthetic: p = 0.039 and p = 0.546).
Conclusion: High-fidelity synthetic patient-level data accurately reproduce clinical outcomes in untreated and BLV-treated CHD patients with cirrhosis. This strategy may overcome some of the challenges in rare diseases.

LBP-010

Safety, tolerability, pharmacokinetics, and pharmacodynamics of DA-1726, an oxyntomodulin analogue, in a higher-dose phase 1 cohort with exploratory noninvasive liver assessment

Chris Fang[1], Yuna Chae[2], Robert Homolka[1], Ji Eun Lee[1], Kyunghyun Lee[1,3], Sung-Jin Kim[1,3], Mi-Kyung Kim[2], Hyung Heon Kim[1]. *[1]MetaVia Inc., Cambridge, United States; [2]Dong-A ST Co., Ltd, Yongin-Si, Korea, Rep. of South; [3]Dong-A ST Co., Ltd, Seoul, Korea, Rep. of South*
Email: ynchae@donga.co.kr

Background and aims: Obesity is associated with metabolic complications, including metabolic dysfunction–associated liver disease. DA-1726 is an oxyntomodulin analogue, acting as a dual glucagon-like peptide-1 and glucagon receptor agonist. In this first-in-human phase 1 study (NCT06252220), a higher-dose cohort further evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics of DA-1726 in obese but otherwise healthy adults, with exploratory noninvasive assessment of liver-related parameters.
Method: In this 48 mg multiple-ascending dose cohort, nine participants received DA-1726 or placebo in a 6:3 randomization ratio. Participants received once-weekly subcutaneous dosing for four weeks without dose titration; six entered an optional four-week extension phase at the same dose (four DA-1726; two placebo).
Results: In this interim analysis, DA-1726 was generally well tolerated. Gastrointestinal (GI) adverse events (AEs) were mainly transient and mild to moderate, with no treatment-related discontinuations or serious AEs. Participants receiving DA-1726 showed progressive reductions in body weight, with mean percent changes from baseline of −6.1% at Day 26 and −9.1% at Day 54 ($p < 0.05$ vs placebo at Day 26), without evidence of plateau through Week 8. Significant changes were also observed in waist circumference (−5.8 cm at Day 26; −9.8 cm at Day 54; $p < 0.05$ vs placebo). At Day 54, the mean change from baseline in controlled attenuation parameter (CAP) was −20.0 dB/m in the 48 mg group versus +24.0 dB/m in the placebo group. Modest improvement from baseline was also observed in liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE; −10.3% vs. +13.8% with placebo), with directional improvement from baseline in FibroScan-aspartate aminotransferase (FAST) score. Cardiovascular parameters, including heart rate and Fridericia-corrected QT interval (QTcF), remained stable with no clinically significant changes observed despite glucagon receptor activation, supporting a favorable safety profile.
Conclusion: DA-1726 was generally well tolerated up to 48 mg, with predominantly mild-to-moderate GI AEs and no new safety signals. Clinically meaningful and statistically significant weight loss was observed. In addition, exploratory FibroScan-based assessments suggest early trends toward improvement in liver-related parameters, supporting further evaluation in longer-term studies.

LBP-011

Pharmacological effects of apixaban and edoxaban in patients with liver cirrhosis

Lucas Gautier[1], Cindy Pereira Portela[1], Debora Bertaggia Calderara[1], Lucas Veuthey[1], Alessandro Aliotta[1], Maxime Zermatten[1], Elise Mdawar-Bailly[2], Sophie Kasmi[2], Darius Moradpour[2], Montserrat Fraga Christinet[2], Lorenzo Alberio[1]. *[1]Division of Haematology and Central Haematology Laboratory, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland; [2]Division of Hepatology and Gastroenterology, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland*
Email: lucas.gautier@chuv.ch

Background and aims: While several patients with liver cirrhosis (LC) require long-term anticoagulation because of atrial fibrillation or venous thromboembolism, data on direct oral anticoagulants (DOAC) use remain limited. Here, we evaluated the pharmacological profiles of two DOAC in this population.
Method: This monocentric clinical trial (NCT05869591) enrolled non-anticoagulated patients with Child-Pugh A (n = 38) and B (n = 4) LC, randomised to receive either edoxaban 60 mg OD (n = 21) or apixaban 5 mg BID (n = 21) for 7 days. Pharmacokinetic and pharmacodynamic parameters were measured at day (d) 1, 3, 8, and 9. Preliminary results include DOAC peak and trough concentrations, *ex vivo* thrombin generation (TG) parameters, and *in vivo* markers of coagulation (prothrombin fragments 1+2 [F1+2], thrombin–antithrombin complexes [TAT], D-dimers [DD]).
Results: The cohort included 12 female (29%) and 30 male (71%) patients, all with preserved renal function and a median MELD score of 8 (range 6–18); 50% were thrombocytopenic (median platelet count 147 G/L; range 58–358). DOAC concentrations exhibited

distinct profiles, with median peak and trough levels of 204 and 17 ng/mL for edoxaban and 158 and 92 ng/mL for apixaban, respectively. No patient had trough concentrations above the values observed in patients without LC [1]. As expected, *ex vivo* TG parameters changed in line with DOAC levels. Overall, compared to non-anticoagulated baseline, DOAC significantly reduced *ex vivo* TG ($p < 0.01$) and *in vivo* coagulation markers (F1+2, TAT, DD; $p < 0.01$). At d8, DOAC significantly decreased F1+2 and DD (−24% and −23%, respectively; $p < 0.01$); the reduction in DD was −32% with edoxaban ($p = 0.08$) and −22% with apixaban ($p < 0.05$). Patients with thrombocytopenia exhibited less DD reduction compared to those with platelets ≥150 G/L (−6% versus −37%; $p < 0.05$).

Conclusion: Edoxaban showed higher peak and lower trough levels than apixaban, which displayed greater variability at trough without exceeding the usual range observed in patients without LC. Based on F1+2 and DD, both DOAC appeared effective in patients with LC. Noteworthy, the only factor identified to impact the anticoagulant effect *in vivo* was platelet count, with thrombocytopenia correlating with a significantly lower DD reduction.

High rate and sustained HBsAg loss achieved with HT-101 plus HT-102 combination therapy in HBeAg-negative, nucleos(t)ide analogue-suppressed patients: ongoing off-treatment results from a multicenter Ib/IIa study

Xieer Liang[1], Chen Liang[2], Jianmei Lin[3], Bei Zhong[3], Huiqing Liang[4], Wen Xie[5], Yujuan Guan[6], Zhihong Liu[1], Xun Qi[2], Dong Wang[7], Zhipeng Zhang[8], Lijuan Ding[8], Zhiping Cui[8], Huaien Song[8], Kun Yue[8], Jinlin Hou[1]. *[1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guanghzou, China; [2]Liver Disease Department, Shanghai Public Health Clinical Centre, Shanghai, China; [3]Infectious Diseases Department, Qingyuan People's Hospital, Guanghzou, China; [4]Infectious Diseases Department, Xiamen Traditional Chinese Medicine Hospital, Xiamen, China; [5]Liver Disease Department, Beijing Ditan Hospital, Beijing, China; [6]Liver Disease Department, Guangzhou Eighth People's Hospital, Guanzhou, China; [7]Hepa Thera Biopharmaceutical Co.Ltd., Shanghai, China; [8]Hepathera, Shanghai, China*
Email: jlhousmu@163.com

Background and aims: HT-101, a GalNAc-conjugated small interfering RNA targeting the S-region of the hepatitis B virus (HBV) genome, and HT-102, a human monoclonal antibody directed against the antigenic loop of HBsAg, have demonstrated synergistic efficacy for HBsAg clearance in patients with chronic HBV infection. Here we report off-treatment follow-up data from the ongoing China-based study (NCT07183306/CTR20244730).

Method: This multicenter, open-label, partial dose-escalation study enrolled HBeAg-negative patients on stable nucleos(t)ide analogue (NA) therapy, with serum HBsAg levels from 100 to 3,000 IU/mL. Participants were assigned to five treatment groups: A (HT-101 400 mg), B (HT-102 300 mg for 24 weeks, followed by HT-101 400 mg for week 24 to 48], C (HT-101 100 mg + HT-102 300 mg), D (HT-101 200 mg + HT-102 300 mg), and E (HT-101 400 mg + HT-102 300 mg). HT-101 and/or HT-102 were administered subcutaneously every 4 weeks for 24 or 48 weeks, with follow-up for up to 48 weeks post-treatment. The primary endpoint was the incidence of treatment-emergent adverse events (TEAEs). Secondary endpoints included HBsAg kinetics, virological and pharmacodynamic markers, and immunogenicity.

Results: Both Group A and Group B have completed the 48-week visit, while Groups C–E have completed the 32-week visit. At week 24, HBsAg seroclearance was observed in 4/20 (20%) participants in Group A and 3/4 (75%) maintained HBsAg loss from end of treatment (week 24) through week 48. In Group B, 4/8 (50%) achieved HBsAg seroclearance at week 48. At week 32 (8 weeks post-treatment), the HBsAg seroclearance rates were 4/8 (50%) in Group C, 8/10 (80%) in Group D, and 8/10 (80%) in Group E respectively. Among combination therapy recipients (Groups C–E), 20/22 (91%) of those who achieved HBsAg seroclearance at week 24 remained HBsAg negative at week 32 (8 weeks off-treatment). The therapy was well tolerated, with most TEAEs being grade 1–2 in severity (e.g., injection site reactions). No drug-related serious adverse events, grade ≥3 events, or alanine aminotransferase flares were observed.

Conclusion: Combination therapy with HT-101 and HT-102 achieved very high rate of HBsAg loss which was sustained for 8 weeks post-treatment. HT-101 monotherapy demonstrated durable HBsAg loss for up to 24 weeks post-treatment. These results support the continued development of HT-101 and HT-102 as a promising strategy for achieving functional cure in patients with chronic HBV infection.

LBP-013

A phase Ib multiple dose ascending study of HH-006 in treatment-naïve participants with chronic hepatitis B virus infection

Xieer Liang[1], Xihua Fu[2], Yujuan Guan[3], Zhihong Liu[1], Wencong Dai[1], Zuoheng Xu[2], Ying Zhuang[4], Guangyu Li[4], Liangfeng Zou[4], Zhongmin Zhou[4], Yonghe Qi[4], Pan Chen[4], Xiyu Zhang[4], Bin Ye[4], Yin Zhang[4], Bin Chen[4], Jianhua Sui[4], Wenhui Li[5], Jinlin Hou[1]. *[1]Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]The Affiliated Panyu Central Hospital of Guangzhou Medical University, Guangzhou, China; [3]Guangzhou Eight People's Hospital, Guangzhou Medical University, Guangzhou, China; [4]Huahui Health Ltd., Beijing, China; [5]National Institute of Biological Sciences, Beijing, China*
Email: jlhousmu@163.com

Background and aims: HH-006 is a human monoclonal antibody (mAb) targeting the PreS1 domain of HBV large (L) envelope protein, with an engineered Fc region to enhance half-life and Fc function. HH-006 has demonstrated a favorable safety profile and the expected pharmacokinetic (PK) profile in healthy volunteers in a phase Ia study. The objectives of this study were to evaluate the safety, tolerability, PK, and antiviral activity of HH-006 in chronic HBV infection (CHB).

Method: This study is a randomized, double-blind, and placebo-controlled study. A total of 36 treatment-naïve CHB participants were enrolled and randomized (9:3 within each dose cohort). At baseline, the mean ± SD HBsAg level among participants was 1,756.4 ± 1,312.52 IU/mL, the mean ± SD HBV DNA level was 3.6 ± 1.38 $\log_{10}$ IU/mL, and the mean ± SD ALT level was 33.4 ± 22.37 U/L. Participants in each dose group (120 mg, 240 mg and 480 mg) received HH-006 or placebo subcutaneous (S.C.) once a week on Day 1, Day 8, Day 15, Day 22 and Day 29, with 24 weeks of follow-up.

Results: All HH-006 treatment-emergent adverse events (TEAEs) were Grade 1 or 2, with no adverse events of special interest (AESIs), serious adverse events (SAEs), or AEs leading to treatment discontinuation. On-treatment AEs were reported in 92.6% (25/27) of participants in the HH-006 treatment groups and 88.9% (8/9) in the placebo group, while treatment-related AEs occurred in 81.5% and 77.8% of participants, respectively. Systemic exposure of HH-006 was increased in a near dose-proportional manner across the 120–480 mg dose range. Following SC injection, the T_{max} ranged from 1 to 3 days post-dose, the mean elimination half-life ranged from 30.6 to 42.6 days. Decreases of HBV DNA and HBsAg were observed across all dose cohorts. At 4 weeks after the final dose, the mean ± SD HBV DNA reduction from baseline was −0.62 ± 0.61, −0.78 ± 0.37, −0.69 ± 0.57 in the HH-006 groups and −0.34 ± 0.72 $\log_{10}$ IU/mL in the placebo group. The maximal HBsAg decrease in the study period was −0.34, −0.40, −0.46 $\log_{10}$ IU/mL in HH-006 treated groups, compared with −0.13 $\log_{10}$ IU/mL in the placebo group.

Conclusion: HH-006 was safe and well-tolerated and demonstrated antiviral activity, with an approximately dose-proportional PK profile, in treatment-naïve patients with CHB. Further studies are

warranted to explore HH-006's potential as single agent or combination use for functional cure of HBV.

LBP-014

Safety, tolerability, pharmacokinetics and pharmacodynamics of an orally innovative GalNAc-conjugated thyroid hormone receptor-beta agonist (Kylo-0603) in healthy volunteers: a multiple ascending dose study

Xingjiang Hu[1], Youlei Wang[1], Qiao Zhang[1], Caixia Yan[1], Zhuojun Zhou[1], Yumei Gu[2], Qinsheng Zhang[2], Tao Guan[2], Kunyuan Cui[2,3], Qingwei Zhao[1]. *[1]Zhejiang Provincial Key Laboratory for Drug Evaluation and Clinical Research, Department of Clinical Pharmacy, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Hygieia Pharmaceuticals Co., Ltd., Hangzhou, China; [3]Kylonova (Xiamen) Biopharma Co., Ltd., Xiamen, China*
Email: huxingjiang@zju.edu.cn

Background and aims: Metabolic dysfunction-associated fatty liver disease (MAFLD) affects over one-fourth of the global adult population and is the leading cause of liver disease worldwide. Kylo-0603, a liver-targeted small molecule, is an orally N-acetylgalactosamine-conjugated thyroid hormone receptor-β agonist designed to improve MAFLD by increasing hepatic fat metabolism and reducing lipotoxicity. A single-center, randomized, double-blind, placebo-controlled, phase 1 study aimed to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of Kylo-0603 in Chinese healthy volunteers (NCT06365580).
Method: Sixty participants were randomized to receive once-daily Kylo-0603 at doses of 1.2, 2, 4, 8, 12, and 16 mg, or placebo for 14 days. Subjects were followed for an additional 7 days off drug for safety assessment.
Results: Means age of 60 participants was 29.7 years old (SD: 5.45) and 50% was female. The exposure of Kylo-0603 exhibited nonlinear manner. The plasma concentrations of Kylo-0603 at doses of 1.2–16 mg were below the lower limit of quantification within 8 hours after administration on Day 1 or Day 14 (except for one participant in 16 mg cohort), without accumulation after multiple doses. The half-life of Kylo-0603 ranged from 0.5 to 1.5 hours. Kylo-0603 was primarily excreted though feces. Kylo-0603 was safe and well-tolerated in this study. No treatment- or dose-related trends were observed for adverse events (AEs). No serious AEs were reported. The majority of AEs and all treatment-related AEs were Grade 1. No gastrointestinal AEs were reported in Kylo-0603 group. No alanine aminotransferase elevations exceeded 1.5×ULN in 1.2–16 mg cohorts. The mean levels of thyroid hormones including thyrotropin (TSH), free triiodothyronine (T3), total T3, free thyroxine (T4) and total T4 in each dose cohort mostly fluctuated within the normal reference range, without symptoms or signs of thyroid dysfunction. Clinically meaningful placebo-adjusted reductions in serum low-density lipoproteins cholesterol levels were observed at doses of 8 mg, 12 mg and 16 mg ($p < 0.05$) on Day 15, with the maximal reduction up to 28.5% in 12 mg cohort. In addition, significant reductions in total cholesterol, Apolipoprotein B, and triglycerides were observed.
Conclusion: Kylo-0603 was safe and well-tolerated in Chinese healthy volunteers in this two-week study. It has great potential to become an innovative therapy for MAFLD with its beneficial effect on lipid parameters.

LBP-015

Thybetador, a potent and selective THR-β agonist: results from a phase 1 first-in-human study in healthy volunteers and participants with elevated LDL-C

Xiangwei Hua[1], Hualing Pan[1], Rong Deng[1], Jia Sun[1], Gaihong Wang[1], Guanguan Zhao[1], Shengsheng Yang[1], Guozhi Li[1], Yun Liu[2], Julia Yang[1], Zhenwei Zhang[1], Peter Wang[1], H. Eric Xu[1]. *[1]Cascade Pharmaceuticals, Inc, Shanghai, China; [2]Shanghai Xuhui District Central Hospital, Shanghai, China*
Email: eric.xu@cascadepharm.com

Background and aims: Thybetador (CS060380) is a novel thyroid hormone receptor-beta (THR-β) agonist. *In vitro*, Thybetador demonstrated high potency, and exhibited >100-fold selectivity for THR-β over THR-α (relative to T3). This Phase 1 first-in-human study evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of Thybetador in healthy volunteers and participants with elevated low-density lipoprotein cholesterol (LDL-C).
Method: The trial comprised two randomized, double-blind, placebo-controlled parts: a Single Ascending Dose (SAD) study (0.2, 1, 2, 5, and 10 mg) and a Multiple Ascending Dose (MAD) study (0.1–2 mg once daily). The SAD part included a food-effect sub-study to assess the impact of a high-fat meal on PK. Safety, PK parameters, and PD markers (including sex hormone-binding globulin [SHBG] and lipid profiles) were assessed.
Results: Thybetador was well tolerated in both SAD group and MAD group. The most common treatment-emergent adverse events (TEAEs) were transient elevations in ALT or AST and reversible reductions in free T4 or total T4, consistent with the mechanism of action. SAD exposure of Thybetador was linear within the dose range of 0.2–10 mg. Plasma concentrations peaked 2–4.5 hours post-dose, with a geo-mean half-life (t1/2) of 9.1–10.9 hours, supporting once-daily (QD) dosing. Food intake had no significant impact on PK. In the MAD study, steady state was achieved within approximately one week. Tmax and t1/2 were similar in SAD and MAD cohorts. The mean of Rac_AUCtau ranged between 1.166–1.495, indicating no obvious accumulation. SHBG, a key PD marker for THR-β activation, increased dose-dependently (0.25–2 mg), rising >100% at 0.25 mg and >200% at 2 mg. Significant reductions were observed in LDL-C, triglycerides (TG), total cholesterol (TC), apolipoprotein B (Apo-B) and Lp(a) after 14 days of treatment.
Conclusion: In this Phase I trial, Thybetador exhibited a favorable safety profile and PK characteristics in both SAD and MAD studies. Robust PD effects were observed in the MAD study. Based on these findings, Phase II investigations are currently ongoing.

LBP-016

Immunogenetic predictors of hepatitis D virus infection progression in Uzbekistan: implications for a national screening strategy

Malika Khodjaeva[1], Zebiniso Sofiya Ismailova[1], Erkin Musabaev[1], Nargiz Ibadullaeva[1], Aziza Khikmatullaeva[1], Shokhista Bakieva[1]. *[1]Research Institute of Virology, Republican Specialized Scientific and Practical Medical Center of Epidemiology, Microbiology, Infectious and Parasitic Diseases, Tashkent, Uzbekistan*
Email: drmusabaev1956@gmail.com

Background and aims: Hepatitis D virus (HDV) infection is the most severe form of viral hepatitis, characterized by rapid progression to liver cirrhosis and hepatic failure. The high prevalence of HDV in Uzbekistan necessitates early identification of patients at high risk of disease progression. National strategies, in accordance with Presidential Resolution No. PP-243 (May 16, 2022), include expanded HDV screening among patients with hepatitis B. Uzbekistan is currently the only Central Asian country implementing a systematic screening approach. Identification of clinically relevant immunogenetic markers is therefore of particular importance. This study aimed to investigate host immunogenetic factors associated with HDV clinical outcomes and assess their relevance for clinical practice and public health.
Method: Patients with HDV infection were stratified into: benign chronic hepatitis, progressive chronic hepatitis, and HDV-associated cirrhosis (Child-Pugh A-C). Immunogenetic analysis included human leukocyte antigen (HLA)-B Bw4/Bw6, interleukin-10 (IL10)-1082C>T (rs1800896), and interleukin-28B (IL28B) polymorphisms

(rs12979860, rs8099917). Associations between immunogenetic markers and disease severity were analyzed to identify predictors of progression for risk stratification and clinical decision-making.
Results: Patients with cirrhosis more frequently exhibited the HLA-B Bw4/Bw4 genotype and a licensed natural killer (NK) cells phenotype (OR 1.67 and OR 2.22). The IL10-1082 TT genotype was significantly more common in progressive hepatitis and cirrhosis (p = 0.033) and absent in benign cases. IL28B rs12979860 genotype distribution differed significantly (p = 0.001): TT predominated in progressive disease, whereas CC was associated with a benign course. The G allele (TG/GG) of rs8099917 was detected exclusively in progressive hepatitis and cirrhosis (p = 0.03). These findings demonstrate a strong association between host immunogenetic profile and HDV progression.
Conclusion: Immunogenetic markers, particularly within the HLA-B/KIR axis and cytokine pathways, are associated with HDV severity and may serve as predictors of progression. Their integration into clinical practice may enable early risk stratification, improve clinical decision-making, and optimize patient management. At the population level, this approach may reduce progression to cirrhosis and hepatic failure through earlier targeted intervention.

LBP-017

Longitudinal analysis of routine laboratory data prospectively identifies clinically significant hepatic fibrosis from the general population, outperforming standard fibrosis scores: validation from the LiveWell multi-modal screening study

Timothy Jobson[1,2], Catherine Denver[1,2], Christina Owen[1], Neil Stevens[2], Axelle Caudrillier[3], Yasmin Hamadache[3], Heath O'Brien[3], Patrick Short[3], Jamie Webb[3], Katie Barnes[3]. *[1]Somerset NHS Foundation Trust, Taunton, United Kingdom; [2]Predictive Health Intelligence Ltd, Wellington, United Kingdom; [3]Sano Genetics Ltd, London, United Kingdom*
Email: katie@sanogenetics.com

Background and aims: Clinically significant hepatic fibrosis (F2+) defines eligibility for emerging metabolic dysfunction-associated steatotic liver disease (MASLD) therapies, but population-level identification is challenging. hepatoSIGHT is a National Health Service (NHS) adopted tool using the Cumulative Liver Damage Index (CLDI, approximating the integral of alanine aminotransferase over time) derived from routine blood tests. We prospectively validated a two-stage approach: CLDI population enrichment followed by a multi-biomarker model including a polygenic risk score (PRS; PGS002283). Data available March 2026.
Method: The general population was risk-stratified by CLDI; the highest-risk 7% (cases) and age- and sex-matched controls across two age cohorts (25–35 and 45–55 years) were recruited for transient elastography (TE) and saliva-based genetic testing performed by Sano Genetics. Logistic regression models using longitudinal laboratory data in hepatoSIGHT were assessed by Receiver Operating Characteristic Area Under the Curve (ROC-AUC). Mediation analysis examined the PRS-CLDI relationship.
Results: 994 participants were recruited. CLDI significantly predicted F2+ fibrosis (TE greater than or equal to 8 kPa; odds ratio (OR) 3.87, p < 0.001) and F4 cirrhosis (OR 5.02, p < 0.01). The best hepatoSIGHT model (age, sex, CLDI, platelet minimum and mean, HbA1c mean; 45–55 age cohort) achieved ROC-AUC 0.748 (95% confidence interval (CI) 0.584–0.890). A model incorporating body mass index (BMI) and extended to the combined age cohorts (age, sex, BMI, CLDI, platelet mean) improved performance (ROC-AUC 0.884, 95% CI 0.79–0.957). This outperforms the published population-level AUC for Fibrosis-4 index (FIB-4) (0.572; Graupera et al., 2022). The number needed to scan (NNS) using TE to identify one F2+ case was 8. Mediation analysis showed a significant indirect effect of PRS via CLDI (p = 0.026), validating CLDI as capturing cumulative genetic hepatic risk.
Conclusion: hepatoSIGHT operates as a two-stage screen: CLDI enriches the highest-risk 7% from routine data; a multi-biomarker model then stratifies this group precisely. This achieves NNS of 8 for F2+ identification by TE, and outperforms published FIB-4 population benchmarks in discriminative performance. PRS mediation validates the biological coherence of CLDI. hepatoSIGHT offers a deployable, evidence-based pathway to identify patients eligible for emerging MASLD therapies. Validation in a large population is warranted.

LBP-018

Improvements in fatigue in patients with primary biliary cholangitis treated with elafibranor: patient-reported outcome measurement information system fatigue short form 7a (PFSF 7a) data from the phase III ELATIVE® trial

David E. Jones[1], Andreas E. Kremer[2], Cynthia Levy[3,4], Nuno Antunes[5], Darren Asquith[6], Nathan Touati[7], Mark Swain[8]. *[1]Translational and Clinical Research Institute and NIHR Newcastle Biomedical Research Center, Newcastle University, Newcastle Upon Tyne, United Kingdom; [2]Department of Gastroenterology and Hepatology, University Hospital Zurich, University of Zurich, Zurich, Switzerland; [3]Schiff Center for Liver Diseases, University of Miami, Miami, Florida, United States; [4]Division of Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, Florida, United States; [5]Ipsen, Cambridge, Massachusetts, United States; [6]Ipsen, London, United Kingdom; [7]Ipsen, Paris, France; [8]Liver Unit, Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, Alberta, Canada*
Email: david.jones@newcastle.ac.uk

Background and aims: Fatigue is the most common and debilitating symptom in primary biliary cholangitis (PBC). In the phase III ELATIVE® trial (NCT04526665), elafibranor (ELA) improved fatigue in patients (pts) with PBC. Here, a breakdown of the Patient-Reported Outcome Measurement Information System Fatigue Short Form 7a (PFSF 7a; a 7-item, 5-point Likert scale tool) was used to further assess the impact of ELA vs placebo (PBO) on fatigue, with changes in total T-score and individual items evaluated.
Method: In ELATIVE®, pts were randomised 2:1 to ELA 80 mg or PBO. Mean (standard error [SE]) change from baseline (BL; CfB) in individual PFSF 7a items raw score (1 = lowest fatigue; 5 = highest fatigue) and total PFSF 7a T-score (lower score represents greater improvements) and achievement of a minimal clinically important difference (MCID; T-score improvement ≥3) were evaluated through Week (Wk) 52 for pts with moderate-to-severe fatigue at BL (T-score ≥60). Statistical testing at Wk 52 was conducted using Student t-test and Fisher exact test for CfB and MCID, respectively.
Results: For pts receiving ELA vs PBO, 46/107 (43.0%) vs 20/52 (38.5%) had moderate-to-severe fatigue at BL. Improvements in PFSF 7a T-score with ELA vs PBO were observed through Wk 52 (mean [SE] CfB: Wk 4: −3.7 [0.9] vs −0.7 [0.9]; Wk 26: −5.6 [1.1] vs −3.9 [1.3]; Wk 52: −6.5 [1.2] vs −2.6 [1.6]; Wk 52: p = 0.076). Greater proportions of pts receiving ELA vs PBO achieved a MCID in PFSF 7a T-score at Wk 4 (24/45 [53.3%] vs 4/20 [20.0%]) and Wk 26 (29/45 [64.4%] vs 6/15 [40.0%]); at Wk 52, statistically significant differences for ELA vs PBO were seen (28/42 [66.7%] vs 5/16 [31.3%]; p = 0.020). Pts receiving ELA vs PBO had greater improvements (mean [SE] CfB) at Wk 52 for the majority of PFSF 7a items, particularly those evaluating mental and physical fatigue: 'extreme exhaustion' (−0.9 [0.2] vs −0.2 [0.3]); 'too tired to think clearly' (−0.7 [0.1] vs −0.2 [0.3]); 'too tired to bath or shower' (−0.7 [0.2] vs −0.1 [0.3]). These items showed greater improvements for ELA vs PBO at all timepoints assessed and had the highest proportions of pts reporting an improvement of ≥1 point/item at Wk 52 (61.9% vs 31.3%; 57.1% vs 31.3%; 54.8% vs 25.0%, respectively).
Conclusion: In these post hoc analyses, a significantly higher proportion of pts receiving ELA vs PBO achieved a MCID in fatigue reduction. Greater improvements with ELA vs PBO were observed through Wk 52 for most PFSF 7a items, suggesting ELA improves multiple aspects of fatigue in PBC.

LBP-019-YI

Data for action: real-world hepatitis c virus and human immunodeficiency virus co-and hepatitis c virus mono-infection epidemiology to inform strategic hepatitis c virus elimination in south africa

Bongani Khanyi[1], Murad Ruf[2], Morubula Manamela[3], Jayendrie Thaver-Kleitmann[3], Ntsakisi Maluleke[4], Lesego Lenabe[5], Sibahle Ngongo[5], Zinhle Makatini[6], Imraan Essa[7], Urvisha Bhoora[5], Nishi Prabdial-Sing[8]. *[1]University of the Witwatersrand-Medical School, Johannesburg, South Africa; [2]Gilead Sciences Europe, Uxbridge, Northern Ireland; [3]National Institute for Communicable Diseases, Johannesburg, South Africa; [4]Gilead Sciences South Africa, Johannesburg, South Africa; [5]University of Pretoria, Tshwane, South Africa; [6]Medical Faculty, Bloemfontein, South Africa; [7]Addington Hospital, Durban, South Africa; [8]National Institute for Communicable Diseases, University of the Witwatersrand, Johannesburg, South Africa*
Email: 2331628@students.wits.ac.za

Background and aims: Real-world data on hepatitis C virus (HCV) burden in South Africa (SA) is scarce. Modelling estimates for active HCV range between 265–920,000. Although, pan-genotypic DAAs are available in the public health sector since 2023, access is only through tertiary hospitals, currently. The 2022 WHO HCV guidelines include, along with harm reduction services, HIV treatment (ART) services as priority settings for integrated service delivery. Whereas SA is committed to elimination goals, funding is a limitation. At present, harm reduction services in SA are mostly reliant on donor funding with only the City of Tshwane providing state services. To inform elimination prioritisation in SA, we aimed to generate HCV epidemiological data in these public health service settings.
Method: We screened adult patients from five public HIV-ART clinics in four cities (2× Johannesburg, Tshwane, Cape Town, and Durban), and unselected People who use drugs (PWUD) clients with known HIV status from two harm reduction sites in Tshwane. HCV-Ab+ were centrally RNA confirmed. We calculated prevalence estimates with 95% confidence intervals overall, by site and sex, with Fisher's exact and Chi-square tests for associations.
Results: With 2,970 of 4,000 (74.3%) HIV-ART patients across five sites were tested, 63.7% were female. Overall HCV-RNA+/HIV coinfection prevalence in ART sites was 0.20% [0.04–0.36], all HCV infections were exclusively in males, 0.56% [CI: 0.11–1.01]. We found no significant prevalence variation across the five sites ($p > 0.05$). We also tested 151/200 (75.5%) PWUD clients, 87% were male, 81% were on Opiate agonist therapy (OAT). There were no significant differences in proportions of client sex or OAT) use between sites. 90% of HCV-Ab tested RNA+, overall RNA prevalence of 35% [CI:27.5–42.7]. More than a third (39%) were HIV coinfected. Testing is ongoing.
Conclusion: As all HCV infections were found in male patients at the adult public HIV ART clinics, once-off HCV screening in adult male HIV-ART patients may be considered. Moreso, we found high rates of active HCV infection with substantial proportions of HCV/HIV coinfection in PWUD clients across both harm reduction sites. To meaningfully advance HCV elimination and prevent accelerated liver disease in HIV coinfected patients, South Africa should embrace both, harm reduction services and public health care facilities at population-level and make DAA accessible through local clinics and community-based service models.

LBP-020

A global Delphi consensus to define chronic liver disease severity: replacing cirrhosis with a stage-based model

Aleksander Krag[1,2], Nikolaj Torp[1,2], Stine Johansen[1,2], Emmanuel Tsochatzis[3], Mary E. Rinella[4], Diana Romero[5], Cristina Ripoll[6], Jaime Bosch[7], Thomas Reiberger[8,9], Annalisa Berzigotti[7], Guadalupe Garcia-Tsao[10,11]. *[1]FLASH -, Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [2]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark; [3]UCL Institute for Liver and Digestive Health, Royal Free Hospital, University College of London (UCL), London, United Kingdom; [4]University of Chicago, Pritzker School of Medicine, Chicago, United States; [5]City University of New York Graduate School of Public Health and Health Policy (CUNY SPH), New York, United States; [6]Internal Medicine IV, Jena University Hospital, Friedrich Schiller University, Jena, Germany; [7]Department of Visceral Surgery and Medicine (Hepatology), Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [8]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [9]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [10]Digestive Diseases Section, Department of Medicine, Yale University, New Haven, United States; [11]Digestive Diseases Section, Department of Medicine, VA-CT Healthcare System, West Haven, United States*
Email: aleksander.krag@rsyd.dk

Background and aims: The term 'cirrhosis' has historically been used to define the late stage of chronic liver disease (CLD) based on histology. Evolving insights into disease mechanisms, wider availability of non-invasive tests (NITs), evidence for reversibility with effective etiologic therapies, and updated natural history studies suggest that the static concept of 'cirrhosis' no longer reflects current understanding of advanced chronic liver disease (ACLD). This study aimed to evaluate whether a modern stage-based definition of CLD severity is warranted among global stakeholders in hepatology.
Method: A structured, modified Delphi process was conducted to investigate international expert consensus, endorsed by the Baveno Cooperation and guided by an expert methodologist. Following a literature review and input from the Baveno Cooperation leadership, a conceptual framework was developed to inform the Delphi statements. Delphi panellists were identified by Baveno Cooperation nomination and through a literature review. Statements were scored using a 5-point Likert scale with opportunity to provide comments. Statements were revised between the Delphi rounds based on agreement and qualitative feedback to improve consensus. Consensus was predefined as a supermajority (≥67% 'agree' or 'somewhat agree').
Results: A total of 456 panellists from 52 countries across six continents participated (83% response rate; 456 of 547 invited). Round 1 included 24 statements, achieving a mean agreement of 86% and generating 1,458 comments. Round 2 had an 83% response rate (377 of 456), included 30 statements, and reached a mean agreement of 93%, with all statements achieving ≥85% agreement and 875 comments. Panellists agreed that cirrhosis-based terminology is outdated and the traditional reliance on histology is misaligned with current clinical practice given the widespread use of NITs. There was strong consensus that the term 'cirrhosis' does not provide sufficient granularity to identify clinically meaningful distinctions, particularly regarding the degree of portal hypertension. A stage-based framework for CLD severity (CLD stages I–IV) was strongly supported: CLD stage I (non-ACLD), CLD stage II (cACLD without clinically significant portal hypertension [CSPH]), CLD stage III (cACLD with CSPH) and CLD stage IV (decompensated, dACLD).
Conclusion: This global Delphi consensus demonstrates broad expert support for moving beyond cirrhosis-based terminology towards a stage-based definition of chronic liver disease.

Background and aims: Chronic Hepatitis D (CHD) is the most severe form of viral hepatitis and current treatments are limited. Brelovitug (BJT-778) is a fully human anti-hepatitis B surface antigen monoclonal antibody. AZURE-1 is a global, randomized, controlled, seamless Phase 2b/3 trial evaluating brelovitug versus delayed treatment (DT) for the treatment of CHD. Here we report on the efficacy and safety from the Phase 2b portion of AZURE-1.
Method: Participants were randomized 2:2:1 to receive open-label brelovitug 300 mg subcutaneous (SC) weekly (QW) self-administered at home, 900 mg SC every 4 weeks (Q4W) administered in the clinic, or delayed treatment (DT) for 24 weeks followed by brelovitug 300 mg QW. Key inclusion criteria were hepatitis D virus (HDV) RNA >500 IU/mL, ALT >upper limit of normal (ULN), and Child-Pugh Score <7; HIV co-infection and compensated cirrhosis with or without portal hypertension was allowed. There were no exclusion criteria for liver stiffness, bilirubin, albumin, INR or maximum ALT. The primary endpoint was a composite of virologic response (HDV RNA ≥2 $\log_{10}$ IU/mL decrease or undetectable HDV RNA) and ALT normalization at W24.
Results: A total of 53 participants were randomized; 21 to 300 mg QW, 20 to 900 mg Q4W, and 12 to DT. The mean (SD) age overall was 46 (8.2) years, 49 (92%) were White, 37 (70%) were male, and 28 (53%) had cirrhosis. Mean (SD) baseline HDV RNA was 5.5 (0.83) $\log_{10}$ IU/mL and ALT was 124 (95.3) U/L, including 11 (21%) with ALT ≥5×ULN and 8 (15%) with liver stiffness >25 kpa. At W12, virologic response occurred in 80% (16/20) including one out of window response, 50% (10/20), and 0% (0/12) for the 300 mg QW, 900 mg Q4W, and DT groups, respectively. At W12, mean (SD) ALT (U/L) values declined from 116 (91.2) at baseline to 46 (17.3) with 300 mg QW, 132 (105.5) to 51 (25.7) with 900 mg Q4W, and 124 (91.4) to 101 (51.7) in DT. Seven participants reported mild injection site reactions and 1 reported mild flu-like syndrome. There were no treatment-related SAEs, Grade ≥3 AEs, or AEs leading to study discontinuation. Further reductions in HDV RNA and ALT are observed after W12. Results at W24 will be shared at time of presentation as the trial is still ongoing.
Conclusion: In individuals with CHD with and without cirrhosis, brelovitug was associated with early improvements in HDV RNA, ALT and was well-tolerated. Multiple Phase 3 trials are ongoing.

Single-dose of a novel monoclonal anti-HBV antibody (HepB mAb19) demonstrates sustained HBsAg suppression beyond 48 weeks: interim results from first-in-human phase I RUHBV1 and SAMBA trials

Han Ngoc Le[1], Siri Nana Halling Svensgaard[2], Zijun Wang[3], Jesper Damsgaard Gunst[2], Vanessa Igbokwe[1], Sidsel Dahl Winther Andersen[2], Henriette Graversen[2], Andre Moraes Nicola[3], Caroline Zöllner[4], Martin Kluge[4], Rachel Scheck[1], Pinkus Tober-Lau[1], David Hillus[1], Münevver Demir[4], Frank Tacke[4], Leif Erik Sander[1], Florian Kurth[1], Michel C. Nussenzweig[3], Thomas Rasmussen[2], Marina Caskey[3], Christian Gaebler[1], Ole S. Søgaard[2]. *[1]Department of Infectious Diseases and Critical Care Medicine, Charité–Universitätsmedizin Berlin, Berlin, Germany; [2]Department of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark; [3]Laboratory of Molecular Immunology, The Rockefeller University, New York, United States; [4]Department of Hepatology and Gastroenterology, Campus Virchow-Klinikum (CVK) and Campus Charité Mitte (CCM), Charité—Universitätsmedizin Berlin, Berlin, Germany*
Email: ngoc-han.le@charite.de

Background and aims: Chronic hepatitis B (CHB) remains a significant global health burden with persistently low rates of functional cure. This interim analysis reports on HepB mAb19 (mAb19), a highly potent, broadly neutralizing monoclonal antibody targeting hepatitis B surface antigen (HBsAg) and incorporating a half-life-extending modification at the Fc region. HepB mAb19 is currently being evaluated in HBeAg-negative CHB patients with HBV DNA below lower limit of quantification receiving standard antiviral therapy in the SAMBA trial in Denmark and Germany and the RUHBV1 trial in the United States. Enrollment was completed in Mid-March 2026.
Method: A total of 35 participants were enrolled (71% male, median age 43 years), with a median HBsAg level of 2418 IU/mL and median liver stiffness below 7 kPa. 20 participants received a single intravenous infusion of mAb19 in four ascending dose groups: 1 mg/kg (n = 8), 3 mg/kg (n = 4), 10 mg/kg (n = 4), and 30 mg/kg (n = 4), with one to two placebo recipients per group. Another 15 participants were enrolled in the open-label group with a defined maximum tolerated dosing of 30 mg/kg. Participants are followed for up to 48 weeks with regular assessments of safety, clinical laboratory, pharmacokinetics, and HBV serology parameters.
Results: Rapid declines in serum HBsAg were observed within 24 hours post-infusion across all dose groups, with a mean reduction of 1.14 $\log_{10}$ IU/ml by day 7. While lower doses resulted in transient reductions lasting up to week 24, participants completing follow-up in the highest dose group demonstrated persistent HBsAg reduction beyond 48 weeks, accompanied by high anti-HBs responses, suggesting durable, dose-dependent antiviral effects of mAb19. To date, all participants receiving infusion with 30 mg/kg have maintained reduced HBsAg levels at follow-up, including one case of sustained HBsAg loss at week 24. No serious adverse events (SAEs) or dose-limiting toxicities were observed. All AEs were transient and predominantly mild (grade 1). Six transient infusion reactions presenting with flu-like symptoms were observed that were possibly related to high baseline HBsAg (mean HBsAg 12478 IU/ml).
Conclusion: HepB mAb19 demonstrated a favourable safety profile and induced rapid, dose-dependent reductions in HBsAg. Sustained suppression beyond 48 weeks and a case of HBsAg loss following a single infusion support its potential for functional cure and provide a strong rationale for further clinical development.

LBP-023

Real-world outcomes in patients with primary biliary cholangitis who initiated elafibranor treatment with baseline alkaline phosphatase levels between 1× to 1.67× the upper limit of normal

Cynthia Levy[1,2], Channa Jayasekera[3], Seema T. Meloni[4], Matthew Sobiesk[4], Deborah Nikolla[4], Christelle Pommie[5], Hugo Gomes da Silva[5], Christopher L. Bowlus[6]. [1]*Schiff Center for Liver Diseases, University of Miami, Miami, Florida, United States;* [2]*Division of Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, Florida, United States;* [3]*Mayo Clinic, Phoenix, Arizona, United States;* [4]*Ipsen, Cambridge, Massachusetts, United States;* [5]*Ipsen, Paris, France;* [6]*Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, California, United States*
Email: clevy@med.miami.edu

Background and aims: Elafibranor (ELA), a peroxisome proliferator-activated receptor (PPAR)-alpha/delta agonist approved as a second-line (2L) treatment (Tx) for primary biliary cholangitis (PBC), demonstrated significant efficacy in the phase III ELATIVE® trial (NCT04526665). Patients (pts) with mildly elevated alkaline phosphatase (ALP; <1.67× upper limit of normal [ULN]) were not included in ELATIVE®. However, these pts can have significant disease burden and could be candidates for Tx. To our knowledge, this is the first real-world study to examine outcomes in pts with PBC with ALP >1 to <1.67× ULN treated with a PPAR agonist.
Method: This retrospective, observational study used the US HealthVerity network, which links data from claims, electronic health and laboratory provider records. The study identification period was Jun 2024–Dec 2025. The date of first observed ELA exposure was defined as the index date (baseline [BL]). Adult pts with PBC who received ≥1 dose of ELA during the study identification period were included. BL characteristics were assessed at the most recent visit prior to index date. Biochemical responses (including change from baseline [CfB]) were assessed using laboratory data through month (M)6 post-index for pts that started ELA as monotherapy or with ursodeoxycholic acid, without another 2L Tx; a post hoc analysis examined the excluded cohort of pts with prior 2L Tx that was discontinued by index date.
Results: A total of 321 pts had ≥1 ELA dose and no prior 2 L Tx. Of those, 111 had both pre- and post-index data, 53 with BL ALP between >1 to <1.67× ULN. At BL, mean (SD) age was 57 (11) years and 94.3% were female. Mean (SD) duration of ELA Tx was 187 (119) days. Mean (SD) ALP decreased from 174 (33) U/L at BL to 131 (52) U/L by M6 ($p < 0.001$), with mean (SD) CfB of −42 (60) U/L and percent CfB of −22.1% (37.1). By M6, 84.9% had an ALP reduction and 58.5% achieved ALP normalisation. In a post hoc analysis of pts with prior 2L Tx (n = 15), mean (SD) ALP was 177 (30) U/L at BL and 144 (50) U/L by M6 ($p < 0.03$), with mean (SD) CfB of −34 (45) U/L and percent CfB of −18.9% (24.8). By M6, 80.0% had an ALP reduction and 46.7% achieved ALP normalisation.
Conclusion: This is the first real-world study to show the effectiveness of ELA in pts with PBC with BL ALP between > 1 and < 1.67 × ULN, where clinically and statistically significant ALP reductions were seen and the majority achieved normalisation by M6. These data may help inform decision-making regarding Tx optimisation.

LBP-024

In F0-F1 and F2-F3 MASH, ≥5% weight loss (WL) significantly lowers VCTE and ELF independent of biopsy fibrosis improvement; resmetirom and not placebo reduction of ELF and VCTE are associated with biopsy improvement of fibrosis, independent of WL

Rohit Loomba[1], Quentin M. Anstee[2], Rebecca Taub[3], Dominic Labriola[3], Robin Mogg[3], Suneil Hosmane[3], Jörn M. Schattenberg[4], Vlad Ratziu[5]. [1]*San Diego School of Medicine, San Diego, United States;* [2]*Newcastle, Newcastle, United Kingdom;* [3]*Madrigal Pharmaceuticals, Conshohocken, United States;* [4]*Saarland University Medical Center, Saarbrücken, Germany;* [5]*Inserm, Paris, France*
Email: rebeccataub@yahoo.com

Background and aims: Resmetirom (Res) is approved for the treatment of adults with MASH and liver fibrosis. Changes in liver stiffness (VCTE), and ELF, a test for F3/F4 stage, are proposed as surrogate endpoints for fibrosis response in MASH. Weight loss (WL) reduces liver stiffness and collagen markers in patients (pts) without significant liver fibrosis (F0-F1) who have obesity/metabolic risk in whom serum markers of fibrosis may be elevated. In Res and placebo (Pbo) treated pts, the impact of ≥5% WL on VCTE and ELF and association with biopsy fibrosis improvement (FI) was examined in F0–F1 and F2–F3 MASH from MAESTRO Phase 3 trials.
Method: Baseline (BL) and Week 52 (W52) VCTE, ELF components were determined in MAESTRO-NASH (NCT03900429) (F2–F3), and MAESTRO-NAFLD-1 (NCT04197479) (F0–F1). Logistic regression models were used to explore associations between Res or Pbo mediated changes (absolute difference for ELF, difference of log transformed for VCTE), changes in weight (≥5% vs <5% WL) and biopsy FI.
Results: In F0-F1 ~14% had ≥5% WL at W52. Mean BL VCTE was 7.6 kPA; ELF, 9.2. In F0–F1, Res did not reduce VTCE, ELF (doi: 10.1038/s41591-023-02603-1). VCTE was significantly reduced in F0–F1 with ≥5% WL (−1.7 kPa, −25.0% (80 mg), −1.2 kPa, −24.3% (100 mg), −1.6 kPa 22.4% (Pbo)) versus (v) <5% WL (0.0 kPa, −3.9% (80 mg); −0.3 kPa, −6.1% (100 mg), −0.3 kPa, −8.9% (Pbo)). ELF was reduced in ≥5% WL v <5% WL with P3NP component showing the most significant reduction: ≥5% WL, −8.8% (80 mg), −8.4% (100 mg), −11.0% (Pbo) v <5%WL, 2.5% (80 mg), −1.8% (100 mg), −2.7% (Pbo). In F2–F3, Res reduced VCTE and ELF (DOI: 10.1056/NEJMoa2309000). Mean BL VCTE was 13.3 kPa; ELF, 9.8. A subset had ≥5% WL at W52 (17% (80 mg), 22%(100 mg), 12% Pbo). VCTE was reduced with WL ≥5% (−3.0 kPa, −18.9% (80 mg), −6.1 kPa, −35.6% (100 mg), −3.5 kPa, −27.8%, (Pbo)) v WL<5% (−2.1 kPa, −10.7% (80 mg), −2.4 kPa, −11.4% (100 mg), −0.49, 0.5% (Pbo)). Independent effects of WL and FI, respectively, on VCTE were demonstrated for Res [$p < 0.001$, $p < 0.001$] and not Pbo [$p < 0.001$, $p = 0.13$]. ELF was reduced with WL ≥5% (−0.32 (80 mg), −0.53 (100 mg), −0.19 (Pbo) v WL<5% (−0.07 (80 mg), −0.07 (100 mg), 0.13 (Pbo)). Independent effects of WL and FI, respectively, on ELF were demonstrated for Res [$p < 0.001$, $p < 0.001$] and not Pbo [$p < 0.001$, $p = 0.14$].
Conclusion: Confounding effects of WL on ELF and VCTE that may be independent of FI must be considered in analyzing MASH treatments. With Res treatment, independent correlations of WL and FI with ELF/VCTE reductions were observed.

United Kingdom; [12]Houston Methodist Hospital, Houston Research Institute, Houston, United States
Email: NoureddinMD@houstonresearchinstitute.com

Background and aims: Efimosfermin alfa, a once-monthly fibroblast growth factor 21 analog, showed histological improvements in fibrosis and metabolic dysfunction-associated steatohepatitis (MASH) activity compared with placebo among participants (pts) with F2/F3 fibrosis after 24 weeks of treatment in a Phase 2 trial (NCT04880031). This *post hoc* analysis assessed changes in non-invasive tests (NITs) liver stiffness measurement (LSM), enhanced liver fibrosis (ELF), and type III collagen pro-peptide (PRO-C3) with efimosfermin in pts with F2/F3 at baseline/biopsy-confirmed MASH from parts B, C, and D.
Method: In this pooled analysis, 120 pts were randomized to receive placebo (n = 40), efimosfermin 225 mg every 4 weeks (Q4W; n = 12), or efimosfermin 300 mg Q4W (n = 68) for 24 weeks. The proportion of patients with a response (defined as ELF reduction ≥0.5, LSM reduction ≥30%, and fibrosis improvement of ≥1 stage without MASH worsening) and PRO-C3 levels were assessed at the closest point to 24 weeks.
Results: Pts receiving placebo, efimosfermin 225 mg, and efimosfermin 300 mg had a mean age of 54.4, 62.3, and 53.8 years and 43%, 75%, and 41% had F3 fibrosis, respectively. By 24 weeks, a higher proportion of pts in the placebo group (33%; 13/40) had no changes in LSM, ELF, or fibrosis improvement than those in the efimosfermin 225 mg (17%; 2/12) or efimosfermin 300 mg (21%; 14/68) groups. A greater proportion of pts in the efimosfermin 225 mg and 300 mg groups achieved a response (8% [1/12] and 7% [5/68], respectively) compared with placebo (3%; 1/40). There was also a greater combined reduction in LSM and ELF in the efimosfermin 225 mg and 300 mg groups (42% [5/12] and 19% [13/68], respectively) than placebo (10%; 4/40). PRO-C3 levels decreased by approximately 20% as early as Week 4 with efimosfermin and remained suppressed through Week 24, while placebo showed smaller, later changes.
Conclusion: Efimosfermin (both doses) produced greater and simultaneous improvements in LSM, ELF, and fibrosis versus placebo; the strong correlation between ELF and LSM improvements supports an early and sustained anti-fibrotic effect. Although there were study limitations with a small sample size of pts receiving efimosfermin 225 mg and the short duration used to assess clinical benefits, these NIT findings complement the histological results and support continued evaluation in F2/F3 MASH for longer durations in the Phase 3 trials.

LBP-026
Hepatic recompensation is associated with sustained transplant-free survival in primary biliary cholangitis decompensated cirrhosis: an international multicenter study from the Global-PBC study group

Email: axm8717@med.miami.edu

Background and aims: Hepatic recompensation has been described in several forms of chronic liver disease. Whether recompensation occurs in primary biliary cholangitis (PBC) remains understudied. We aimed to determine its rate in decompensated PBC and evaluate its impact on liver transplant-free survival (TFS).
Method: We conducted a retrospective international multicenter cohort study using the Global PBC Study Group database (16 centers; North America, South America, Europe, and Asia). Patients with PBC cirrhosis and a documented index decompensating event (ascites, variceal bleeding, or hepatic encephalopathy [HE]) were included; those with PBC-autoimmune hepatitis overlap or without proper follow-up were excluded. Recompensation was defined as the composite of MELD 3.0 < 10, absence of new decompensating event throughout 12 months after index decompensation (ID), and no ongoing use of diuretics or HE treatments for at least 12 months. All patients were treated with ursodeoxycholic acid for at least 12 months. Among patients event-free at 12 months, Kaplan-Meier and Cox regression assessed predictors of TFS. Sensitivity analysis used imputed MELD 3.0 values.
Results: Of 348 patients with decompensated PBC (86% female, median age at ID 63 years, median MELD 3.0 at ID 14), index events included ascites (73%), variceal bleeding (22%), and HE (14%). At 12 months, 195 patients (56%) were event-free; 12 (6.2%) achieved recompensation. Without the treatment-free criterion, 33 additional patients qualified (45 total, 23.1%). Among these 195 patients (139 events; median follow-up 50.1 months), those with MELD 3.0 < 10 at 12 months had markedly longer TFS than those without (median 97.5 vs 44.0 months; log-rank p < 0.001). Failure to achieve MELD 3.0 < 10 predicted liver transplantation or death on univariate (HR 2.34, 95%CI 1.45–3.78, p < 0.001) and multivariable analysis adjusted for treatment-free status (HR 2.34, 95%CI 1.45–3.78, p < 0.001). Treatment-free status alone was not independently associated with TFS (p = 0.3). Findings were consistent in the imputed sensitivity analysis for missing MELD 3.0 values (HR 1.92, 95%CI 1.27–2.89, p = 0.002).
Conclusion: Hepatic recompensation is not only achievable but clinically meaningful in decompensated PBC. A MELD 3.0 < 10 at 12 months identifies a subgroup with substantially improved TFS.

LBP-027
ARO-INHBE demonstrates clinically meaningful reductions in liver fat as monotherapy and in combination with low-dose tirzepatide in adults with obesity

John Baker[1], Jane Kerr[2], Renate Koops[3], Grigoriy Shekhtman[4], Eric Garcia-Medel[4], Ran Fu[4], James Hamilton[4], Ildiko Lingvay[5], Carel Le Roux[6], Rohit Loomba[7], Arun J. Sanyal[8], Rinki Murphy[9]. *[1]Middlemore Hospital, Te Whatu Ora Counties Manuaku, Middlemore, New Zealand; [2]New Zealand Clinical Research, Christchurch, New Zealand; [3]Aoteoroa Clinical Trials, Auckland, New Zealand; [4]Arrowhead Pharmaceuticals, Pasadena, United States; [5]Division of Endocrinology, University of Texas Southwestern Medical Center, Dallas, United States; [6]University College Dublin, Dublin, Ireland; [7]Division of Gastroenterology and Hepatology, University of California at San Diego, San Diego, United States; [8]Division of Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University, Richmond, United States; [9]Department of Medicine, Faculty of Medical and Health Sciences, University of Auckland, Auckland, New Zealand*
Email: r.murphy@auckland.ac.nz

Background and aims: Excess hepatic fat is a key driver of metabolic dysfunction-associated steatohepatitis (MASH). The *INHBE* gene encodes Activin E, a hepatokine thought to promote fat storage in adipocytes. Predicted *INHBE* loss of function variants are associated with a favorable metabolic profile and lower risk of type 2 diabetes (T2DM). ARO-INHBE is an investigational siRNA designed to silence hepatic *INHBE* expression.

Method: Participants with obesity (BMI 30–50 kg/m^2), with T2DM (HbA1c 6.7%–9.5%) and without T2DM (HbA1c <6.5%), were enrolled in a Phase 1/2a, randomized, placebo-controlled study evaluating the safety, tolerability, pharmacokinetics, and pharmacodynamics of ARO-INHBE. Participants received one (D1) or two (D1 and D29) subcutaneous doses of ARO-INHBE, as monotherapy (n = 6 per group, allocated 2:1 to 50, 100, 200, or 400 mg vs placebo[PBO]), or in combination with 5 mg tirzepatide (n = 12 per group; allocated 2:1 to 100, 200, or 400 mg vs PBO), and were followed for up to 169 days. The primary endpoint was incidence of treatment-emergent adverse events (TEAEs). Exploratory endpoints included changes in serum Activin E levels, body composition (MRI), liver fat content (LFC) by MRI proton density fat fraction (MRI-PDFF), and biochemical parameters.
Results: Of 121 participants, 78 (64.5%) were female; mean age was 45.3 years; 20% had T2DM. Baseline mean BMI was 36.9 kg/m^2, mean LFC was 8.9%; 42.1% had LFC ≥8%. ARO-INHBE achieved durable and dose-dependent reductions in serum Activin E, with a mean maximum reduction of 85.3% after a single 400 mg dose. Participants without T2DM with baseline LFC ≥8% receiving ≥200 mg ARO-INHBE monotherapy (n = 10; baseline LFC 14.5 ± 5.1%), had a placebo-adjusted post-dose LFC reduction of 44% ($p < 0.01$). In participants with T2DM (baseline LFC 16.9 ± 9.1%), combination therapy with ARO-INHBE 400 mg and TZP 5 mg led to greater LFC reduction than TZP alone (−59% [n = 7] vs −20% [n = 6], p = 0.01). ARO-INHBE was well-tolerated. Most TEAEs were mild and no TEAEs led to study or study drug discontinuation. No adverse laboratory trends (including HbA1c, ALT, and lipids) were observed.
Conclusion: RNAi-mediated silencing of *INHBE* with ARO-INHBE was well-tolerated and produced clinically meaningful reductions in LFC as monotherapy or combination therapy with low-dose tirzepatide in individuals with obesity with and without T2DM. Targeting Activin E may represent a novel therapeutic strategy for MASH and obesity-related metabolic dysfunction. The AROINHBE-1001 study is ongoing.

Republic of (formally known as Zaire); [2]University of North Carolina at Chapel Hill, Chapel Hill, United States; [3]École de Santé Publique, Université de Kinshasa, Kinshasa, Congo, Dem. Republic of (formally known as Zaire); [4]Abbott Laboratories, Altavista, United States; [5]Rutgers University, New Brunswick, United States; [6]Albert Einstein College of Medicine, New York City, United States*
Email: nnb4@unc.edu

Background and aims: Eliminating vertical transmission of hepatitis B virus (HBV) is possible by combining birth-dose (HepB-BD) vaccine and maternal antiviral prophylaxis; these strategies are not yet available in low-resource settings like Democratic Republic of Congo (DRC). We conducted a randomized double-blind placebo-controlled trial of prophylaxis for all HBV-infected women (regardless of viral load). Our trial is among the first to evaluate this approach and launched prior to updated WHO guidelines recommending prophylaxis-for-all where viral load testing is inaccessible.
Method: We screened pregnant women at three maternity centers in Kinshasa using HBV surface antigen (HBsAg) rapid tests. Eligible participants (age ≥18, HBsAg+, HIV−, normal creatinine <1.3 mg/dL) were randomized at 28–32 weeks' gestation to placebo or tenofovir disoproxil fumarate (TDF), taken once daily from enrollment through 4 weeks postpartum. Infants received HepB-BD, preferably <24 hours of life. Primary outcomes were effectiveness (infant HBsAg status at 6 months), safety (side effects, alanine aminotransferase (ALT) levels, and hepatitis flares [ALT ≥5× the upper limit of normal]) and surveyed acceptability of study activities. Secondary outcomes included medication adherence via survey and dried blood spot (DBS) tenofovir diphosphate (TFVdp) concentrations, and receipt/timeliness of HepB-BD.
Results: 307 of 14,027 (2.2%) pregnancies screened were HBsAg+. 119/164 (73%) enrolled mothers and 115/151 (76%) infants completed follow-up. There was no vertical transmission: 115 infants tested HBsAg-negative at 6 months. No major safety concerns were observed: 34 (41%) TDF and 24 (29%) placebo recipients reported mild-to-moderate side effects, ALT levels were similar between arms, and there were no hepatitis flares. Acceptability was high (93% in placebo and 87% in TDF arm). Adherence was lower by DBS TFVdp concentrations than self-report: 42% on TDF reported taking 2–6 doses/week and 58% took 7 doses/week, but concentrations indicated 84% took <2, 16% 2–6 and 0% 7 doses/week. 85% of infants received HepB-BD; 53% were timely, with lower coverage in the TDF vs placebo arm (81% vs 89% vaccinated; 49% vs 56% timely). Viral load testing is in progress.
Conclusion: No infants were HBV+ in this prophylaxis-for-all plus HepB-BD trial in DRC, despite suboptimal antiviral adherence and untimely birth-dose vaccine. A layered approach was safe and should be considered in DRC and similar low-resource settings to maximize prevention.

LBP-029

Weight loss–independent Glucagon effect led to rapid, clinically significant reductions in MASH severity, including steatosis and liver stiffness, during a 48-week randomized controlled trial of dual agonist DD01

Mazen Noureddin[1,2], Rashmee Patil[3], Dimple Desai[4], Rohit Puskoor[5], Winston Dunn[3,6], Jaehee Shin[7], Dennis To[8], Adam Bell[8], Daniel Lee[8], Yen-Huei Lin[8]. *[1]Houston Methodist Hospital, Department of Medicine, Sherrie and Alan Conover Center for Liver Disease and Transplantation, JC Walter Jr Transplant Center, Houston, United States; [2]Houston Research Institute, Houston, United States; [3]Pinnacle Clinical Research, San Antonio, United States; [4]South Texas Research Institute, Edinburg, United States; [5]Pinnacle Clinical Research, Austin, United States; [6]University of Kansas Medical Center, Kansas City, United States; [7]D&D Pharmatech Co, Seongnam-si, Korea, Rep. of South; [8]Neuraly, Inc., Gaithersberg, United States*
Email: noureddinmd@pinnacleresearch.com

Background and aims: DD01 is a dual GLP-1/glucagon receptor agonist designed to leverage complementary metabolic pathways for the treatment of MASLD/MASH. While GLP-1 receptor agonism improves glycemic control and reduces caloric intake, glucagon receptor activation promotes hepatic lipid oxidation, increases energy expenditure, and may directly reduce liver fat independent of weight loss. DD01 is being investigated for these liver-directed effects in MASH.
Method: DD01-DN-02 is an ongoing phase 2 48-week randomized, double-blind, placebo-controlled trial (NCT06410924), with endpoints at 12 (primary) and 48 (secondary) weeks. Key inclusion criteria for this study are ≥10% liver fat content (LFC) by MRI-PDFF and having 2 metabolic risk factors (MASLD population) OR biopsy showing F1–F3 fibrosis with NAS≥4 (MASH population). Participants were randomized 1:1 to receive 40 mg DD01 (with 2-week dose escalation only) or placebo weekly via subcutaneous injection.
Results: A total of 67 patients were randomized, 33 to the DD01 arm and 34 to the placebo arm. DD01 treatment resulted in substantial and clinically meaningful reductions in hepatic steatosis, with >50%

reduction in LFC in >70% of subjects after 12 weeks ($p < 0.0001$ vs placebo). Rapid reductions in LFC were accompanied by significant reductions in liver stiffness as assessed by MRE and compared to placebo-treated subjects (−19.7 vs −7.2; $p < 0.01$) and a significant relative reduction in ELF score (−2.5 vs 1.5; $p < 0.01$). In DD01-treated patients who lost ≥5% bodyweight at 12 weeks, there was an 81.1% (−85.3, −76.9) reduction in MRI-PDFF from baseline ($p < 0.0001$). Among patients with <5% bodyweight loss, those treated with DD01 achieved a 37.4% reduction in MRI-PDFF (95% CI, −72.9, −1.9), versus an increase of 1.6% (−30.4, 33.6) in placebo subjects. In the same population, there was a 19.2% (−37.5, −0.9) reduction in MRE in the DD01 arm, versus a 7.7% (−24.2, 8.9) reduction in the placebo arm ($p = 0.02$). Histological outcomes, including Week 48 biopsy data, are expected to be available at the time of conference presentation.
Conclusion: DD01 demonstrated significant reductions in liver fat and improvements in markers of MASH severity at 12 weeks, including in patients with minimal weight loss, supporting potential weight-independent hepatic effects. Further data, including histological outcomes at 48 weeks, will help clarify the durability and clinical relevance of these findings.

LBP-030

Rotational thromboelastometry–guided transfusion strategy versus conventional management in difficult-to-treat acute variceal bleeding in ACLF: a randomised controlled trial

Madhumita Premkumar[1], Prerna Sharma[1], Anchal Sandhu[1], Kamal Kajal[1], Harish Bhujade[1], Arka De[1], Sweta Rose[1], Muhammad Ashraf[1], S. Balaraja[1], Naveen Dandia[1], Ajay Kumar Duseja[1], Jasmina Ahluwalia[1], Narender Kumar[1], Deepy Zohmangaihi[1], K. Rajender Reddy[2]. *[1]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [2]Penn Medicine, Philadelphia, United States*
Email: drmadhumitap@gmail.com

Background and aims: Acute variceal bleeding (AVB) in acute-on-chronic liver failure (ACLF) is portal hypertension-driven and managed with vasoactive therapy and endoscopic control. However, a subset may be difficult to treat, requiring substantial transfusion support, predisposing to adverse events (AEs).
Method: In this single-centre, randomised, double-blind trial, patients with difficult-to-treat AVB were assigned (1:1) to a rotational thromboelastometry (ROTEM)-guided or a standard coagulation test (SCT)-guided transfusion strategy. Difficult-to-treat AVB was defined as (i) bleeding from multiple sites in addition to the primary variceal source (esophageal [EV], gastric[GV], or both), including post-EVL ulcer bleeding; and/or (ii) failure to control bleeding despite appropriate pharmacologic and endoscopic therapy, and/or (iii) requirement for escalation to rescue therapies such as balloon tamponade, Danis-Ella self-expanding metal stent(SEMS) placement, or pre-emptive or salvage TIPS. The primary endpoint was the rebleeding rate at 48 hours, Day 5, and Day 42. Secondary endpoints included blood component utilisation, intensive care need, AEs, and survival.
Results: Of 1,341 screened patients, 262 were randomised (ROTEM, n = 132; SCT, n = 130; aged 45.1 ± 11.6 years; MELD-Na 24.2 ± 9.7; 89% men; 64.5% alcohol-associated; 73% had shock). Difficult-to-treat bleeding included multiple bleeding sites (n = 113), active spurting (n = 112), or failure-to-control bleed (n = 37; 17-TIPS and 20-SEMS). Bleeding sources were small esophageal varices (EV, 9.2%), large EV (76.7%) and gastric varices (14.1%). Baseline characteristics were comparable. Rebleeding rates at 48–120 hours (4.6%), 6–42 days (13.4%), and 42–180 days (8.8%) were similar. ROTEM significantly reduced the need for fresh frozen plasma (29.2% vs 7.6%) and platelet units (26.9% vs 9.1%; $p < 0.001$), and transfusion-related AEs (6.8% vs 14.6%; $p = 0.047$), without differences in ICU admission or 180-day mortality (34.7%). Independent predictors of rebleeding were multiple bleeding sites (adjusted hazard ratio[aHR] 1.9;95%CI:1.1–2.5; $p = 0.007$) and CLIF-C ACLF score (aHR 1.04; 95%CI: 1.01–1.07; $p = 0.022$). Rebleeding (subdistribution HR [sHR] 1.4; 95%CI:1.2–3.9; $p = 0.026$), and Grade 2 ACLF grade (sHR 5.0;95%CI:1.5–16.3; $p = 0.007$), and Gr 3 (sHR 18.9;95%CI:5.5–65.6; $p < 0.001$) predicted 180-day mortality.
Conclusion: In ACLF with difficult-to-treat AVB, ROTEM-guided transfusion reduced plasma and platelet exposure and AEs without compromising bleeding control or survival.

LBP-031

AHB-137 monotherapy elicits high functional cure rates and sustained DNA suppression in treatment-naïve chronic hepatitis B participants: results from an ongoing phase II study

Yunqing Qiu[1], Haibing Gao[2], Dazhi Zhang[3], Youwen Tan[4], Meihong Yu[1], Xiaowei Xu[1], Xiangmei Wang[2], Shan Zhong[3], Xingbei Zhou[4], Mingyue Chen[5], Kaili Zhang[5], Chen Yang[5], Yeming Pan[5], Di Zhao[5], Miao Wang[5], Cheng Yong Yang[5,6], Guofeng Cheng[5,6], Hao Wang[5]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]Mengchao Hepatobiliary Hospital of Fujian Medical University, Fuzhou, China; [3]The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China; [4]The Third People's Hospital of Zhenjiang, Zhenjiang, China; [5]Ausper Biopharma Co., Ltd., Hangzhou, China; [6]Ausperbio Therapeutics Inc., Foster City, United States*
Email: qiuyq@zju.edu.cn

Background and aims: AHB-137 has demonstrated promising efficacy with a favorable safety profile in nucleos(t)ide analogue (NA) suppressed HBeAg-negative chronic hepatitis B (CHB) patients. The ongoing phase II study (NCT06829329) evaluates AHB-137 in treatment-naïve CHB patients. Here we present the End of Study (EOS) results from Part A.
Method: Part A is a randomized, double-blind, placebo-controlled study in treatment-naïve CHB participants (baseline (BL) HBsAg 100–10,000 IU/mL, HBV DNA 20–2,000 IU/mL). Participants received 16-week AHB-137 (300 mg) or placebo (4:1) weekly as monotherapy (without NA), followed by a 24-week off-treatment follow-up. Primary endpoint was complete response (CR; HBsAg <0.05 IU/mL and HBV DNA <10 IU/mL) at End of Treatment (EOT). Functional cure (FC; sustained CR) was evaluated at EOS (24 weeks off all treatment). Efficacy and safety were evaluated using per-protocol set (PPS) and safety set (SS), respectively.
Results: The PPS included 31 participants (AHB-137, n = 25; placebo, n = 6). AHB-137 monotherapy demonstrated rapid and potent HBV DNA suppression, with 100% of participants achieving HBV DNA <10 IU/mL by week 16 (EOT). Profound HBsAg reduction was also observed: 84% (16/19) of participants with BL HBsAg ≤3,000 IU/mL achieved HBsAg loss by EOT; all 6 participants with BL HBsAg >3,000 IU/mL showed ≥4.5 $\log_{10}$ IU/mL HBsAg reduction, and 3 achieved HBsAg loss. Overall, 68% (17/25) achieved CR at EOT. Safety was consistent with prior studies in NA-suppressed patients, with most treatment related adverse events being Grade 1–2, including reversible ALT/AST elevations associated with rapid HBsAg decline. One treatment-related SAE was reported, characterized by ALT elevation with concomitant bilirubin and HBV DNA increases. No clinical symptoms were reported, and the event resolved completely without sequelae. At EOS, 32% (8/25) achieved FC. Responses were particularly favorable in participants with BL HBsAg ≤1,000 IU/mL, with 70% (7/10) achieving FC. Among those with BL HBsAg >1,000 IU/mL, 33% (5/15) achieved partial cure at EOS, with sustained HBV DNA suppression and HBsAg <10 IU/mL.
Conclusion: In treatment-naive CHB participants, AHB-137 monotherapy demonstrated potent inhibition of HBV DNA replication and profound reduction of HBsAg, resulting in a high FC rate. Overall, AHB-137 was generally well-tolerated, coupled with durable off-treatment HBV DNA suppression. These data support the further development of AHB-137 in a broader CHB population.

LBP-032

Denifanstat and resmetirom combination therapy rapidly decreased atherogenic lipids in healthy adults in Phase 1 open-label trial

Mary E. Rinella[1], Arun J. Sanyal[2], Wen-Wei Tsai[3], Shipra Gupta[3], Cristina Alonso[4], Katharine Grimmer[3], Eduardo Martins[3], Marie O' Farrell[3], Rohit Loomba[5]. *[1]University of Chicago, Chicago, IL, United States; [2]Virginia Commonwealth University School of Medicine, Richmond, VA, United States; [3]Sagimet Biosciences, San Mateo, CA, United States; [4]Rubio Metabolomics, Derio, Bizkaia, Spain; [5]UC San Diego School of Medicine, La Jolla, CA, United States*
Email: wen-wei.tsai@sagimet.com

Background and aims: Increased *de novo* lipogenesis drives development of MASH, with fatty acid synthase (FASN) being the key enzyme. In a Ph2b trial, an oral FASN inhibitor Denifanstat (Deni) improved fibrosis and MASH resolution and prevented progression to cirrhosis. Resmetirom (Res), an FDA-approved thyroid hormone receptor beta agonist for MASH with F2/F3 fibrosis, reduced liver fat by increasing lipid oxidation. Combination of Deni and Res may increase efficacy through complementary mechanisms of liver fat reduction and Deni's direct anti-fibrotic effect, as demonstrated in preclinical MASH models. This Ph1 trial evaluated safety, PD and PK of the combination.
Method: Forty healthy adults (20/cohort) received 50 mg Deni and weight-based Res (80/100 mg). Cohorts 1 and 2 completed 7 days of monotherapy lead-in for Deni or Res respectively followed by 7 days of combination therapy. Blood was analyzed for multi-omic profiling, and Deni and Res PK.
Results: All treatments were generally well tolerated. Total cholesterol was significantly decreased by 23.4 and 16.4 mg/dL at the end of treatment (EOT) in cohorts 1 and 2 ($p < 0.001$), and decreased by 6.6 and 13.2 mg/dL with monotherapy of Deni and Res at day 7. The observed reductions ranged from ~1.1-fold decrease to greater than a 2.4-fold decrease relative to a hypothetical additive reduction, suggesting a potential synergistic lipid lowering effect with combination. LDL-cholesterol also dropped by 16.7 mg/dL (cohort 1) and 13.6 mg/dL (cohort 2) at EOT ($p < 0.001$). Polyunsaturated triglycerides (TG) were specifically increased by 2-week Deni treatment, while Deni and Res decreased saturated TG both alone and in combination. Serum sex hormone binding globulin was increased by 40% with Res monotherapy ($p < 0.001$), but not with Deni, and further increased to 58% with combination therapy at EOT ($p < 0.001$), showing rapid target engagement for Res. At day 7 (monotherapy) and day 14 (combination), plasma $AUC_{0\text{-}tau}$ (ng*h/mL) for Deni was 13110 and 14970; for Res $AUC_{0\text{-}tau}$, it was 7054 and 4580.
Conclusion: These Phase 1 results showed strong target engagement for Deni and Res, alone and in combination. The combination significantly reduced atherogenic lipids, suggesting cardiovascular benefits. Together with prior fibrosis improvement data, the safety, PD/biomarker and PK results support further clinical evaluation of Deni/Res combination for MASH and fibrosis.

Elafibranor treatment results in rapid reductions in biochemical markers and symptom burden in real-world practice: interim results from the prospective, non-interventional ELFINITY phase IV global study in patients with primary biliary cholangitis

Jörn M. Schattenberg[1,2], Peter Fickert[3], Kris V. Kowdley[4,5], Ashis Mukhopadhya[6], Seema Jaitly[7], Christelle Pommie[8], Marwan Sleiman[8], Phil Troke[7], Michael Trauner[9]. *[1]Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany; [2]Saarland University, Saarbrücken, Germany; [3]Department of Internal Medicine, Division of Gastroenterology and Hepatology, Medical University Graz, Graz, Austria; [4]Liver Institute Northwest, Seattle, United States; [5]Elson S. Floyd College of Medicine, Washington State University, Washington, United States; [6]Department of Gastroenterology, Aberdeen Royal Infirmary, NHS Grampian, Aberdeen, United Kingdom; [7]Ipsen, London, United Kingdom; [8]Ipsen, Paris, France; [9]Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*
Email: joern.schattenberg@uks.eu

Background and aims: Elafibranor (ELA) is a peroxisome proliferator-activated receptor (PPAR)-alpha/delta agonist approved for primary biliary cholangitis (PBC) second-line treatment. We present Month (M)3 data from the ongoing global, prospective, non-interventional phase IV ELFINITY study (NCT06447168) assessing real-world effectiveness and safety of ELA.
Method: ELFINITY will recruit ~424 patients (pts) receiving ELA 80 mg/day in real-world settings, to be followed for up to 5 years. Change from baseline (BL; CfB) in ALP, ALP normalisation and biochemical response (ALP <1.67× upper limit of normal [ULN] with ≥15% reduction from BL, and TB ≤ ULN) were reported at M3. A subgroup analysis was conducted to evaluate obeticholic acid (OCA)-experienced pts in ALP categories (<1, 1–<1.67, 1.67–<3 and ≥3× ULN) at BL and at M3. Moderate-to-severe (mod–sev) fatigue was defined as PBC-40 Fatigue ≥29 or Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue ≤30 (lower scores indicate higher fatigue), and mod–sev pruritus as PBC-40 Itch ≥7 or 5-D Itch ≥12. Pts with mod–sev symptoms achieving minimum clinically important differences (MCID) were reported (improvements PBC-40 Fatigue ≥5, PBC-40 Itch ≥1.5 and 5-D Itch ≥3). FACIT-Fatigue CfB was reported at M3. Pts receiving ≥1 dose were assessed. Completion of PRO instruments was not mandatory; missing data were not imputed.
Results: As of Oct 25, 55 pts were included in this analysis; 53 received ≥1 dose. Of pts with BL data, 27/51 (53%) had ALP ≥1.67× ULN. Mean (SD) ALP CfB to M3 was –0.7× ULN (0.7). At M3, 28/51 (55%) had biochemical response and 11/49 (22%) with BL ALP > ULN had ALP normalisation; 3 maintained normal BL ALP to M3. Of OCA-experienced pts, 7 improved and 1 worsened by 1 ALP category at M3; 8 maintained the same category. At BL, 25/44 (57%) had mod–sev fatigue by PBC-40 Fatigue and 18/44 (41%) by FACIT-Fatigue. In these pts, 8/14 (57%) improved ≥ MCID in PBC-40 Fatigue and mean (SD) FACIT-Fatigue CfB was 8.2 (13.1; n = 10) at M3. BL mod–sev pruritus was reported in 9/44 (20%) pts by PBC-40 Itch and 14/43 (33%) by 5-D Itch, of whom 3/3 (100%) and 6/8 (75%) improved ≥ MCID at M3. By M3, 6 pts discontinued. 26/53 (49%) had TEAEs, none serious/severe. TEAEs in ≥5 pts included fatigue (n = 6), headache (n = 5), diarrhoea (n = 5) and nausea (n = 5).
Conclusion: In this M3 interim analysis, ELA led to rapid improvements in ALP and both fatigue and pruritus, and was well tolerated, suggesting ELA is effective in real-world practice.

LBP-034-YI

Real-world experience with seladelpar in primary biliary cholangitis: first results from the Italian RESTART-PBC study

Background and aims: A substantial proportion of patients with PBC do not respond adequately to first-line UDCA therapy. Seladelpar, a selective PPAR-δ agonist, has been recently approved as second-line treatment. The RESTART-PBC study aims to evaluate its effectiveness and safety in a real-world setting.
Method: In this multicenter observational study, adult patients from the Italian PBC Registry treated with seladelpar according to approved criteria were included. Prior seladelpar trial participants were excluded. Biochemical response was evaluated in those with at least one follow-up assessment, and defined as: adequate (ALP <1.67×ULN and normal bilirubin), POISE (adequate plus ≥15% ALP reduction), and complete (normal ALP and bilirubin). Symptoms were assessed using Worst Itch Numeric Rating Scale (WI-NRS), PBC-40, and 5-D Itch. Longitudinal changes were analyzed with linear mixed-effects models and reported as LS-means (95%CI). Kaplan–Meier estimates were used for cumulative response.
Results: Overall, 167 patients were included [median age 55 years; 90% female; median disease duration 6.3 years; 54 (32%) with cirrhosis; 19 (11%) with PBC/autoimmune hepatitis variant]. Prior second-line exposure included fibrates (48 patients, 29%) and/or obeticholic acid (96 patients, 57%), with median washouts of 7 (IQR 0–287) and 189 (IQR 110–249) days, respectively. At baseline, 48% of patients were already in adequate and 9% in complete response. Among the 129 patients with at least one follow-up assessment, median follow-up after seladelpar start was 6 months. Probabilities of maintaining/attaining adequate, POISE, and complete response were 67%, 46%, and 31% at 3 months, and 80%, 62%, and 42% at 6 months, remaining stable at 9 months. Responses were similar regardless of prior second-line therapy or washout duration. Discontinuation occurred in 3 patients (2.4%): 2 for intolerance and 1 for drug interaction. WI-NRS significantly decreased at 3 months (−1.03; −40%) and over time ($p < 0.001$). Among patients with WI-NRS≥4, 58% improved to <4. Improvements were also observed in PBC-40 total score ($p < 0.001$) and fatigue ($p = 0.030$).
Conclusion: These interim real-world data confirm seladelpar effectiveness and safety regardless of prior second-line exposure. Initiation at ALP <1.67×ULN in a substantial subgroup of both switch and naïve patients suggests a shift toward earlier, proactive treatment aiming at ALP normalization, particularly in advanced fibrosis.

LBP-035

Scalable bioreactor production of functional iPSC-derived hepatic microtissues demonstrates unprecedented therapeutic efficacy in a preclinical model of acute liver failure

Dilyana Todorova[1], Elise Warter[1], Kenita Fock-Sing[1], Helene Riesterer[1], Charlene Francois[1], Solenn Guilbert[1], Jens Schroeder[1], Emilie Faggiani[1], Peter Andersen[1,2]. [1]*Treefrog Therapeutics, Bordeaux, France;* [2]*Johns Hopkins School of Medicine, Department of Medicine, Baltimore, United States*
Email: dilyana.todorova@treefrog.fr

Background and aims: Pluripotent stem cell (PSC)–derived cell replacement therapies represent a promising strategy for restoring liver function in patients suffering from multiple types of liver disease including acute or chronic liver failure. Early clinical and preclinical studies have demonstrated the safety and feasibility of PSC-derived approaches, including both single-cell suspensions and 3D tissue formats. However, clinical efficacy remains limited, underscoring the need for improved graft functionality and robust, scalable manufacturing processes to enable clinical translation and commercialization.
Method: iPSC-derived hepatic microtissues were generated using TreeFrog Therapeutics' proprietary high-throughput cell encapsulation technology (C-Stem™) in standard stirred-tank bioreactors, creating a biomimetic 3D microenvironment that supports growth factor-guided differentiation. In vitro functionality was assessed by quantifying albumin, alpha-1-antitrypsin (A1AT), factor VII secretion, urea production, and cytochrome P450 (CYP3A4) activity in comparison with primary human hepatocytes (PHH). Comprehensive characterization of microtissue composition and cellular identity was performed using molecular and histological analysis. In vivo efficacy was evaluated in a carbon tetrachloride (CCl_4)-induced mouse model of acute liver failure following transplantation of microtissues on a biocompatible scaffold.
Results: iPSC-derived hepatic microtissues generated with C-Stem™ displayed expression of key hepatic markers, characteristic morphology and robust functional activity. Levels of albumin, A1AT, factor VII secretion, ureagenesis, and CYP3A4 activity approached or exceeded those observed in PHH. In vivo, transplantation of hepatic microtissues resulted in a 70% increase in survival in CCl_4-treated mice compared to controls, demonstrating significant therapeutic benefit comparable to PHH.
Conclusion: This study demonstrates the superior functional performance and therapeutic efficacy of C-Stem™-produced iPSC-derived hepatic microtissues in a preclinical model of liver failure. The observed survival benefit, combined with a scalable and reproducible manufacturing process, supports the development of a clinically and commercially viable cell therapy product and provides a

strong rationale for progression toward clinical trials following safety validation.

LBP-036

Pemvidutide treatment led to fibrosis regression after 24 weeks in patients with metabolic dysfunction-associated steatohepatitis: quantitative digital pathology analysis from the IMPACT phase 2b, multicenter, randomized, placebo-controlled trial

Naim Alkhouri[1,2], Shaheen Tomah[3], Julio Gutierrez[3,4], John Suschak[3], Yukti Choudhury[5], Elaine Chng[5], Jay Yang[3], M. Scot Roberts[3], Rachel Garner[3], Sarah Browne[3], M. Scott Harris[3], Christophe Arbet-Engels[3], Mazen Noureddin[1,6,7]. Ltd, Singapore, Singapore;* [6]*Houston Methodist Hospital, Houston, United States;* [7]*Houston Research Institute, Houston, United States*
Email: nalkhouri@summitclinicalresearch.com

Background and aims: Pemvidutide is a balanced 1:1 glucagon/GLP-1 dual receptor agonist in development for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) where the direct hepatic effects of glucagon may provide greater efficacy over existing therapies. IMPACT was a 48-week, phase 2b, randomized, placebo-controlled, double-blind trial in patients with biopsy-confirmed MASH and fibrosis stage F2 or F3 (NCT05989711). At the week 24 (W24) primary endpoint, pemvidutide treatment showed statistically significant histologic MASH resolution and trends toward fibrosis improvement by conventional pathology reading. Artificial intelligence (AI) and noninvasive tests (NITs)-based analyses showed consistent evidence of anti-fibrotic activity as early as 24 weeks. Here, we evaluated fibrosis regression using second harmonic generation (SHG)/two-photon excited fluorescence (TPEF) microscopy imaging with a quantitative AI-based image analysis algorithm, Histoindex qFibrosis®.
Method: 212 patients were randomized 1:2:2 to receive once-weekly subcutaneous pemvidutide (1.2 mg or 1.8 mg) administered without dose titration, or placebo (PBO). Between January and March 2026, biopsies from 183 patients (1.2 mg [n = 35]; 1.8 mg [n = 77]; PBO [n = 71]) with unstained slides available at baseline (BL) and W24 were imaged by SHG/TPEF and analyzed using qFibrosis®. The qFibrosis® analysis incorporated a correction for the steatotic area of each BL and W24 slide image.
Results: At W24, qFibrosis®-based continuous analyses showed significant improvements in fibrosis in both the 1.2 mg and 1.8 mg pemvidutide doses. Mean changes in continuous qFibrosis® values of −1.25 and −1.08 were observed in the 1.2 mg and 1.8 mg, respectively, compared with −0.15 in PBO ($p < 0.001$ for both). Regression of fibrosis by at least 1-stage occurred in 68.6% ($p < 0.001$ vs. PBO), 54.5% ($p = 0.002$ vs. PBO), and 29.6% of patients in the 1.2 mg, 1.8 mg, and PBO groups, respectively. Overall, 58.9% of patients receiving pemvidutide had a ≥1 qFibrosis® stage regression.
Conclusion: Pemvidutide treatment for 24 weeks resulted in significant fibrosis regression in patients with F2 or F3 MASH as measured by qFibrosis® quantitative digital pathology. These data, together with previous AI- and NIT-based analyses, may support an antifibrotic effect with pemvidutide treatment as early as 24 weeks.

LBP-037

Seladelpar leads to decreases in serum proteins associated with PBC disease severity: proteomic analysis from the pivotal RESPONSE trial

Michael Trauner[1], Yan Liang[2], Peyvand Amini[2], Grant Budas[2], Kyung Min Kwon[2], Barry Crittenden[2], Anna Zagorska[2]. [1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria;* [2]*Gilead Sciences Inc., Foster City, United States*
Email: anna.zagorska@gilead.com

Background and aims: Seladelpar (SEL), a first-in-class delpar (selective PPAR-delta agonist), is approved for second-line treatment of PBC and has shown efficacy in improving cholestasis and pruritus in the pivotal Phase 3, placebo (PBO)-controlled RESPONSE study (NCT04620733). Based on these clinical findings, the aim of this analysis is to further evaluate the effects of SEL on longitudinal changes in serum proteins.
Method: In the RESPONSE study, 193 patients with PBC were randomized 2:1 to receive SEL 10 mg or PBO for 12 months. Serum proteomes were profiled from 862 samples from 180 patients at baseline, months 1, 3, 6 and 12 using 11k SomaScan Assay version 5.0, which measured 9852 human proteins. Data normalization, calibration, and quality control processes were performed according to the manufacturer's instructions. Baseline correlations between protein levels and clinical metrics were evaluated using Spearman correlation. Longitudinal changes were analyzed with mixed-effects models, estimating PBO-adjusted changes from baseline at each post-baseline time point.
Results: At month 12, 71 proteins were significantly upregulated and 87 were significantly downregulated from baseline in the SEL arm, compared to the PBO arm (adjusted p-value <0.05). SEL treatment led to a decrease in proteins known to be associated with cholestasis (NT5E, PIGR, STX2), pruritic conditions (FOLH1, IL-22, IL18R1), inflammation (SAA1, MIF, IL1RL1), and fibrosis (WNT5A, FBLN5, THY1). SEL treatment also increased canonical PPAR-delta targets involved in improving lipid metabolism (ACADVL, APOA1, FGF21). Notably, 60 proteins which decreased with SEL showed correlation ($r > 0.3$, adjusted p-value <0.05) with markers of cholestasis (ALP, GGT, total bile acid), pruritus (IL-31, ATX, clinical pruritus scores) and fibrosis (liver stiffness, ELF score) at baseline.
Conclusion: SEL treatment resulted in rapid, sustained and significant changes in serum proteome over time. SEL led to reductions in proteins associated with cholestasis, pruritus, inflammation and fibrosis consistent with the biochemical and clinical symptomatic improvements observed in patients treated. SomaScan analysis identified potential novel biomarkers reflective of PBC disease severity and markers indicative of PPAR-delta pathway engagement that will require further validation.

LBP-038

A novel trientine tetrahydrochloride formulation administered once-a-day for people living with Wilson disease: results from a phase 2 study

Emmanouil Tsochatzis[1], Andrew Holt[2], Elaine Kamara[3], Samuel Shribman[4], Varinder Athwal[5], Katherine Martin[5], David Nicholl[2], Richard Parker[6], Joanna Moore[6], Farah Lawrence-Wilde[3], Nick Manamley[3], C. Omar Kamlin[3], Aftab Ala[7]. [1]*Royal Free Hospital, London, United Kingdom;* [2]*University Hospital Birmingham, Birmingham, United Kingdom;* [3]*Orphalan SA, London, United Kingdom;* [4]*National Hospital for Neurology and Neurosurgery, University of London, London, United Kingdom;* [5]*University of Manchester, Manchester University NHS Foundation Trust Hospitals, Manchester, United Kingdom;* [6]*Leeds University Hospitals NHS Trust, Leeds University, Leeds, United Kingdom;* [7]*Liver Institute, Kings College Hospital, Royal Surrey County Hospital, London, United Kingdom*
Email: emmanouil.tsochatzis@nhs.net

Background and aims: Wilson's disease (WD) is a rare disorder of impaired copper transport requiring lifelong therapy. Adherence is challenging (at least twice daily, separate from food/other medications), thus simplifying treatment may be beneficial. The aim of this study was to assess tolerability, adherence, treatment satisfaction of a novel trientine tetrahydrochloride formulation administered once-a-day (QD TETA-4HCl), compared with standard of care (SoC).
Method: Phase 2 decentralised study (NCT07010575) of adults with WD (Leipzig score ≥4) on maintenance therapy prescribed at least twice daily either a chelator, zinc salts, or combination identified by 6

UK tertiary centres. Following enrolment subjects were switched to receive QD TETA-4HCl (mg-for-mg rounded to nearest full tablet for chelators or 600 mg trientine base [2 tablets] for zinc conversion) for 28-days followed by SoC for 28-days. Adverse events (AEs) and non-ceruloplasmin bound copper (NCC-Sp) was measured. Patient reported outcomes included treatment satisfaction questionnaire for medication (TSQM-9; 3 domains convenience, effectiveness, satisfaction) and Morisky medication adherence score (MMAS-8; less than 6 considered poorly adherent).

Results: Ten (7 male) patients, mean (range) age 35.3 (21–55) years enrolled with hepatic (2), neurologic (3), mixed (3), asymptomatic (2) phenotypes. SoC therapies were trientine (4), zinc (3), DPA (2), combination (1) and switched to either 2 or 3 QD TETA-4HCl tablets. Nine AEs (8 mild, 1 moderate [thrombocytopaenia]) were reported in 7 subjects; no dose changes occurred, all resolved. Mean (90% CI) serum NCC-Sp at baseline, 28d after QD TETA-4HCl and after 28d SoC was unchanged; 46.2 (37.1, 55.3), 48.6 (39.7, 57.4) and 49.3 (40.6, 58.0) mcg/L respectively. TSQM-9 convenience domain showed significant improvements; mean (90% CI) at baseline, 28d after QD TETA-4HCl and 28d after SoC was 43.1 (26.3, 59.9), 85.0 (78.4, 91.6) [p = p = 0.008], and 40.7 (26.9, 54.4), respectively. At the same timepoints, TSQM-9 Effectiveness did not change; 61.1 (54.5, 67.7), 67.3 (54.2, 80.4) and 66.1 (60.0, 72.3) and TSQM-9 Satisfaction improved; 69.9 (61.1, 78.7), 85.7 (75.3, 96.1) [p = 0.057], and 67.3 (58.5, 76.1). At same timepoints, adherence significantly improved; MMAS-8 score was 4.8 (3.7, 5.8), 7.7 (7.4, 8.0) [p = 0.002] and 5.0 (4.0, 5.9).

Conclusion: People living with WD report positive impact on convenience and adherence after 28d of QD TETA-4HCl whilst demonstrating favourable tolerability and biomarker stability.

LBP-039

Survodutide reduces steatosis and fibrosis in a MASH human liver spheroid model through direct glucagon receptor agonism

Philip Vonschallen[1], Radina Kostadinova[1], Agnieszka Pawlowska Pawlowska[1], Joel Zvick[1], Natacha Levy[1], Bonnie Razzaghi[1], Anna Savchenko[1], Francisco Verdeguer[1], Thomas Klein[2]. *[1]Insphero, Schlieren, Switzerland; [2]Boehringer Ingelheim Pharma, GmbH & Co. KG, Biberach, Germany*
Email: philip.vonschallen@insphero.com

Background and aims: Survodutide, a novel glucagon receptor (GCGR)/glucagon-like peptide-1 receptor (GLP1R) dual agonist is currently in Phase 3 clinical trials for obesity and metabolic dysfunction-associated steatohepatitis (MASH). Here we report insights into the mechanism of action of Survodutide in human MASH liver spheroids.

Method: Human liver spheroids phenocopying MASH human livers were investigated to decipher the mechanism of GCGR/GLP1R agonism. Concentration dependent (0.3–10 µM) treatment with Survodutide in liver spheroids was compared with 3 µM long-acting glucagon receptor agonist (LaGCGR) and 3 µM Tirzepatide (GLP1R/GIPR). Spheroids were treated for 10 days followed by the measurement of intracellular triglycerides and glycogen. The fibrotic biomarkers procollagen type I (PNIP) and type III peptide (PIIINP) were detected from the media supernatant at days 7 and 10. Additional spheroids were harvested at day 10 to perform RNAseq.

Results: Triglyceride content in spheroids detected at day 10 was significantly ($p < 0.001$) reduced in all concentrations of Survodutide starting from 0.3 µM (Survodutide = 751 pmol/microtissue (MT), versus DMSO control = 1086 pmol/MT). LaGCGR showed a similar lipid lowering efficacy (757 pmol/MT $p < 0.001$) whereas tirzepatide (1067 pmol/MT) showed no effect. Intracellular glycogen content was significantly reduced with Survodutide treatment at all concentrations, most pronounced at 3 µM (37 ng/MT; p-value <0.05) and with 3 µM LaGCGR (39 ng/MT). However, Tirzepatide (122 ng/MT) failed to elicit any change in glycogen content versus control (88 ng/MT). PIIINP detection in the supernatant as a fibrotic marker showed concentration dependent reduction by Survodutide (EC50 = 0.36 µM), most pronounced at 3 µM (0.08 ng/MT/day, $p < 0.001$) and LaGCGR 3 µM (0.07 ng/MT/day, $p < 0.001$) vs control (0.17 ng/MT/day). Tirzepatide showed no effect (0.17 ng/MT/day). RNAseq analysis demonstrated differences between Survodutide and Tirzepatide in regulation of transcriptional programs known for glucagon receptor activating drugs such as activation of catabolic pathways including glycolysis, fatty acid oxidation and oxidative phosphorylation.

Conclusion: Collectively, the combination of biochemical, biomarkers and transcriptomic analysis in this study suggests a liver-targeted effect of Survodutide to prevent steatosis and fibrosis in MASH patients, which distinguishes from Tirzepatide's mechanism of action.

LBP-040

Functional cure rate in chronic hepatitis B virus infected participants receiving elebsiran and pegylated interferon alfa: final results from the phase 2 ENSURE study

Grace Lai-Hung Wong[1], Man-Fung Yuen[2], Bingliang Lin[3], Mark Douglas[4], Chong Zhu[5], Ke Cao[5], Alex Tian[5], Xiaofei Chen[5], Qing Zhu[6], David Margolis[6], Zhi Hong[6], Jidong Jia[7]. *[1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, China; [2]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; [3]The Third Affiliated Hospital, Sun Yat-, Sen University, Guangzhou, China; [4]The Westmead Institute for Medical Research, The University of Sydney and Westmead Hospital, Sydney, Australia; [5]Brii Biosciences (Beijing) Co. Limited, Beijing, China; [6]Brii Biosciences, Inc., Durham, NC, United States; [7]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China*
Email: wonglaihung@mect.cuhk.edu.hk

Background and aims: The ENSURE study is a controlled, partially-randomized evaluation of an HBV targeting siRNA, elebsiran, plus pegylated interferon alfa (PEG-IFN) versus PEG-IFN alone. Published results show a higher hepatitis B surface antigen (HBsAg) loss rate in combination cohorts versus PEG-IFN at 24 weeks (W) post the end of treatment (EOT). Additionally, prior treatment with BRII-179 led to a higher HBsAg loss in those with previous hepatitis B surface antibody (anti-HBs) response. Here, we report the functional cure (FC) result, defined as sustained HBsAg loss with undetectable HBV DNA for at least 24W after stopping all treatment, including nucleos(t)ide analogues (NA).

Method: In Part 1, virologically suppressed participants with chronic HBV infection on NA therapy, with screening HBsAg >100 and ≤3000 IU/mL, were randomized at a ratio of 1:1:1 to one of three cohorts: elebsiran 200 mg or 100 mg + PEG-IFN, or PEG-IFN alone, for 48W. In Part 2, participants who previously received elebsiran and BRII-179 were enrolled to receive elebsiran 100 mg + PEG-IFN for 48W. NA was given daily until stopping criteria were met at 24W post EOT. An additional 24W NA discontinuation monitoring period (NDMP) was conducted to confirm FC in participants who stopped NA.

Results: 55 and 31 participants enrolled in Part 1 and Part 2, respectively. In Part 1, 4/19 (21%) and 5/18 (28%) participants from the elebsiran 200 mg or 100 mg + PEG-IFN cohorts were eligible for stopping NA compared to 1/18 (6%) in PEG-IFN cohort. At the end of NDMP, FC was achieved in 2/19 (11%) and 3/18 (17%) participants from the elebsiran 200 mg or 100 mg + PEG-IFN cohorts, respectively, compared to 1/18 (6%) in the PEG-IFN cohort. In Part 2, 9/31 (29%) participants met NA stopping criteria. At the end of NDMP, 8/31 (26%) participants achieved FC, with 7/19 (37%) in BRII-179 anti-HBs responders compared to 1/12 (8%) in non-responders. In combination treated participants achieving HBsAg loss at EOT, HBsAg rebound rates were 38% and 55% in those with or without BRII-179 exposure, respectively. No participants who had HBsAg rebound had ALT flare. All 12 participants with positive baseline hepatitis B e antigen did not achieve sustained HBsAg loss.

Conclusion: Compared to PEG-IFN, the addition of elebsiran resulted in higher FC rate. Furthermore, BRII-179 experienced participants achieved higher FC rate, especially in anti-HBs responders, suggesting that BRII-179 might play an important role in achieving lasting immunological control of the virus.

LBP-041

HSK31679, a thyroid hormone receptor beta agonist, improves histological outcomes in Asian patients with MASH and F2–F3 fibrosis: a 52-week phase 2b randomized, double-blind, placebo-controlled trial

Feng Xue[1], Jianfeng Liu[2], Jinjun Chen[3], Xing Li[4], Sikui Wang[5], Yawen Luo[6], Bangjie Zhang[7], Jiawei Geng[8], Weihong Wang[9], Rui Zhao[10], Chuanwu Zhu[11], Junjun Bi[12], Xiqing Guo[13], Lungen Lu[14], Guang-Ming Li[15], Hong Peng[16], Li Dong[17], Guohong Ge[18], Danying Cheng[19], Xianfei Zhong[20], Lvfeng Yao[21], Feng Gao[22], Shiyao Chen[23], Jiaojian Lv[24], Liang Xu[25], Guodong Zhang[26], Xiaozhong Wang[27], Gang He[28], Yaocai Li[29], Xiuping Jin[30], Wang Jing[31], Huiying Rao[32], Shuilin Sun[33], Yunzhen Shi[34], Min Meng[35], Jing Zhang[36], Muyessar Maimaitiyiming[37], Chao Wu[37], Cunliang Deng[38], Zong Zhang[39], Yan Bi[40], Xiaohua Li[41], Tingting Wu[42], Weifang Zeng[42], Lai Wei[43]. *[1]Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Key Laboratory of Digital Intelligence Hepatology (Ministry of Education), School of Clinical Medicine, Tsinghua Medicine, Tsinghua University, Department of Gastroenterology, Binzhou Medical University Hospital, Beijing, China; [2]Cangzhou People's Hospital, Cangzhou, China; [3]Nanfang Hospital, Guangzhou, China; [4]Pingxiang People's Hospital, Pingxiang, China; [5]Liaocheng People's Hospital, Liaocheng, China; [6]Affiliated Hospital of Zunyi Medical University, Zunyi, China; [7]The Third Affiliated Hospital of Xinxiang Medical University, Xinxiang, China; [8]The First People's Hospital of Yunnan Province, Kunming, China; [9]Huzhou Central Hospital, Huizhou, China; [10]The Sixth People's Hospital of Shenyang, Shenyang, China; [11]The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, China; [12]People's Hospital of Zezhou County, Jincheng, China; [13]Chongqing University Three Gorges Central Hospital, Chongqing, China; [14]Shanghai General Hospital, Shanghai, China; [15]The Sixth People's Hospital of Zhengzhou, Zhengzhou, China; [16]Guizhou Provincial People's Hospital, Guizhou, China; [17]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [18]Changzhou Third People's Hospital, Changzhou, China; [19]Beijing Ditan Hospital, Beijing, China; [20]The People's Hospital of Leshan, Leshan, China; [21]Mengchao Hepatobiliary Hospital of Fujian Medical University, Fuzhou, China; [22]Linyi People's Hospital, Linyi, China; [23]Minhang Hospital, Fudan University, Shanghai, China; [24]Lishui People's Hospital, Lishui, China; [25]Tianjin Second People's Hospital, Tianjin, China; [26]Pingmei Shenma Medical Group General Hospital, Pingdingshan, China; [27]Xinjiang Uygur Autonomous Region Traditional Chinese Medicine Hospital, Urumqi, China; [28]Jiangmen Central Hospital, Jiangmen, China; [29]Maoming People's Hospital, Maoming, China; [30]North China University of Science and Technology, Tangshan, China; [31]Affiliated Traditional Chinese Medicine Hospital of Southwest Medical University, Luzhou, China; [32]Peking University People's Hospital, Beijing, China; [33]The Second Affiliated Hospital of Nanchang University, Nanchang, China; [34]Dongyang People's Hospital, Dongyang, China; [35]Anyang People's Hospital, Anyang, China; [36]Beijing Youan Hospital, Beijing, China; [37]The First People's Hospital of Kashi Prefecture, Kashgar, China; [38]Mianyang 404 Hospital, Mianyang, China; [39]Shandong Public Health Clinical Centre, Jinan, China; [40]The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China; [41]Shanghai Seventh People's Hospital, Shanghai, China; [42]Haisco Pharmaceutical Group Co., Ltd., Chengdu, China; [43]Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Key Laboratory of Digital Intelligence Hepatology (Ministry of Education), School of Clinical Medicine, Tsinghua Medicine, Tsinghua University, Beijing, China, Beijing, China*
Email: weilai@tsinghua.edu.cn

Background and aims: Resmetirom, a liver-targeted thyroid hormone receptor beta agonist, has been approved in the United States and European Union for noncirrhotic MASH with moderate-to-advanced fibrosis, based largely on data from predominantly White populations. In our phase 2a study, HSK31679 reduced liver fat content (LFC) in Asian patients with metabolic dysfunction-associated steatotic liver disease. This phase 2b trial evaluated the histological efficacy and safety of HSK31679 after 52 weeks in Asian patients with MASH and F2/F3 fibrosis, including a substantial proportion of non-obese patients.
Method: In this multicenter, randomized, double-blind, placebo-controlled phase 2b trial, 186 patients with biopsy-confirmed MASH and F2/F3 fibrosis were randomized 1:1:1 to once-daily oral HSK31679 80 mg, HSK31679 160 mg, or placebo. The primary endpoint was improvement in MASH without worsening of fibrosis at week 52. Secondary endpoints included improvement in MASH with at least one-stage fibrosis improvement, at least 30% relative reduction in LFC by MRI-PDFF, and changes in lipid parameters.
Results: Baseline characteristics were comparable across groups. At week 52, the primary endpoint was met in 37.3% and 30.0% of participants receiving HSK31679 80 mg and 160 mg, respectively, versus 10.0% with placebo (both $p < 0.001$). In the BMI-stratified analyses, both doses showed higher rates of response than placebo in participants with BMI <28 kg/m^2 (nominal $p < 0.05$ for both comparisons). Rates of MASH improvement with at least one-stage fibrosis improvement were 22.0%, 18.3%, and 5.0%, respectively (both $p < 0.05$ vs placebo). More participants receiving HSK31679 achieved ≥30% reduction in MRI-PDFF at week 52 (52.5% and 53.3% vs 25.0%; both $p < 0.01$). HSK31679 also improved multiple lipid parameters, with no significant difference in body weight change between groups. HSK31679 was generally safe and well tolerated; gastrointestinal adverse events were slightly more frequent than with placebo but were mild to moderate, and no drug-related serious adverse events, discontinuations, or deaths occurred.
Conclusion: HSK31679 significantly increased the rate of MASH improvement without worsening of fibrosis at week 52, with reductions in LFC and improvements in multiple lipid parameters, with a favorable safety and tolerability profile. Histological benefit was also observed in non-obese participants despite no significant between-group difference in body-weight change.

LBP-042

Safety, tolerability, sustained hepatitis B surface antigen reduction and HBsAg clearance ratio in chronic hepatitis B patients treated with long-term BW-20507

Man-Fung Yuen[1], Grace Lai-Hung Wong[2], Chitchai Rattananukrom[3], Pisit Tangkijvanich[4], Khuanchai Supparatpinyo[5], Sakkarin Chirapongsathorn[6,7]. *[1]The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]The Chinese University of Hong Kong, Hong Kong, China; [3]Division of Gastroenterology and Hepatology, Department of Medicine, Srinagarind Hospital, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand; [4]Center of Excellence in Hepatitis and Liver Cancer, Chulalongkorn University, Bangkok, Thailand; [5]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand; [6]Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand; [7]Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand*
Email: mfyuen@hku.hk

Background and aims: BW-20507 is an N-acetylgalactosamine conjugated small interfering RNA (siRNA) designed to target the hepatitis B virus (HBV). Preclinical studies have demonstrated its distinct antiviral activity and promising potential for the treatment of HBV infection. Here, we present preliminary data from an ongoing study evaluating the long-term safety, tolerability, and antiviral activity of BW-20507 in patients with chronic HBV infection (CHB).
Method: This is a long-term treatment phase in subjects who previously received 3 doses of BW-20507 and had been followed for

40 weeks. Subjects enrolled in the study will receive BW-20507 300 mg every 4 weeks for 24 weeks (7 doses), followed by every 8 weeks for 72 weeks (9 doses). Subjects who meet the predefined nucleoside analogs (NUCs) discontinuation criteria may stop NUCs between Weeks 48 and 72 and will be closely monitored, with NUCs re-initiated as needed according to the prespecified retreatment criteria. During the follow-up period (Weeks 96–120), no further BW-20507 will be administered, and subjects will either continue NUCs or be monitored off NUCs, with re-initiation based on the same retreatment criteria.
Results: Twenty-two patients (mean age 46.6 years old; M: F 20:2; HBeAg positive 22.7%) with CHB were enrolled. Up to the cutoff date, all subjects had completed the D197 visit (Week 28 visit). Treatment was well tolerated in all subjects, with a favorable safety profile. No treatment discontinuations occurred and no treatment-related SAE was reported. Mean baseline HBsAg level was 569.0 IU/mL (2.76 $\log_{10}$ IU/mL). 21 (95.5%) and 19 (86.4%) patients had baseline HBsAg <3,000 IU/mL and <1000 IU/mL respectively. On Day 197, the mean maximal reduction of HBsAg was 2.85 $\log_{10}$ IU/mL and all of the subjects achieved HBsAg <3 IU/mL. Ten (45.5%) subjects achieved HBsAg clearance for at least 1 follow-up visit. HBsAg clearance rate was 87.5% (7/8) in subjects with baseline HBsAg ≤50 IU/mL, versus 52.6% (10/19) in those with HBsAg ≤1000 IU/mL.
Conclusion: Long-term treatment with BW-20507 was well tolerated and demonstrated a favorable safety profile in patients with CHB. Continued BW-20507 treatment can lead to higher rates of HBsAg clearance over time.

LBP-043
First evidence of elimination and inactivation of cccDNA in liver biopsies collected from patients with chronic hepatitis B treated with PBGENE-HBV
Man-Fung Yuen[1], Alina Jucov[2,3], Emily Harrison[4], James Harris[5], Keely Dulmage[4], Andrew Van Cott[4], Abhishek Chandiramani[4], Neil Leatherbury[4], Janel Lape[4], Peter Balfe[5], Jeff Smith[4], Cassandra Gorsuch[4], Stanley Frankel[4], Jane McKeating[5], Mark S. Sulkowski[4,6], Edward J. Gane[7]. *[1]Queen Mary Hospital, The University of Hong Kong, Hong Kong, Hong Kong; [2]Arensia Exploratory Medicine GmbH, Düsseldorf, Germany; [3]Nicolae Testemitanu State University of Medicine and Pharmacy, Chişinău, Moldova; [4]Precision BioSciences Inc., Durham, United States; [5]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [6]Division of Infectious Diseases, Johns Hopkins Bayview Medical Center, Johns Hopkins University & Medicine, Baltimore, United States; [7]New Zealand Clinical Research, Auckland, New Zealand*
Email: mfyuen@hku.hk

Background and aims: PBGENE-HBV is a first-in-class gene editor utilizing ARCUS technology designed to cure hepatitis B by elimination or inactivation of cccDNA, the sole source of new infectious viral particles and HBV replication. The PBGENE-HBV target site is highly conserved in both cccDNA and integrated HBV DNA and is essential in cccDNA for viral polymerase function.
Method: PBGENE-HBV is being evaluated in a Phase 1 trial for safety and efficacy in participants controlled on nucleos(t)ide analogs (Yuen et al. AASLD abstract 5017). Liver biopsies were analyzed from two voluntary participants dosed in Cohort 2 (0.4 mg/kg). In one participant, biopsies were collected pre-treatment and after the second dose administration. In the other participant, a post-treatment biopsy only was collected after the third and final dose. Both short- and long-read sequencing techniques have been utilized to evaluate editing of cccDNA and integrated HBV DNA. In addition, HBV RNA and HBsAg in the blood were evaluated for antiviral activity.
Results: Sequencing confirmed editing of cccDNA and integrated HBV DNA at both the DNA and RNA level with a high degree of concordance. In the first participant, paired biopsies showed a 10-fold (1-log) decrease in the percentage of cccDNA-derived RNA transcripts after two administrations of PBGENE-HBV, supporting cccDNA elimination. In the 0.16% of cccDNA-derived transcripts remaining, edits were present in 23% of sequences, supporting cccDNA inactivation. In a second participant who underwent a post-treatment biopsy only, collected after 3 doses, edits were found in 80% of remaining cccDNA transcripts, suggesting cumulative effect of repeat administrations of PBGENE-HBV. This patient had detectable pgRNA in the blood at baseline which became and remained undetectable after dosing, corresponding with undetectable pgRNA in the biopsy. In all biopsy samples, HBsAg transcripts were expressed predominantly from integrated HBV DNA rather than cccDNA. Durable HBsAg declines in the blood were observed in both participants 9 months after initial dosing.
Conclusion: Biopsy data demonstrate the first evidence of elimination and inactivation of cccDNA in HBV patients through gene editing with PBGENE-HBV. Antiviral activity was evidenced by loss of detectable pgRNA, as well as durable HBsAg declines. These data support continued evaluation of PBGENE-HBV dose and schedule as a curative therapy.

LBP-044
Integrated serum proteomics and N-glycoproteomics for non-invasive biomarkers in primary biliary cholangitis
Dong Zhao[1], Liangjun Zhang[1], Zuzhi Xu[1], Xiaoman Xie[1], Qiong Pan[1], Jin Chai[1]. *[1]the First Affiliated Hospital (Southwest Hospital) of Third Military Medical University (Army Medical University), Cholestatic Liver Diseases Center, the First Affiliated Hospital (Southwest Hospital) of Third Military Medical University (Army Medical University), Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) Medical Research Center, the First Affiliated Hospital (Southwest Hospital) of Third Military Medical University (Army Medical University), Chongqing, China*
Email: jin.chai@cldcsw.org

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune disease characterized by small bile duct injury and cholestasis. Diagnosis based on current serological tests and clinical treatment with ursodeoxycholic acid (UDCA) are challenging, particularly with autoimmune hepatitis (AIH) overlap. In this study, we aim to identify non-invasive serum biomarkers for PBC to reduce reliance on liver biopsy.
Method: We performed proteomics and N-glycoproteomics on 737 serum samples from controls, patients with PBC, AIH, and their overlap syndrome (PBC+AIH) across nine centers. The cohort is divided into discovery and validation sets. Machine learning was applied to build biomarker panels with serum omics and clinical variables in the discovery cohort, which were further confirmed in the validation cohort.
Results: A diagnostic panel comprising one protein, one N-glycoprotein, and conventional clinical variables, achieved ROC-AUC >0.9 in distinguishing PBC, greatly improving the diagnostic accuracy over current serological diagnosis. Additionally, two models for staging PBC and UDCA treatment response were developed. A five-protein panel can realize ROC-AUC >0.8 in differentiating early-stage from later stage of PBC. Another panel incorporating one protein, one N-glycoprotein, and clinical variables, exhibited satisfactory performance in predicting UDCA treatment response with ROC-AUC >0.9. SHAP analysis highlighted the important contribution of novel biomarkers to the model, supporting their potential biological relevance in PBC progression.
Conclusion: Our study has identified a few panels of serum biomarkers that effectively differentiate PBC from other autoimmune liver diseases, stage PBC without a liver biopsy, and predict the UDCA treatment response.

WEDNESDAY 27 TO SATURDAY 30 MAY

Acute liver failure and drug induced liver injury – Clinical

TOP-178

Predicting in-hospital mortality in drug-induced liver injury

Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: lawinsteve.ls@gmail.com

Background and aims: Drug-induced liver injury (DILI) causes substantial morbidity and is the leading cause of acute liver failure (ALF) in Western countries. Unlike other liver diseases, no validated prognostic scores exist specifically for DILI. We developed an interpretable machine learning (ML) model to predict in-hospital DILI mortality and identify key risk factors across injury patterns and drug classes.
Method: This retrospective cohort study used the National Inpatient Sample (2019–2022) to identify adult DILI hospitalizations (ICD-10: K71.x). Patients were classified by injury pattern (ALF, hepatocellular necrosis, cholestatic, acute hepatitis, chronic) and causative drug class using T-codes. The primary outcome was in-hospital mortality. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, LightGBM) were trained using temporal validation (2019–2021 training, 2022 testing) with 69 clinical features. SMOTE addressed class imbalance. Performance was evaluated using AUC-ROC, sensitivity, and specificity. SHAP analysis identified key predictors.
Results: Among 11,296 DILI hospitalizations, overall mortality was 5.9%. Mortality varied by injury pattern: ALF 16.4%, severe hepatocellular necrosis 9.6%, chronic DILI 5.5%, cholestatic 3.4%, and acute hepatitis 2.9%. By drug class, antineoplastic agents had the highest mortality (7.3%), followed by cardiovascular drugs (7.2%) and acetaminophen (6.5%). Random Forest achieved the best performance (AUC 0.912; sensitivity 84.7%; specificity 86.0%).SHAP analysis showed systemic severity markers dominated prediction: organ failure count (1.32), age (0.86), respiratory failure (0.70), underlying malignancy (0.59), mechanical ventilation (0.46), and metabolic acidosis (0.36). Specific drug class contributed minimally compared to physiologic derangement, suggesting clinical trajectory rather than causative agent determines outcomes.
Conclusion: This ML model accurately predicts DILI mortality using routine clinical data. Key findings: (1) ALF carries 5-fold higher mortality than other DILI phenotypes; (2) antineoplastic agents, not acetaminophen, have the highest mortality; (3) systemic organ failure burden, rather than causative drug, dominates mortality prediction. These findings support developing a DILI-specific prognostic score emphasizing physiologic severity over etiology for early identification of high-risk patients requiring intensive monitoring or transplant evaluation.

Acyl-CoA synthetase long-chain family member 4 as a novel prognostic biomarker for poor outcome in drug-induced liver injury

Yu Wang[1], Pengchong Li[2], Xue Wang[1], Mengmeng Zhang[1], Yan Wang[1], Zikun Ma[1], Yao Meng[1], Tiantian Guo[1], Jiahao Yuan[1], Yubo Zhong[1], Jinxin Gu[1], Cen Zhang[1], Sihan Dong[1], Jun Li[3], Xinyan Zhao[1], Jidong Jia[1]. [1]*Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China, State Key Laboratory of Digestive Health, Beijing, China, National Clinical Research Center of Digestive Diseases, Beijing, China, Beijing, China;* [2]*Department of Gastroenterology, Beijing Friendship Hospital, Capital Medical University, Beijing, China, State Key Laboratory of Digestive Health, Beijing, China, National Clinical Research Center of Digestive Diseases, Beijing, China, Beijing, China;* [3]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China, Hangzhou, China*
Email: wang-yu@mail.ccmu.edu.cn

Background and aims: Early risk stratification in drug-induced liver injury (DILI) remains a major clinical challenge. We aimed to identify a novel biomarker to improve prognostic assessment in DILI and to evaluate whether its prognostic value is specific to DILI compared with autoimmune and virus-related liver disease.
Method: We performed proteomic profiling of human liver tissue from patients with DILI and analyzed publicly available single-nucleus RNA sequencing (snRNA-seq) datasets from DILI-associated acute liver failure (DILI-ALF) and healthy controls. Candidate molecules were validated in in vitro and in vivo DILI models. A multicentre prospective DILI cohort (NCT05060289) was used to evaluate the prognostic performance of serum biomarkers, benchmarked against five established DILI prognosis models. Disease specificity was assessed in independent cohorts of autoimmune hepatitis (AIH) and chronic hepatitis B (CHB).
Results: Liver proteomics revealed marked activation of ferroptosis and identified acyl-CoA synthetase long-chain family member 4 (ACSL4) as a central hub in DILI-ALF. SnRNA-seq analysis showed consistent upregulation of ACSL4 in hepatocytes from DILI-ALF patients compared with healthy controls, which was confirmed by double immunofluorescence staining. In vitro and in vivo DILI models further supported a pathogenic role of ACSL4-mediated ferroptosis, as siRNA-mediated ACSL4 knockdown in vitro and pharmacological ACSL4 inhibition in vivo both attenuated liver injury. In the prospective DILI cohort, serum ACSL4 concentrations were significantly higher in patients with poor outcomes than in those with favourable outcomes (924.98 vs. 471.06 pg/mL, $p < 0.001$). ACSL4 demonstrated excellent prognostic performance (AUROC = 0.953), significantly outperforming Hy's Law, nHy's Law and Robles-Diaz (all $p < 0.001$), and marginally surpassing DrILTox ALF (AUROC = 0.884) and MELD (AUROC = 0.884). Moreover, in a real-world validation cohort, the ACSL4-based model achieved an AUROC of 0.904 (95% CI, 0.750–1.000). In contrast, elevated ACSL4 levels were not observed in AIH or CHB patients with poor outcomes.
Conclusion: ACSL4 is a novel biomarker with high accuracy for predicting poor outcome in DILI. Its prognostic elevation appears specific to DILI relative to AIH and CHB and it performs comparably or better than existing prognostic models. ACSL4 shows strong potential for early risk stratification and may help guide clinical decision-making in patients with suspected DILI.

SAT-056

Active pharmacovigilance and performance of K18, M-CSFR, and GLDH as DILI biomarkers for diagnosis and prognosis in a complex hospitalized population in Brazil

Raquel Boff[1], Vittoria Sampaio[1], Paola Hoff Alves[1], Ana Lazzari[1], Isabela Carvalhal[2], Tiago Onofrio Soares[2], Theo Futuro Telöken[3], Nelson Suarez Uribe[1], Hidayat Ullah Kassim[1], Rui Davila[4], Fernando Hertz Wolff[5], Jeronimo De-Conto-Oliveira[4], Mercedes Robles-Díaz[6], Dvora Joveleviths[1]. Dos Sinos, Porto Alegre, Brazil; [4]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [5]Hospital Moinhos De Vento, Porto Alegre, Brazil; [6]Universidad De Málaga, Málaga, Spain
Email: raquelboff80@gmail.com

Background and aims: Drug-Induced Liver Injury (DILI) diagnosis is complex, relying on the exclusion of other causes and non-specific liver tests with suboptimal sensitivity. This study evaluated the diagnostic potential of Cytokeratin-18 (K18), Macrophage Colony-Stimulating Factor Receptor (MCSFR), and Glutamate Dehydrogenase (GLDH) in hospitalized patients with DILI, pre-existing liver disease (PLD), and controls, were comorbidities and polypharmacy complicate investigation.
Method: Prospective study with active pharmacovigilance conducted between 2019 and 2025 for biomarker development, analyzing medical history by RedCap under international DILI criteria (alanine aminotransferase (ALT) >5× upper limit of normal (ULN), ALT 3–5× ULN with total bilirubin (TB) >2 mg/dL, and alkaline phosphatase (ALP) >2× ULN). Cases were adjudicated by RUCAM and expert opinion. Biomarkers were quantified via ELISA/Luminex. Diagnostic performance was assessed by ROC curves (AUC) and associations by Spearman's coefficient.
Results: From 2,500 records, 23 cases of DILI, 41 cases of PLD, and 18 controls (similar clinical profiles but normal aminotransferases) were confirmed. Active pharmacovigilance (RUCAM score) detected 20 DILI cases, significantly outperforming traditional methods (Naranjo), which reported only 2. The primary suspected drug classes were antibiotics (39.0%), antifungals (14.1%), and antineoplastics (9.4%). The mean age was 50.24 years (SD 15.59), with a 60.9% female (DILI group). Median DILI latency: 60.15 days (SD 85.4); 45.8% (n = 10) showed a hepatocellular pattern. RUCAM scores were distributed as: 3–5 (n = 6; 26.1%), 6–8 (n = 15; 65.2%), and ≥9 (n = 2; 8.7%). The biomarkers K18, MCSFR, and GLDH did not show significant differences in diagnostic of DILI, AUC values of 0.610, 0.565, and 0.554, respectively. In PLD, K18 (AUC 0.696) outperformed ALT (AUC 0.557) in differential diagnosis. GLDH (AUC 0.806) and MCSFR (AUC 0.707) predicted mortality in DILI and pre-existing liver disease, respectively.
Conclusion: Biomarkers provide critical insight into the progression and severity of DILI, playing a significant prognostic role. ALT's non-specificity reinforces the need for clinical evaluation.

SAT-057

Drug-induced liver injury: a survey among members of the society of liver disease in Africa

Maurizio Bonacini[1], Patricia Jones[2], Wendy Spearman[3], Manal El-Sayed[4], Karin Siebelt[5]. *[1]Mission Gastroenterology, San Francisco, United States; [2]University of Miami, Coral Gables, United States; [3]University of Cape Town, Cape Town, South Africa; [4]Ain-Shams Univ., Cairo, Egypt; [5]Amed Education, Amsterdam, Netherlands*
Email: bonacim08@gmail.com

Background and aims: Drug-induced liver injury (DILI) represents the most common cause of liver failure in Europe, most frequently acetaminophen (APAP), idiosyncratic cases ranking second. The USA DILI network has published detailed descriptions of DILI and provided regulators with surveillance data. There is no known DILI registry in Africa. The aim is to report African practitioners' experiences with DILI.
Method: A survey was co-developed by AASLD/SOLDA, consisting of 28 questions about participant demographics and their experience with DILI. This was sent to 2038 SOLDA members. 337 responses were received from 36 African countries.
Results: 51% of responders were physicians, 7% nurses, 4% pharmacists and 38% other practitioners. Thirty-one percent were Gastrointestinal/Liver, 23% Infectious Diseases, 17% general medicine and 29% other. Two thirds were in academic and/or public positions and 1/3 in private practice. Countries were geographically well represented, the highest response number being from Nigeria (64). When asked about DILI significance, 58.5% answered significant or very significant, 30.5% moderately significant and 11% not very significant. Respondents estimated that 56% of their patients take traditional remedies or herbal or dietary supplements (HDS). 52% percent of practitioners see ≥6 DILI cases/year. The median number of prescription medications DILI seen was 5/year. Most frequently cited culprits: Tuberculosis (TB) medications (47.6%), APAP (24.5%), antibiotics (17%, 40% of which were Amoxycillin/clavulanate), HIV meds (13.6%) and NSAIDS (9%). Median number of DILI due to traditional meds or HDS was 3 cases/year for each category. About 55% of respondents have seen a fatal case of DILI. Of the 80 fatal cases, the most common culprits were HDS (37), TB medications (19), analgesics/APAP (14); HIV drugs (7), antibiotics (2) and Ecstasy (1). Greater than 75% have access to liver and serological tests to exclude competing causes and 46% to liver biopsies. HLA testing is available to 30% of respondents. Fifty-five percent note that a registry is not available in their country; 86% would report cases to a central DILI registry.
Conclusion: Almost 60% of African practitioners view DILI as a significant problem. TB medications are the main culprits but HDS may have more impact on mortality. Most responders have access to basic liver/serology tests and almost 50% to liver biopsies. The vast majority would contribute to a DILI registry. These data support the creation of an African DILI registry.

SAT-058

Our experience of immune-mediated hepatotoxicity: five-year data from a London cancer centre

Annabelle Chung[1], Alberto Fusi[1], Arjuna Singanayagam[1], Styliani Germanou[1]. *[1]St George's Hospital, London, United Kingdom*
Email: annabelle.chung@stgeorges.nhs.uk

Background and aims: Immune-mediated hepatotoxicity (IMH) is a well-known adverse effect of immune checkpoint inhibitors (ICI). Management involves interruption to immunotherapy, steroid treatment, and second line immunosuppression in steroid-refractory cases, usually on the Acute Oncology Care Unit to avoid hospital admissions. Here, we aimed to assess the management and outcomes of IMH in our cancer service over the last 5 years.
Method: Cancer patients who received ICIs and subsequently developed IMH between 2021 and 2025 at St George's Hospital, London, UK, were analysed. Data collected from our electronic records included patient demographics, cancer treatment, IMH management and outcomes. Grading of hepatitis was defined as per published guidelines.
Results: 46 patients were included, the majority with lung (41.3%), skin (28.3%) or renal cell (19.6%) cancer. ICI regimes varied - singlet ICI (34.8%), dual ICI (28.3%) or with chemotherapy (37.0%). 28.2% of patients showed evidence of hepatic steatosis on imaging. The proportion of patients with Grade 3–4 IMH did not differ between those with hepatic steatosis (8/11, 72.7%) and those with a normal ultrasound (19/26, 73.1%). Overall, 72.3% of all cases were Grade 3–4. Average time between ICI treatment and onset of hepatitis was 116.6 days (range 12–412), following an average of 3.3 cycles (range 1–10). Patients treated with dual ICIs (PD-1 with CTLA-4; n = 12) experienced a shorter mean time to IMH (83.6 days) compared to those receiving singlet ICI (142.6 days; n = 34). 93.5% of patients were managed with high dose corticosteroids - 72.7% were steroid-responsive. 25% required an additional agent with mycophenolate mofetil (MMF). Mean length of treatment was 61.5 days, excluding 3 patients (8.8%) who require MMF indefinitely. 7 patients died during treatment, but only one death was toxicity-related. 80.9% of cases resolved. Only 23.9% of patients (n = 11) were rechallenged with singlet ICI following IMH and recurrence did not occur. 93.5% of patients required at least 1 visit to our ambulatory unit (mean 7.6, range 1–23). 17% of patients required inpatient admission, however this has reduced between 2021 (40%) and 2025 (0%).

Conclusion: Our five-year data demonstrates that IMH can be managed effectively on an outpatient basis. Although IMH is treatable, it often leads to cessation of ICIs. Guidance on rechallenging ICI remains dependent on clinician experience and multidisciplinary team input, thus highlighting the ongoing challenges of managing IMH.

SAT-059

Trastuzumab is associated with acute hepatitis and chronic porto-sinusoidal vascular disease in the french-speaking network for the study of the hepatotoxicity of health products (REFHEPS)

Bénédicte Delire[1], Lucy Meunier[2], Magdalena Meszaros[2], José Ursic Bedoya[2], Isabelle Rosa[3], Amel Zahhaf[2], Eleonora De Martin[4], François Duhoux[5], Cédric van Marcke[5], William Jacot[6], Séverine Guiu[6], Yves Horsmans[1], Dominique Larrey[2,7].

Email: benedicte.delire@saintluc.uclouvain.be

Background and aims: Trastuzumab (TRA) is a targeted therapy that exists as either a monoclonal antibody or an antibody-drug conjugate:TRA-deruxtecan (T-DXd)/TRA-emtansine (T-DM1). All are used to treat breast cancer (BC) and other solid tumors and are associated with drug-induced liver injury (DILI).
Method: Patients assessed by the French-speaking network for the study of the hepatotoxicity of health products (REFHEPS) between January 2022 and December 2025 were evaluated. Those with TRA/T-DXd/T-DM1-induced liver toxicity were included. Hepatotoxicity was defined as ALT or AST ≥5× ULN, ALP ≥2× ULN, or total bilirubin ≥2× ULN associated with ALT ≥3× ULN or the appearance of signs of portal hypertension (PH).Approval by an ethics committee (IRB number: 198711).
Results: Twenty-three of the 332 cases collected in the REFHEPS involved TRA/T-DXd/T-DM1: 12 T-DM1, 7 T-DXd, 1 T-DM1 and nivolumab, 1 T-DM1 and pertuzumab, 1 TRA, and 1 TRA+pertuzumab+tucatinib. All but one of the patients were female, median age 59 years (33–82). Twenty-one patients were treated for BC, 1 for ovarian tumor and 1 for bladder carcinoma. DILI phenotype was cholestatic in 4 cases, cytolytic in 3 and mixed in 1. Fifteen patients did not meet the biological criteria for DILI but had minimal biological abnormalities and/or signs of PH. When applicable, the median RUCAM score was 7 and DILIN grade for causality assessment was probable. Hepatic damage was symptomatic in 6 cases, three had variceal haemorrhage. Fifteen patients in the cholestatic/ minimal biological abnormalities and PH groups had liver biopsy. Histological analysis was consistent with porto-sinusoidal vascular liver disease (PSVD) in all patients whose evolution was chronic. PSVD was related to T-DM1 in 9 cases, to T-DXd in 7, to T-DM1 and nivolumab in 1, to T-DM1 and pertuzumab in 1, and to TRA in 1. In the cytolytic and mixed group, 2 patients had a biopsy showing an acute lobular hepatitis in one case and a cholestatic hepatitis in the other. Two patients experienced resolution of liver enzymes while another patient only showed improvement in hepatic tests after three months.One patient died due to oncological progression and liver failure. Acute hepatitis was associated with T-DM1 in 2 cases, to T-DXd in 1 and to a combination of TRA-Pertuzumab-Tucatinib in 1.
Conclusion: TRA, T-DXd and T-DM1 are associated with DILI, including acute hepatitis and chronic PSVD. Further data are needed to predict the development of clinical PH in patients treated with these molecules.

SAT-060

Hepatotoxicity patterns associated with antibody-drug conjugates in clinical trials: a systematic review and meta-analysis

Yinuo Dong[1], Yang Zhi[1], Xiao-Yun Li[2], Xiaohong Lei[3], Yimin Mao[1].
[1]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]The First Affiliated Hospital, Fujian Medical University, Fuzhou, China; [3]Shanghai Tenth People's Hospital, Shanghai, China
Email: noradong@sjtu.edu.cn

Background and aims: Antibody-drug conjugates are widely used in cancer therapy, yet hepatotoxicity remains a key safety concern that may interrupt treatment and, in rare cases, cause fatal outcomes. We conducted a systematic review and meta-analysis to characterize the incidence, severity, and patterns of hepatotoxicity associated with contemporary antibody-drug conjugates in clinical trials.
Method: We performed a systematic review and meta-analysis of prospective clinical trials evaluating antibody-drug conjugates in adult patients with solid tumors or hematological malignancies. PubMed, Embase, Web of Science, and the Cochrane Library were searched from inception to September 15, 2025. Hepatotoxicity outcomes were defined by the Common Terminology Criteria for Adverse Events and included any grade and grade ≥3 elevations of alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma-glutamyl transferase (GGT), and total bilirubin (TBIL), as well as veno-occlusive disease (VOD). Pooled incidences were estimated and between study heterogeneity was assessed. Prespecified subgroup analyses were conducted by payload class, antibody target, treatment strategy, cancer type, and linker type.
Results: A total of 164 clinical trials comprising 201 cohorts and 16,584 patients were included. Laboratory defined hepatotoxicity was frequent, with pooled incidences of any grade ALT and AST elevations of 20.7% and 22.07%, while grade ≥3 elevations occurred in 3.61% and 3.43%, respectively. Cholestatic pattern abnormalities were less common, with pooled incidences of any grade ALP, GGT, and TBIL elevations of 10.92%, 8.42%, and 8.45%, and grade ≥3 events of 2.54%, 3.27%, and 2.92%. VOD was infrequent and was confined to calicheamicin-based antibody-drug conjugates, specifically gemtuzumab ozogamicin and inotuzumab ozogamicin. Subgroup analyses indicated that payload class was a key determinant of severe hepatotoxicity, with DNA-damaging payloads showing the highest incidence of grade ≥3 events, whereas topoisomerase I inhibitor based payloads consistently showed the lowest. Compared with monotherapy, combination regimens were associated with higher incidences of hepatocellular injury.
Conclusion: Hepatotoxicity associated with antibody-drug conjugates is common but mostly low grade, with severe events confined to specific platforms. Recognition of payload-, target-, and treatment-related risk differences may help optimize ADC use and hepatic monitoring in clinical practice.

SAT-061-YI

Acute liver failure: a 10-year analysis emphasizing the critical role of multidisciplinary approach

Michela Helga Falzone[1], Rachele Gastaldi[1], Margherita Saracco[1], Gabriella Tomaiuolo[1], Chiara Manuli[1], Silvia Strona[1], Maria Torrani Cerenzia[1], Chiara Stratta[2], Maurizio Berardino[2], Francesco Lupo[3], Renato Romagnoli[3], Silvia Martini[1]. *[1]SSD Insufficienza epatica e trapianto epatico, AOU Città della salute e della scienza di Torino, Turin, Italy; [2]SC Anestesia e Rianimazione 2, AOU Città della salute e della scienza di Torino, Turin, Italy; [3]SC Chirurgia Generale*

2, AOU Città della salute e della scienza di Torino, Turin, Italy
Email: michelahelga.falzone@unito.it

Background and aims: Acute liver failure (ALF) is a life-threatening condition in patients (pts) without prior liver disease. Survival depends on etiology, timely referral, complication management and liver transplant (LT). In Europe 8% of LTs are performed annually for ALF. We reported ALF LT outcomes in Italian high-volume LT Centre over the last 10 years (y).
Method: Emergency ALF LTs (Jan 2016–Sep 2025) were included, with follow-up ending in Oct 2025. Revised King's College criteria were used to determine the need for emergency LT.
Results: Of 1542 total LTs, 32 (2.1%) were performed for ALF. Median (med) age was 49 y [IQR 28–58], 50% male. Etiologies: 44% viral (mainly HBV), 13% autoimmune, 13% Wilson, 9% heat stroke, 6% drug-induced (valproate, disulfiram), 6% A. phalloides, 6% HELLP, 3% indeterminate. Onset was 59% hyperacute, 25% acute and 16% subacute (O'Grady classification). Med transfer time from peripheral centers to our Centre was 1 day (d) [1–3]. At presentation: med bilirubin 13.7 mg/dl [6.5–20.1], INR 4.0 [2.8–5.7], creatinine 1.1 mg/dl [0.6–1.4], MELD 35 [29–38]. Hepatic encephalopathy grade 3–4 affected 19 pts, with med arterial ammonia of 258 mcmol/l [182–395], 79% requiring endotracheal intubation; no one developed intracranial hypertension. Pre-LT complications were acute kidney injury (AKI) (53%), hemodynamic instability needing vasopressors (47%), infections (25%). 17 pts (53%) underwent hemodialysis (HD) — 5 for AKI, 8 for hyperammonemia, 4 for both; 3 pts (9.4%) plasmapheresis. Med transfer-to-listing time was 1 d [0–2] and LT waiting time 1 d [1–2]. Med MELD was 36 [32–41]. One intraoperative death occurred due to cardiac arrest at reperfusion. Med extubation time was 3 d [1–6]; ICU stay 7 d [4–11]; overall hospitalization 26 d [16–54]. Post-LT 11/17 pts (65%) needed HD, 16/31 (52%) had infections and 12/31 (39%) early neurologic complications (delayed consciousness recovery, seizures). We observed 1/31 Yerdel-I portal vein thrombosis (43 d post-LT), 6/31 early acute rejection (med RAI 4/9) and 12/31 biliary complications (1 re-LT 39 d post-LT due to biliary necrosis). After a med follow-up of 4.3 y [1.7–6.3], mortality was 9.7%: 1 septic shock and 1 lymphoma within 3 months, 1 lung cancer after 6 y. 1- and 5- survival rates were 93%, 9-y 80%.
Conclusion: Emergency life-saving LT for ALF is a rare indication. Despite illness severity, high survival rate underscores the value of prompt multidisciplinary care.

Background and aims: Drug-induced liver injury (DILI) is the most frequent cause of acute liver failure (ALF) in high-income countries. While positive rechallenge has been associated with high mortality and liver transplant rate, data on "negative rechallenge" and the risk factors associated with DILI relapse are scarce. This study aimed to assess the incidence, characteristics, and safety of drug rechallenge in a real-world cohort.
Method: All DILI cases included in the DILI-cat registry were collected. Classical DILI criteria were used (ALT ≥5×ULN; AP ≥2×ULN or ALT ≥3 ULN + bilirubin ≥2×ULN). In patients who were retreated with a drug from the same family, time to retreatment, relapse and its severity were also recorded.
Results: 274 DILI cases were recorded in 10 university hospitals. Roughly, half were women, median age 59 years, 33% with history of dyslipidemia, 15% diabetes, 31% arterial hypertension and 10% chronic liver disease (mainly MASLD). Regarding DILI, most frequent drugs were antibiotics (21%), lipid-lowering (18%), oncohematological drugs (18%) and analgesics (11%). Biochemical pattern: hepatocellular (54%), cholestatic (29%) and mixed (17%). Up to 81% presented a RUCAM >6 points (likely or very likely causality). Forty-eight patients (18%) had exposure to ≥1 potentially hepatotoxic drug. Up to 40% patients were admitted to hospital, 4 (2%) developed ALF, but none died or required liver transplant. Overall, 41 (15%) subjects were retreated within a median time of 5 months (IQR 2–11) from the initial DILI episode. Retreatment was more common among DILI due to lipid-lowering (12/38, 32%) and oncohematological drugs (16/41, 30%), in comparison to antibiotics or antituberculosis agents ($p = 0.021$). Higher rechallenge rate was observed among subjects presenting with cholestatic pattern, in contrast to hepatocellular or mixed (28% vs 15% vs 19%, $p = 0.10$). Positive rechallenge (i.e. DILI relapse) was observed in 3/41 (7%) retreated patients. Two of the 3 cases were reported after exposure to the same drug: Irinotecan/oxaliplatin, latency time 1 month, hepatocellular pattern; co-trimoxazole, latency 6 months, cholestatic. The third occurred after switching within the analgesic class (metamizole to ibuprofen, cholestatic pattern, latency 1 month)). None of the relapses developed severe hepatitis.
Conclusion: Rechallenge after a DILI episode is not infrequent in clinical practice, and the rate of relapse is relatively low, especially among oncohematological and lipid-lowering drugs.

SAT-067
Multicenter evaluation of large language models versus hepatologists for prognostic prediction in drug-induced liver injury

Haoshuang Fu[1], Yanan Du[1], Gangde Zhao[2], Yan Zhuang[3], Tianhui Zhou[1], Rongtao Lai[1], Ruidong Mo[1], Qing Xie[1]. [1]*Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China;* [2]*Department of Infectious Diseases, Ruijin North Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China;* [3]*Department of Infectious Diseases, Wuxi Xinrui Hospital, Shanghai Jiao Tong University School of Medicine, Wuxi, China*
Email: 15670612801@163.com

Background and aims: Drug-induced liver injury (DILI) is the leading cause of acute liver failure in Western countries, and approximately 20% of patients progress to chronicity, potentially resulting in cirrhosis. The large language models (LLMs) provide new opportunities for clinical decision support. However, their prognostic value in DILI remains unclear. This study evaluated the performance of LLMs in predicting DILI outcomes and compared them with human experts.
Method: A total of 943 patients with RUCAM scores >6 were enrolled from three medical centers and classified as recovery, chronicity, or death at 6-month follow-up. Patients were divided into internal and external cohorts by enrolling centers. Three LLMs (GPT-5.1, Gemini-2.5 Pro, and DeepSeek-3.2) were evaluated using zero-shot prompting, and ensemble strategies (voting, OR, and AND rules) were applied to improve predictive stability. Junior, middle, and senior

hepatologists independently estimated the probability of progression to chronicity or death. Model performance was assessed using AUROC, accuracy, sensitivity, specificity, and agreement metrics.
Results: For chronic DILI, the senior hepatologist achieved the highest AUROC (0.61) and accuracy (70%). Among LLMs, GPT-5.1 showed the best performance (AUROC 0.59) with an accuracy of 53%, outperforming junior and middle hepatologists but remaining numerically inferior to senior expertise. DeepSeek demonstrated the highest sensitivity (0.80), whereas the middle hepatologist exhibited the highest specificity (0.86). Gemini-2.5 Pro showed the strongest agreement with the senior hepatologist ($\kappa = 0.43$). For lethal DILI, the senior hepatologist achieved an AUROC of 0.87 with accuracy of 83%, while GPT-5.1 yielded the highest LLM AUROC (0.86) with accuracy of 77%, outperforming junior and middle hepatologists but remaining inferior to senior expertise. Gemini-2.5 Pro demonstrated the highest sensitivity (0.86), whereas the middle hepatologist achieved the highest specificity (0.83). Across overall, internal, and external cohorts, the LLM-AND strategy maintained stable AUROC and accuracy without substantial inter-cohort variation.
Conclusion: LLMs demonstrated clinically relevant prognostic capability for DILI outcomes. The AND ensemble strategie improved robustness across cohorts and achieved performance comparable to senior hepatologists, supporting the potential role of aggregated LLMs as reliable decision-support tools in DILI prognosis.

SAT-068

Long-term outcomes following checkpoint inhibitor-induced liver injury

Kenza Faouzi[1], Alexandre Maria[1], Stéphanie Faure[1], Candice Lesage[1], Cyril Coustal[1], Marie Dupuy[1], Charles Catney[1], Georges-Philippe Pageaux[1], Quentin Thomas[2], Xavier Quantin[2], Lucy Meunier[1], Lina Hountondji[1]. *[1]Regional University Hospital Center of Montpellier, Montpellier, France; [2]Montpellier Cancer Institute, Montpellier, France*
Email: lina.hountondji@outlook.fr

Background and aims: Immune checkpoint inhibitors (ICIs) have become a cornerstone in the treatment of many cancers, significantly improving patient prognosis and survival. However, checkpoint inhibitor-induced liver injury (CHILI) occurs in up to 25% of treated patients and raises major challenges regarding the resumption of anticancer therapy once hepatitis has resolved. ICI rechallenge is associated with a 20–30% risk of hepatitis recurrence, and alternative treatments are often preferred despite limited data This study aimed to evaluate oncological management after CHILI and the risk of liver toxicity recurrence according to subsequent anticancer strategies over a two-year follow-up.
Method: CHILI-Outcomes is a retrospective, observational, multicenter study including adult patients treated with ICIs and discussed at the ImmunoTox multidisciplinary board. Clinical and biological data were collected at diagnosis and during follow-up up to 24 months. Data on cancer characteristics, oncological treatments, treatment rechallenge, hepatitis recurrence, and survival were analyzed. Chronic CHILI was defined as persistent abnormal liver tests at 6 months.
Results: Eighty-three patients were included between December 2018 and August 2023, predominantly men (61.4%), with a median age of 66.5 years. The main cancer types were lung cancer (35%) and melanoma (30.1%), mostly stage IV (66.2%). ICIs were mainly anti-PD(L)1 monotherapy (73.5%), and hepatitis severity was predominantly CTCAE grade III (75.9%). Corticosteroids were used in 74.4% of patients, and 5.1% required second-line immunosuppression. Chronic CHILI developed in 7.2% of patients. After a median follow-up of 25.5 months, 66.3% of patients resumed anticancer therapy, including ICIs (52.4%), tyrosine kinase inhibitors (29.5%), or chemotherapy (17.9%). Hepatitis recurred in 13 patients after ICI rechallenge and was attributed to ICIs alone in 11 cases and to combined ICI plus TKI in 2 cases. A favorable oncological response (complete, partial or stable) was observed in 33.7% of patients at 6 months (n = 28) and in 31.3% at 12 months (n = 26). Overall mortality was 43%, mainly related to cancer progression, while death from liver failure remained rare (8.4%).
Conclusion: In conclusion, most patients resumed anticancer treatment after CHILI, frequently with ICI rechallenge. Although hepatitis recurrence was more common with ICIs, long-term morbidity and mortality were primarily driven by oncological progression, with a low rate of chronic liver injury.

SAT-069

Significant liver fibrosis in patients with steatotic liver disease treated with Tamoxifen or Aromatase inhibitors: a cardiometabolic risk–driven phenomenon

Jae Yoon Jeong[1], Na Ryung Choi[1], Jung Hee Kim[2], Ju-Yeon Cho[3], Won Sohn[4]. *[1]Ewha Womans University Mokdong Hospital, Ewha Womans University College of Medicine, Seoul, Korea, Rep. of South; [2]Hallym University Dongtan Sacred Heart Hospital, Dongtan, Korea, Rep. of South; [3]Saint Louis University School of Medicine, Saint Louis University Hospital, St. Louis, United States; [4]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South*
Email: jyjeong76@hanmail.net

Background and aims: This study aimed to assess the risk of liver fibrosis in patients with steatotic liver disease (SLD) receiving tamoxifen or aromatase inhibitors. In particular, we investigated cardiometabolic factors associated with liver fibrosis in this population and compared the impact of tamoxifen and aromatase inhibitors on liver fibrosis.
Method: We conducted a cross-sectional study using a cohort from a tertiary referral hospital that included patients with SLD and breast cancer treated with tamoxifen or aromatase inhibitors. Liver fibrosis was assessed using transient elastography (TE). Significant fibrosis was defined as a liver stiffness measurement (LSM) ≥8.0 kPa. We evaluated the risk of significant fibrosis and fibrosis-related risk factors, including cardiometabolic factors such as overweight/obesity, prediabetes/diabetes, high blood pressure/hypertension, hypertriglyceridemia, and decreased high-density lipoprotein cholesterol levels.
Results: A total of 413 patients were included: 268 received tamoxifen and 145 received aromatase inhibitors. The mean age was 53 years. The mean LSM was 4.86 ± 2.52 kPa, and the prevalence of significant fibrosis was 6.3% (n = 26). In multivariable analysis, significant fibrosis was independently associated with hypertriglyceridemia (odds ratio [OR] 3.23, 95% confidence interval [CI] 1.08–9.55, p = 0.035) and high blood pressure/hypertension (OR 2.63, 95% CI 1.03–6.77, p = 0.044). However, the use of tamoxifen was not associated with a higher risk of significant fibrosis compared with aromatase inhibitors (OR 1.32, 95% CI 0.56–3.09, p = 0.531). There was no significant difference in the prevalence of significant fibrosis between patients receiving tamoxifen and those receiving aromatase inhibitors. The mean LSM values were 4.88 ± 2.52 kPa in the tamoxifen group and 4.82 ± 2.16 kPa in the aromatase inhibitor group (p = 0.841).
Conclusion: In patients with SLD and breast cancer receiving tamoxifen or aromatase inhibitors, liver fibrosis is more strongly associated with cardiometabolic risk factors than with endocrine therapy itself. These findings suggest that careful management of cardiometabolic risk factors is crucial in patients with SLD undergoing endocrine therapy.

SAT-070

Clinical relevance of albumin binding kinetics in patients undergoing extracorporeal albumin detoxification

Stine Koball[1,2,3], Adrian Dominik[1,3], Sebastian Koball[1], Michael Hinz[1], Jan Stange[1]. [1]*University of Rostock, Rostock, Germany;* [2]*Albutec GmbH, Rostock, Germany;* [3]*ProMedTec Germany GmbH, Rostock, Germany*
Email: stine.koball@gmail.com

Background and aims: Liver failure is associated with toxin accumulation that impairs albumin binding, increases toxin bioavailability, and promotes secondary organ failure with adverse clinical outcomes. Current extracorporeal liver support strategies like Multiple Pass Albumin Dialysis aim to restore albumin detoxification capacity by removing albumin-bound toxins and water-soluble toxins. This study aimed to characterize albumin binding kinetics using a dansylsarcosine-based method, evaluating its clinical relevance in patients with liver failure undergoing extracorporeal albumin detoxification. Functional assessment of albumin may provide essential guidance for timing and selection of detoxification therapies.
Method: Data was analyzed using the OPALESCE trial database, including patients treated with Molecular Adsorbents Recirculating System (MARS) and Open Albumin Dialysis (OPAL) therapy. Albumin binding kinetics at Sudlow site II were assessed by dansylsarcosine titration and ligand binding curve analysis using a modified binding model. The parameters Bmax (maximum number of binding sites) and Kd (binding affinity, defined as the ligand concentration at half saturation) were derived. Kinetic parameters were validated against previously published albumin function markers, including albumin binding capacity and electron spin resonance-based measures and then correlated with clinical scores.
Results: Higher Bmax values and lower Kd values were associated with better clinical status, including improved organ function scores. Correlations were observed with Glasgow Coma Scale, Sepsis-related Organ Failure Assessment score, Hepatic Encephalopathy Grade, Model for End-stage Liver Disease score, and Acute-on-Chronic Liver Failure-related scores. Treatment with extracorporeal albumin detoxification resulted in measurable improvements in albumin binding kinetics, reflected by increasing Bmax and decreasing Kd values, consistent with trends observed in established albumin function markers. These findings indicate partial reversibility of impaired albumin binding through extracorporeal support.
Conclusion: Dansylsarcosine-based kinetic modeling enables functional characterization of albumin binding in liver failure. Albumin binding function impaired by toxin accumulation shows improvement after extracorporeal albumin detoxification. Differentiation between reversible and irreversible albumin dysfunction may support individualized therapeutic decision-making and optimization of liver support strategies.

SAT-071

The dosage effect of polyene phosphatidylcholine injection for treating patients with acute drug-induced liver injury: a cohort trial

Ming Kong[1], Jiaqi Li[1], Yu Chen[1]. [1]*Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: chybeyond1071@ccmu.edu.cn

Background and aims: Polyene phosphatidylcholine (PPC) injection is widely used for various liver diseases in China. However, the optimal dosage of PPC injection for acute drug-induced liver injury (DILI) remains unclear. This study aims to investigate the dosage effect of polyene phosphatidylcholine in treating DILI.
Method: We conducted a cohort study involving patients with acute drug-induced liver injury who were admitted to Beijing Youan Hospital, Capital Medical University, Beijing, China. The patients were equally divided into two groups: the control group received 930 mg/d of PPC injection combined with other hepatoprotective agents; the study group received 1860 mg/d of PPC injection combined with the same other hepatoprotective agents, with a treatment duration of 7–14 days. The primary endpoint was above 50% reduction in alanine aminotransferase (ALT) after 7days treatment.
Results: A total of 60 patients with acute DILI were enrolled, with 30 patients in each group. There were no significant statistical differences in baseline ALT, aspartate aminotransferase (AST), total bilirubin (TBIL), age, or gender between the two groups. After 7 days treatment, the proportion of above 50% reduction in ALT was significantly higher in study group than control group (86.7% vs. 63.3%, $p = 0.037$). After 14 days treatment, the proportion of above 50% reduction in ALT was higher in study group (96.0% vs. 72.4%, $p = 0.028$), and the reduction proportion in AST was greater in study group (−79.3% [−86.9%, −68.1%] vs. −61.3% [−78.4%, −34.6%], $p = 0.035$). There were no serious adverse reactions in each group.
Conclusion: In this study, the study group showed more significant reductions in ALT and AST, which preliminarily indicates that higher dosage of polyene phosphatidylcholine is more effective in DILI, with well tolerated.

SAT-072

RECAM versus RUCAM for drug-induced liver injury diagnosis: a systematic review and validation study

Weiqian Lou[1], Chengwei Chen[2], Rongtao Lai[1]. [1]*Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China;* [2]*Liver Disease Research Center, 905th Hospital of PLA Navy, Shanghai, China*
Email: lairongtao1202@163.com

Background and aims: Drug-induced liver injury (DILI) has emerged as the predominant etiology of acute liver injury worldwide. While RUCAM served as the gold standard causality assessment method for three decades, the introduction of the electronic revision RECAM in 2022 generated substantial debate concerning diagnostic superiority and real-world applicability. To compare the diagnostic accuracy of RECAM against RUCAM across heterogeneous patient cohorts and determine the feasibility of RECAM as a replacement tool in routine clinical practice.
Method: A systematic literature search of PubMed, Embase, and Web of Science (January 2020–December 2024) identified validation studies directly comparing RECAM and RUCAM performance. Inclusion criteria required reporting of the area under receiver operating characteristic curve (AUROC), sensitivity, specificity, or inter-rater agreement (weighted kappa). We extracted data stratified by population characteristics, DILI phenotype (conventional pharmaceuticals versus herbal products), and discriminatory metrics.
Results: Two large-scale multicenter validation cohorts met inclusion criteria. Japanese investigators (RECAM-J 2023) evaluated 538 confirmed DILI patients and 128 alternative diagnosis controls, demonstrating an AUROC of 0.88 for probable/highly probable DILI detection after excluding viral hepatitis penalty scores. Chinese multicenter data encompassed 481 DILI cases (301 conventional drugs, 180 herbals) and 100 liver injury mimics spanning five tertiary centers. RECAM outperformed RUCAM across all subgroups: combined cohort AUROC 0.947 versus 0.867 ($P = 0.0016$), conventional agents 0.923 versus 0.819 ($P = 0.0185$), and herbal products 0.972 versus 0.911 ($P = 0.0199$). Principal scoring divergence between instruments derived from latency period interpretation, hepatitis B serology weighting, and prior drug hepatotoxicity classification. RECAM exhibited enhanced inter-observer reproducibility, electronic health record integration potential, and concordance with adjudicated expert consensus diagnoses.
Conclusion: RECAM demonstrates better diagnostic accuracy than RUCAM in diverse populations, particularly for herbal medicine-induced liver injury. Prospective validation among general practitioners and in specialized scenarios (e.g., immune checkpoint inhibitors, chronic DILI, transplant recipients) remains necessary before RUCAM replacement can be recommended.

SAT-073

Extreme hyperferritinemia is associated with high short-term mortality in acute liver failure and acute-on-chronic liver failure

Jonathan Lee[1], Diana Garcia[1], Costica Aloman[2,3], Nancy S. Reau[1]. [1]*Rush University Medical Center, Chicago, United States;* [2]*Westchester Medical Center, Valhalla, United States;* [3]*New York Medical College, Valhalla, United States*
Email: jonoslee@outlook.com

Background and aims: Ferritin has been studied as a prognostic biomarker. Studies have shown a significant correlation between marked ferritinemia and increased all-cause mortality in chronic liver diseases. Past investigations into the causes of extreme hyperferritinemia (EHF) have observed a high prevalence of liver disease, but few studies have focused on the type of liver injury and their associated mortality. This study aims to characterize the most common etiologies of EHF and to explore their associated prognostic outcomes.
Method: We performed a retrospective, single-center study on all adult patients presenting with a serum ferritin level >10,000 μg/L between January 1, 2014 and December 31, 2024. Demographics, laboratory values, etiology of EHF, and survival duration from time of ferritin result to death were collected. Chi-square and unpaired T-tests were used for bivariate analysis, as appropriate. A p-value of <0.05 was deemed statistically significant.
Results: 718 adult patients (mean age 56 years) met inclusion criteria with a median follow-up period of 272 days. Most patients were male (55.6%) and a plurality were Black (42.9%). The mean ferritin level was 23860 μg/L (range 10014–60000 μg/L). 377 (52.5%) patients lived and 341 (47.5%) patients died on follow-up. Mean ferritin levels were significantly higher in non-survivors than survivors (25107 vs 22675 μg/L, $p = 0.004$). Older age was significantly associated with mortality (60.2 vs 53.8 years, $p < 0.001$). EHF was most associated with liver disease (28.3%), infection (25.9%), and malignancy (15.9%). Acute liver failure (ALF) (88.7%) and acute-on-chronic liver failure (ACLF) (9.4%) comprised the majority of liver disease etiologies associated with EHF. The most common ALF etiologies were ischemic hepatitis (68.9%) and drugs/toxins (19.4%), whereas alcohol-associated hepatitis (84.2%) was the most common underlying chronic liver disease state identified in ACLF. ALF was associated with a significantly higher mean ferritin level than ACLF (28947 vs 20654 μg/L, $p = 0.004$). 54.4% of ALF patients died (mean survival 35 days) versus 42.1% of ACLF patients (mean survival 7 days).
Conclusion: There was a high prevalence of ALF and ACLF in EHF. EHF was associated with poor prognosis and significant overall short-term mortality. Our findings underscore the potential value of ferritin as an additional tool for overall mortality risk stratification. Future research should explore the prognostic value of non-EHF in ALF and ACLF.

SAT-074

Antineoplastic drug–associated hepatic steatosis: evidence from the FDA adverse event reporting system

Yanjie Lin[1], Gui-Qiang Wang[2], Hong Zhao[2]. [1]*Department of Infectious Disease, Center for Liver Disease, Peking University First Hospital, Beijing, China;* [2]*Department of Infectious Disease, Center for Liver Disease, Peking University First Hospital, Department of Infectious Diseases, Peking University International Hospital, Beijing, China*
Email: zhaohong_pufh@bjmu.edu.cn

Background and aims: Since drug-induced hepatic steatosis is relatively rare but closely related to adjusting the treatment of the primary disease, preventing liver steatosis and its inflammation. This study investigated the risk factors of drug-induced hepatic steatosis by analyzing a large dataset from the FDA Adverse Event Reporting System (FAERS).
Method: The reporting odds ratios (ROR) and information component (IC) were used to evaluate the reports of hepatic steatosis from the first quarter of 2004 to the third quarter of 2024. Univariate, LASSO and multivariate regression analyses were used to explore the risk factor. Moreover, the time to onset of hepatic steatosis was also assessed.
Results: Overall, 16,767 cases related to fatty liver disease were found in FAERS. In total, 117 drugs were found to be associated with hepatic steatosis, with antineoplastic drugs (28/117), antiviral drugs (18/117), psychotropic drugs (17/117), and immunomodulatory drugs (12/117) being the most common. Age under 41 years old, a heavier weight and 13 different drugs, including 3 antineoplastic drugs of interest, namely Methotrexate, Pegaspargase, and Tamoxifen, were risk factors for hepatic steatosis. The median time to onset was 123.50 days, while the onset of Pegaspargase was faster, with a median time of only 19 days ($p < 0.001$).
Conclusion: With the increasing variety of drugs, it's necessary to focus on hepatic steatosis and steatohepatitis caused by drugs, and adjust the therapeutic drugs in a timely manner to reduce the incidence of liver fibrosis, liver cirrhosis and prevent the interruption of treatment for the primary disease.

SAT-075

Predicting the unpredictable: machine learning outperforms MELD for ICU mortality in acute liver failure

Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: jeril.lasington@gmail.com

Background and aims: Acute liver failure (ALF) carries high ICU mortality, yet validated ICU-specific prediction tools remain limited. Traditional scores like MELD were not designed for acute presentations in critically ill patients. We developed and validated machine learning (ML) models to predict hospital mortality in ALF using readily available clinical parameters.
Method: This retrospective cohort study used MIMIC-IV (v3.1) to identify adults with ALF requiring ICU admission (2008–2022). Patients with pre-existing chronic liver disease or cirrhosis were excluded to focus on acute presentations. Predictors from the first 24 hours included demographics, vital signs, laboratory values, and ICU interventions. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, Gradient Boosting) were trained using 80/20 stratified splits with five-fold cross-validation. Performance was evaluated using AUC-ROC, AUPRC, and calibration analysis. SHAP analysis assessed feature importance.
Results: Among 2,024 ALF patients (mean age 60.1 years; 56.2% male), hospital mortality was 40.7%. Vasopressor support was required in 48.4% and mechanical ventilation in 46.1%. Random Forest achieved highest discrimination (AUC 0.804, 95% CI 0.765–0.841), significantly outperforming MELD (AUC 0.609) with 32% relative improvement. Cross-validation demonstrated model stability (AUC 0.79 ± 0.03). At optimal threshold, sensitivity was 59%, specificity 82%, PPV 69%, and NPV 74%. Feature importance revealed markers of shock (lactate, MAP), metabolic derangement (pH), and hepatocyte injury (ALT) as dominant predictors. Top features included maximum lactate (0.078), minimum pH (0.069), age (0.062), minimum MAP (0.055), and shock index (0.052).
Conclusion: ML significantly outperforms traditional MELD for ICU mortality prediction in ALF. The model identified clinically interpretable predictors emphasizing hemodynamic instability and metabolic derangement over liver-specific parameters alone. This tool may assist early risk stratification and resource allocation for critically ill ALF patients.

SAT-076

Impact of liver biopsy on causality assessment in checkpoint inhibitor–induced liver injury

Lucy Meunier[1], Alexandre Maria[1], Benjamin Riviere[1], Bénédicte Delire[2], Yves Horsmans[2], Dominique Larrey[1,3,4], Eleonora De Martin[5], Lucia Parlati[6], Marie Dupuy[1], Stéphanie Faure[1], Lina Hountondji[1]. [1]*Montpellier Hospital, Montpellier, France;* [2]*Saint Luc University, Bruxelles, Belgium;* [3]*CHU Montpellier, 34, Montpellier, France;* [4]*CHU Montpellier, Liver Unit, Montpellier, France;* [5]*Villejuif hospital, Paris, France;* [6]*Cochin Hospital, Paris, France*
Email: lucy-meunier@chu-montpellier.fr

Background and aims: The diagnosis of checkpoint inhibitor–induced liver injury (CHILI) remains challenging due to the lack of specific biomarkers. Consequently, the reliability of the RUCAM score for assessing causality of liver test abnormalities under ICIs, as well as the role of liver biopsy in diagnosing and staging CHILI, remains uncertain. The aim of this study was to evaluate whether liver histology impacts causality assessment in suspected CHILI.
Method: This study included adult patients diagnosed with CHILI who were followed for 6 months after liver biopsy at Montpellier University Hospital. All enrolled patients underwent a standardized causality assessment using the RUCAM score, independently calculated by two senior hepatologists responsible for patient inclusion. Discrepancies were resolved by consensus. RUCAM is a 14-point causality assessment tool categorized as follows: ≤0 (excluded), 1–2 (unlikely), 3–5 (possible), 6–8 (probable), and ≥9 (highly probable).
Results: Among the 50 patients, 58% were male, with a median age of 65 years (range 29.8–83.4). The median time from ICI initiation to hepatitis onset was 81 days (range 10–561). Anti–PD-1 monotherapy was the most frequently implicated regimen (n = 30; 60%). Liver injury patterns were hepatocellular in 42% (n = 21), cholestatic in 34% (n = 17), and mixed in 24% (n = 12). The median RUCAM score prior to liver biopsy was 7 (probable) (range 1–11), and 42 patients (84%) were classified as having probable or highly probable CHILI after biopsy. Interobserver agreement for RUCAM scoring was almost perfect, with an absolute agreement of 90.0% (κ = 0.80; 95% CI [0.63–0.97]). No discordance was observed in histological interpretation between observers. Although liver biopsy findings did not modify the RUCAM score, they contributed to confirming or questioning the diagnosis in 80% of cases (n = 40).
Conclusion: In patients with suspected CHILI, liver biopsy significantly influences causality assessment without modifying the RUCAM score. While RUCAM demonstrates good interobserver reproducibility, its limitations in CHILI underscore the added value of histological evaluation in selected cases. Causality assessment in CHILI is complex, as time to onset may be prolonged and concomitant treatments are frequent. Additional factors, including response to corticosteroids and the presence of other immune-related adverse events, should be integrated into diagnostic evaluation.

SAT-077

Lipopolysaccharide binding protein as a predictive biomarker for the onset of acute kidney injury in cirrhosis

Tadashi Namisaki[1], Masafumi Oyama[1], Tatsuya Nakatani[1], Kosuke Kaji[1], Hitoshi Yoshiji[1]. [1]*The Department of Gastroloenterology, Nara Medical University, Kashihara, Japan*
Email: tadashin@naramed-u.ac.jp

Background and aims: We aimed to identify plasma biomarkers that predict the onset and clinical outcomes of acute kidney injury (AKI) in patients with liver cirrhosis (LC).
Method: This retrospective case–control study included 182 patients with LC: 91 patients who developed AKI (AKI group) and 91 patients who did not develop AKI (non-AKI group) as controls. Plasma levels of lipopolysaccharide-binding protein (LBP), soluble CD163 (sCD163), and soluble mannose receptor (sMR) were measured at the time of AKI diagnosis in the AKI group and at a comparable clinical assessment in the non-AKI group. We investigated independent risk factors for AKI onset using multivariable logistic regression. Within the AKI group, we further examined predictors of 90-day mortality from AKI onset and poor treatment response (lack of AKI improvement) using multivariable models, and compared cumulative survival between groups stratified by biomarker cutoffs.
Results: Compared with the non-AKI group, the AKI group had significantly higher plasma levels of renin, angiotensin II, LBP, sCD163, and sMR. In multivariable analysis, LBP ≥2550 ng/mL was independently associated with AKI onset in patients with LC (odds ratio [OR] 4.30; 95% confidence interval [CI] 1.82–10.2; p < 0.001). Among patients with AKI, sMR levels were significantly higher in those who died within 90 days of AKI onset than in those who survived beyond 90 days. sMR ≥1595 ng/mL was an independent risk factor for 90-day mortality (OR 5.98; 95% CI 1.70–21.1; p = 0.0054), and cumulative survival was significantly lower in the high-sMR group (≥1595 ng/mL) than in the low-sMR group (<1595 ng/mL). In addition, sMR levels were significantly higher in patients with poor treatment response than in those whose AKI improved. sMR ≥1460 ng/mL was identified as a risk factor for poor treatment response (OR 3.52; 95% CI 1.09–11.3; p = 0.035), and treatment response rates were significantly higher in the low-sMR group (<1460 ng/mL) than in the high-sMR group (≥1460 ng/mL).
Conclusion: In patients with LC, elevated LBP may predict AKI onset, whereas elevated sMR may predict short-term survival and treatment response after AKI develops. These biomarkers may reflect endotoxin-related inflammation and macrophage activation and could enable earlier risk stratification and more tailored management of cirrhosis-associated AKI.

SAT-078

Association between biochemical patterns of DILI and histological findings in liver biopsies

Tayna Domingos[1], Vinicius Nunes[1], Luiz Antônio Rodrigues de Freitas[1], Genário Oliveira Santos Júnior[1], Raymundo Parana Ferreira Filho[1], Maria Schinoni[1]. [1]*University Hospital of Bahia, Salvador, Brazil*
Email: tayna.s.domingos@gmail.com

Background and aims: Drug-induced liver injury (DILI) presents a broad clinical and histological spectrum. While the biochemical classification into hepatocellular, cholestatic, and mixed patterns is central to clinical evaluation, its correlation with histology and severity remains limited.This study aimed to identify the histological correlates responsible for the clinical severity associated with different biochemical patterns of DILI.
Method: A cross-sectional study was conducted in individuals with DILI who underwent liver biopsy.Clinical, biochemical, and histopathological variables were evaluated.
Results: A sample of 58 patients was analyzed according to their biochemical pattern: hepatocellular (n = 41), cholestatic (n = 7), and mixed (n = 10). The hepatocellular pattern showed greater clinical severity, with progression to acute liver failure (ALF) in 73.2% of cases, compared to 0% in the cholestatic pattern and 40% in the mixed pattern (p < 0.05). This group presented higher medians of ALT (740 U/L), AST (889 U/L), and INR (2.35), in contrast to the cholestatic (ALT 208 U/L; AST 134 U/L; INR 1.0) and mixed (ALT 281.5 U/L; AST 306 U/L; INR 1.0) patterns. The presence of massive/submassive necrosis (n = 31) was significantly associated with the biochemical profile (p < 0.05). The group with necrosis consisted mainly of hepatocellular (83.9%) and mixed (16.1%) patterns, while the group without necrosis included all cholestatic cases (25.9%), as well as portions of the hepatocellular (55.6%) and mixed (18.5%) patterns. Clinical severity was higher in the group with necrosis, where 93.5% of patients progressed to ALF/transplant, compared to 18.5% in the group without necrosis (p < 0.05). Biochemically, necrosis presented higher values of: AST [median 843 (349–3041) vs. 348 (151–1000) U/L; p < 0.05], ALT [693 (467–1365) vs. 320 (210–935) U/L; p < 0.05], and INR [3.27 (2–5) vs. 1.02 (1–1.38); p < 0.05]. Furthermore, Hy's Law was

present in 83.8% of those with massive/submassive necrosis ($p < 0.05$). In contrast, hepatocellular ballooning was more frequent in the cholestatic pattern (71.4%) compared to the hepatocellular (9.8%) and mixed (20%) patterns ($p < 0.05$),indicating predominant cellular activity without progression to liver failure.
Conclusion: DILI severity is primarily driven by massive/submassive necrosis. While the hepatocellular pattern identifies risk, necrosis extent is the key prognostic determinant, surpassing isolated inflammation.These findings reinforce histological-biochemical integration for risk stratification.

SAT-079

Plasma exchange improves transplant-free survival in acute liver failure: a patient-level meta-analysis

Miguel Sogbe[1], Javier Perez de Rojas[2], Monica Rubio-Ardanaz[1], Paloma Sangro[3], Manuel de la Torre[3], Delia D'Avola[3], Mercedes Iñarrairaegui[1], Josepmaria Argemi[1], Bruno Sangro[1,3], Jose Ignacio Herrero[1]. *[1]Liver Unit, Clinica Universidad de Navarra, Pamplona, Spain, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Pamplona, Spain, Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain, Pamplona, Spain; [2]Department of Preventive Medicine Clinica Universidad de Navarra, Universidad de Navarra, Pamplona, Spain; [3]Liver Unit, Clinica Universidad de Navarra, Madrid, Spain, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Pamplona, Spain, Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain, Madrid, Spain*
Email: msogbe@unav.es

Background and aims: Acute liver failure (ALF) is associated with high short-term mortality, and liver transplantation (LT) remains the only definitive treatment. However, limited organ availability and strict eligibility criteria restrict its applicability and point to the need for effective alternative therapies. Plasma exchange (PE) has been proposed as a liver support strategy in ALF, but existing evidence is conflicting. We aimed to assess the impact of PE on transplant-free survival in ALF and to evaluate post-transplant outcomes when PE is used as a bridge to LT.
Method: A systematic search of PubMed/MEDLINE and Scopus was conducted to identify eligible studies published up to March 2025. Studies comparing PE with standard medical treatment (SMT), with LT allowed in both groups, were included. Eligible studies were required to report Kaplan-Meier survival curves with log-rank results and/or hazard ratios (HRs). Individual patient data were reconstructed from published Kaplan-Meier curves. The primary endpoint was transplant-free survival. Secondary analyses evaluated post-transplant survival among patients undergoing LT after PE versus SMT. Pooled HRs were estimated using one-stage Cox proportional hazards models with shared frailty, with sensitivity analyses using alternative meta-analytic approaches.
Results: Six studies comprising 447 patients were included. Among patients managed without LT, mortality was 47.6% (77/162) in the PE group compared with 80.8% (160/198) in the SMT group. PE was associated with significantly improved transplant-free survival (HR: 0.39; 95% CI, 0.29–0.52) compared to SMT. This finding was robust across sensitivity analyses, including cluster-robust Cox regression (HR: 0.41; 95% CI, 0.30–0.55) and a two-stage fixed-effects meta-analysis (pooled HR: 0.37; 95% CI, 0.28–0.49), with moderate heterogeneity (Cochran's $Q = 8.45$, $p = 0.13$; $I^2 = 40.8\%$). Among patients undergoing LT, mortality was 14.0% (6/43) in the PE+LT group and 18.1% (8/44) in the SMT+LT group. PE was not associated with improved post-transplant survival (HR: 0.84; 95% CI, 0.29–2.44).
Conclusion: In patients with ALF, PE is associated with a significant improvement in transplant-free survival but does not confer a clear survival benefit as bridge to LT. These findings support the use of PE as an effective supportive therapy for patients with ALF who are not immediate candidates for LT.

SAT-083

Concomitant medications associated with acute liver injury risk following amoxicillin/clavulanate exposure unexplained by other causes: signal detection analyses using electronic health record data

Richard Noriega[1,2], Jimmy Efird[3,4], Timothy Arnold[5,6], Chad Dorn[1,2], Ruth Reeves[1,2], Ayako Suzuki[1,7]. *[1]Health Services Research, Tennessee Valley Healthcare System VA, Nashville, TN, United States; [2]Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN, United States; [3]VA Cooperative Studies Program Coordinating Center, Boston VA, Boston, MA, United States; [4]School of Medicine, Case Western Reserve University, Cleveland, OH, United States; [5]Human Systems Integration, Office of Clinical Informatics, Office of Health Informatics, Digital Health Office, Veterans Health Administration, Washington, DC, United States; [6]College of Pharmacy, University of Michigan, Ann Arbor, MI, United States; [7]Gastroenterology, Duke University, Durham, United States*
Email: ayako.suzuki@duke.edu

Background and aims: Drug-induced liver injury (DILI) is an increasingly important public health issues. Although several genetic risk factors for DILI have been identified, clinical risk factors remain poorly defined, limiting risk stratification. We developed an electronic health record (EHR)-based framework to identify acute liver injury following amoxicillin/clavulanate exposure unexplained by alternative causes (ALI-AMX/CLAV) as a scalable DILI phenotype (PMID: 36547811). Using this approach, we explored concomitant medications associated with the risk of ALI-AMX/CLAV to identify potential clinical risk determinants.
Method: We analyzed Veterans Health Administration EHR data (1999–2015), comprising 1.4 million AMX/CLAV exposures in a predominately male population. We identified 2,249 ALI-AMX/CLAV cases and 4,427 acute liver injury cases associated with other causes (ALI-OTR). All medications co-administered at the time of AMX/CLAV exposure were extracted. Odds ratios (ORs) with 95% confidence intervals (CIs) were computed for each concomitant medication by comparing ALI-AMX/CLAV and ALI-OTR cases with AMX/CLAV-exposed referents without ALI. Models were adjusted for age, sex, race/ethnicity, care setting (inpatient vs. outpatient), and pre-existing liver conditions. Associations were categorized as specific to ALI-AMX/CLAV, ALI-OTR or shared across ALI phenotypes.
Results: Among AMX/CLAV-exposed individuals, 1582 unique concomitant medications were identified. After adjustment, 32 medications were associated with increased odds of ALI-AMX/CLAV only, 79 with ALI-OTR only, and 341 and 45 medications were associated with increased or decreased odds of both ALI-AMX/CLAV and ALI-OTR, respectively. Of the 32 medications specific to ALI-AMX/CLAV, 3 were anti-cholinergic, 9 had potential immunostimulatory effects, 4 were anti-androgenic, and 4 were antiviral agents, including two anti-HIV medications.
Conclusion: Distinct concomitant medications associated with increased odds of ALI-AMX/CLAV, many with immunostimulatory or anticholinergic properties, were identified. Anti-androgenic agents, potentially counteracting androgen-mediated immunosuppression, also emerged as important risk determinants in this male-dominant population. These findings generate biologically plausible mechanistic hypotheses for modifiers of AMX/CLAV-related liver injury risk and highlight the utility of EHR-based signal detection for future DILI risk assessment strategies.

SAT-084-YI

Development and external validation of the RE-AD score: a clinical-based machine learning tool for acute decompensation prediction in compensated advanced chronic liver disease

Marco Vicardi[1], Lorenz Balcar[2], Leonardo Antonio Natola[1], Filippo Cattaazzo[1], Manuele Bicego[1], Vincenzo Dimaria[1], Michele Bevilacqua[1], Aldo Filice[1], Anna Mantovani[1], Katia Donadello[1], Laura Alaimo[1], Georg Semmler[2], David Poulakos[2], Adrian Wunderbaldinger[2], Jan Embacher[2], Lucie Simonis[2], Andrea Ruzzenente[1], Veronica Paon[1], Donatella Ieluzzi[1], Nicola Zeni[3], Roberta Gagliardi[3], Rosa Lombardi[4], Enrico Polati[1], Luca Dalle Carbonare[1], David Sacerdoti[1], Mattias Mandorfer[2], Salvatore Piano[1], Andrea Dalbeni[1]. [1]*University of Verona and University and Hospital Trust (AOUI) of Verona, Verona, Italy;* [2]*Medical University of Vienna, Wien, Austria;* [3]*University of Padova, Padova, Italy;* [4]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy*
Email: marcovica98@gmail.com

Background and aims: Patients with compensated advanced chronic liver disease (cACLD) remain at risk of acute decompensation (AD), including acute-on-chronic liver failure, which carries high short-term mortality. Most available prognostic tools primarily predict overall hepatic decompensation and include a substantial proportion of non-acute decompensation (NAD) events, which usually follow a more indolent course. Therefore, accurate prediction of short-term AD in cACLD remains challenging. We aimed to develop and externally validate the Risk Estimation of Acute Decompensation (RE-AD) score, using machine learning (ML) to predict AD within 12 months and compare its performance with established scores.
Method: This multicenter retrospective study included consecutive cACLD patients from Verona and Vienna University Hospitals (2017–2024), followed for 12 months or until AD. The development cohort (n = 1,440) was analyzed using regularized ML with Leave-One-Out cross-validation and LASSO feature selection. External validation was performed in an independent cohort from Padua (n = 110). Model performance was assessed in terms of discrimination, calibration, and clinical utility. RE-AD was compared with FIB-4, APRI, ALBI, RESIST-HCV, ANTICIPATE ± NASH, Baveno VII criteria, and SAVE.
Results: Overall, 81 of 1,550 patients (5.2%) developed AD within 12 months. RE-AD incorporates age, number of hospital admissions (elective and non-elective) and infection episodes requiring antibiotics in the previous 12 months, serum albumin, and INR. Internal validation showed good discrimination (AUC 0.818, 95% CI 0.78–0.85), acceptable calibration, and high negative predictive value (99.1%), outperforming most comparators except for ALBI and SAVE. In external validation, RE-AD showed excellent discrimination (AUC 0.910, 95% CI 0.84–0.98), ranking highest among all comparators. High sensitivity (90.0%) and negative predictive value (98.9%) supported its role as a rule-out tool.
Conclusion: RE-AD is a clinically interpretable ML-based score designed to predict short-term acute decompensation in cACLD, addressing a clinical gap not fully covered by existing tools. The score demonstrated preserved discrimination across internal and external cohorts and relies exclusively on routinely available clinical variables, unlike some established scores (e.g. SAVE) requiring less frequently assessed information such as varices. These features support the use of RE-AD for individualized risk stratification and rule-out strategies in cACLD.

SAT-085

Fulminant autoimmune hepatitis: clinical presentation, diagnostic modalities, outcome and prognostic factors

Alejandra Villamil[1], Eduardo Mullen[1], Paola Casciato[1], Maria Acosta[1], Juan Bandi[1]. [1]*Hospital Italiano de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina*
Email: alejandra.villamil@hospitalitaliano.org.ar

Background and aims: Fulminant autoimmune hepatitis (AIH) is one of the leading causes of acute liver failure (ALF) in Latin America (18–26%). Early diagnosis and prompt initiation of corticosteroids may be lifesaving and could prevent the need for liver transplantation (LT). However, rapid diagnostic tools and reliable prognostic markers remain limited. Aims: To characterize the clinical presentation, diagnostic modalities, outcomes, and prognostic factors associated with fulminant AIH.
Method: A retrospective analysis was conducted on 307 consecutive patients evaluated for fulminant hepatic failure between 1994 and 2023. Eighty-six patients (28%) fulfilled simplified criteria for fulminant AIH; 7 with cirrhosis were excluded. Patients were analyzed in two periods based on the availability of transjugular liver biopsy (Group 1: 1994–2005, n = 28; Group 2: 2006–2023, n = 51). Autoantibodies, IgG, gammaglobulin, and ceruloplasmin were obtained in all cases; LC1 testing was added in 2009. Meprednisone (1 mg/kg orally or via nasogastric tube) was initiated at diagnosis.
Results: Seventy-nine fulminant AIH patients were evaluated. Encephalopathy was hyperacute in 1 patient, acute in 33 (41.7%), and subacute in 45 (55.9%). Overall, 63/79 (80%) patients died or required LT within a median of 7.8 days (range 1–34). Sixteen (20%) survived, 47 (60%) underwent LT, and 16 (20%) died without LT. Prognosis improved in Group 2 (71% vs 87% LT or death; $p < 0.05$), parallel to shorter time to diagnosis and steroid initiation (2.1 ± 1.7 vs 4.6 ± 2.1 days; $p < 0.05$). Liver biopsy (performed in 46/51 Group 2 patients) defined diagnosis in 29% and revealed massive or hemorrhagic centrilobular necrosis, both associated with poor outcomes. On multivariate analysis, independent predictors of poor prognosis were grade III/IV encephalopathy at treatment initiation (OR 5.11; 95% CI 2.18–10.23; $p = 0.04$) and lack of ≥20% improvement in PT/INR by day 3 of steroids (OR 6.07; 95% CI 1.49–27.45; $p = 0.01$). Early initiation of steroids (<36 hours of admission) was associated with better survival/ liver transplantation.
Conclusion: Early diagnosis—particularly through rapid-access liver biopsy—facilitates timely steroid therapy and improves survival in fulminant AIH. The integration of rapid ELISA-based autoantibody testing warrants further evaluation in high-prevalence settings.

SAT-086

A simple five-variable model integrating GWAS variants predicts chronic outcomes in drug induced liver injury

Weiwei Lou[1], Jingjing Jiang[1], Weiqian Lou[1], Xichen Zhu[1], Rongtao Lai[1], Qing Xie[1]. [1]*Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*
Email: lairongtao1202@163.com

Background and aims: In clinical practice, progression to chronic liver injury occurs in 6%-39% of drug induced liver injury (DILI) cases. However, reliable prognostic tools remain lacking. We aimed to investigate whether genetic variants associated with DILI susceptibility may predict chronic outcomes and thus fill the gap between genetic discovery and clinical translation.
Method: Between 2018 and 2023, we prospectively enrolled 338 well characterized DILI patients at Shanghai Ruijin Hospital. Chronic DILI was defined as persistent liver test abnormalities beyond 6 months. It developed in 167 (49.4%) patients. We analyzed the genotype of two significant single nucleotide polymorphisms (rs72631567, rs28531257), which were combined with routinely available laboratory parameters. These lab parameters included peak alanine aminotransferase, low-density lipoprotein cholesterol, and monocyte count. A light gradient boosting machine learning algorithm was trained on 270 patients and validated independently on 68 patients.
Results: Both genetic variants at rs72631567 and rs28531257 showed significant associations with chronic DILI progression. The integrated model achieved an area under the curve (AUC) of 0.92 (95% confidence interval 0.89–0.95) in the training cohort and 0.81 (0.70–0.91) in validation, substantially outperforming clinical variables alone (AUC, 0.57, $P < 0.001$). SHAP analysis revealed that rs72631567 contributed the greatest predictive weight, followed by peak transaminase levels.

Conclusion: The current work demonstrates that susceptibility variants from genome-wide association studies can be prognostic. Our five-variable tool requires only standard blood tests and straightforward genotyping. Early identification of high-risk patients may help determine the intensity of monitoring and therapeutic decisions, thus making precision medicine practical for DILI management.

SAT-087

Individualised treatment benefit of double plasma molecular adsorption system in patients with liver failure

Cai Gao[1], Beiling Li[2], Jian Zu[1], Rajiv Jalan[3], Jinjun Chen[2,4], Yee Hui Yeo[5]. *[1]School of Mathematics and Statistics, Xi'an Jiaotong University, Xi'an, China; [2]Hepatology Unit, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]Institute for Liver and Digestive Health, University College Hospital, Royal Free Campus, London, United Kingdom; [4]Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China; [5]Cedars-Sinai Medical Center, West Hollywood, United States*
Email: yeehui.yeo@cshs.org

Background and aims: Despite increasing use of the double plasma molecular adsorption system (DPMAS) in patients with liver failure, reported short-term survival benefits remain inconsistent, suggesting substantial heterogeneity in treatment response. Simple comparisons between DPMAS and standard medical treatment (SMT) may therefore be clinically insufficient. We aimed to estimate individualised treatment benefit and identify patients most likely to benefit from DPMAS.
Method: We conducted a prospective, multicentre cohort study of adults with liver failure (total bilirubin ≥12 mg/dL and international normalised ratio ≥1.5) treated with DPMAS or SMT across 50 hospitals. The primary endpoint was 28-day transplant-free mortality. Individualised treatment effects were estimated using a machine learning–based causal framework, predicting 28-day mortality under SMT and DPMAS for each patient. Absolute risk reduction was calculated as the difference between predicted risks, and patients were categorised into high-, indeterminate-, and low-benefit groups. Model interpretability was assessed to identify key variables associated with treatment benefit. Baseline characteristics across benefit strata were compared to identify distinct phenotypes.
Results: A total of 1,210 patients with liver failure were included, of whom 625 received DPMAS and 585 received SMT. Crude 28-day transplant-free mortality was 14.9% in the DPMAS group and 20.9% in the SMT group. Among the tested models, a CatBoost classifier within a doubly robust machine learning framework demonstrated the best performance. Predicted individualised treatment effects showed marked heterogeneity. Patients in the high-benefit tertile experienced an estimated absolute risk reduction of up to 13.7%, with a 22.06% difference in 28-day survival benefit between the high- and low-benefit groups. Key variables differentiating benefit strata were identified. The low-benefit group comprised two predominant phenotypes: patients with low baseline risk and mild disease, and patients with advanced, refractory multi-organ failure.
Conclusion: In this large multicentre cohort, the survival benefit of DPMAS was highly heterogeneous. Individualised treatment effect modelling identified clinically distinct subgroups with substantial differences in benefit, supporting a targeted-use strategy for DPMAS to improve patient selection and inform future clinical trials.

SAT-088

HLA-B*35:01 as a potent genetic risk factor for drug-induced liver injury in chinese patients: a prospective multicenter study

Mengmeng Zhang[1], You Deng[1], Yun Zhu[2], Liwei Liu[3], Liuyi Chang[4], Zhengsheng Zou[2], Liang Wang[5], Zikun Ma[1], Yao Meng[1], Tiantian Guo[1], Mengyu Zhao[1], Meng He[1], Xinyan Zhao[1]. *[1]Liver Research Center, Beijing Friendship Hospital,Capital Medical University, Beijing, China; [2]The Fifth Medical Center of PLA General Hospital, Beijing, China; [3]Beijing You'an Hospital, Capital Medical University, Beijing, China; [4]Yuncheng Central Hospital, Shanxi Medical University, Shanxi, China; [5]The Second Hospital & Clinical Medical School, Lanzhou University, Lanzhou, China*
Email: zhangmengmeng707@163.com

Background and aims: Idiosyncratic drug-induced liver injury (DILI), distinct from intrinsic type, is unpredictable and can lead to severe outcomes, including liver transplantation or death in 5–10% of cases. However, the genetic architecture of DILI in Chinese patients remains poorly defined. This study aimed to identify HLA susceptibility loci in a well-defined Chinese DILI cohort to facilitate the identification of high-risk individuals.
Method: Between June 2022 and December 2025, we prospectively enrolled patients from eleven centers across China. Patients with unclear drug exposure or confounding liver diseases (e.g., alcoholic liver disease, autoimmune hepatitis) were excluded. DILI diagnosis and culprit drug identification were adjudicated by a panel of three independent clinical experts for each case. To account for multiple comparisons across HLA alleles, the false discovery rate (FDR) was controlled using the Benjamini-Hochberg procedure, with reported q-values <0.05 considered significant. All analyses were performed using R software (version 4.4.1).
Results: A total of 547 patients were enrolled including 350 (64%) female and median age 55 years (IQR 45–64). Herb-induced liver injury was the predominant cause (299/547, 54.7%), with *Polygonum multiflorum* (90/547, 16.5%), *Scutellaria baicalensis* (65/547, 11.9%), and *Psoralea corylifolia* (35/547, 6.4%) identified as the most common agents. Hepatocellular injury was the major clinical phenotype. Among them, 374 patients had complete high-resolution HLA genotyping data. In this genetically characterized cohort, HLA-B*35:01 was carried by 136 patients (36.4%), including 6 homozygotes. The allele frequency was significantly elevated compared to population controls (0.225 vs. 0.001; $p = 3.30 \times 10^{-43}$), yielding an odds ratio (OR) of 54.4 (95% CI 18.24–256.37). This association remained significant after rigorous multiple testing correction ($q = 1.37 \times 10^{-41}$). Notably, the frequency of HLA-B*35:01 did not differ significantly between DILI cases attributed to *Polygonum multiflorum* or *Scutellaria baicalensis* and those caused by other herbs.
Conclusion: This study identifies HLA-B*35:01 as a key genetic risk factor for DILI in Chinese patients. Its association across multiple herbs suggests a shared pathogenic mechanism, supporting the potential for genetic risk assessment.

SAT-089-YI

Clinical characteristics, risk factors, and outcomes of immunotherapy-related hepatotoxicity: experience from a large retrospective cohort

Yang Zhi[1], Yinuo Dong[1], Jieting Tang[1], Yimin Mao[1]. *[1]Division of Gastroenterology and Hepatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, NHC Key Laboratory of Digestive Disease, Shanghai, China*
Email: maoym11968@163.com

Background and aims: Immunotherapy-related hepatotoxicity (IRH) is an increasingly recognized adverse event of immune checkpoint inhibitors (ICIs) that may compromise treatment continuity and outcomes. This study aimed to define the clinical characteristics, risk factors, and outcomes of IRH in a large real-world cohort of patients treated with ICIs.
Method: We conducted a retrospective, multicenter, electronic medical record-based study. Patients with malignancies who received ICI therapy at five tertiary centers in China from November 2018 to November 2024 with available liver biochemistry data both before and after ICI initiation were screened for eligibility. Patients with normal baseline liver biochemistry who developed abnormalities, as well as those with abnormal baseline who experienced a marked worsening following ICI therapy, were initially identified and

underwent causality assessment through an expert opinion process. Patients with confirmed IRH were classified into the IRH group, whereas those with non-IRH constituted the control group. The severity of liver injury was assessed using both the Common Terminology Criteria for Adverse Events (CTCAE) and the international expert working group (EWG) criteria for drug-induced liver injury (DILI).

Results: Of 15,835 patients screened, 4,641 (29.3%) were adjudicated as having IRH, while 10,043 served as non-IRH controls. Based on CTCAE criteria, 3,736 patients (80.5%) experienced grade 1 liver injury and 444 (9.6%) developed high-grade IRH (≥ grade 3). In contrast, by EWG criteria, 4,148 patients (89.4%) did not meet the diagnostic threshold for DILI, and only 9 (0.2%) were classified as having ≥ grade 3 liver injury. Although biochemical normalization was observed in most patients, 50 (1.1%) died or required liver transplantation within 21 days of the first IRH episode. Multivariable analysis demonstrated that younger age and anti-cancer regimen were independently associated with all-grade IRH. Hepatocellular carcinoma and higher baseline aminotransferase levels were additionally associated with an increased risk of high-grade IRH. Among patients with high-grade IRH, 184 (41.4%) were rechallenged with ICI, of whom 86 (46.7%) developed recurrent IRH, including 29 (33.7%) with high-grade IRH.

Conclusion: Marked discrepancies were observed between CTCAE and EWG grading of IRH severity. Younger age and anti-cancer regimen were consistently associated with increased risk of IRH, and rechallenge appeared feasible even in patients with prior high-grade IRH.

Acute liver failure and drug induced liver injury – Experimental and pathophysiology

Serum glycomics at admission predict liver transplantation-free survival in patients with acetaminophen-induced acute liver failure

Lorenz Grossar[1], Nicky Somers[1], Emma Butaye[1], Nicolas Debusschere[1], Thomas Vanwolleghem[2], Géraldine Dahlqvist[3], Jean Delwaide[4], Jef Verbeek[5], Lindsey Devisscher[6], Sander Lefere[1], Leander Meuris[7], Nico Callewaert[7], Sarah Raevens[8], Anja Geerts[8], Hans Van Vlierberghe[8], Xavier Verhelst[8]. *[1]Ghent University, Department of Internal Medicine and Paediatrics, Liver Research Centre Ghent, Ghent, Belgium; [2]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Antwerp, Belgium; [3]Hepatogastroenterology and Liver Transplantation, Cliniques Universitaires Saint-Luc, Brussels, Belgium; [4]Department of Gastroenterology and Hepatology, CHULiege, Liège, Belgium; [5]Department of Gastroenterology and Hepatology, University Hospitals Leuven, Leuven, Belgium; [6]Liver Research Centre Ghent, Ghent University, Gut-Liver Immunopharmacology Unit, Ghent, Belgium; [7]VIB Center for Medical Biotechnology, VIB, Department of Biochemistry and Microbiology, Ghent University, Ghent, Belgium; [8]Ghent University Hospital, Department of Gastroenterology and Hepatology, Liver Research Centre Ghent, Ghent, Belgium*
Email: lorenz.grossar@ugent.be

Background and aims: Acute liver failure (ALF) is a rare but potentially life-threatening clinical syndrome characterized by hepatocellular damage and impaired liver function. In the Western world, the majority of cases are caused by acetaminophen (APAP) overdose. In subjects not responding to medical therapy, emergency liver transplantation (ELT) is required to avoid fatal outcome. The decision to list a subject for ELT is based on imperfect prediction rules with strong specificity, but limited sensitivity, thereby providing good ruling-in capacity but unacceptably poor ruling-out performance. We investigated the potential to derive a serum glycomics biomarker able to predict transplant-free survival.

Method: We performed a prospective, multicenter study in five referral centers for ELT in Belgium, between 2014 and 2024. In 91 patients with APAP-related ALF, serum samples were collected within 24 hours of admission for analysis of the total serum N-glycome. Relative glycan abundancies underwent central log-ratio transformation before comparison between outcome groups to enable robust comparison of compositional data. Elastic net regression was used to derive a glycan score predictive of ELT. The optimal cut-off for classification was defined by the Youden index.

Results: Seven out of 91 (7.7%) subjects underwent ELT, with two deaths occurring after liver transplantation. Another five (5.5%) subjects died without undergoing prior ELT. In subjects in need of ELT, we observed an increase of the agalacto, core-fucosylated glycan NGA2F, and of the agalacto, core-fucosylated, bisecting glycan NGA2FB (independent t-test, p-values 0.0356 and 0.0239, respectively). After elastic net regression, a glycan score predictive of liver transplantation was derived, mainly characterized by a relative increase of undergalactosylation and fucosylation, and decreased branching of glycans. At the optimal cut-off of 0.0815, this biomarker predicted ELT with a sensitivity of 85.7%, specificity of 73.8%, and a negative predictive value of 98.4%. The area under the receiver operating curve was 0.833 (95% confidence interval: 0.711–0.955).

Conclusion: A distinct glycomic signature can be determined on serum admission samples of APAP-ALF patients, reliably ruling-out subjects not requiring ELT. Application of this serum biomarker could avoid unnecessary harm in subjects who would otherwise undergo ELT, and thus avoid significant morbidity and healthcare costs.

A novel mechanism by which the FABP4/CD36 axis exacerbates cholestasis via antagonizing FXR signaling

Yuelin Xiao[1], Tianhui Zhou[1], Haoshuang Fu[1], Shuying Song[1], Ziqiang Li[1], Qing Xie[1]. *[1]Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*
Email: cherlynxiao@163.com

Background and aims: Cholestatic liver injury involves multi-cell crosstalk, with liver macrophage activation key to amplifying injury. However, specific mediators directly disrupting bile acid (BA) homeostasis remain unclear. Farnesoid X receptor (FXR), a master regulator of BA metabolism (synthesis, transport, detoxification), is a common cholestasis driver due to impaired function. Our prior clinical data showed fatty acid-binding protein 4 (FABP4)—a macrophage-enriched lipid chaperone—is significantly elevated in cholestatic liver disease serum. Given its role in metabolic inflammation, we proposed that FABP4 drives liver injury not only through classical pro-inflammatory effects but, more importantly, by directly interfering with the hepatoprotective FXR signaling axis, thereby dominating the dysregulation of BA homeostasis.

Method: We used a multidisciplinary approach (genetic: Fxr-deficient mice; pharmacological: FABP4 inhibitor BMS309403) to induce cholestasis with alpha-naphthylisothiocyanate (ANIT). Liver injury was assessed via histology, serum biochemistry (ALT/AST, ALP, etc), and inflammatory markers. Molecular mechanisms were explored using immunohistochemistry, Western blotting, qRT-PCR, and in vitro experiments.

Results: In vivo results showed that inhibition of FABP4 by BMS309403 significantly protected WT mice against ANIT-induced liver injury, inflammation, and cholestasis. However, this protection was lost in *Fxr*$^{-/-}$ mice. Regardless of whether they received BMS309403 treatment, *Fxr*$^{-/-}$ mice exhibited comparable levels of necrosis, inflammation, elevated serum ALT/AST levels, and cholestasis, suggesting that the regulatory effect of the BMS inhibitor on key downstream targets (i.e, the BA synthetic enzymes CYP7A1 and

CYP8B1) is entirely dependent on FXR. In vitro experimental analysis also confirmed this hierarchical relationship: when FXR was silenced, the ability of BMS309403 or FABP4 knockdown to regulate gene networks was weakened. Furthermore, inhibiting FABP4 or its partner CD36 directly modulated FXR, CYP7A1, and CYP8B1 in primary hepatocytes, placing the FABP4/CD36 complex upstream of FXR signaling.
Conclusion: This study confirms macrophage-derived FABP4 is a key upstream FXR signaling suppressor in cholestatic liver disease. It drives cholestatic injury by blocking this core hepatoprotective pathway, causing uncontrolled BA toxicity. We reveal a novel immune-metabolic circuit (FABP4/CD36 to FXR) and validate FABP4 as a potential target for restoring BA homeostasis in cholestasis.

TOP-207
Serpine1 as a potential therapeutic target in pyrrolidine alkaloids-induced hepatic sinusoidal obstruction syndrome
Yifan Ma[1], Hong Gao[1]. [1]*Zhongshan Hospital, Fudan University, Evidence-based Medicine Center, Fudan University, Shanghai, China*
Email: gao.hong@zs-hospital.sh.cn

Background and aims: Hepatic sinusoidal obstruction syndrome (HSOS) induced by pyrrolidine alkaloids (PAs) is a life-threatening liver injury lacking standardized models that reflect its chronic progression in humans. This study aimed to establish a clinically relevant chronic PA-HSOS murine model and identify therapeutic targets by dissecting molecular mechanisms underlying endothelial injury.
Method: A 28-day murine PA-HSOS model was developed using key alkaloids (including seneciphylline, senecionine, and their N-oxide derivatives) from Gynura segetum, mirroring human exposure. Disease progression was evaluated via hematological profiling, CT imaging, histopathology, and transcriptomic analysis. A hepatocyte-liver sinusoidal endothelial cell (LSECs) co-culture system validated molecular pathways, while TM5441, a Serpine1 inhibitor, was tested for therapeutic efficacy.
Results: The murine model recapitulated human PA-HSOS features, including elevated liver enzymes (ALT and AST), coagulation dysfunction (prolonged PT/APTT and increased D-dimer), hepatomegaly, sinusoidal fibrosis, and loss of function of LSECs. RNA sequencing identified Serpine1 as the top upregulated gene, linked to p53 signaling. Co-culture experiments confirmed Serpine1-driven activation of the p53 pathway, promoting endothelial senescence. TM5441 treatment reduced the Serpine1-p53 axis activity, improved liver function, normalized coagulation, and restored LSECs integrity, with attenuated inflammation and fibrosis.
Conclusion: This study establishes the first chronic PA-HSOS model that faithfully mimics human disease and identifies Serpine1 as a pivotal therapeutic target. Targeting the Serpine1-p53 pathway with TM5441 represents a promising strategy for mitigating endothelial injury.

Email: sumansantra22@yahoo.in

Background and aims: Drug-induced liver injury (DILI) is a major global health concern. Anti-tubercular drugs account for the majority of DILI cases in India. Isoniazid (INH) is frequently associated with hepatotoxicity and can progress to chronic liver injury. The mechanisms linking INH-induced hepatocyte injury to hepatic stellate cell (HSC) activation and fibrosis remain incompletely understood. Exosomes are increasingly recognized as mediators of hepatocyte–non-parenchymal cell communication. This study aimed to evaluate whether exosomal microRNAs (miRNAs) released from INH-treated hepatocytes promote efferocytosis of HSCs and drive HSCs activation in chronic DILI.
Method: Exosomes were isolated from conditioned media of E47 cell line with or without INH treatment and were characterized using NTA, electron microscopy and Western blotting. Small RNA sequencing was performed to compare miRNA profiles between the 2 groups. Differentially expressed miRNAs were analyzed for functional relevance to phagocytosis and efferocytosis pathways. Selected miRNAs were validated using miRNA mimic transfection. Efferocytosis of HSCs and their activation were assessed by confocal microscopy, collagen type I (Col1a1) expression, and collagen secretion.
Results: Exosomal profiling demonstrated distinct miRNA cargo between with or without INH-treated hepatocytes. RNA sequencing identified multiple differentially expressed miRNAs. Top 10 down-regulated miRNAs in INH-treated exosomes were related to phagocytosis and cytoskeletal regulation. Among these, hsa-miR-145-5p was identified as a key regulator targeting RAC1, a mediator of cellular engulfment. Functional restoration of miR-145-5p using a miRNA mimic altered RAC1 expression and modulated HSC behavior. HSCs exposed to exosomes from INH-treated hepatocytes had increased engulfment of dead hepatocytes and phenotypic activation as evidenced by increased Col1a1 expression and total collagen secretion.
Conclusion: Exosomal miRNAs released from INH-treated hepatocytes contribute to HSC activation by promoting engulfment of dead hepatocytes. Down regulation of hsa-miR-145-5p and subsequent RAC1-dependent signalling appear to play a central role in this process. These findings highlight a novel exosome-mediated mechanism linking hepatocyte injury to fibrogenic HSC activation in INH-induced chronic DILI and suggest that targeting exosomal miRNA signalling may represent a potential therapeutic strategy to limit fibrosis in DILI.

THU-057-YI
Targeting impaired efferocytosis in acute-on-chronic liver failure: human mechanistic insights and murine macrophage therapeutic efficacy
Sunidhi Diwakar[1], Deepanshu Maheshwari[1], Nidhi Nautiyal[1], Sandeep Kumar[1], Manisha Manisha[1], Anupam Kumar[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: dr.anupamkumar.ilbs@gmail.com

Background and aims: Impaired efferocytosis contributes to inflammation and defective repair in cirrhosis and ACLF, but its role in ACLF remains unclear. We assessed efferocytosis in ACLF vs healthy and compensated (Comp.) cirrhosis patients and tested whether healthy bone marrow–derived Mϕ restore efferocytosis and promote liver repair in an ACLF mouse model.
Method: Blood samples were collected from healthy (n = 10), comp. cirrhosis (n = 20), and ACLF (n = 50) patients. $CD14^+$ monocytes were differentiated into Mϕ using Mϕ Colony-Stimulating Factor over 7 days. Efferocytosis and MER Tyrosine Kinase (MERTK)/T-cell Immunoglobulin and Mucin domain-containing protein 4 (TIM4) expression were analysed via flow cytometry and confocal imaging. Mϕ proteomics was performed and Energy metabolism assessed with Seahorse bioanalyzer. Mitochondrial (Mt) respiration's impact on efferocytosis in healthy assessed with rotenone, complex I inhibitor. In a murine ACLF model, Green Fluorescent Protein (GFP^+) Mϕ or saline were injected post-injury, followed by imaging, histology, and functional analysis.

Results: Mϕ single efferocytosis showed marked decline from healthy to cirrhosis to ACLF ($p < 0.0001$). Continuous efferocytosis was similarly low in ACLF and cirrhosis, but lower than in healthy ($p < 0.0001$). MERTK ($p < 0.001$) and TIM4 ($p < 0.001$) were higher in ACLF vs healthy and cirrhotic Mϕ. Global protein profiling of Mϕ showed early Mt biogenesis, fatty acid oxidation defects in cirrhosis, worsening in ACLF. Mϕ Mt energy metabolism declined from cirrhosis ($p < 0.001$) to ACLF ($p < 0.001$) compared to healthy. Healthy Mϕ showed ($p < 0.01$) reduction in efferocytosis with rotenone-induced Mt respiration defects. These data show Mt defects impair Mϕ efferocytosis in ACLF, despite increased efferocytosis receptors. Healthy mice Mϕ therapy in ACLF mouse model improved liver histology, reducing ballooning, necrosis, Inflammation. It decreased fibrosis ($p < 0.001$), High mobility group box 1($p < 0.0001$), Apoptotic$^+$ cells ($p < 0.001$), while enhancing hepatocyte proliferation ($p < 0.0001$) in treated group vs controls. therapy increased liver F4/80$^+$ ($p < 0.001$), efferocytosis ($p < 0.001$), phagocytosis ($p < 0.001$) vs controls, increased in-vitro BM cell maturation to Mϕ ($p < 0.0001$), efferocytosis function ($p < 0.0001$).
Conclusion: Impaired Mt metabolism reduces Mϕ efferocytosis in ACLF despite increased MERTK and TIM4. Healthy Mϕ transfer restores efferocytosis, reduces liver injury and inflammation, promotes regeneration, supporting Mϕ therapy in ACLF.

Sex-dependent modulation of acetaminophen-induced liver injury in diet-induced metabolic steatohepatitis

José Fernandez-Checa[1], Laura Fábrega[1], Paula Segales[2], Susana Nuñez[1], Manuel Romero-Gómez[3], M. Carmen Garcia-Ruiz[1].
[1]Institute of Biomedical Research of Barcelona, IIBB-CSIC, CIBEREHD, Barcelona, Spain; [2]Institute of Biomedical Research of Barcelona, IIBB-CSIC, Barcelona, Spain; [3]Unit of Digestive Diseases, Hospital Universitario Virgen del Rocio, CIBEREHD, Sevilla, Spain
Email: checa229@yahoo.com

Background and aims: Metabolic Dysfunction–Associated Steatohepatitis (MASH) alters hepatic lipid metabolism, inflammatory signaling and stress responses, potentially modifying susceptibility to drug-induced liver injury (DILI). Acetaminophen (APAP) overdose is the leading cause of acute DILI worldwide, yet the impact of diet-induced MASH on APAP hepatotoxicity, particularly in a sex-dependent context, remains poorly defined. This study aimed to determine whether MASH differentially sensitizes male and female livers to APAP-induced injury and to identify the underlying metabolic and stress-related mechanisms.
Method: Male and female C57BL/6J mice were fed a standard chow or a high-fat, high-cholesterol diet (HFHC; 60% kcal fat, 0.5% cholesterol) for 12 weeks to induce MASH features. Mice then received a single dose of APAP (300 mg/kg) and were sacrificed 4 hours post-administration. Hepatic injury and key metabolic, inflammatory, and stress-related pathways were assessed using biochemical, histological, and molecular approaches.
Results: HFHC feeding induced hepatic steatosis and metabolic dysfunction in both sexes but resulted in more severe macrosteatosis in males. This was associated with a stronger suppression of fatty acid oxidation pathways and enhanced lipogenic signaling in male livers. APAP administration exacerbated liver injury in HFHC-fed mice, with males displaying higher transaminase levels and impaired autophagic flux.
Inflammatory analyses revealed a pronounced pro-inflammatory response in males, characterized by macrophage and neutrophil infiltration and increased expression of pro-inflammatory mediators, whereas females exhibited a comparatively attenuated inflammatory profile with upregulation of anti-inflammatory and reparative markers. Combined HFHC feeding and APAP exposure amplified mitochondrial and ER stress signaling by STARD1–SAB axis activation, predominantly in males. Sex-specific differences were also observed in cholesterol metabolism, suggesting distinct adaptive capacities to metabolic and xenobiotic stress.
Conclusion: Diet-induced MASH enhances susceptibility to APAP hepatotoxicity in a sex-dependent manner. Although APAP sensitizes both sexes, male mice exhibit greater metabolic disruption, stress signalling activation, inflammation, and liver injury, while females show relative protection. These findings highlight biological sex as a critical modifier of DILI risk in MASH and support the need for sex-informed approaches in drug safety and liver disease management.

Email: jgconsuegra@cbm.csic.es

Background and aims: Estrogens exert a significant influence on liver physiology, with clear sex-based differences and metabolic alterations following menopause or ovariectomy (OVX). While their protective role against chronic liver diseases has been widely proposed, their involvement in drug-induced liver injury (DILI) remains poorly understood. Given the increasing prevalence of polypharmacy and acetaminophen (APAP) use in postmenopausal women, our study aims to explore how long-term oestrogen deprivation, mimicking the postmenopausal state, modulates susceptibility to APAP-induced liver injury. Understanding this relationship may provide key insights for improving clinical management and risk assessment in postmenopausal patients.
Method: 12-week-old female mice were either ovariectomized (OVX) or sham-operated. After 5 months they were treated with an APAP overdose (600 mg/Kg) and sacrificed after 6 hours.
Results: The TUNEL assay, revealed that OVX mice have less necrotic tissue than control, that correlated with less levels of GPT and GOT. Our results also showed that OVX animals exhibited an improved oxidized-to-reduced glutathione ratio and, overall, higher glutathione levels, an indicator of enhanced cellular well-being. These results were consistent with increased transcript levels of protective genes against cellular oxidative stress, such as HO-1, GCLC, GSR and GSTA, targets of the transcription factor NRF2.
Previous research had highlighted that NRF2 is activated by lipids that accumulates within the cells and prime the cells to protection against oxidative stress. As oestrogen deprivation induces hepatic lipid accumulation, we hypothesized a lipid-mediated protective mechanism. We demonstrated that after OVX there is an accumulation of fatty acids and less fatty acid oxidation (FAO), further validated by liver bulk RNA-seq analysis. Our data in mouse were corroborated by gene expression data from a cohort of human liver biopsies where we found higher levels of NRF2 and HO-1 expression in old women

(more than 50 years) than in younger women and men suggesting similar mechanisms activated in humans.
Conclusion: Estrogen deprivation leads to lipid accumulation within the liver, that further activates the oxidative stress response elements via NRF2 that might be exhibiting a protecting phenotype against APAP induced injury. These results are promising and open the door to diet-derived treatments against drug-induced liver injuries.

THU-060
Neutrophil calcium dynamics and recruitment in acetaminophen induced liver injury
Barbara Fidelix Santana[1], Guilherme Gomes[1], Isadora Feng[1], Sandhra Carvalho[1], Maria Eduarda Favalessa[1], Yuri Capato[1], Marcelo Souza[1], Maria Fernanda Amorim[1], Alfredo Goes[1], André Oliveira[1], Maria de Fátima Leite[1]. [1]*UFMG, ICB UFMG, Belo Horizonte, Brazil*
Email: bfidelixs@gmail.com

Background and aims: Acetaminophen (APAP) overdose is a major cause of drug-induced liver injury (DILI), in which neutrophils play a key role by responding to hepatocyte-derived danger signals and coordinating tissue repair. This study investigated how intracellular and extracellular calcium regulate neutrophil migration toward APAP-injured liver spheroids.
Method: Human neutrophils isolated from healthy donors were co-cultured with HepG2 liver spheroids pre-treated with APAP. Neutrophil migration and intracellular calcium dynamics were analyzed using confocal microscopy and automated cell tracking. Intracellular and extracellular calcium were selectively inhibited using BAPTA/AM and EGTA, respectively.
Results: Neutrophils exposed to APAP-treated spheroids exhibited enhanced recruitment compared with control spheroids, migrating longer distances (138.0 ± 96.8 micrometers vs. 75.9 ± 32.7 micrometers, $p < 0.001$) and accumulating preferentially near injured tissue (83.5 ± 10.3 percent vs. 66.2 ± 2.4 percent, $p = 0.034$). APAP injury did not alter the peak amplitude of intracellular calcium signals in neutrophils compared with controls ($p = 0.21$), indicating that increased recruitment was not driven by calcium signal magnitude. Chelation of extracellular calcium markedly impaired neutrophil motility, reducing migration distance and abolishing directional movement (all $p \leq 0.003$). Under these conditions, APAP treatment failed to promote neutrophil recruitment, demonstrating that calcium influx is essential for injury-directed migration. In contrast, inhibition of intracellular calcium mobilization did not suppress motility but significantly reduced directionality ($p = 0.01$), indicating loss of guided migration. Combined inhibition of extracellular calcium entry and intracellular calcium mobilization resulted in reduced neutrophil motility and directionality, with no differences between APAP-treated and control spheroids.
Conclusion: Collectively, our data demonstrate that although mobilization of calcium from intracellular stores is required for neutrophil directionality toward APAP-injured cells, it is not sufficient to sustain neutrophil migration. Instead, calcium entry emerges as the rate-limiting step for effective neutrophil motility. Given the critical role of neutrophils in liver repair during DILI, elucidating the mechanisms governing their recruitment to sites of injury may provide novel opportunities to improve the clinical management of patients with DILI.

THU-061
Cell-microcapsule-mediated oral delivery of nanoenzymes alleviates drug-induced liver injury via the gut-liver axis
Xiaoyu Huang[1 2,2], Fengmei Wang[1]. [1]*Tianjin First Central Hospital, Nankai University, Tianjin, China;* [2]*Nankai University, Tianjin, China*
Email: wangfengmeitj@126.com

Background and aims: Drug-induced liver injury (DILI) represents a major clinical challenge characterized by mitochondrial dysfunction, excessive reactive oxygen species (ROS) production, and inflammation. This study aims to investigate a novel liver-targeted oral delivery system utilizing cell-encapsulated nano-antioxidants to alleviate DILI and elucidate its mechanisms involving redox homeostasis and gut microbiota modulation.
Method: We designed a liver-targeted oral delivery system encapsulating nanoenzymes within cell vesicles to generate biocompatible anti-inflammatory nanoparticles. These nanoparticles are designed to resist gastric acid degradation and facilitate absorption via intestinal M cells for translocation to the liver. To validate safety and efficacy, a mouse model of DILI induced by APAP was employed. The therapeutic agents were administered orally one day prior to and concurrently with APAP injection. Mice were euthanized 24 hours later. Liver tissues were collected for histopathological examination, measurement of inflammatory cytokines, and molecular analyses including Western blotting.
Results: The cell microcapsules loaded with nanoenzymes demonstrated excellent ROS scavenging capacity, high stability within the intestinal environment, and favorable biocompatibility. In vivo tracking confirmed that the microcapsules effectively targeted macrophages in the liver. In the APAP-induced DILI mouse model, the nanoenzyme-loaded yeast cell microcapsules significantly alleviated body weight loss, hepatic fibrosis, and hepatocyte necrosis compared to the control group. Treatment also resulted in a marked reduction of inflammatory cytokines. Mechanistically, the intervention remodeled the gut microbiota, characterized by an increase in short-chain fatty acid levels through the suppression of harmful bacteria and the enhancement of beneficial bacterial populations.
Conclusion: This natural product-targeted oral delivery system offers a novel therapeutic approach for drug-induced liver injury through synergistic anti-inflammatory, antioxidant, and gut microbiota-modulating effects. The study elucidates the precise mechanism by which these nano-antioxidant agents protect against liver injury, laying the groundwork for the future development of nano-therapeutic materials for DILI management.

THU-062
A preclinical model of acute alcoholic hepatitis (AAH) in humanized liver mice
Eleanna Kaffe[1], Negin Farzad[2], Ruiqi Li[2], Yuval Kluger[2], Rong Fan[2], Wajahat Mehal[2], Richard Flavell[2]. [1]*Univ of Penn, Philadelphia, United States;* [2]*Yale University, New Haven, United States*
Email: eleana.kaffe@pennmedicine.upenn.edu

Background and aims: Acute Alcoholic hepatitis (AAH) is characterized by hepatocyte dysfunction, cholestasis, immune dysregulation, and high mortality[1–5]. A major limitation in the field is lack of preclinical models that reproduce all the above features. We evaluated whether a mouse with a humanized liver and immune system (HL-HIS) recapitulates key features of AAH.
Method: HL-HIS mice, containing human hepatocytes, human non-parenchymal cells (NPCs), and human immune system, were exposed to short-term alcohol feeding. Hepatocyte function, immune composition, and transcriptomic changes were analyzed and compared with human AAH datasets.
Results: Alcohol exposure induced severe steatosis, human-specific hepatocyte injury, cholestasis, impaired cholesterol-to–bile acid conversion, immune profile as in AAH and transcriptomic changes resembling the immune and hepatocyte dysfunction seen in AAH. Hepatocyte dysfunction included impaired antioxidant defense and bile acid synthesis as well as loss of HNF4α signaling. Immune profiling revealed reduced circulating T cells, increased hepatic cytotoxic T cells, and reduced liver-resident NK and Kupffer cells with impaired antimicrobial/antiviral programs. Hepatocyte steatosis and dysfunction were strongly dependent on signals from human NPCs.
Conclusion: HL-HIS mice faithfully model cholestasis, immune dysregulation, and hepatocyte dysfunction in AAH, providing a translational platform to dissect disease mechanisms. This model

reveals for the first time that hepatocyte steatosis and dysfunction are regulated in a paracrine manner and are not a direct effect of alcohol.

PLPP2 drives liver repair and regeneration via remodeling phosphatidylethanolamine metabolism after acute liver injury

Fan Li[1], Yiming Wang[2], Hao Wang[1], Ling Lu[1], Ming Ni[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, Nanjing, China;* [2]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*
Email: drlifan1999@163.com

Background and aims: Acute liver injury is commonly caused by overdose-drug, toxins, or ischemia. The liver possesses a remarkable regenerative capacity, wherein metabolic remodeling plays a crucial role. However, the specific metabolic shift that initiates hepatocyte regeneration remains unclear. We aimed to identify the key metabolic process driving the transition from liver injury to regeneration.
Method: We employed multi-time-point proteomic and metabonomic profiling to identify the key metabolic pathway and associated regulatory genes. We analysed liver samples from DILI patients and employed gene-modified mice. Transcriptomic and metabolomic were applied to validate the underlying mechanism.
Results: Multi-time-point multi-omics analyses demonstrated that phosphatidylethanolamine undergoes a dynamic metabolic reprogramming, with PLPP2 exhibiting synchronous changes among the enzymes regulating PE metabolism. Liver biopsy samples from patients with drug-induced liver injury corroborated the PLPP2 alterations. In murine models, hepatocyte-specific deletion of PLPP2 demonstrated its protective effect against ALI. Mechanistically, the resolution of ER stress was accompanied by a robust upregulation of PLPP2 during the regenerative phase. This shift promotes liver repair and regeneration by initiating the PE biosynthesis. PE, upon binding to PEBP1, modulated its affinity and strengthened its interaction with GLI1, thereby disrupting the association between ITCH and GLI1 and preventing the ubiquitination and degradation of GLI1. Additionally, PE promotes autophagy by facilitating the lipidation of LC3B. The increase of in ER-localized PE mediated by PLPP2 also contributed to alleviation of ER stress, thus establishing a positive feedback loop. Pharmacologic activation of PLPP2 may represent a promising therapeutic strategy for ALI.
Conclusion: The transition from reduction to elevation of PE maps to the pathological shift of liver from injury to regeneration following ALI, wherein PLPP2 serves as a switch initiating PE biosynthesis. Thus, targeting PLPP2 may represent a promising therapeutic strategy for ALI.

THU-068

Alarmin interleukin-33 protects against liver injury and promotes hepatocyte proliferation in acute liver failure

Mengqi Li[1], Hongshan Wei[2], Fan Xiao[3]. [1]*Capital Medical University, Beijing, China;* [2]*Department of Gastroenterology, Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [3]*National Center for Infectious Diseases, Beijing Ditan Hospital, Capital Medical University, Beijing Key Laboratory of Viral Infectious Diseases, Institute of Infectious Diseases, Beijing Institute of Infectious Diseases, Beijing, China*
Email: lmq000330@163.com

Background and aims: Interleukin-33 (IL-33), a member of the interleukin-1 (IL-1) family, regulates immunity and tissue repair, but its role in acute liver failure (ALF) remains unclear. This study evaluated the effects and mechanisms of IL-33 in concanavalin A (Con A)-induced murine ALF.
Method: Female C57BL/6J mice received concanavalin A (Con A, 10 mg/kg) with or without recombinant interleukin-33 (1 microgram per mouse, 2 h prior). Hepatic injury was assessed by serum transaminase levels and histological analysis. Interleukin-33 and inflammatory cytokines were quantified by enzyme-linked immunosorbent assay, quantitative real-time polymerase chain reaction, and Luminex. Flow cytometry was performed to analyze hepatic regulatory T cells and ST2-positive regulatory T cells, while hepatocyte proliferation (Ki-67) was evaluated by immunohistochemistry. Survival following lethal Con A challenge (25 mg/kg) was also assessed.
Results: Interleukin-33 was markedly upregulated during concanavalin A-induced liver injury ($p < 0.001$). Pretreatment with interleukin-33 was associated with reduced alanine aminotransferase ($p < 0.001$) and aspartate aminotransferase ($p < 0.001$) levels, as well as attenuated histological damage in concanavalin A (10 mg/kg)-treated mice ($p < 0.05$); however, increased mortality was observed under lethal challenge. Interleukin-33 treatment was associated with elevated serum interleukin-1 beta ($p < 0.001$), monocyte chemoattractant protein 1 ($p < 0.01$), and tumor necrosis factor alpha ($p < 0.05$) levels, together with increased hepatic interleukin-1 beta ($p < 0.05$) and monocyte chemoattractant protein 1 ($p < 0.05$), while hepatic tumor necrosis factor alpha expression was reduced ($p < 0.001$). In addition, interleukin-33 was associated with increased hepatic regulatory T cell proliferation ($p < 0.05$) and programmed cell death protein 1 expression ($p < 0.05$), particularly in ST2-positive regulatory T cells, as well as enhanced hepatocyte Ki-67 expression ($p < 0.001$).
Conclusion: Interleukin-33 appears to exert dual effects in acute liver failure, being associated with attenuated hepatic injury, enhanced immunoregulatory responses, and increased hepatocyte proliferation, while also increasing mortality under conditions of excessive immune activation. These findings suggest that interleukin-33 may represent a potential therapeutic target for acute liver failure; however, optimized combination strategies may be required to balance therapeutic efficacy and safety.

THU-069

Hepatocyte-specific activation of Mad2l1 protects against acute liver injury by preserving mitochondrial stress responses and restraining inflammatory amplification

Qiuhong Liu[1], Qingqing Hu[1]. [1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*
Email: liuqh@zju.edu.cn

Background and aims: Acute liver injury (ALI) and liver failure syndromes are characterized by severe hepatocyte damage and rapid deterioration of liver function occurring within a short period of time. Mad2l1 is a key protein in the spindle-assembly checkpoint (SAC) that can significantly affect the cell cycle and effectively induce apoptosis. However, the role of Mad2l1 in ALI has not yet been examined.

Method: Intrahepatic Mad2l1 expression was determined in both human and mouse ALI models. *Mad2l1*+/-, Alb^{cre} *Mad2l1*$^{f/f}$, and wild-type mice were were challenged by two independent ALI models, induced by acetaminophen (APAP) and lipopolysaccharide/D-galactosamine (LPS/D-GalN). Liver samples were collected for proteomics and post-translational modification proteomics (PTM) analysis. Histological, biochemical, and molecular studies were performed to evaluate liver injury in mice. Primary hepatocytes and hepatic cell lines were exposed to APAP or LPS/TNF-α for in vitro analysis.
Results: Intrahepatic Mad2l1 expression was significantly upregulated in human and mouse ALI models. Mice with systemic, liver-specific, or hepatocyte-specific Mad2l1 deficiency were vulnerable to ALI. Consistently, immunoblotting revealed increased expression of inflammatory, mitochondrial stress, and cell-death markers in Mad2l1-deficient livers, whereas hepatocyte-targeted Mad2l1 overexpression conferred protection. Integrated proteomics and PTM profiling revealed revealed injury-type–dependent programs: LPS/D-GalN injury featured suppression of mitochondrial oxidative phosphorylation/respirasome and RNA processing/translation (including reduced YTHDF2), alongside enrichment of complement–coagulation/platelet activation and leukocyte trafficking/phagocytosis pathways with prominent acylation remodeling; APAP injury preferentially showed peroxisome-centered metabolic rewiring with limited early PTM changes. Mad2l1 perturbation was further associated with altered ferroptosis-related proteins and mitochondrial oxidative stress markers in both cells and liver tissues.
Conclusion: Hepatocyte-targeted Mad2l1 deficiency worsens APAP- and LPS/D-GalN–induced liver injury by disrupting mitochondrial stress programs and amplifying inflammation, whereas Mad2l1 overexpression is protective. Hepatocyte-specific Mad2l1 might be a novel therapeutic target for ALI.

THU-070

Construction of engineered biliary trees with P-glycoprotein efflux function and enhanced resistance to drug-induced injury

Jun Li[1], Shiwen Ma[1], Jiaxian Chen[1], Meiqian Hu[1], Jiaojiao Xin[1], Dongyan Shi[1], Jing Jiang[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The reconstruction of functional biliary trees (FBT) is crucial in the development of bioengineered liver. Decellularized liver scaffolds (DLS), a common platform for FBT, suffer from mechanical instability, resulting in luminal collapse and consequent hypoxic stress that severely impairs FBT function. Additionally, current engineered biliary constructs lack the necessary injury resistance to endure the pathological microenvironment associated with end-stage liver disease. This work aimed to construct macro-scale FBT with enhanced injury resistance using rat DLS optimized by genipin and mouse primary cholangiocytes.
Method: The newly developed FBTs were systematically evaluated through functional assays, transcriptomic analysis, and hepatotoxic drug-induced injury testing to validate their structural stability and injury resistance.
Results: The FBT exhibited an optimized microenvironment with enhanced structural stability and fluid mechanical properties, which facilitated cholangiocyte adhesion and alleviated hypoxic stress, as evidenced by downregulation of the HIF pathway. Morphological evaluation revealed that the bioengineered FBT recapitulated the hierarchical branching architecture of native biliary networks, with well-organized luminal structures and proper apical-basal polarity. Scanning electron microscopy identified elongated, upright primary cilia projecting from the luminal cholangiocytes, while JC-1 staining confirmed preserved mitochondrial membrane potential—indicative of cellular health. Functionally, the FBT exhibited enhanced bile acid transport, marked by the upregulation of *Slc51a/Slc51b* (encoding OST-α/OST-β) and *Abcc3* (encoding MRP3), along with enhanced retinoic acid synthesis capacity. Compared to 2D monolayers, the FBT exhibited a superior polarity barrier and enhanced efflux capacity for toxic substances, supported by the upregulation of Abcb1a, which encodes the key efflux transporter P-glycoprotein (P-gp). Notably, such FBT maintained homeostasis and exhibited unique resistance to hepatotoxic injury. This toxic resistance was linked to P-gp-mediated efflux function in FBT, as demonstrated by the impairment of this protection following verapamil-mediated activity inhibition of P-gp.
Conclusion: The efflux transporter P-gp plays a critical role in the injury resistance of FBT. Our macro-scale FBT, with enhanced toxic efflux function and injury resistance, provides a promising strategy for bioengineered liver construction and clinical translation.

THU-071-YI

Bacteroides intestinalis AM1 remodels liver microbiome and toxic metabolites, highlighting a novel therapeutic strategy in acute liver failure

Sushmita Pandey[1,2], Neha Sharma[1], Nupur Sharma[1], Sadam H. Bhat[1], Vipul Sharma[1], Yash Magar[1], Abhishak Gupta[3], Babu Mathew[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Sanju Yadav[1], Manisha Yadav[1], Rakhi Maiwall[1], Anju Katyal[2], Shiv Kumar Sarin[1], Jaswinder Maras[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India;* [2]*Dr. B R Ambedkar Center for Biomedical Research, University of Delhi, New Delhi, India;* [3]*Artemis Hospital Gurgaon, Gurugram, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF), clinical syndrome of rapid hepatocellular injury with metabolic and linked microbial derangements. We investigated metabolic and microbial markers associated to predisposition to early mortality in ALF patients. We use Bacteroides intestinalis-AM1 to improve ALF outcomes.
Method: A plasma metabolomic and metaproteomic signature predicting non-survival in ALF was identified in 40 patients and 5 healthy controls and validated in 270 ALF patients using high-resolution mass spectrometry and machine-learning approaches. The therapeutic efficacy of *Bacteroides intestinalis* AM-1 was further confirmed in a preclinical acetaminophen-induced ALF mouse model.
Results: ALF non survivors (ALF-NS) exhibited elevated levels of primary bile acids and tryptophan metabolites, associated with inflammation, cell death, and mitochondrial dysfunction ($p < 0.01$, FDR<0.01, FC>1.5). Elevated chenodeoxycholic acid (CDCA; logFC >10) was associated with an increased risk of early mortality in ALF patients (hazard ratio >1.7; $p < 0.05$), which was independently validated in preclinical ALF mouse model. Additionally, ALF-NS exhibited an increased prevalence of pathogenic bacterial species Firmuctes, actinobacteria and others (FC.1.5; $p < 0.05$) and significant impairment of key microbial modulators involved in bile acid and other toxic metabolite regulation like chenodeoxycholic acid and cholic acid ($p < 0.05$). Oral *Bacteroides intestinalis* AM-1 (10^9 CFU/mL) supplementation in APAP-treated mice reduced muricholic acid and CDCA levels by restoring beneficial commensals like bacteriodes, lactobacillus and others ($p < 0.05$). *Bacteroides intestinalis* AM-1 enhanced glutathione-mediated NAPQI detoxification via upregulation of L-histidine amino-ligase and glutathione synthetase enzymes (FC>1.5; $p < 0.05$), while suppressing IL-1β/TLR4 signaling, oxidative stress, mitochondrial dysfunction, and caspase-3-mediated necroptosis in the liver of preclinical ALF model ($p < 0.05$).
Conclusion: Elevated plasma chenodeoxycholic acid (CDCA) is associated with poor prognosis in acute liver failure. Increase in pathogenic microbiome and loss of detoxifying commensals increase early mortality risk. *Bacteroides intestinalis* AM-1 restores microbiome balance, enhances glutathione synthesis, and reduces toxic metabolites, inflammation, mitochondrial dysfunction, and necro-apoptosis in a preclinical ALF model, thereby showing clear therapeutic benefits in a preclinical ALF model.

THU-072

Uncovering immune related mechanisms in drug-induced liver toxicity of sitaxsentan using human ex vivo precision-cut liver slices

Kevin Schmidt[1], Dana Oldenkott[1], Angelika Stucki-Koch[1], Josef Fangmann[2], Heiko Aselmann[2], Katherina Sewald[1], Jan Fiedler[1], Susann Dehmel[1]. [1]*Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany;* [2]*Krh Hospital Siloah, Hannover, Germany*
Email: kevin.schmidt@item.fraunhofer.de

Background and aims: Hepatotoxicity is a major reason for failure in clinical development and post-marketing withdrawal of therapeutics. Overcoming limitations of other pre-clinical liver models, human precision-cut liver slices (hPCLiS) retain the 3D complexity of the hepatic microenvironment, which is necessary to understand immune-related mechanisms in drug induced liver injury (irDILI). Here, we aim to uncover irDILI of endothelin receptor antagonist (ERA) sitaxsentan, withdrawn from the market due to hepatotoxicity.
Method: hPCLiS were prepared from tumor-distant liver resections using a Krumdieck slicer and cultivated under carbogen atmosphere. Immune cell abundance in hPCLiS was analyzed via flow cytometry. Immune responsiveness was shown by stimulation of hPCLiS with LPS, poly I:C, and anti-CD3/28 beads. HPCLiS were treated with sitaxsentan, ambrisentan, or acetaminophen (APAP) for 48 h. Release of lactate dehydrogenase into culture supernatant and cellular metabolic activity measurement by WST-1 turnover were used as indicators for general cytotoxicity. Cytokine protein levels as well as mRNA expression of inflammatory and hepatocyte markers were assessed using multiplex MSD platform and qPCR, respectively.
Results: Flow cytometry analysis revealed comprehensive immune cell presence (20–40%) including high T cell content (66%) with more abundant $CD8^+$ than $CD4^+$ cells (ratio 2.5) and 17% NKT cells. Of note, distinct cytokine secretion profiles of hPCLiS exposed to LPS, poly I:C, and anti-CD3/28 beads confirmed immune reactivity of the tissue. While no changes in general cytotoxicity were visible for both investigated ERAs, sitaxsentan preferentially induced secretion of IL-12p70, IL-13 and IL-2 hinting at Kupffer cell and NKT cell activation. In contrast, ambrisentan exposure did not induce such distinct cytokine pattern, which aligns with the less toxic clinical profile of the drug. Expectedly, toxicity of APAP in escalated doses was reflected by decreased metabolic activity and IFN-γ induction.
Conclusion: In summary, our data suggest early activation of Kupffer cells after sitaxsentan treatment, which could trigger further immune cell activation leading to hepatotoxicty. Shedding light on the yet unknown irDILI effects of sitaxsentan, the herein presented results advocate for hPCLiS as an invaluable pre-clinical model to assess safety of novel therapies, particularly addressing concerns about immune-mediated liver toxicity.

THU-073-YI

Plasma bacteriophage diversity correlates with microbiome diversity and contributes todiseases severity and poor outcome in acute liver failure

Neha Sharma[1], Sushmita Pandey[1], Manisha Yadav[1], Vasundhra Bindal[1], Sanju Yadav[1], Nupur Sharma[1], Babu Mathew[1], Gaurav Tripathi[1], Vipul Sharma[1], Rakhi Maiwall[1], Shvetank Sharma[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF) causes rapid liver injury and high infection-related mortality, but despite links to gut–liver axis disruption and microbial dysbiosis, the role of altered bacteriophage diversity in disease severity is still unclear.
Method: A total of 40 ALF patients and 5 Healthy controls(HC) were enrolled. Baseline Samples were collected before antibiotics. Plasma Peptide based bacteriophage diversity, metaproteome, and circulating indicator of gut barrier injury and microbial translocation (FABP2, LBP, and CD14) was analysed on ALF Non-Survivors(ALF-NS); n = 32, ALF-survivors(ALF-S); n = 8 and HC; n = 5.
Results: ALF-NS exhibited increased intestinal permeability and microbial translocation, with elevated FABP2 (1.62-fold), LBP (3.03-fold), and CD14 (8.01-fold), alongside marked gut microbiome dysbiosis identified bacterial peptides >15 phylum and >25 genera and showed higher Alpha/Beta diversity with increase in Firmicutes, Actinobacteria and others, functionally associated to energy, amino acids, xenobiotic metabolism compared to ALF-S and HC($p < 0.05$). ALF showed predominance of lytic phages (59.0%) with reduced temperate phages (27.6%) compared to HC. ALF-NS exhibited phageome restructuring with reduced Myoviridae (15.27% vs S 19.63%) and Inoviridae (0.83% vs S 1.46%), alongside enrichment of Corticoviridae (0.19% vs S 0.07%) and Siphoviridae (27.87% vs S 24.51%), and increased pathogenic phages including *Enterobacteria phage K11*, *Vibrio phage KVP40* ($p < 0.05$). Also, Shannon index viral diversity correlates with Shannon Diversity of bacterial ($R^2>0.9$, $p < 0.05$). Cross-correlation analysis revealed that increased *Lactococcus phage rt1*(11.8-fold) in ALF-NS was inversely associated with reduced abundance of beneficial commensal *Lactococcus* ($R^2>0.7$, $p < 0.05$). In ALF-NS, enrichment of pathobionts *Enterobacter* and *Pseudomonas* was inversely associated with marked depletion of their bacteriophages *Pseudomonas* phage D3 (0.065-fold) and *Enterobacteria* phage N4 (0.36-fold) ($p < 0.05$). This phage loss demonstrated strong prognostic performance (AUROC > 0.9) and was associated with increased mortality risk (hazard ratio 1.4; 95% CI 1.12–1.83; log-rank $p < 0.05$) showing that phage diversity in ALF regulates bacterial abundance and disease severity.
Conclusion: ALF-NS exhibit a pronounced loss of pathobiont-targeting bacteriophages, driving microbial dysbiosis, heightened disease severity, underscoring bacteriophage diversity as a critical regulator of microbial balance and ALF progression.

THU-074

Biomolecular mapping of circulating extracellular vesicles to develop AI driven prognostic panels for stratifying acute liver failure patients at risk of early mortality

Neha Sharma[1], Sushmita Pandey[2], Vasundhra Bindal[2], Manisha Yadav[2], Sanju Yadav[2], Nupur Sharma[2], Babu Mathew[2,3], Gaurav Tripathi[2], Vipul Sharma[2], Rakhi Maiwall[2], Shvetank Sharma[2], Jaswinder Maras[2]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi, India;* [3]*Institute of Liver and Biliary Sciences (ILBS), New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Acute liver failure (ALF) is a severe condition with high mortality, marked by microbial and metabolic factors in the blood. Plasma-derived exosomes, reflecting inflammation, offer a non-invasive tool to identify ALF patients at high risk of early mortality.
Method: Plasma samples from 50 ALF (25 non-survivors(ALF-NS), 25 survivors(ALF-S) patients and 20 controls were processed for extracellular vesicle isolation using protein organic solvent precipitation (PRoSPR) and characterized by transmission electron microscopy, dynamic light scattering, nanoparticle tracking analysis, and proteomic analysis, followed by meta-proteomic and metabolomic profiling. An identified diagnostic metabolite panel was validated in a separate cohort (220 ALF; 153 ALF-NS, 67 ALF-S) using HRMS and machine learning.
Results: Plasma-derived exosomes (120–200 nm) were characterised with a concentration of $3.25 \times 10^{11} \pm 0.55$ particles/mL, zeta potential of -30.67 ± 3.6 mV, and >20 EV-specific proteins (Vesiclepedia) ($p < 0.01$). Exosomal metabolomics identified over 1,000 metabolites, with more than 800 significantly altered in ALF. ALF-NS showed pronounced enrichment of long-chain fatty acid β-oxidation, and bile acid pathways, linking metabolic dysregulation to inflammation and disease severity. Bacterial-peptide identified >15 phyla and >25 genera based alpha/beta diversity was higher in ALF-NS

corresponding to increase in Bacteroidota, Actinomycetota functionally linked to energy and xenobiotic metabolism ($p < 0.05$). Higher EV levels of *Enterococcus ceocorum* and Klebsiella pneumoniae in non-survivors correlated with metabolites, Clinical parameters and severity ($r^2 > 0.8$, $p < 0.05$). A panel of five extracellular vesicle–derived metabolites showed strong prognostic potential in acute liver failure, achieving (AUC = 0.98) and a high hazard ratio (17.58). Deoxycholic acid-3-glucuronide(8.8 fold) showed highest normalized importance and predicted early-mortality with >95% accuracy/sensitivity/specificity using ANN and ML. Interestingly, Upregulation of β-glucuronidase (>2-fold) and reduced ABCC3 (MRP3) impaired bile acid efflux, driving intracellular bile acid accumulation and exacerbating hyperinflammation and oxidative stress in acute liver failure non-survivors.

Conclusion: Plasma-derived exosome metabolite cargo panel indicates hyper-inflammation and advanced glycation specific to non-survivors, potentially identifying ALF patients at risk of early mortality.

Assessing drug-mediated inhibition of liver transporter function with functional MRI: proof of concept

Sam Jenkins[1], Oliver Spear[1], Elliot Checkley[1], Marta Tibiletti[2], Thazin Min[3], Paul Hockings[4], Aleksandra Galetin[5], Gerry Kenna[2], Geoff Parker[2,6], Gunnar Schuetz[7], Daniel Scotcher[5], John Waterton[2,8], Ian Rowe[3,9], Steven Sourbron[10], Benjamin Rea[3,10]. [1]*Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom;* [2]*Bioxydyn Ltd, Manchester, United Kingdom;* [3]*Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [4]*Antaros Medical, Chalmers University of Technology, Gothenburg, Sweden;* [5]*Centre for Applied Pharmacokinetic Research, The University of Manchester, Manchester, United Kingdom;* [6]*UCL Hawkes Institute, Department of Medical Physics and Biomedical Engineering, University College London, London, United Kingdom;* [7]*Bayer AG, Berlin, Germany;* [8]*Centre for Imaging Sciences, Faculty of Biology Medicine & Health, The University of Manchester, Manchester, United Kingdom;* [9]*Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom;* [10]*University of Sheffield, Sheffield, United Kingdom*
Email: s.sourbron@sheffield.ac.uk

Background and aims: Assessing the risk of drug-mediated liver injury (DILI) and liver-mediated drug-drug interactions (DDI) for new drugs requires biomarkers that respond to drug effects on hepatic transporters. Unfortunately, predictions of changes in liver exposure are currently difficult to verify clinically. A potential solution is provided by dynamic MRI with the contrast agent gadoxetate, a known substrate of OATP1B1, OATP1B3, NTCP, MRP2 and MRP3. A recent study in rats with six test drugs has demonstrated that this method can detect different levels of transporter inhibition. The aim of this study was to test whether these results translate to humans, using two strong inhibitors (rifampicin and ciclosporin) and one drug that is not expected to inhibit gadoxetate transport (metformin).

Method: This prospective study included 20 healthy volunteers, split between rifampicin (n = 8), ciclosporin (n = 6) and metformin (n = 6) groups. Each participant underwent two visits separated by 1–4 weeks. At the second visit, a clinical dose of rifampicin (600 mg), metformin (1000 mg) or ciclosporin (100 mg) was administered orally prior to imaging. MRI data were analysed to measure the uptake rate k(he) of gadoxetate from extracellular space (e) into hepatocytes (h), and the excretion rate k(bh) from hepatocytes (h) to bile (b). Two MRI scans were performed on each visit, the first to measure acute drug effects, and the second to assesses functional recovery after acute inhibition. One quarter of a clinical dose of gadoxetate was administered for each scan.

Results: Rifampicin reduced k(he) with −93 ± 1.6% ($p < 0.001$) and k(bh) with −55 ± 29% ($p = 0.015$). Ciclosporin reduced k(he) with −79 ± 6.4% ($p = 0.002$) and k(bh) with −70 ± 20% ($p < 0.001$). Metformin did not have a measurable effect on k(he) (13 ± 53%, $p = 0.99$) or on k(bh) (−2.0 ± 45%, $p = 0.37$). In the ±4 hours after peak drug concentration, k(he) increased with 215 ± 88% for ciclosporin ($p = 0.005$) and 29 ± 12%, for metformin ($p = 0.005$), but did not change significantly for rifampicin (44 ± 45%, $p = 0.1$). k(bh) did not show systematic changes in the same time frame for any of the drugs.

Conclusion: Results demonstrate that gadoxetate MRI can characterise drug-mediated inhibition of hepatocellular uptake and biliary excretion in humans. The method may be useful for assessment of DILI and DDI during drug development, and potentially in patient management.

Disclosure: Transporter assessment for DILI or DDI is an off-label use of gadoxetate.

THU-076

Variation of CD39-positive tregs in idiosyncratic drug-induced liver injury

Maria Vargas[1], Stuart Astbury[1], Jane I. Grove[1], Guruprasad Aithal[1]. [1]*University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom*
Email: guru.aithal@nottingham.ac.uk

Background and aims: The pathogenesis of idiosyncratic drug-induced liver injury (DILI) involves a loss of immune tolerance, primarily characterised by a $CD8^+$ cytotoxic T cell response. The liver is considered an immunologically tolerant organ; a key inhibitory mechanism of this tolerance is mediated by regulatory T cells (Tregs), which not only inhibit antigen-presenting cells but also secrete anti-inflammatory cytokines such as interleukin-10 (IL-10) and transforming growth factor-beta (TGF-β). CD39 is an ectonucleotidase expressed on Tregs. It converts adenosine triphosphate into adenosine monophosphate, which is then converted into anti-inflammatory adenosine (by CD73), conferring immune-suppressive activity. $CD39^+$ Tregs are reduced in other autoimmune inflammatory diseases. We aimed to evaluate the Treg response in DILI.

Method: We evaluated CD39 expression in Treg cells ($CD4^+CD25^{hi}CD127^{low}FOXP3^+$), using peripheral blood samples from 11 DILI cases and 11 controls (5 healthy and 6 autoimmune hepatitis [AIH]). Cell subtype results are shown as proportions, while marker expression is shown by geometric mean fluorescence intensity (gMFI). Statistical analysis was performed using the Kruskal-Wallis test, with a significance threshold of $p < 0.05$. Outliers were identified using the ROUT method with Q1%.

Results: We observed decreased counts of total T cells ($CD3^+$), $CD4^+$, and $CD8^+$ T cells in DILI samples. Treg levels in DILI were 4.3% (0.3–14.1) of the $CD4^+$ subset, compared to 2.8% (0.8–5.7) in healthy controls and 2.8% (0.7–5.7) in AIH controls, showing no significant differences between the groups. In DILI, $CD39^+$ Tregs decreased significantly compared with healthy controls (56.6% of Tregs [6.4–96.8] vs. 90.5% [69.7–95.2], $p = 0.0158$), whereas $CD39^{low}$ Tregs increased in DILI relative to healthy controls (42.9% [3.2–93.4] vs. 4.7% [0.9–29.7], $p = 0.046$). $TGFβ^+$Tregs were significantly higher in DILI samples (3.4% of Tregs, range 1–31.6; $p = 0.0306$) compared to healthy controls (0.9%, range 0.75–2.9). No significant correlation was observed between CD39 and TGFβ expression (Spearman r = −0.3 in healthy controls; AIH r = 0.7; and DILI r = 0.52, p = ns). Therefore, the downregulation of $CD39^+$ Tregs in DILI does not correlate with TGFβ secretion.

Conclusion: Tregs in DILI are present in normal numbers and express elevated TGFβ. However, they exhibit functional deficits, particularly a decrease in the $CD39^+$ Treg subset, potentially contributing to the pathogenesis of DILI.

THU-077

Systematic drug screening in a patient-derived bile duct organoid biobank deciphers context-dependent bile duct injury mechanisms

Ziye Chen[1], Tianzi Luo[2], Mingming Ren[2], Yadi Geng[2], Yakun Liu[2], Meidai Liang[2], Zixuan Wang[3], Hui Bai[2], Yunfang Wang[1]. [1]*Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua Medicine, Tsinghua University,, Beijing, China;* [2]*Clinical Translational Science Center, Beijing Tsinghua Changgung Hospital, Beijing, China;* [3]*Liver Research Center, Beijing Tsinghua Changgung Hospital, Beijing, China*
Email: medical_chan@163.com

Background and aims: Drug-induced liver injury (DILI) is a major cause of clinical trial attrition. The mechanisms of its cholangiopathic subtype (DIBDI) are poorly understood, and crucially, how pre-existing biliary disease affects injury and repair remains unknown. Current bile duct organoid (BDO) models, limited in pathological scope, cannot address this. We therefore constructed a comprehensive BDO biobank to systematically investigate how disease background dictates susceptibility to and recovery from DIBDI.
Method: We established a biobank of patient-derived BDOs representing key pathological states (normal, dilation, cholangitis, choledocholithiasis), which were validated for morphological, phenotypic, and functional fidelity. To systematically investigate drug-induced injury, we screened six pharmacologically diverse agents known to cause bile duct damage (including glibenclamide, omeprazole, amitriptyline, chlorpromazine, moxifloxacin, azithromycin) using this platform. A refined injury model was then established, enabling the functional assessment of damage and repair dynamics. Finally, we employed integrated label-free imaging and Drug-seq to decipher the state-specific metabolic phenotypes and molecular mechanisms.
Results: Validation confirmed the high fidelity of our BDO biobank to patient tissues. Utilizing this platform for multi-drug screening, we discovered that drug-induced injury susceptibility is highly context-dependent, varying with both the specific agent and the underlying pathology. Drug-seq analysis provided high-resolution, dynamic transcriptomic landscapes for each drug-state combination. This approach identified both shared and state-specific signaturesof injury. A set of pathways—most prominently involving p53 signaling, cytoskeletal remodeling, and mitochondrial clearance—was consistently modulated across multiple drugs. The expression dynamics of genes within these pathways (e.g., *TESC*, *MUC1*, *GDF15*) defined distinct molecular trajectories that predicted and explained the functional sensitivity outcomes, mapping molecular perturbations directly to phenotypic responses.
Conclusion: Collectively, we have established a unique and pathologically diverse BDO biobank and we have enabled the first systematic exploration of how pre-existing disease dictates DIBDI outcomes. This work directly addresses a long-standing gap in mechanistic models and provides essential insights for stratifying hepatotoxicity risk and guiding targeted therapeutic interventions.

THU-078

Characterisation and applicability of a 3D coculture spheroid model for drug-induced liver injury

Neele Wewer[1], Lisa Rogalski[1], Julia Böhme[1], Maxi Paul[1], Dajana Lichtenstein[1]. [1]*German Federal Institute for Risk Assessment, Berlin, Germany*
Email: neele.wewer@bfr.bund.de

Background and aims: Conventional 2D monoculture lack the complex network of cell–cell and cell–matrix interactions that are crucial for maintaining physiological functionality. Many toxicological responses in hepatic tissue are dependent on the interplay between different liver cell types, which cannot be fully replicated in monocultures. To improve the predictability of human toxicity, we developed a 3D liver model by coculturing four different cell types as a spheroid, providing a more accurate *in vitro* representation of human liver physiology.
Method: For determination of optimal culture conditions, various cell lines, different cell numbers per spheroid, and suitable coculture media were evaluated. The final model comprises hepatocytes (HepaRG), macrophages (THP-1), endothelial cells (HMEC-1) and hepatic stellate cells (HHSteC), with 4,000 cells per spheroid in total. The spheroids were maintained for six days with cell-type ratios resembling those found *in vivo* in human liver tissue. The model was functionally characterized by morphological assessment, fluorescence imaging of cell-specific markers, mRNA expression analysis, and quantification of liver-specific secretion markers, specific CYP enzymes and transporters. To demonstrate the model's applicability, both mono- and coculture spheroids were exposed to reference compounds known to target liver-related endpoints.
Results: The presence of all four cell types as well as their typical morphological phenotypes could be provided by fluorescence imaging. To investigate the effects of a more physiological environment on hepatic function, mRNA and protein quantification data of the 3D coculture model were compared with those from a 3D monoculture of HepaRG cells after three and six days. Data exhibited similar protein expression of liver-specific CYP enzymes and transporters in mono- and coculture spheroids despite the differences in HepaRG cell numbers. Treatment with reference compounds displayed endpoint-specific responses, causing drug-induced liver injury such as phospholipidosis, inflammation, and impaired xenobiotic metabolism.
Conclusion: In conclusion, this 3D liver model is a promising *in vitro* system displaying relevant human liver physiology and enables the investigation of drug-induced liver injury mechanisms.

THU-079

Macrophage GPR65 sensing of lactate triggers pro-inflammatory polarization and aggravates APAP-induced liver injury

Miaomiao Wu[1]. [1]*Anhui Medical University, Hefei, China*
Email: wumiaomiao@ahmu.edu.cn

Background and aims: Acetaminophen-induced liver injury (AILI) is the leading cause of acute liver failure (ALF), yet the mechanisms driving excessive inflammation and disease progression remain poorly defined. Elevated serum lactate is a strong predictor of poor prognosis in APAP-related ALF, but the mechanistic basis for this association is unclear.
Method: Mouse models of AILI were combined with genetic and pharmacologic inhibition of lactate-GPR65 signaling, bone marrow transplantation, and macrophage-targeted AAV-F4/80-mediated modulation to determine functional of Macrophage GPR65. Bulk and single-cell RNA sequencing, macrophage functional assays, and analyses of blood samples from patients were performed to elucidate the underlying immunometabolic mechanisms and clinical relevance.
Results: We demonstrate that lactate functions not as a passive metabolic by-product but as an active immunometabolic driver in AILI. Excessive glycolysis caused marked lactate accumulation, which activated the macrophage GPR65 to induce pro-inflammatory polarization and promote inflammatory mediator release. Genetic deletion or pharmacologic blockade of lactate production or GPR65 signaling markedly attenuated AILI. GPR65 was selectively enriched in macrophages within the APAP-damaged liver and was also elevated in circulating monocytes of patients, correlating with inflammatory cytokines and disease severity. Single-cell analyses revealed that GPR65 promotes sustained differentiation of monocytes into CD68+ inflammatory macrophages, whereas Gpr65 deficiency favored the emergence of HMOX1+ macrophages with tissue-repair features, thereby reshaping the hepatic immune microenvironment toward reduced inflammation.
Conclusion: This study identifies lactate–GPR65 signaling as a key immunometabolic pathway that governs macrophage pro-

inflammatory polarization and amplifies hepatic inflammation during AILI, establishing GPR65 as a potential therapeutic target in drug-induced and inflammatory liver injury.

THU-083

IPA ameliorates acute-on-chronic liver failure by suppressing neutrophil extracellular trap formation

Hang You[1], Jing Xiao[1], Zongyi Liu[1], Yong Sun[1], Yu Zhang[1], Li Wei[1], Ning Ling[1], Hong Ren[1], Peng Hu[1], Shiying Li[1], Mingli Peng[1].
[1]*Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China, Chongqing, China*
Email: 1336438976@qq.com

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by numerical alterations and impaired function of neutrophils. Accumulating evidence suggests that gut microbiota and their metabolites play a pivotal role in the pathogenesis of HBV-related ACLF. This study aimed to investigate the potential role of the tryptophan metabolite indole-3-propionic acid (IPA) in HBV-ACLF.
Method: Using an integrated multi-omics approach combining metagenomic sequencing, targeted metabolomics, and bioinformatics, we profiled the gut microbiota–metabolite associations in ACLF and compared them with those in patients with decompensated cirrhosis (DC), compensated cirrhosis (CC), and chronic hepatitis B (CHB). The protective effects of IPA on ACLF mice were examined through in vivo and in vitro experiments, and the mechanism underlying IPA-mediated inhibition of neutrophil extracellular trap (NET) formation was further validated by immunoprecipitation, immunofluorescence, and related methods.
Results: Analysis of the CHB–CC–DC–ACLF disease progression revealed that, based on metagenomics, both α- and β-diversity of the gut microbiota were significantly lower in the ACLF stage than in the DC, CC, and CHB stages. Gene enrichment analysis indicated significant alterations in tryptophan metabolism, with marked downregulation of key enzymes involved in IPA metabolism (FLDB, ACDA). Further analysis showed a significant reduction in IPA-producing microbial taxa (Firmicutes, Ruminococcus and Faecalimonas). Targeted metabolomics demonstrated that IPA levels in plasma, feces, and liver tissue were markedly decreased in ACLF and closely correlated with AST, ALT, TBil, and INR. IPA supplementation improved survival in ACLF mice, ameliorated liver and kidney function, and suppressed the expression of inflammatory cytokines (TNF-α, IL-6). Mechanistically, IPA reduced the proportion of pro-inflammatory neutrophils and inhibited NET formation. Furthermore, IPA attenuated hepatocyte apoptosis by targeting the MAPK/p38 signaling pathway.
Conclusion: Our findings underscore the potential of the microbial metabolite IPA in ameliorating ACLF. As a gut-derived metabolite, IPA represents a promising therapeutic candidate with translational potential.

Defective antigen-presenting cell interleukin 23 support limits interleukin 22 production by mucosal-associated invariant T cell and tissue repair in chronic drug-induced liver injury

Cailun Zou[1], Zherui Liu[2], Zhuoya Deng[3], Zhengsheng Zou[2,4].
[1]*Department of Gastroenterology, China-Japan Friendship Hospital, Beijing, China;* [2]*Peking University 302 Clinical Medical School, Beijing, China;* [3]*Beijing Youan Hospital, Capital Medical University, Beijing, China;* [4]*Senior Department of Hepatology, Chinese PLA General Hospital, Beijing, China*
Email: zoucl302@163.com

Background and aims: Chronic drug-induced liver injury (DILI) is characterised by persistent hepatic inflammation and impaired tissue repair, yet the immunological mechanisms driving chronicity remain poorly defined. Mucosal-associated invariant T (MAIT) cells are highly enriched in the liver and implicated in tissue repair through interleukin 22, but their role in chronic DILI and the upstream signals regulating MAIT-cell repair functions are unclear. We aimed to define MAIT-cell involvement in chronic DILI and identify upstream molecular pathways governing MAIT-cell-mediated hepatic repair as potential therapeutic targets.
Method: We analysed MAIT cells in healthy controls (HC, n = 30), acute DILI (n = 43) and chronic DILI (n = 50) by flow cytometry. Plasma IL-23 was measured in HC (n = 26), acute DILI (n = 27) and chronic DILI (n = 27). Data-independent acquisition plasma proteomics was performed in HC (n = 8), acute DILI (n = 10) and chronic DILI (n = 10). Phorbol 12-myristate 13-acetate (PMA)-differentiated THP-1 macrophages were conditioned with pooled patient serum and analysed for IRAK4 and phosphorylated p65. Healthy-donor MAIT cells were stimulated with recombinant IL-23 or co-cultured with serum-conditioned macrophages to quantify IL-22 expression in MAIT cells.
Results: MAIT-cell proportions were reduced in both acute and chronic DILI versus HC, but chronic DILI showed higher HLA-DR expression, indicating persistent activation. Cytotoxic markers did not increase in chronic versus acute DILI. IL-22-positive MAIT cells were lower in chronic than acute DILI and inversely correlated with alanine and aspartate aminotransferase within chronic DILI. Chronic DILI serum reduced MAIT IL-22 ex vivo despite inducing HLA-DR. Proteomics highlighted suppressed toll-like receptor signalling, including reduced IRAK4 and nuclear factor kappa B 1, and THP-1 macrophages exposed to chronic DILI serum showed reduced IRAK4 and p65 phosphorylation. Plasma IL-23 correlated positively with IL-22-positive MAIT cells in chronic DILI ($r = 0.411$; $p = 0.033$). Recombinant IL-23 increased MAIT IL-22 dose-dependently, whereas chronic DILI-conditioned macrophages supported weaker MAIT IL-22 responses than acute DILI-conditioned macrophages.
Conclusion: Chronic DILI is characterised by persistently activated MAIT cells with selective IL-22 deficiency driven by impaired APC innate signalling and reduced IL-23 support. Targeting the APC-IL-23-MAIT-IL-22 axis may provide a mechanism-based therapeutic strategy for chronic DILI.

Alcohol-related liver disease and MetALD – Clinical

Fecal microbiota transplant for alcohol use disorder in patients with cirrhosis: a randomized controlled trial

Srajit Singh[1], Vinod Arora[1], Mohit Varshney[1], Vikas Khillan[1], Sukriti Baweja[1], Pramod Gautam[1], Rajan Vijayaraghavan[1], Harshvardhan Tevethia[1], Manisha Yadav[1], Shiv Kumar Sarin[1].
[1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: vinod_ucms@yahoo.com

Background and aims: Alcohol use disorder (AUD) worsens outcomes in alcohol related liver disease (ALD), with limited approved pharmacological therapies and a high relapse rate. Gut dysbiosis is increasingly recognised to influence alcohol craving, relapse, and disease progression. Preliminary studies suggest that fecal microbiota transplantation (FMT) may reduce alcohol craving; however, data in patients with ALD, particularly from Asia, remain limited. We evaluated the safety and efficacy of FMT as an adjunctive therapy for AUD in patients with ALD.
Method: In this single centre, randomised controlled trial, 54 patients with ALD and AUD were randomised in 1:1 ratio to receive either a single session of FMT delivered via upper gastrointestinal endoscopy plus standard medical therapy (SMT, comprising baclofen and structured AUD counselling) or SMT alone. The primary endpoint was the proportion of patients achieving and maintaining alcohol

abstinence at one month. Secondary endpoints included alcohol abstinence at 3 and 6 months; lapse and relapse severity; alcohol craving Obsessive Compulsive Drinking Scale (OCDS) and the Alcohol Use Disorders Identification Test (AUDIT) score; adverse events; disease severity scores like MELD and MELD Na and gut microbiota changes analysed before and after FMT using stool metagenomic analysis.
Results: Baseline characteristics including age (43.3 vs 45.6); CTP (6.8 vs 7.4); MELD (11.9 vs 12.7); OCDS (22.2 vs 21.6) and AUDIT (20.5 vs 19.3) scores were comparable between both arms. At 1 month, complete abstinence showed a favourable trend in FMT arm (52% vs 33.3%) and reached significance at 3 months, compared to SMT (22% vs 0%, $p < 0.023$), with sustained benefits at 6 months (11% vs 0). Relapse rates were significantly lower in the FMT arm at 3 and 6 months (36% vs 79.2%, $p = 0.04$; 45.5% vs 100%, $p < 0.01$). OCDS and AUDIT scores declined earlier and significantly more in FMT group ($p < 0.05$) at 1, 3 and 6 months. FMT resulted in improvement in MELD and MELD Na scores. Stool metagenomic analysis revealed that abstinent FMT patients had reduced alpha diversity along with increased ruminococcaceae, bifidobacteriaceae and decreased prevotellaceae and clostridiaceae, whereas relapse was associated with expansion of clostridiaceae and bacteroidaceae species.
Conclusion: FMT administration reduced relapse episodes and improves liver severity scores in ALD patients with AUD, with concordant gut microbiome changes supporting a mechanistic link.

GLP-1 RA use reduces the incidence of alcohol-associated hepatitis and risk of death in type 2 diabetes mellitus and alcohol use disorder in a routine clinical care stetting

Neha Shah[1], Vinay Jahagirdar[1], Kavin Parmar[1], Arun J. Sanyal[1].
[1]*Virginia Commonwealth University School of Medicine, Richmond, United States*
Email: shahn24@vcu.edu

Background and aims: Alcohol-associated hepatitis (AH) is an important complication of alcohol use disorder (AUD). GLP-1 receptor analogs (GLP-1 RA) have recently been shown to reduce alcohol craving and are being evaluated for AUD. It is not known if GLP-1 RA reduces the risk of AH in those with AUD. The aim of this study was to determine if GLP-1 RA use reduced (1) the risk of developing AH and (2) other liver and cardio-renal-metabolic (CRM) outcomes and (3) improve mortality in those with T2DM and AUD.
Method: A retrospective analysis of adults with T2DM and AUD from 2020–2025 was performed using the TriNetX collaborative research database, which includes patient level anonymized data from over 100 million individuals across multiple health systems in USA and Europe. GLP-1 RA use was established from prescriptions and outcomes assessed during period of active prescription use. Key outcomes were mortality, AH, ascites, encephalopathy, atrial fibrillation, heart failure and MACE. Those who received GLP-1 RA were compared to propensity score match (PSM) controls who did not. PSM was done for age, gender, race, BMI, nicotine dependence, hypertension, laboratory parameters (bilirubin, AST, ALT, creatinine, INR, A1C) and statin use. The absolute and relative risks from time-dependent proportional hazards models were computed. Time to event analyses with Kaplan-Meier curves and across-group comparisons with logrank test were done.
Results: A total of 131900 individuals with T2DM with AUD were identified with 15300 who received a GLP-1 RA for at least 1 year. Following PSM, GLP-1 RA decreased the incidence of AH (HR: 0.20–0.27, $p < 0.0001$ for all) with greatest decrease in those > 60 yrs. Within 6 mo-3 yrs, absolute risk of AH decreased to 0.2% to 0.8% with GLP-1 RA, compared to 1.3% to 2.0% without GLP-1 RA (HR 0.2–0.4 $p <$ 0.0001 for all). GLP-1 RA improved other liver related events: new diagnosis cirrhosis (HR 0.21–0.57), ascites (0.21–0.32), encephalopathy (HR: 0.24–0.54) $p < 0.01$ for all. It also decreased atrial fibrillation (HR: 0.31–0.44), heart failure (HR: 0.33–0.44) and 5-point MACE (HR: 0.26–0.75) $p < 0.001$ for all. It further decreased sepsis (HR: 0.24–0.31). Overall GLP-1 RA reduced all-cause mortality (HR: 0.29–0.42, $p < 0.0001$ for all).
Conclusion: GLP-1 RA use reduced development of AH in those with AUD and T2DM. These data provide a strong rationale to study this in a prospective randomized trial inclusive of diabetic and non-diabetic individuals.

Email: astridmarot@gmail.com

Background and aims: Recent data suggest an increased risk of alcohol-related liver disease (ARLD) in patients with prior bariatric surgery (BS). The aims were to evaluate the impact of prior BS on mortality in patients with ARLD at different stages of severity (i.e. compensated ARLD, decompensated ARLD, and alcohol-associated hepatitis [AAH]) and to assess the risk of hepatic decompensation in those with compensated ARLD both with and without prior BS in a large multicenter retrospective study.
Method: We included 794 patients with ARLD in 3 Belgian centers between January 4th 2010 and 31st December 2024. The median follow-up was 2.6(IQR 0.4–6.8) yrs. Cumulative incidence functions were applied in patients with AAH and those with compensated and decompensated ARLD separately. Competing-risks regression procedures were performed.
Results: Almost 15% of patients (115/794) with ARLD had a prior BS. At inclusion, 377 patients had a compensated ARLD, 189 had a decompensated ARLD, and 228 had an AAH. Compared to the non-BS group, patients with a prior BS were predominantly female (50.4%vs 27.5% $p < 0.001$), younger (51 vs 56 yrs $p < 0.001$) with a higher proportion of Child-Pugh C (47.4% vs 27.4% $p < 0.001$). They were also younger at transplantation (48 vs 58 yrs, $p < 0.001$) and at death (50 vs 59 yrs $p < 0.001$). In patients with AAH, cumulative incidence of death at 6 months was not different between both groups (33.9%vs 47.4% $p = 0.1$). In multivariate analyses, age (SHR1.03 $p = 0.001$) and MELD score (SHR1.08 $p < 0.001$) were independently associated with mortality but not prior BS. In patients with compensated and decompensated ARLD, cumulative incidence of death at 3 yrs was not different between both group (23.1%vs 21.5% $p = 0.77$). In multivariable analyses, MELD score (SHR1.19 $p < 0.001$) abstinence (SHR0.31 $p = 0.01$) and prior BS (SHR5.98 $p = 0.03$) were independently associated with mortality. In compensated ARLD, hepatic decompensation was more frequent in the BS group compared to the non-BS group. In multivariable analyses, MELD score (SHR1.12 $p <$ 0.001) and prior BS (SHR2.24 $p = 0.02$) were independently associated with hepatic decompensation.
Conclusion: Despite being younger at inclusion, liver transplantation and death, ARLD patients with a prior BS have more severe liver disease than those with no prior BS. Prior BS is associated with higher mortality in patients with compensated and decompensated ARLD, but not in patients with AAH. In compensated ARLD, prior BS is also associated with a higher risk of first hepatic decompensation.

Alcohol-related liver disease with latent fibrosis: an indolent phenotype in abstinent patients

David Heitmann[1], Lucía Ramón[2], Lorenzo Ciocca[1], Queralt Herms[1], Martina Perez-Guasch[1,2,3], Ruth Nadal[3], Marta Cervera Carbonell[3], Nicole Casanova[3], Cautar El Maimouni[1,3], María José Moreta[1,3], Anna Soria[1,3], Adrià Juanola[1,2,3], Isabel Graupera[1,2,3], Núria Fabrellas[2,3], Jordi Gratacós-Ginès[1,3], Pere Ginès[1,2,3], Elisa Pose[1,2,3]. *[1]Hospital Clínic De Barcelona, Barcelona, Spain; [2]Universitat de Barcelona - Facultat de Medicina i Ciències de la Salut, Barcelona, Spain; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain*
Email: heitmann@clinic.cat

Background and aims: Liver fibrosis, together with alcohol abstinence, is the main prognostic factor in alcohol-related liver disease (ArLD). Liver stiffness measurement (LSM) by transient elastography, which correlates with the degree of fibrosis, has also prognostic value. Some patients show advanced fibrosis on liver biopsy but discordantly low LSM, suggesting a distinct clinical phenotype. The aim was to characterize these patients and assess their prognosis.
Method: We prospectively includedconsecutive patients with ALD who underwent liver biopsy at Hospital Clínic of Barcelona from 2013 to 2025 (LiverModel cohort). Patients with non-advanced fibrosis (METAVIR <F3), clinical decompensation at baseline, and lacking baseline LSM were excluded. Two groups were defined according to LSM: <10 kPa and ≥10 kPa. Liver-related events (LRE) included portal hypertension–related decompensation, hepatocellular carcinoma, liver transplantation, or liver-related death. Prognosis was assessed by an Andersen–Gill Cox regression model (allowing recurrent events), adjusted for age and sex. A subanalysis was performed in patients with sustained abstinence throughout follow-up, assessed by self-report and family interview, or by urinary ethyl glucuronide when available.
Results: A total of 115 patients were included: 23 (20%) with LSM < 10 kPa and 92 (80%) with LSM ≥10 kPa. The proportion of females (26% vs. 23%) and mean age (64 vs. 60 years) were similar (p > 0.05). No differences were observed in the prevalence of metabolic risk factors. Patients with LSM <10 kPa had lower MELD scores (9 vs. 11, p = 0.01). Abstinence at inclusion (48% vs. 43%) and its duration (4 vs. 5 months) did not differ (p > 0.05). Over a median follow-up of 3.6 years, 7 LRE occurred in 2 patients with LSM <10 kPa, while 43 LRE occurred in 23 patients with LSM≥ 10 kPa. In the overall cohort, LSM≥ 10 kPa showed a trend toward a higher risk of LRE (HR 2.14; 95% CI 0.59–7.71; p = 0.25). In patients with sustained abstinence (n = 71), no patient with LSM <10 kPa experienced a LRE, whereas 17 patients with LSM≥ 10 kPa accumulated 29 LRE. Predictive models could not estimate a finite HR due to complete separation between groups, indicating a near-zero risk in LSM <10 kPa. Patients whose LSM decreased from ≥10 kPa at baseline to <10 kPa during follow-up (n = 35) did not develop any LRE.
Conclusion: Abstinent patients with advanced fibrosis but LSM < 10 kPa have a very low risk of LRE, suggesting the existance of latent fibrosis with a favorable prognosis.

FRI-041-YI

Increasing phosphatidylethanol correlates with increasing liver stiffness – a prospective longitudinal analysis of 1397 individuals at risk of steatotic liver disease

Katrine Tholstrup Bech[1], Nikolaj Torp[1], Helle Schnefeld[1], Stine Johansen[1], Camilla Dalby Hansen[1], Katrine Thorhauge[1], Johanne Kragh Hansen[1], Mette Lehmann Andersen[2], Ida Villesen[1], Anine Andersen[1], Charlotte Mary Gjøl[1], Gunilla Calov[1], Markus Maagaard[1], Ea Kyed[1], Ellen Lyngbeck Jensen[1], Maria Fogt[1], Kathrine Sejer Sørensen[1], Peter Andersen[1], Marianne Bergmann[3], Aleksander Krag[1], Maja Thiele[1], Mads Israelsen[1]. *[1]FLASH - Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [2]Department of Gastroenterology and Hepatology, Herlev Hospital, Herlev, Denmark; [3]Department of Biochemistry and Immunology, Sygehus Lillebælt, University Hospital of Southern Denmark, Vejle, Denmark*
Email: katrine.tholstrup.bech@rsyd.dk

Background and aims: The role of phosphatidylethanol (PEth) for subclassification within SLD is emerging, but the use of repeated assessment remains unstudied. We examined how longitudinal changes in alcohol intake assessed by PEth and self-report correlated with changes in liver stiffness in SLD.
Method: Prospective, single-centre study of adults with type 2 diabetes, BMI ≥30 kg/m^2, or current/prior excessive alcohol consumption. We measured PEth, self-reported alcohol intake, and liver stiffness using vibration-controlled transient elastography (VCTE) at two visits with two years apart. We defined changes in alcohol intake as moderate if PEth changed ≥20 ng/mL, and substantially if ≥80 ng/mL. Similarly, moderate if self-reported intake changed ≥10 g/day and substantially if ≥20/30 g/day (F/M). A relative change in VCTE ≥30% was considered significant. We used logistic regression analyses to investigate the correlation between changes in alcohol measures versus VCTE.
Results: We included 1397 participants with a mean time of 2.3 years (±0.6) between visits. Baseline age was 57 years (±9), 62% were male, and 18% had VCTE ≥8 kPa. At follow-up, changes in alcohol intake were more frequently detected by PEth than by self-report, both for increases (moderate: 24% vs. 10%; substantial: 14% vs. 3%) and decreases (moderate: 29% vs. 20%; substantial: 16% vs. 8%). For VCTE, 11% increased and 25% decreased. In univariable analyses, increased VCTE correlated with increased PEth (moderate: OR 1.59, 95% CI 1.11–2.28, p = 0.012; substantial: OR 1.96, 95% CI 1.30–2.98, p = 0.001), but was not correlated with self-reported alcohol intake (moderate: OR 1.04, 95% CI 0.60–1.80, p = 0.90; substantial: OR 0.75, 95% CI 0.27–2.12, p = 0.59). Neither decrease in PEth nor self-reported alcohol intake correlated with VCTE decrease. In multivariable analyses, PEth increases were the only predictors of VCTE increase (moderate: OR 1.61, 95% CI 1.11–2.34, p = 0.012 vs. substantial: OR 1.99, 95% CI 1.30–3.06, p = 0.002), while type 2 diabetes, BMI ≥30 kg/m^2, age, sex, and follow-up time were not.
Conclusion: Increasing phosphatidylethanol levels rather than self-reported alcohol consumption predicts worsening of liver stiffness in low-prevalence populations. Consequently, alcohol biomarkers may be the best suited tool for monitoring alcohol intake in patients with steatotic liver disease.

FRI-042

Current management of acute alcoholic hepatitis in France: results from a prospective cohort of 466 patients

Jean-François Cadranel[1], Thierry Thévenot[2], Armand Abergel[3], José Ursic Bedoya[4], Sarah Mouri[5], Jerome Boursier[6], Noemi Reboux[7], Nicolas Carbonell[8], Marco Vano[9], Moana Gelu-Simeon[10], Marika Rudler[5], Francois Durand[9], Honore Zougmore[1], Philippe Pulwermacher[1]. *[1]Ghpso Creil, Creil, France; [2]Chu Besançon, Besançon, France; [3]Chu Clermont-Ferrand, Cournon-d'Auvergne, France; [4]Chu Montpellier, Montpellier, France; [5]CHU Pitié Salpêtrière, Paris, France; [6]Chu Angers, Angers, France; [7]Internat La Cavale Blanche, Brest, France; [8]CHU Saint-Antoine Paris, Paris, France; [9]CHU Beaujon, Clichy, France; [10]CHU Pointe à Pitre, Pointe à Pitre Guadeloupe, France*
Email: jeanfrancois.cadranel@ghpso.fr

Background and aims: The objectives of this prospective multicentre study conducted in general hospitals, university hospitals were to collect the results of a prospective cohort of patients (pts) with acute alcoholic hepatitis (AAH), focusing, in cases of severe AAH, on the role of transjugular liver biopsy (TLB), treatment with N-acetylcysteine (NAC), prolonged corticosteroid (C) therapy in cases with an

intermediate Lille score on day 7, and transfer to a liver transplant centre (LTC).
Method: From October 2022 to March 2024, a pre-established anonymous Google questionnaire to be completed for each patient with AAH was sent to participating departments. Patients with severe AAH are the subject of this analysis. The results were expressed as mean ± standard deviation; a multivariate analysis was performed. The study focused on liver biopsy requierment, and use of N Acetylcystein and criteria for transfer to liver transplant center.
Results: 358 patients with severe AHF were included in this analysis. 266 (64.3%) were from a university hospital. Mean age 54 years (10). H 246 (74.2%). Mean TP 37% (12.3). The Maddrey score was 68.5 (45.4). 86.4% of patients were in Pugh stage C. Average MELD score 25.4 (6.34). 82.1% underwent TLB (215). TLB was performed much more often in university hospitals than in general hospitals (215 (82.1) vs 56 (51), p < 0.01). There was no difference in the use of NAC between university hospitals and general hospitals. Sixty-nine patients (19.2%) received NAC-C treatment. The PT of these patients was lower, 33.4 (11.6) vs. 37.5 (12), p = 0.01. 87 patients (24.3%) were transferred to a TC. Transfer to a TC was much more common in patients followed at a CHU: 78 (30%) vs. 9 (10%), p < 0.001; in cases of high MELD score (1.01 [1 to 1.01, p = 0.0013], Child-Pugh score C (3.75 [1.45–13.1, p = 0.001]. Transfer to TC was also more common in cases where C was discontinued in the event of an intermediate score on day 7: 4.70 [2.27–10.6, p < 0.01]; whereas patients who received NAC were transferred less often (9.52%, 23%) [0.36–0.15, 0.75, p < 0.02]. In multivariate analysis, transfer to TC was less common in cases treated with NAC-C (0.14 [0.04–0.5, p = 0.003]) and more common in cases where C was discontinued on day 7 in cases with an intermediate score (3.58 [1.27–10, p = 0.015]).
Conclusion: Potential benefits of routine LB, combination of NAC/C and prolongation in cases of intermediate Lille score to reduce transfers to liver transplant centers should be evaluated.

FRI-043
Sequential day-4 and day-7 Lille model to minimize unnecessary corticosteroid exposure in non-responders with severe alcohol-related hepatitis
Nicolas Conquet[1], Laura Weichselbaum[2], Nicolas Goossens[1], Marie Ongaro[1], Eric Trépo[2], Massimo Leo[1], Laurent Spahr[1], Christophe Moreno[2], Clemence Canivet[1]. [1]*Division of Gastroenterology, Hepatology and Nutrition, HUG, Geneva, Switzerland;* [2]*Department of Gastroenterology, Hepatopancreatology, and Digestive Oncology, Hôpital Universitaire de Bruxelles, Université Libre de Bruxelles, Brussels, Belgium*
Email: clemence.canivet@hug.ch

Background and aims: Early evaluation of corticosteroid response using the day-4 Lille Model (LM4) has been proposed as an alternative to the conventional day-7 assessment (LM7) in severe alcohol-related hepatitis (AH). However, a subset of patients classified as responders at LM4 subsequently become non-responders at LM7, a group associated with poorer prognosis. We aimed to assess, in a multicenter European cohort, the performance of a sequential LM4–LM7 strategy to predict 3-month mortality and reduce unnecessary corticosteroid exposure.
Method: We included biopsy-proven severe AH (Maddrey ≥32) from Geneva (12/2016–08/2024) and Brussels (07/2006–07/2015). Response was defined as LM <0.45. The primary endpoint was 3-month mortality (death or liver transplantation). A 2-step algorithm was developed in Geneva and validated in Brussels: (1) discontinuation of corticosteroids in LM4 non-responders; (2) among LM4 responders, discontinuation in LM7 non-responders. Data are expressed as median (IQR).
Results: *Derivation cohort (n = 64):* age of 54 (49–59) years, 67% male; baseline bilirubin 211 (108–309) µmol/L, INR 1.8 (1.6–1.9). *Validation cohort (n = 166):* age of 53 (46–58) years, 62% male; bilirubin 256 (142–410) µmol/L, INR 1.8 (1.6–2.2). Three-month mortality was 33% and 37%, respectively. In the derivation cohort: 42 (66%) and 38 (59%) patients were considered as responders at LM4 and LM7, respectively. Median LM4 and LM7 values were similar (0.36 vs 0.35; p = 0.87), with concordant responder/non-responder classification in 58/ 64 patients. In the validation cohort: 97 and 105 patients were considered LM4 and LM7 responders, respectively, with agreement in 152/166 patients. Median LM4 was 0.32 (0.16–0.64) and LM7 0.26 (0.09–0.62, p = 0.87). *Two-step algorithm*: LM4 allowed early corticosteroid discontinuation in 22 patients in the derivation cohort. LM7 reclassified 12% of LM4 responders (5/42) as non-responders, with 60% mortality. Overall, mortality was 16% in responders versus 56% in non-responders. In the validation cohort, 69 patients discontinued corticosteroids at day 4, and LM7 reclassified only 3 additional patients (66% mortality). Mortality remained markedly higher in non-responders than responders (61% vs 29%).
Conclusion: A sequential LM4–LM7 strategy enables earlier withdrawal of ineffective corticosteroid therapy without risk of undertreatment, while maintaining prognostic accuracy. Prospective studies are warranted to confirm its clinical utility.

FRI-044
Hot & cold fibrosis biomarkers as prognostic tools for assessment of cardiovascular and liver-related events in patients with alcohol-related liver disease
Andressa de Zawadzki[1], Maja Thiele[2], Stine Johansen[2], Ida Villesen[2], Peter Andersen[2], Ida Ziegler Spedtsberg[2], Morten Karsdal[1], Diana Julie Leeming[1], Aleksander Krag[2]. [1]*Nordic Bioscience Clinical Studies A, Herlev, Denmark;* [2]*Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark, Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark, Odense, Denmark*
Email: anza@nordicbio.com

Background and aims: Alcohol overuse increases the risk of alcohol-related liver disease (ALD) and cardiovascular disease (CVD). Patients with advanced ALD face higher risks of liver-related complications, CVD and infections. Non-invasive tests have been widely used to assess risk of liver-related outcomes, however, biomarkers to identify ALD patients at risk of CVD remain an unmet clinical need. This study evaluates the prognostic value of PRO-C6 (endotrophin), a fibroblast activity biomarker linking wound healing and fibrogenesis, combined with C4G (T cell activity biomarker, reflecting hot & cold fibrosis endotypes) for predicting cardiovascular and liver-related events in patients with ALD.
Method: Serum levels of nordicPRO-C6 (type VI collagen formation) and nordicC4G (type IV collagen fragment degraded by granzyme-B, a T cell specific protease) were assessed in the GALAXY EU funded cross-sectional cohort of 450 patients with biopsy-proven ALD including 5 years of follow up. The prognostic utility of baseline levels of PRO-C6 and C4G for CVD and decompensation was evaluated using Aalen–Johansen cumulative incidence curves with death as a competing risk. Fine–Gray models estimated hazard ratios across biomarker tertiles to define risk stratification cut-offs.
Results: In 450 patients with ALD, elevated levels of the fibroblast activity biomarker PRO-C6 were associated with an increased risk of CVD ($PRO\text{-}C6_{cutoff}$ = 8.0 ng/mL, HR_{CVD} = 2.35, p < 0.01) and decompensating events ($PRO\text{-}C6_{cutoff}$ = 11.2 ng/mL, $HR_{decompensation}$ = 4.87, p < 0.001). Increased C4G levels stratified ALD at higher risk of decompensation ($C4G_{cutoff}$ = 33.0 ng/mL, $HR_{decompensation}$ = 3.40, p < 0.01), without prognostic utility for CVD events. The ratio PRO-C6/C4G differed significantly between patients with and without CVD events (p < 0.001). Combined PRO-C6 and C4G cut-offs improved risk stratification, with lower C4G levels correlating to a poor CVD prognosis and higher C4G levels linked to higher risk of liver-related events.
Conclusion: Increased fibroblast activity is linked to higher risk of liver-related and cardiovascular events in patients with ALD. Furthermore, a distinct immune cell T-cell activity endotype

enables to stratify ALD patients at risk of specific clinical outcomes. Patients with decreased immune cell activity (cold fibrosis endotype) have a poorer prognosis for CVD outcomes, whereas those with increased immune cell activity (hot fibrosis endotype) have a higher risk of liver-related events.

FRI-050

Dynamics of steatotic liver disease subtype classification and predictors of significant fibrosis in Latin America: the STELLA study

Luis Antonio Diaz[1], Francisco Idalsoaga[2], Mário Pessoa[3], Claudia Pinto Oliveira[3], Patricia Momoyo Zitelli[3], Scherezada Mejia[4], Ezequiel Ridruejo[5], Mirta Peralta[6], Cesar Castro[7], Jorge Luis Garavito Rentería[7], Rommel Zambrano Huailla[7], Gustavo Ayares[2], Nancy Solis[2], Francisco Barrera[2], María Paz Orellana[2], Sebastián Marciano[8], Adrian Gadano[8], Jorge Martinez[8], María José Acosta[8], Martin Tagle[9], Hugo Cedrón[9], Ismael de Jesus Yepes Barreto[10,11], Dalis Pérez[10], Maria Saavedra[12], Samuel Perez[12], Estefanía Liza[13], Javier Diaz-Ferrer[13], Lorena Castro[14], Loreto Aguilar[14], Roberto Pérez Ravier[15], María Belen Martínez[15], Natalie Vilcinskas Y Botteron[15], Manuel Mendizabal[16], Daniela Simian[17], Juan Pablo Roblero[17], Pamela Gil[17], Arun J. Sanyal[18], Juan Pablo Arab[18], Marco Arrese[2]. *[1]University of California San Diego, La Jolla, United States; [2]Pontificia Universidad Católica de Chile, Santiago, Chile; [3]Hospital das Clínicas da Faculdade de Medicina da U S P, São Paulo, Brazil; [4]Hospital Juárez De México, Ciudad de México, Mexico; [5]Centro de Educación Médica e Investigaciones Clíni, Buenos Aires, Argentina; [6]Hospital De Infecciosas Francisco Muñiz, Buenos Aires, Argentina; [7]Hospital Nacional Arzobispo Loayza, Lima, Peru; [8]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [9]Clínica Anglo Americana, San Isidro, Lima, Peru; [10]Centro Médico Gastropack, Cartagena, Colombia; [11]UNIVERSIDAD DE CARTAGENA, Cartagena, Colombia; [12]Clínica Ces, Medellín, Colombia; [13]Hospital Edgardo Rebagliati Martins, Lima, Peru; [14]Clínica Universidad de Los Andes, Santiago, Chile; [15]Hospital Central de Mendoza, Mendoza, Argentina; [16]Hospital Universitario Austral, Pilar, Argentina; [17]Hospital Clínico Universidad de Chile, Santiago, Chile; [18]Virginia Commonwealth University, Richmond, United States*
Email: luisdiazpiga@gmail.com

Background and aims: Latin America is underrepresented in prospective steatotic liver disease (SLD) studies despite a high metabolic burden. This multinational study aims to identify the main predictors of significant fibrosis among adults with SLD in Latin America.

Method: Cross-sectional analysis of prospectively enrolled adults with SLD (2023 criteria) at 14 tertiary centers in six countries (Argentina, Brazil, Chile, Colombia, Mexico, and Peru). We recorded self-reported alcohol intake and the Chilean Mediterranean Dietary Index (MDI, adapted for regional use). Fibrosis was assessed by liver biopsy and/or vibration-controlled transient elastography (VCTE). Significant fibrosis was defined as ≥F2 on biopsy or VCTE ≥8 kPa (if biopsy unavailable). Predictors of significant fibrosis were examined using binary logistic regression, including age, sex, ethnicity, body mass index (BMI), type 2 diabetes mellitus (T2DM), MDI, family history of advanced fibrosis, and SLD subtype.

Results: We included 634 participants (median age 63 [54–70] years; 59.8% women; 42.2% self-reported Hispanic/Latino ethnicity; 22.0% had a first-degree relative with advanced fibrosis). The median BMI was 30.3 [26.9–33.9] kg/m^2, and the T2DM prevalence was 46.9%. The median alcohol intake was 0 [0–28] g/week. Based on prior clinician-assigned SLD subtype, 85.3% were MASLD, 5.7% MetALD, and 9.0% ALD. At enrollment, 62.8% with prior MetALD reported alcohol intake within the MASLD alcohol range, while 52.6% and 43.9% with prior ALD were within the MASLD and MetALD alcohol ranges, respectively. Significant fibrosis prevalence was 49.7%. In the adjusted model, age (OR 1.03, 95% CI 1.00–1.06; p = 0.023), Hispanic/Latino ethnicity (OR 3.61, 95% CI 1.67–7.78; p = 0.001), T2DM (OR 4.41, 95% CI 2.31–8.42; p < 0.0001), ALD (reference MASLD; OR 21.85, 95% CI 4.18–114.18; p < 0.0001), and family history of advanced fibrosis (OR 2.30, 95% CI 1.11–4.76; p = 0.025) were independently associated with higher odds of significant fibrosis, whereas higher MDI adherence was associated with lower odds (OR 0.77, 95% CI 0.65–0.92; p = 0.004).

Conclusion: In this multicenter study, significant fibrosis was mainly associated with ALD, T2DM, older age, and family history, while higher Mediterranean diet adherence was protective. Lower self-reported alcohol intake at enrollment than implied by prior diagnoses highlights the need for longitudinal ascertainment of prior alcohol exposure to improve SLD subtype classification and clinical decision-making (FONDECYT 1241450).

FRI-051

Medications for alcohol use disorder after liver transplantation in the US: patterns, timing, and survival

Wei Zhang[1], Luis Antonio Diaz[2], Cassy Sun[3], Kelly Hsu[4], Stephanie Mrowczynski[5], Heidi Yeh[6], Ana Ivkovic[7], Peng-Sheng Ting[5], Emily Bethea[7], Giuseppe Morelli[5]. *[1], Newton, United States; [2]University of California San Diego, Pontificia Universidad Católica de Chile, La Jolla, United States; [3]Harvard T.H. Chan School of Public Health, Boston, United States; [4]Tuft University School of Medicine, Boston, United States; [5]Tulane School of Medicine, New Orleans, United States; [6]Division of transplant surgery, Massachusetts General Hospital, Boston, United States; [7]Massachusetts General Hospital, Boston, United States*
Email: wzhang50@mgh.harvard.edu

Background and aims: Alcohol-associated liver disease (ALD) is now the leading indication for liver transplantation (LT). Up to 20% of LT recipients resume alcohol use within 1 year and 30–40% within 5 years, worsening graft outcomes and long-term prognosis. Despite this high risk, post-transplant use of medications for alcohol use disorder (MAUD) has not been systematically evaluated. We aimed to characterize real-world MAUD prescribing after LT and examine its association with post-transplant mortality.

Method: We conducted a retrospective cohort analysis of adults transplanted for ALD at two liver transplant centers in the United States. We fit a Cox proportional hazards model with time since LT (days) as the analysis time. Covariates were age at LT, sex, race, Model for End-Stage Liver Disease (MELD) score at LT, any documented post-LT alcohol relapse, and MAUD use. The endpoint was time to death after LT.

Results: We included 274 recipients; the median age at LT was 55.2 years (IQR 44.9–61.7), 29.2% were women, and 91.2% were White or Caucasian. The median follow-up was 4.4 years (IQR 2.6–6.5). Post-LT MAUD was prescribed in 21.2% of patients. Among patients who received MAUD, the most common therapies after LT were naltrexone (72.4%), acamprosate (27.6%), gabapentin (20.7%), and topiramate (5.2%). Some patients received more than one MAUD. Among MAUD initiators, 34.8% started treatment before relapse and 65.2% after relapse. In the adjusted model, alcohol relapse was independently associated with a higher hazard of mortality (HR 4.00; 95% CI 1.15–13.92; p = 0.029). Age, sex, race, and MELD at LT were not significant predictors. MAUD use showed a non-significant trend toward lower mortality (HR 0.31; 95% CI 0.06–1.57; p = 0.159).

Conclusion: In this cohort study, the use of MAUD after LT in ALD remains low and was commonly initiated reactively after alcohol relapse. Alcohol relapse after LT strongly predicted adverse outcomes, whereas receipt of MAUD was associated with a favorable but non-significant association with survival. These findings support the systematic integration of MAUD into routine post-LT care and support multicenter evaluation of this approach.

FRI-052

The impact of early alcohol abstinence on further decompensation in alcohol-associated liver disease

Diego Drumond Westgeest e Sousa[1], Yigit Yazarkan[1], Alberto Calleri[1], Blake Kassmeyer[2], Kamalpreet S. Hara[1], Tiffany Wu[1], Puru Rattan[1], Vijay Shah[1], Patrick S. Kamath[1], Douglas Simonetto[1]. [1]*Mayo Clinic, Division of Gastroenterology and Hepatology, Rochester, Minnesota, United States;* [2]*Mayo Clinic, Division of Clinical Trials and Biostatistics, Rochester, Minnesota, United States*
Email: diegowestgeest@gmail.com

Background and aims: Further decompensation is common in patients with cirrhosis and is associated with worse clinical outcomes. However, the impact of early alcohol abstinence and alcohol-associated hepatitis (AH) on subsequent decompensation in alcohol-associated liver disease (ALD) remains poorly defined. We aimed to assess the impact of early alcohol abstinence and AH on further decompensation in ALD.
Method: Consecutive adult patients hospitalized for decompensated ALD (2020–2024) were identified via the Rochester Epidemiology Project using validated ICD-9/10 codes with manual confirmation. AH was defined according to NIAAA criteria. Cumulative incidence of further decompensation was estimated using competing-risk methods, with death, liver transplantation, and TIPS treated as competing events. The effect of further decompensation on mortality was assessed using time-dependent Cox models. Landmark analyses at 3 months evaluated the impact of alcohol abstinence on further decompensation using adjusted cause-specific Cox models.
Results: A total of 121 patients were included; 90 (74.4%) were male, with a median age of 58 years (IQR, 46.1–66.0). Ascites was the most common initial decompensation, followed by encephalopathy and variceal bleeding, and 24 (19.8%) patients presented with multiple events at first hospitalization. Median follow-up was 23.8 months (IQR, 5.0–47.0), during which further decompensation occurred in 87 (71.9%) patients after a median of 3.7 months (IQR, 1.3–8.6). The cumulative incidence of further decompensation did not differ between patients presenting with single versus multiple initial decompensation events (Gray's test $p = 0.39$). In time-dependent Cox models, further decompensation was associated with a significantly higher risk of all-cause mortality (HR 5.39, 95% CI 2.46–11.81; $p < 0.001$). In adjusted cause-specific Cox models, alcohol abstinence within 3 months was independently associated with a reduced hazard of further decompensation (HR 0.40, 95% CI 0.20–0.81; $p = 0.01$), while older age and the presence of AH were associated with increased risk (HR 1.04, 95% CI 1.02–1.07; $p < 0.001$ and HR 2.50, 95% CI 1.31–4.80; $p = 0.006$, respectively).
Conclusion: Further decompensation strongly predicts mortality in ALD. Early alcohol abstinence within 3 months is associated with a reduced risk of subsequent decompensation, whereas the presence of alcohol-associated hepatitis identifies patients at higher risk, underscoring the need for closer follow-up and targeted interventions.

Email: jan.embacher@meduniwien.ac.at

Background and aims: Alcohol abstinence improves outcome and facilitates hepatic recompensation in alcohol-related cirrhosis (ALD). Although disease severity determines recompensation, lab-based surrogates of hepatic function may be unreliable in severe-acute conditions such as alcohol-related hepatitis (AH). We therefore evaluated the context-dependent prognostic value of MELD and albumin at abstinence and 90 days (D90) for predicting recompensation (Baveno VII) and liver-related death (LRD).
Method: Patients with decompensated ALD who achieved abstinence and had paired laboratory assessments at baseline (time of abstinence) and after 90 (±30) days of abstinence were included. Alcohol relapse and liver transplantation were treated as competing events.
Results: Among 100 patients (72% male, median age 54 years), 56 presented with AH at baseline. Patients with AH were younger (52 vs. 58 years) and showed higher baseline levels of bilirubin, AST, and INR. At D90, a 20% decrease in MELD was more common in patients with AH (70% vs. 39%), whereas a 20% increase in albumin occurred at a similar rate (43% vs. 50%). Over a median follow-up of 43 months, 24% of patients recompensated, and 16% experienced LRD. In patients without baseline AH, neither baseline MELD or albumin were associated with recompensation, while both D90-MELD and D90-albumin showed a trend (SHR 0.89, $p = 0.063$; SHR 1.08, $p = 0.092$) in a competing-risks regression analysis and D90-MELD predicted LRD (SHR 1.16, $p < 0.001$). In contrast, a 20% MELD decrease strongly predicted recompensation (SHR 4.60, $p = 0.020$). This effect was further amplified by concomitant 20% albumin increase (SHR 8.31, $p < 0.001$), while 20% albumin increase alone only showed a trend (SHR 2.99, $p = 0.095$). No LRD occurred among patients without AH achieving combined MELD/albumin improvement. In AH patients, neither baseline nor D90 values predicted recompensation, yet D90-albumin (SHR 0.84, $p = 0.005$) and D90 MELD (SHR 1.18, $p = 0.003$) predicted LRD. Further, while a 20% MELD decrease was numerically linked to recompensation (SHR 2.98, $p = 0.147$), and LRD (SHR 0.27, $p = 0.065$), there was no association for albumin dynamics.
Conclusion: While the prognostic value of lab-based surrogates of hepatic function in patients with decompensated ALD at the time of abstinence is limited by concomitant AH, re-assessment after 90 days of abstinence and evaluation of early biochemical improvements substantially improve prognostic accuracy.

FRI-054

Community-based alcohol-related liver disease early recognition and assessment (CALDERA): effect on drinking behaviour, markers of liver injury and emergency hospital attendance

Callum Higgins[1], Peter Strathern[1], Cherry Fung[1], Kirsty McCaughey[1], Aileen Billsdon-McGrane[2], Claire Kerr[2], Derek Scollon[2], Ewan H Forrest[1,3]. [1]*University of Glasgow, Glasgow, United Kingdom;* [2]*Department of Gastroenterology, Glasgow Royal Infirmary, Glasgow, United Kingdom;* [3]*Glasgow Royal Infirmary, Glasgow, United Kingdom*
Email: ewan.forrest@ggc.scot.nhs.uk

Background and aims: Early detection of alcohol-related liver disease (ALD) is vital to prevent progressive liver damage. This study assessed the effects of liver assessment including vibration controlled transient elastography (VCTE) in patients with alcohol use disorder (AUD) attending the community Glasgow Alcohol and Drug Recovery Service (GADRS).
Method: Liver assessment was available for patients attending the North East (NE) GADRS for AUD. This included VCTE by FibroScan to measure liver stiffness (LSM). Two patient cohorts were studied. Cohort 1 consisted of patients who attended community GADRS between July and October 2024 and compared those who had a liver assessment with those who had not. Any cause hospital Emergency

Department (ED) attendance in the year prior to and after initial ADRS review was recorded. Cohort 2 consisted of patients who attended NE GADRS between 2019 and January 2025 who had more than one liver assessment. Estimated alcohol use (UK units) in the week prior to each assessment was noted and changes in LSM were annualised. Again, ED attendance in the year prior to and after the index assessment was recorded. Results are expressed with 95% Confidence Intervals.
Results: In Cohort 1, 98 patients had a liver assessment group and 119 did not. In the year after assessment there was an absolute reduction in ED attendances by 37 (20%) in those who had a liver assessment compared with a fall of 5 (2%) ED attendances in those who didn't ($p < 0.001$). In Cohort 2, 112 patients had had follow-up VCTE with a median interval of 0.91 (0.73, 1.10) years. The median baseline LSM was 6.2 (5.4, 7.4): 41 (36%) had a LSM >8 kPa and 15 (13%) >12 kPa. On comparison between those with high LSM (>8 kPa) and those with low LSM (<8kPa) at index assessment, there was a reduction in follow-up LSM (-1.39 *vs* 0.22 kPa; $p = 0.012$) and alcohol use (−70 *vs* 0.0 units; $p = 0.003$) amongst high LSM patients. High LSM patients had a reduction in ED attendances by 10 (14%) compared with a rise of 16 (11%) ED attendances in low LSM patients ($p < 0.001$).
Conclusion: Detection of advanced ALD is feasible in the community using VCTE. After liver assessment, emergency hospital attendance fell compared with those who did not have a liver assessment. In those who had repeat liver assessments, the fall in ED attendance was most obvious in those with a high baseline LSM. Those with high initial LSM were also more likely to reduce their alcohol consumption and improve their LSM reading on follow-up.

FRI-055
Alcohol-metabolite associations differ by liver steatosis status: a metabolomics study in finnish men
Konsta Hakkarainen[1,2], Fredrik Åberg[3], Lilian Fernandes Silva[2], Anniina Oravilahti[2], Taru Tukiainen[2], Markku Laakso[2], Ville Männistö[1,2]. *[1]Department of Medicine, Kuopio University Hospital, Kuopio, Finland; [2]Faculty of Health Sciences, School of Medicine, Institute of Clinical Medicine, University of Eastern Finland, Kuopio, Finland; [3]Transplantation and Liver Surgery, Helsinki University Hospital and University of Helsinki, Helsinki, Finland*
Email: konsta.hakkarainen@gmail.com

Background and aims: Recent studies have shown that alcohol-induced liver injury is amplified in the presence of steatotic liver disease, but the underlying metabolic alterations remain poorly characterized. We examined whether liver steatosis modifies the associations between alcohol consumption and circulating plasma metabolites in a large population-based cohort of men.
Method: A total of 10188 middle-aged men (mean age 57.5 ± 7.1 yrs, mean BMI 27.9 ± 4.8 kg/m2, mean alcohol use 105.8 ± 141.7 g/wk) from the METabolic Syndrome In Men (METSIM) study were classified as having non-steatotic or steatotic liver using Fatty Liver Index (FLI, <30 vs. >60), with validation using Hepatic Steatosis Index (HSI, <30 vs. ≥36). Plasma metabolites were quantified using the Metabolon Global Discovery panel. Alcohol-metabolite associations were assessed by regression models with multiple confounder adjustment. Overlap weighting was performed to consider differences in alcohol use distributions between liver steatosis groups. The Benjamini-Hochberg Procedure was used for multiple testing correction.
Results: Of 1259 metabolites, a total of 222 showed statistically significant differences in the alcohol–metabolite interaction between steatosis groups, consistently identified using both FLI and HSI (Benjamini-Hochberg-corrected p-values from 0.048 to 2.4×10^{-42}). Of these metabolites, 57% were lipids, 21% xenobiotics, and 13% amino acids, with the remaining metabolites distributed across smaller pathway categories. Several metabolites considered to have protective effects against oxidative stress (such N-acetylglycine and N-acetylmethionine), showed a weaker alcohol-associated increase in individuals with liver steatosis, suggesting a possible reduced hepatic capacity to counteract oxidative stress in steatosis. Interestingly alcohol interaction with theanine, previously reported to have protective effects against alcohol-induced liver injury, was similarly lower. In contrast, several lipids demonstrated stronger alcohol-associated increases in liver steatosis.
Conclusion: Differences in alcohol-metabolite associations between those with and without liver steatosis suggest increased susceptibility to alcohol-related toxicity in individuals with steatosis. These findings support the concept that steatosis alters systemic metabolic responses to alcohol, potentially contributing to elevated liver injury risk.

FRI-056
The evaluation of a novel multidisciplinary hepatology clinic
Gideon Hanibal[1], Heather Lewis[1]. *[1]Department of Hepatology, St Mary's Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, London, United Kingdom*
Email: gideon.hanibal21@imperial.ac.uk

Background and aims: Alcohol-related liver disease (ALD) is a leading cause of liver morbidity and mortality, intrinsically linked with alcohol use disorder (AUD). Multidisciplinary care models integrating hepatology and addiction services may improve patient outcomes, but direct comparisons to standard hepatology care are limited. This retrospective study evaluated the effectiveness of a multidisciplinary alcohol hepatology clinic versus a general hepatology clinic in reducing alcohol consumption and improving clinical-related outcomes in ALD patients.
Method: Data from 142 patients (71 per cohort) attending a multidisciplinary alcohol clinic or a general hepatology clinic at St Mary's Hospital were analysed. Demographics, alcohol consumption, abstinence rates, Fibroscan Liver Stiffness Measurement (LSM) and Fibroscan Controlled Attenuation Parameter (CAP) scores were collected pre- and post-clinic intervention. Use of pharmacological treatment for AUD was also recorded. Statistical significance was set at $p < 0.05$.
Results: Both clinics showed significant reductions in weekly alcohol consumption (multidisciplinary: mean 65.2 to 35.8 units/week, $p < 0.01$; general hepatology: 65.2 to 54.4 units/week, $p = 0.03$). When comparing clinics, the multidisciplinary clinic achieved a significantly greater median reduction in consumption (30 vs 14 units/week, $p = 0.03$) and higher abstinence rates (41.7% vs 19.1%, $p = 0.02$). Pharmacological treatment use was also significantly higher in the multidisciplinary clinic (50.7% vs 4.41%, $p < 0.01$). Fibroscan LSM improved significantly in the multidisciplinary cohort (median 14.3 to 10.1 kPa, $p = 0.01$), but not in the general hepatology clinic. No significant changes were observed in Fibroscan CAP scores.
Conclusion: The multidisciplinary clinic demonstrated superior improvements in alcohol reduction, abstinence, pharmacotherapy use and liver fibrosis. However, its retrospective design and baseline cohort differences limit comparability and generalisability, warranting future prospective, multi-centre research. This pilot study supports multidisciplinary clinics as an effective model for improving alcohol and clinical-related outcomes in ALD patients. Larger, prospective studies are necessary to support broader clinical implementation.

Email: johanne.kragh.hansen@rsyd.dk

Background and aims: Gut barrier impairment is a driver of hepatic inflammation in alcohol-related liver disease (ALD) due to translocation of microbial products. However, microbial translocation may also cause systemic low-grade chronic inflammation. ReFerm®, an oat-based postbiotic fermented with *Lactobacillus plantarum* 299v, improves gut barrier integrity, but its impact on systemic inflammation is unclear. This post-hoc analysis of the GALA-POSTBIO trial examined associations between ReFerm®-induced barrier improvements and systemic inflammation in patients with ALD.
Method: In the randomized GALA-POSTBIO trial, 56 patients with advanced ALD were allocated 1:1 to ReFerm® or the control product Fresubin® (medical protein supplement) for 24 weeks. Systemic inflammation was assessed by plasma C-reactive protein (CRP). Intestinal barrier integrity was evaluated via plasma intestinal fatty acid–binding protein (I-FABP). Patients were classified as responders or non-responders based on a reduction in I-FABP relative to baseline.
Results: Median age was 63 years (IQR 57–67), 83% were male, and most had cirrhosis (F2/F3/F4: 4/15/33). Alcohol intake was similar between groups. Forty-one patients completed the study per protocol, with I-FABP results for 36. Baseline CRP was comparable (ReFerm® 1.8 mg/L (IQR 0.7–4.3) vs. Fresubin® 1.9 mg/L (IQR 1.1–3.6)). At 24 weeks, CRP decreased in the ReFerm® group (1.2 mg/L (IQR 0.6–2.2)) but increased in the Fresubin® group (2.5 mg/L (IQR 1.2–3.1)), with the between-group difference approaching significance ($p = 0.053$). Reduction in I-FABP, indicating improved gut barrier, was more frequent with ReFerm® (OR 5.2, 95% CI 1.25–21.57; $p = 0.044$). Among ReFerm® patients with decreased I-FABP, CRP was lower than in those with increased I-FABP (1.2 vs. 4.0 mg/L, $p = 0.06$), a pattern not seen in the Fresubin® group.
Conclusion: Postbiotic supplementation improved gut barrier integrity, which was associated with lower systemic inflammation in advanced ALD. These findings support further research in whether this effect is direct or mediated by improved liver inflammation.

FRI-058-YI

Prevalence and timing of comorbidities among patients with alcohol-related liver cirrhosis: a nationwide study of 11,989 patients with cirrhosis

Gustav Jakobsson[1,2], Ying Shang[2], Linnea Widman[2], Hannes Hagström[2,3]. *[1]Capio Sankt Görans Sjukhus, Stockholms Stad, Sweden; [2]Department of Medicine, Huddinge, Karolinska Institute, Huddinge, Sweden; [3]Division of Hepatology, Department of Upper GI, Karolinska University Hospital, Stockholm, Sweden*
Email: gustav.jakobsson@ki.se

Background and aims: Alcohol-related liver cirrhosis (ARLC) is the most severe and end-stage form of alcohol-related liver disease caused by long-term heavy alcohol consumption. ARLC seldom causes any symptoms before hepatic decompensation, leading to diagnosis at a late stage when the prognosis is dismal. Patients with ARLC may have a different set of comorbidities than the general population, thus identifying these comorbidities could allow for screening of pre-cirrhotic disease in specific patient groups. Our aim was to compare the prevalence of comorbidities among patients with ARLC and the general population and to assess the timing of comorbidity diagnoses relative to ARLC diagnosis.
Method: We used Swedish national registers to identify all new cases of ARLC (ICD-10 code: K70.3) from 2006 to 2020 (n = 11,989) with up to 10 controls (n = 113,657), matched on age, sex, and place of residence. Comorbidities were identified from 1998 to 2020 using ICD-codes from all in- and outpatient contacts with specialized care. To capture conditions primarily treated in primary care, we additionally used data on drug dispensation from the National Prescribed Drug register.
Results: At the time of ARLC diagnosis, the most prevalent comorbidities among cases were alcohol use disorder (51.3% vs 3.3% in the general population), hypertension (51.8% vs 37.7%), anemia (46.5% vs 15%), fractures (32.2% vs 14.7%) and depressive disorders (31.2% vs 16.1%). All differences were significant (p-value< 0.001). The median time to diagnosis of comorbidities before ARLC was 55.6 months for alcohol use disorder (IQR 17.3–108.9), 23.0 months for anemia (IQR 9.3–72.0), 78.5 months for hypertension (IQR 39.0–122.5), 71.7 months for fractures (IQR 30.3–124.7) and 67.0 months for depressive disorders (IQR 28.9–113.1).
Conclusion: Our study shows that the prevalence of comorbidities differs between patients with ARLC and the general population. Several of these comorbidities were diagnosed years before ARLC, suggesting that it is possible to identify high-risk groups where targeted screening for liver disease or targeted interventions could be possible and thereby modify disease progression. For instance, more than 50% of patients who later develop ARLC have a prior diagnosis of AUD, diagnosed at a median of 4 years before ARLC diagnosis. Our findings suggest a window of opportunity in which high-risk groups for future liver disease may be identified well before cirrhosis develops.

FRI-059

Limited overlap between high phosphatidylethanol, alcohol use disorder, and liver fibrosis in 6,231 individuals screened for steatotic liver disease

Stine Johansen[1,2], Katrine Tholstrup Bech[1,2], Helle Schnefeld[1,2], Johanne Kragh Hansen[1,2], Camilla Dalby Hansen[1,2], Ellen Lyngbeck Jensen[1,2], Ea Kyed[1,2], Markus Maagaard[1,2], Gunilla Calov[1,2], Mette Lehmann Andersen[1,2,3], Maria Fogt[1,2], Anine Andersen[1,2], Charlotte Mary Gjøl[1,2], Katrine Thorhauge[1,2], Peter Andersen[1,2], Ida Villesen[1,2], Nikolaj Torp[1,2], Maja Thiele[1,2], Aleksander Krag[1,2], Mads Israelsen[1,2]. *[1]FLASH - Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [2]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark; [3]Department of Gastroenterology and Hepatology, Herlev Hospital, Herlev, Denmark*
Email: stine.johansen@rsyd.dk

Background and aims: Excessive alcohol intake is common, yet only a minority of individuals develop significant liver fibrosis. Conversely, many patients with alcohol-related liver disease (ALD) do not meet criteria for alcohol use disorder (AUD). Understanding of the co-existence is limited and based on self-reported alcohol intake, which is prone to underreporting. Phosphatidylethanol (PEth), a direct alcohol biomarker, allows for more accurate quantification of recent alcohol intake. We aimed to investigate how PEth implementation influences understanding of the relationship between liver fibrosis severity, AUD and alcohol intake.
Method: We conducted a prospective screening study including individuals from the general population or at risk of steatotic liver

disease due to excessive alcohol intake or metabolic dysfunction. Assessment included liver stiffness measurement (LSM), PEth, and risk of AUD using the Alcohol Use Disorders Identification Test (AUDIT). We estimated the prevalence and overlap of recent alcohol intake corresponding to MetALD (PEth 20–199 ng/mL) and high alcohol intake corresponding to ALD (PEth ≥200 ng/mL), high risk of AUD (AUDIT ≥16), and significant fibrosis (LSM ≥10 kPa).
Results: We investigated 6,231 individuals for steatotic liver disease. Median age was 57 (52–62) years, 52% were women and 28% reported excessive drinking for >5 years. At inclusion, 3.4% had LSM ≥10 kPa; 8.3% had AUDIT ≥16, 42% had PEth 20–199 ng/mL, and 17% PEth ≥200 ng/mL. In patients with significant fibrosis, high risk of AUD was found in 10% with MetALD and 49% with ALD. Conversely, among patients with high risk of AUD and high alcohol intake (AUDIT ≥16, PEth ≥200), 12% had significant fibrosis. Overlap between all three markers increased was limited: fewer than 3% (38 of 1,363) had AUDIT ≥16, LSM ≥10 kPa, and PEth ≥200 ng/mL concurrently. Both AUDIT ≥16 and PEth ≥200 ng/mL were associated with an increased risk of significant fibrosis ($OR_{AUDIT\ \geq 16}$: 1.37 (95%CI 1.04–1.70), p < 0.001) & $OR_{PEth\ \geq 200}$: 1.10 (95%CI 0.81–1.39), p < 0.001).
Conclusion: High PEth, high AUDIT scores, and increased LSM display limited overlap, indicating that self-reported high risk of alcohol use disorder, objective high alcohol intake, and liver fibrosis identify largely distinct patient groups. Only 1 in 10 with high PEth and high risk of AUD have significant liver fibrosis. In contrast, 10 to 50% of those with elevated PEth and significant fibrosis are at high risk of AUD.

FRI-060
Cardiometabolic risk factors are not associated with lower lifetime alcohol consumption in newly diagnosed patients with alcohol-related liver disease: a clinical cohort study
Linnea Juhl Vestergaard[1], Gro Askgaard[1], Lone Galmstrup Madsen[1], Peter Jepsen[2], Anna Emilie Kann[1], Jonas Hedelund Rønn[1]. *[1]Zeland University Hospital, Naestved, Denmark; [2]Aarhus University Hospital, Aarhus, Denmark*
Email: linve@regionsjaelland.dk

Background and aims: It is thought that cardiometabolic risk factors (CMRFs) act synergistically with alcohol consumption in the development of cirrhosis. Therefore, patients with CMRFs might develop alcohol-related liver disease at a lower level of alcohol consumption.
We aimed to assess whether a lower lifetime alcohol consumption was associated with CMRFs in newly diagnosed patients with alcohol-related liver disease (ALD).
Method: We included patients with newly diagnosed ALD at Zealand University Hospital, Denmark, 2021–2025. All patients underwent a standardized clinical assessment, including anthropometrics, biochemical tests (including Phosphatidyl ethanol [PEth]), and transient elastography. Lifetime alcohol consumption was assessed by the Lifetime Drinking History interview. CMRFs included obesity (BMI ≥30), hypertension, diabetes, and dyslipidemia (treated or measured). One standard drink equaled 12 g of pure ethanol. We used logistic regression to estimate odds ratios (OR) for CMRFs according to lifetime alcohol consumption, adjusted for sex, age and Child-Pugh class.
Results: Among 109 patients with ALD, 76% were men, mean age was 62 years, and 74.7% had cirrhosis. Patients reported a median lifetime alcohol consumption of 53,952 drinks (IQR: 31,968; 84,984) over a median of 41 drinking years, corresponding to a median weekly consumption of 25 drinks (IQR: 14; 41) during drinking periods. Median PEth was 0.22 micromole/L (IQR: 0.01; 1.21). Number of CMRFs was 0 or 1 in 46% of patients, 2 in 32%, and 3 or 4 CMRFs in 23% of patients. The median number of CMRFs was 1 for patients with a lifetime alcohol consumption of < 45,000 drinks and 2 for patients with a lifetime alcohol consumption of 45,000–70,000 drinks and ≥ 70,000 drinks. Lifetime alcohol consumption was not associated with CMRFs with adjusted ORs of 1.41 (95% CI: 0.48–4.08) for obesity, 2.23 (0.80–6.19) for diabetes, 1.18 (0.49–2.86) for hypertension, and 1.56 (0.66–3.70) for dyslipidemia when a lifetime alcohol consumption of ≥ 45,000 drinks was compared to < 45,000 drinks. Patients with 3–4 CMRFs vs 0–2 CMRFs tended to have a higher lifetime alcohol consumption of ≥ 45,000 vs. < 45,000 (OR of 3.18 [0.99–10.2], p = 0.051).
Conclusion: Cardiometabolic risk factors were not associated with lower lifetime alcohol consumption in newly diagnosed ALD patients. On the contrary, having multiple cardiometabolic risk factors tended to be associated with higher lifetime alcohol consumption.

FRI-061
Hazardous alcohol use amongst persons with compensated cirrhosis from different etiologies: a liver cirrhosis network study

Kamath[3], Matthew Robert Kappus[12], Srinivasan Dasarathy[7]. *[1]University of California San Francisco, San Francisco, United States; [2]Northwestern University, Chicago, United States; [3]Mayo Clinic, Rochester, United States; [4]University of Southern California, Los Angeles, United States; [5]University of Miami, Miami, United States; [6]Virginia Commonwealth University, Richmond, United States; [7]Cleveland Clinic, Cleveland, United States; [8]University of Michigan, Ann Arbor, United States; [9]University of California San Diego, La Jolla, United States; [10]Columbia University, New York, United States; [11]Cornell University, New York, United States; [12]Duke University, Durham, United States*
Email: mandana.khalili@ucsf.edu

Background and aims: Alcohol-associated liver disease (ALD) is the most common etiology of cirrhosis in the United States. We aim to describe alcohol use among a large prospectively assembled cohort of patients living with cirrhosis and different etiologies of liver disease.
Method: Baseline demographics, clinical characteristics, and alcohol use in adults (≥18 years) with compensated cirrhosis enrolled in 10 U. S. centers within Liver Cirrhosis Network (LCN) Cohort Study were assessed. Etiology of liver disease was investigator assigned and categorized as ALD, metabolic-dysfunction associated liver disease (MASLD), viral hepatitis, ALD + another etiology (combo-ALD), and other. Alcohol Use Disorders Identification Test -Consumption (AUDIT-C) evaluated alcohol use in past 12 months. In those with positive AUDIT-C score (3+ in women, 4+ in men), full AUDIT was performed.
Results: Among 1205 participants, characteristics were: median age 62 (IQR 52, 69) years, 50% male, 75% White, 27% Hispanic, 30% with high school or less education, and 44% employed. Overall, 8.7% had positive AUDIT-C score and 277 (23%) had an ALD or combo-ALD etiology. Eight patients with MASLD had alcohol use levels that met MetALD criteria. A significant proportion of ALD (26%) or combo-ALD (22%) had positive AUDIT-C score vs. MASLD (3.4%), viral hepatitis (5.9%), and other etiology (4.3%). Among those with positive AUDIT-C and ALD or combo-ALD, 61% and 28%, respectively, had high-risk or greater drinking (AUDIT score 16+). Among the ALD subgroups, a higher proportion had a history of prior cirrhosis decompensation compared to non-ALD (22% vs. 4%). On vibration-controlled transient elastography, the mean CAP score in ALD and combo-ALD was lower compared to MASLD (median [IQR] = 249 [211, 281] and 260 [229, 298] vs. 282 [246, 316], respectively), and 43% and 37% had no steatosis (vs. 20% in MASLD). Similarly, among 514 with MR elastography, the proton density fat fraction was lower in ALD and combo-ALD vs MASLD (median = 2.8% and 3.6% vs. 5.5%) despite similar mean liver stiffness measures (median = 5.1 and 4.6 vs. 5.1 kPA).
Conclusion: At LCN entry, overall, 8.7% of participants with compensated cirrhosis and 23% of ALD groups had a positive

AUDIT-C score, with nearly two-thirds of ALD group reporting high-risk drinking. This highlights the importance of screening for alcohol use among those with cirrhosis in order to provide interventions to reduce alcohol intake in this at-risk population.

FRI-062

Impact of on-demand nalmefene–mediated alcohol reduction on liver function and noninvasive fibrosis and steatosis measures in patients with alcohol use disorder and metabolic dysfunction–associated alcohol-related liver disease

Yohei Koizumi[1,2], Masashi Hirooka[2], Yoichi Hiasa[2]. [1]*Koizumi Clinic, Yawatahama, Ehime, Japan;* [2]*Department of Gastroenterology and Metabology, Ehime University Graduate School of Medicine, Toon, Ehime, Japan*
Email: shachiyo2@yahoo.co.jp

Background and aims: Patients with metabolic dysfunction–associated alcohol-related liver disease (MetALD) are at risk of progressive hepatic steatosis and fibrosis due to the combined effects of metabolic dysfunction and ongoing alcohol consumption. Early-stage, patient-centered alcohol reduction strategies and reliable tools for short-term treatment monitoring are needed in this emerging disease entity. This study aimed to evaluate the impact of on-demand nalmefene–mediated alcohol reduction on alcohol consumption and its effects on liver function and noninvasive elastography-based measures of hepatic fibrosis and steatosis in patients with alcohol use disorder (AUD) and MetALD.
Method: This pilot study included 48 patients with MetALD and 55 patients with metabolic dysfunction–associated steatotic liver disease (MASLD) as a control group. Patients with MetALD received on-demand nalmefene (18 mg), self-administered on days perceived to carry a high risk of alcohol consumption, over a 24-week period, while MASLD patients underwent standard lifestyle intervention. Liver function tests, liver stiffness assessed by shear wave elastography, and hepatic fat quantification using attenuation imaging were evaluated at baseline and at 12 and 24 weeks.
Results: All patients in the MetALD group received at least one dose of nalmefene, and 42 completed the 24-week follow-up. Monthly heavy drinking days decreased by a mean of 15.5 days, and mean daily alcohol consumption was reduced by 48.7 g/day. At week 24, the nalmefene-treated MetALD group showed significantly greater reductions in serum transaminases ($P = 0.037$) and gamma-glutamyl transferase ($P = 0.041$) compared with the MASLD group. Liver stiffness decreased by 22% and hepatic fat content by 19%, showing trends toward improvement, although these changes did not reach statistical significance. Nalmefene was generally well tolerated, with mostly mild adverse events, including dizziness and nausea.
Conclusion: On-demand nalmefene was associated with clinically meaningful reductions in alcohol consumption and biochemical markers of liver injury in patients with alcohol use disorder and MetALD. Favorable short-term trends in noninvasive elastography-based measures support their potential role as sensitive tools for treatment monitoring in early-stage MetALD. A patient-driven pharmacological alcohol reduction strategy combined with metabolic risk management may represent a feasible early intervention and monitoring pathway for this population.

FRI-067

Recompensation in alcohol related liver disease is infrequent and should not delay transplantation assessment

Arushi Kumar[1], Ian Rowe[1,2], Richard Parker[1,2]. [1]*Leeds Teaching Hospital NHS Trust, Leeds, United Kingdom;* [2]*Leeds Institute for Medical Research, University of Leeds, Leeds, United Kingdom*
Email: arushi.kumar2@nhs.net

Background and aims: Alcohol-related liver disease (ArLD) is the most prevalent cause of liver-related mortality. Liver transplantation remains an effective solution in selected patients with decompensated disease. Recent studies have outlined definitions of recompensation and shown an associated survival benefit; however, translating this to clinical practice remains undetermined. We aim to quantify the rates of recompensation in decompensated ArLD and compared the risk of death at specific timepoints to inform decisions regarding the timing of liver transplantation.
Method: The ALLHEAL study is a prospective database study of patients with ArLD. We examined outcomes in people with decompensated alcohol-related cirrhosis (d-AC) or alcohol-related hepatitis (AH) at the time of entry to the study. Multi-state modelling and landmark modelling was used to describe outcomes over time in those who remained decompensated at three months, six months, one year and two years after baseline. Rates of recovery compared to baseline were explored and recompensation was based on Baveno, excluding the requirement for removal of the aetiologica agent i.e alcohol to explore the role of abstinence.
Results: 143 patients were included: the median age was 52 years (IQR 44–58), 52% were male and 30 (21%) had AH. Over a median follow-up of 79 months (IQR 20–101), 70 (49%) patients died and 13 (9.1%) underwent liver transplantation. Recompensation occurred in 30 (21%) patients with a cumulative incidence of 11% (6.7–17%) at one year and 15% (10–22%) at two years from baseline. The cumulative incidence of recompensation was consistently lower than the risk of death or transplantation which was 30% (23–38%) and 41% (32–49%) at one year and two years from baseline respectively. This was also noted in the 64 patients who were abstinent during follow-up, although rates of transplantation were higher. In multivariable analysis, abstinence during follow-up (SDH 2.62, 1.10–2.67, $p = 0.030$), first presentation of liver disease (SHD 3.39, 1.45–7.96, $p = 0.005$) and the presence of AH at baseline (SDH 3.61, 1.37–9.55, $p = 0.010$) were associated with a greater likelihood of recompensation.
Conclusion: In decompensated ALD, recompensation is uncommon and outweighed by the risk of death or transplantation. Delaying transplantation in the hope of recompensation may lead to worse outcomes in most patients. Proactive consideration of liver transplantation at the same time as alcohol rehabilitation could offer better outcomes in ArLD.

FRI-068

Beyond maddrey and MELD: machine learning transforms mortality prediction in critically ill alcohol-associated hepatitis

Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: jeril.lasington@gmail.com

Background and aims: Alcohol-associated hepatitis (AAH) carries substantial short-term mortality, particularly among ICU patients. Traditional prognostic scores including MELD and Maddrey's Discriminant Function (DF) were developed for transplant prioritization and corticosteroid eligibility rather than ICU mortality prediction. We developed machine learning (ML) models for predicting ICU mortality in AAH and compared performance against established clinical scores.
Method: This retrospective cohort study used MIMIC-IV (v3.1) to identify adults with AAH requiring ICU admission (2008–2022). Predictors from the first 24 hours included demographics, liver function tests, renal parameters, metabolic markers, hemodynamics, cirrhosis complications, and ICU interventions. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, Gradient Boosting) were trained using 80/20 stratified splits with five-fold cross-validation. Performance was compared against MELD, MELD-Na, Maddrey DF, and SOFA using bootstrap DeLong testing ($n = 2000$).
Results: Among 1,084 AAH patients (mean age 49.2 years; 62.1% male; 45.2% with concurrent cirrhosis), hospital mortality was 27.8%. Random Forest achieved highest discrimination (AUC 0.872, 95% CI 0.819–0.918), significantly outperforming MELD (0.769, +13%, $p = 0.0007$), MELD-Na (0.757, +15%, $p = 0.0002$), Maddrey DF (0.806, +8%, $p = 0.029$), and SOFA (0.820, $p = 0.031$). Feature importance revealed

bilirubin as the dominant predictor, followed by sepsis, creatinine, INR, and pH, reflecting the multiorgan nature of severe AAH. Notably, sepsis emerged as the second most important predictor, highlighting infection's critical role in AAH mortality.
Conclusion: ML significantly outperforms all traditional scoring systems for ICU mortality prediction in AAH. The integration of hepatic dysfunction (bilirubin, INR), systemic illness (sepsis, lactate), and renal impairment explains this superior performance. These findings support developing AAH-specific ICU prognostic tools beyond liver-centric scores, with particular attention to early sepsis identification and aggressive infection management in this vulnerable population.

FRI-069
Mortality prediction in alcohol-associated hepatitis
Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: jeril.lasington@gmail.com

Background and aims: Alcohol-associated hepatitis (AAH) hospitalizations and mortality increased during the COVID-19 pandemic. Traditional prognostic scores (MELD, Maddrey DF, Lille) were developed in earlier cohorts and require laboratory values often missing from administrative databases. We developed an interpretable machine learning (ML) model to predict in-hospital AAH mortality using admission-level variables and examined pandemic-era trends.
Method: This retrospective cohort study used the National Inpatient Sample (2019–2022) to identify adult AAH hospitalizations (ICD-10: K70.10, K70.11). Patients were categorized by severity: AAH without ascites, AAH with ascites, hepatorenal syndrome (HRS), and hepatic failure. The primary outcome was in-hospital mortality. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, LightGBM) were trained using temporal validation (2019–2021 training, 2022 testing) with 55 clinical features including demographics, MELD proxies, hepatic decompensation, infections, and alcohol-related complications. Procedural variables were excluded to avoid data leakage. SHAP analysis enabled model interpretation.
Results: Among 109,005 AAH hospitalizations, overall mortality was 4.3%. Mortality rose significantly: 3.8% (2019) to 4.7% (2022), a 25% relative increase ($p < 0.001$). Hospitalizations grew 19% from 2019–2021 before declining in 2022. Mean age was 47.3 years; 65.5% were male. Mortality by severity: HRS 24.2%, hepatic failure 15.8%, AAH with ascites 4.9%, AAH without ascites 1.7%. LightGBM achieved excellent performance (AUC 0.916; sensitivity 83.3%; specificity 86.0%). Top SHAP predictors were acute kidney injury (1.17), sepsis (0.69), age (0.40), renal dysfunction (0.39), and metabolic acidosis (0.35). Liver-specific predictors included HRS (0.28) and coagulopathy (0.25).
Conclusion: This ML model accurately predicts AAH mortality using admission-level data. Key findings are that AAH hospitalizations and mortality rose substantially during the pandemic; HRS carries 14-fold higher mortality than AAH without ascites; AKI and sepsis are dominant predictors, supporting early fluid resuscitation and infection monitoring. This tool can identify high-risk patients at admission for early goals-of-care discussions, ICU triage, and transplant evaluation.

FRI-070
Metabolic comorbidities are associated with lower in-hospital mortality in alcoholic liver disease hospitalizations: a nationwide analysis (NIS 2019–2022)
Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: jeril.lasington@gmail.com

Background and aims: The overlap between metabolic dysfunction and alcohol-related liver disease (MetALD) is increasingly recognized, but its impact on acute outcomes remains unclear. We investigated the association between metabolic comorbidities (obesity, type 2 diabetes, hypertension, dyslipidemia) and in-hospital mortality among patients hospitalized with alcoholic liver disease (ALD).
Method: Using the National Inpatient Sample (2019–2022), we identified adult ALD hospitalizations (weighted N = 2,008,684). Metabolic comorbidity was defined as ≥1 condition present. Multivariable logistic regression assessed associations with in-hospital mortality, adjusting for age, sex, decompensation, cirrhosis, alcohol use disorder, and critical illness markers (sepsis, acute kidney injury, mechanical ventilation). Subgroup and dose-response analyses by metabolic burden score (0–4) were performed.
Results: Overall mortality was 5.8%. Patients with metabolic comorbidities (64.8%) had lower crude mortality than those without (5.4% vs. 6.6%; $p < 0.001$). After full adjustment, metabolic comorbidity was associated with reduced mortality (aOR 0.684; 95% CI 0.673–0.695). A dose-response relationship emerged: aOR 0.801 per 1-unit increase in burden score (p-trend <0.001), with mortality declining from 6.6% (burden 0) to 3.9% (burden 4). Protection was consistent across most subgroups and strongest in older patients (aOR 0.55 for ≥70 years), but absent in females (aOR 1.02). Patients without metabolic comorbidities were younger yet had higher rates of acute decompensation and alcohol-related severity markers, largely explaining this inverse association.
Conclusion: Metabolic comorbidities were paradoxically associated with lower in-hospital mortality in ALD, showing a clear dose-response effect. This likely reflects phenotypic differences: pure ALD patients experience more severe acute alcohol injury, while those with metabolic overlap follow more chronic courses with fewer precipitating events. These findings underscore heterogeneity within ALD/MetALD populations and have implications for acute risk stratification.

FRI-071
Restoration of ethanol-induced Bifidobacterium bifidum depletion ameliorates alcohol-related liver disease
Yating Li[1], Xiaowei Xu[1], Lanjuan Li[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Infectious Diseases Department, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: liyating1991@126.com

Background and aims: Alcohol-related liver disease (ALD) is characterized by intestinal barrier dysfunction and gut microbiota dysbiosis. Analysis of our clinical cohort documented a marked depletion of the *Bifidobacterium* genus in patients with ALD and the functional screening has identified *Bifidobacterium bifidum (B. bifidum)* as a particularly depleted species with protective properties. Based on this, the present study aims to investigate the therapeutic potential of *B. bifidum* against ALD and elucidate its underlying mechanisms.
Method: The study enrolled 140 participants, including 40 healthy controls, 55 ALD patients, and 45 patients with non-metabolic liver disease. An ALD mouse model was established using a Lieber-DeCarli ethanol diet for 8 weeks. Based on human cohort findings, *B. bifidum* isolated and cultured from healthy human donor feces, was administered via oral gavage daily during the 8-week modeling period. An integrated approach combining bacterial 16S rRNA gene sequencing, targeted/untargeted metabolomic profiling, liquid chip technology, and validation of critical regulatory factors at transcriptional and translational levels was employed.
Results: Cohort analysis revealed a marked depletion of *Bifidobacterium* genus in ALD. Functional screening identified *B. bifidum* as a protective candidate. In murine models, pretreatment

with *B. bifidum* significantly ameliorated liver weight and the liver-to-body weight ratio, hepatic steatosis, and lowered serum aminotransferase levels. The intervention restored gut barrier integrity, reducing LPS-binding protein and increasing tight junction proteins. Furthermore, *B. bifidum* administration mitigated gut microbial dysbiosis, characterized by a reduction in the abundance of pathogenic taxa (*Klebsiella*, *Proteus* and *Escherichia-Shigella*) and an enrichment of beneficial genera (*Actinobacteria* and *Bifidobacterium*). These microbiome alterations were functionally correlated with shifts in lipid metabolism. Mechanistically, *B. bifidum*-derived metabolites, particularly short-chain fatty acids suppressed the hepatic expression of *de novo* lipogenesis genes (*Accα*, *Fasn*, *Srebp-1c*). *B. bifidum* modulated the hepatic TLR expression profile, specifically downregulating TLR2/TLR4 while upregulating TLR12, which consequently attenuated the production of pro-inflammatory cytokines (*Il1b*, *Il6*, *Tnfa*).

Conclusion: Our findings suggest that *B. bifidum* has potential as a probiotic for preventing and treating ALD, offering novel insights into liver disease management.

FRI-072

Physical activity reduces the risk of alcohol-attributable liver fibrosis and liver-related events

Email: liuchuan101z@163.com

Background and aims: The impact of physical activity on alcohol-attributable liver fibrosis and liver-related events (LREs) is under-researched. Our study aims to investigate the influence of physical activity on liver fibrosis and LREs in individuals who consume alcohol at least once per month.

Method: This prospective study included a total of 261,927 participants and comprised cross-sectional and longitudinal components. The cross-sectional component analyzed data from the Chinese LiverHealth cohort (N = 6,867) and the UK Biobank cT1 cohort (N = 19,919), with liver fibrosis (defined as liver stiffness ≥ 8 kPa measured by FibroScan or cT1 ≥ 800 ms by magnetic resonance imaging) as the outcome. The longitudinal component enrolled 255,060 participants from the UK Biobank, including a wearable device subcohort (N = 56,484), with LREs (specifically hepatocellular carcinoma, cirrhosis, and its complications) as the outcome. Physical activity was assessed via questionnaire or wearable device. In the wearable device cohort, moderate-to-vigorous physical activity (MV-PA) bouts were derived using a two-level Random Forest classifier and categorized as short (<3 in), medium (3 to <5 min; 5 to <10 min), and long (>10 min).

Results: Compared with inactive participants (reported no MV-PA), the multivariable-adjusted odds ratio (OR) for liver fibrosis was significantly lower among those with physical activity (OR, 0.776 [0.616–0.977], p = 0.031 in the LiverHealth cohort; OR, 0.979 [0.970–0.988], p < 0.001 in the UK Biobank cT1 cohort). In the longitudinal UK Biobank cohort, physical activity was independently associated with a lower risk of LREs in multivariable Cox regression analyses (hazard ratio [HR], 0.774 [0.699–0.856], p < 0.001). Furthermore, in the wearable device cohort, compared with bouts of less than 3 minutes, the risk of LREs was lower for bouts of 3 to <5 minutes (HR, 0.499 [0.250–0.998], p = 0.049), 5 to <10 minutes (HR, 0.459 [0.256–0.822], p = 0.009), and >10 minutes (HR, 0.328 [0.186–0.581], p < 0.001). Additionally, a near-linear dose-response relationship was observed between the daily duration of MV-PA and LRE risk in longitudinal UK biobank cohort and wearable device subcohort.

Conclusion: Physical activity is significantly associated with a reduced risk of alcohol-attributable liver fibrosis and liver-related events.

FRI-073

Digital pathology and multi-omic profiling in abstinent patients with alcohol-related decompensated cirrhosis shows significant degrees of fibrosis regression associated to clinical improvement

Lisa Longato[1], Luc Francis[1], Gareth Muirhead[1], Tu Vinh Luong[2,3], Jennifer Watkins[2,3], Nafia Guljar[1], Athiva Shankar[1], Cristina Albert[1], Massimo Pinzani[3,4], Gautam Mehta[3], Anne E. Wyman[5], Kevin Moore[3], Camila Gabriela De Brito[2], Vandana Gupta[5], Paresh Thakker[5], Mathieu Petitjean[6], Morten Karsdal[7], Bevan Emma Huang[1], Chris Stevenson[1], Haakan Wennbo[5], Giuseppe Mazza[1]. *[1]Engitix Therapeutics, London, United Kingdom; [2]Department of Cellular Pathology, Royal Free London NHS Foundation Trust, London, United Kingdom; [3]Institute for Liver and Digestive Health, University College London, London, United Kingdom; [4]Irccs Ismett-Upmc, Palermo, Italy; [5]Early Clinical Development GI Therapeutic area unit Takeda Pharmaceuticals, Boston, United States; [6]PharmaNest Inc., Princeton, United States; [7]Nordic Bioscience A/S, Herlev, Denmark*
Email: Lisa.Longato@engitix.com

Background and aims: Sustained alcohol abstinence is known to improve the prognosis of patients with alcohol-related liver disease (ALD) at every stage of the disease. This study was aimed at the in-depth histological and molecular characterization of fibrosis regression in a cohort of abstinent ALD patients.

Method: Extent of fibrosis regression in explants from a cross-sectional cohort of 42 patients with decompensated ALD cirrhosis who underwent liver transplant was assessed by conventional and digital pathology. Serum biomarkers were assessed by ELISA and livers were profiled by scRNAseq and spatial transcriptomics.

Results: Pathologist-led assessment of histological features according to a modified Beijing classification categorized 70% of the cohort with

features of fibrosis regression, either moderate (n = 24) or advanced (n = 5). The remaining non-regressive samples were shown to display either features of progressive disease (n = 3) or an indeterminate pattern of fibrosis regression (n = 10). AI-assisted digital pathology analysis confirmed the histologic features, showing a significant decrease in the phenotypic fibrosis composite score in the regressive vs non-regressive groups (mean ± SEM: 3.2 ± 0.2 vs 5.2 ± 0.2; P < 0.05). Patients showing regression had been abstinent for longer (25.8 ± 3.5 vs 9.2 ± 0.9 months) and displayed selectively improved indices of hepatic function such as reduced bilirubin (40.4 ± 5.2 vs 155.3 ± 25.9 µM/L), INR (1.38 ± 0.06 vs 1.63 ± 0.11) and MELD-Na (13.4 ± 0.9 vs 20.2 ± 1.2) compared to non-regressive patients, respectively (all P < 0.05). The same patients displayed significantly (P < 0.05) reduced ELF scores (11.9 ± 0.2 vs 13.4 ± 0.4) and ProC3 levels (31.8 ± 2.4 vs 58.3 ± 9.0). scRNAseq analysis revealed shifts in the composition of liver cells in regressive samples, specifically increased hepatocytes and mononuclear phagocytes, and reduced cholangiocytes and connective tissue cells. The increase in macrophages was largely driven by the selective expansion of 2 subpopulations in regressive samples. Spatial profiling showed nodule expansion in regression with upregulation of metabolic pathways in nodules relative to septal areas.

Conclusion: Histological fibrosis regression can be achieved in patients with decompensated ALD cirrhosis who maintain abstinence. Patients with fibrosis regression display improved measures of organ function, reduced serum biomarkers of fibrosis, and a molecular/cellular signature indicative of reduced damage, parenchymal regeneration, and ongoing tissue repair.

FRI-074

Bio-molecular landscape of hyper-oxidized and cysteinylated albumin signature linked to immune activation and hyperinflammation in severe alcohol-related hepatitis

Babu Mathew[1], Sushmita Pandey[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Vipul Sharma[1], Nupur Sharma[1], Yash Magar[1], Manisha Yadav[1], Neha Sharma[1], Sanju Yadav[1], Shvetank Sharma[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Severe alcohol-associated hepatitis (SAH) is characterized by oxidative stress and systemic inflammation. In SAH, reduced human mercaptalbumin (HMA) shifts toward oxidized isoforms, HNA1 (cysteinylated) and HNA2 (hyper-oxidized), which are pro-inflammatory. The macromolecular cargo bound to these isoforms may influence disease severity and outcomes.

Method: We enrolled 125 adults: 60 with SAH (30 survivors, 30 non-survivors), 50 with decompensated cirrhosis, and 15 healthy controls. HNA1 and HNA2 were purified by anion exchange chromatography and analyzed using UHPLC-HRMS–based multi-omics. Albumin-bound macromolecules were quantified and correlated with functional status, severity scores, and survival using multivariate statistical analysis.

Results: Albumin redox fractionation revealed distinct macromolecular signatures linked to severity, mortality, and therapeutic relevance. In SAH non-survivors, HMA was enriched with inflammatory and oxidative cargo including L-cystathionine (FC = 5.7), N,N-Dimethylhistidine (FC = 3.3), ceramide Cer(t18:1(6OH)/24:0(2OH)) (FC = 3.4), and PRMT1 (FC = 11), along with bacterial peptides from *Ehrlichia chaffeensis* (FC = 10.9). Pathways involved mitochondrial immune responses and IL-23 signaling. HNA1 displayed a pathogenic profile with elevated Elaidic carnitine (FC = 5.9), Heptanoylcarnitine (FC = 4.3), histidine (FC = 3.8), leukotriene C4 (FC = 3.1), TG(17:2/20:5/20:5) (FC = 7.9), and tetranor-PGE1 (FC = 6.5). Proteins including MAP4K1 (FC = 8) and Interferon-α1 (FC = 6.6), and peptides from *Listeria monocytogenes* and *Klebsiella pneumoniae* indicated microbial translocation. Pathways included necroptosis, interferon, and prostaglandin signaling. HNA2 carried hyper-inflammatory and hypoxia-related cargo: Eicosadienoic acid (FC = 5.3), PE(P-16:0/15:1) (FC = 5.4), PPIA (FC = 5), and peptides from *Campylobacter concisus*. Pathways involved TNFR1, HIF-1, and kynurenine signaling. HNA1/HNA2-bound molecules correlated strongly with MELD-Na, DF, ALBI, and PALBI. PPIA (HR = 1.68) and Eicosadienoic acid (HR = 1.30) emerged as predictors and candidate drug targets. HNA2 was most strongly associated with sustained inflammation, hypoxia, and metabolic exhaustion.

Conclusion: In SAH patients who died within 30 days, HNA2 binds hyper-inflammatory, hypoxia-responsive, and microbial molecules, amplifying systemic inflammation and metabolic failure, establishing HNA2 as a potential therapeutic target.

FRI-075

Association of protein-calorie malnutrition with in-hospital complications in patients hospitalized with alcohol-associated cirrhosis

Jazmin Mexia Cabrales[1], Fatima Shafiq[1], Hassan Sinan[1], Madonna Johnson[1], Frances Lee[2]. [1]*Department of Medicine, NYC Health + Hospitals/Elmhurst, Icahn School of Medicine at Mount Sinai, New York City, United States;* [2]*Icahn School of Medicine at Mount Sinai, New York, United States*
Email: jazmin.mexia@gmail.com

Background and aims: Malnutrition is highly prevalent among patients with cirrhosis and is particularly common in alcohol-associated liver disease. Despite EASL guidelines recommendations for early nutritional assessment, malnutrition is frequently under-recognized during hospitalization. Data evaluating the association between malnutrition and clinical outcomes among hospitalized patients with alcohol-associated cirrhosis remains limited.

Method: We conducted a single-center retrospective cohort study using the Mount Sinai TriNetX electronic health record (EHR) network. Adults ≥18 years hospitalized with alcohol-associated cirrhosis were identified and categorized into two cohorts based on the presence or absence of a documented diagnosis of malnutrition. Propensity score matching (1:1 nearest neighbor), was performed using age, sex, comorbidities and baseline markers of cirrhosis severity, including ascites, portal hypertension, esophageal varices, chronic kidney disease, diabetes, and heart failure. Outcomes were assessed 1–90 days after the index event and included: short-term all-cause mortality, acute kidney failure, spontaneous bacterial peritonitis, acute hepatic failure and 90-day readmission. Risk ratios (RRs) with 95% confidence intervals (CIs) were calculated with statistical significance set at p < 0.05.

Results: After propensity score matching, 1,550 patients with alcohol-associated cirrhosis and documented malnutrition were compared with 1,550 patients without malnutrition. Patients with malnutrition experienced a significantly higher incidence of acute kidney injury compared with those without malnutrition (21.2% vs 10.5%; risk ratio [RR] 2.03, 95% CI 1.66–2.47; p < 0.0001). Malnutrition was also associated with a higher risk of spontaneous bacterial peritonitis (6.8% vs 3.3%; RR 2.04, 95% CI 1.47–2.84; p < 0.0001). Acute hepatic failure, ninety-day readmission rates and all-cause mortality did not differ significantly between groups.

Conclusion: Among hospitalized patients with alcoholic cirrhosis, protein-calorie malnutrition was independently associated with a markedly increased risk of acute kidney injury and spontaneous bacterial peritonitis, but not with short-term mortality, readmission or acute hepatic failure. These findings suggest that malnutrition in alcohol-associated cirrhosis is a strong marker of vulnerability to in-hospital complications and highlight the importance of early nutritional recognition and intervention during hospitalization.

FRI-076-YI

Alcohol-associated amino acid signature linked to zonal glutamine synthetase serves as a biomarker of metabolic adaptation in steatotic liver disease

Masaaki Mino[1], Eiji Kakazu[1], Taiji Yamazoe[1], Michitaka Matsuda[1], Tatsuya Kanto[1]. [1]*Japan Institute for Health Security, The Research Center for Hepatitis and Immunology, Ichikawa, Japan*
Email: kakazu.e@jihs.go.jp

Background and aims: The impact of alcohol on free amino acids (FAAs) and intrahepatic metabolism within the spectrum of steatotic liver disease remains poorly understood. We aimed to identify an alcohol-specific FAA signature using a large-scale biobank and elucidate its pathological and metabolic basis through human tissue and murine models.
Method: We analyzed a Japanese population biobank (n = 23,036). Subjects were classified into MASLD (n = 3,504), MetALD (n = 519), and alcohol-related liver disease (ALD) (n = 899) based on alcohol intake and steatotic liver indices (FLI≥60, HSI>36, and questionnaire data). Plasma concentrations of 20 FAAs were quantified using LC–MS/MS. In a clinical cohort of chronic liver disease (n = 1,326), we examined the glutamate/glutamine (Glu/Gln) ratio across modified ALBI (mALBI) grades. Zone 3 glutamine synthetase (GS) expression was evaluated in an ALD human tissue microarray (n = 53; fibrosis stages F0–F4). Mechanistically, C57BL/6J mice were subjected to the national institute on alcohol abuse and alcoholism (NIAAA) ethanol-binge protocol (n = 5), and livers were analyzed 9 h post-binge by metabolomics and RNA-seq.
Results: In the biobank, steatotic liver was associated with broad FAA remodeling (16 increased and 4 decreased vs controls). A characteristic "High-Glu/Low-Gln" signature was progressively enhanced from MASLD to MetALD to ALD. In the clinical cohort, the Glu/Gln ratio differed by etiology; in MASLD, the ratio declined with worsening liver function, whereas in MetALD and ALD, it increased up to mALBI grade 2b and dropped sharply at grade 3. In human tissue samples, GS expression in zone 3 increased with fibrosis progression (F0–F3), suggesting compensatory upregulation, but was lost in cirrhosis (F4). Murine models corroborated this mechanism, showing hepatic Glu accumulation, induction of zone 3-enriched genes (*Cyp2e1, Cyp1a2*), and glutathione depletion, consistent with alcohol-driven pericentral oxidative stress. These findings suggest that zone 3 GS is upregulated in earlier stages but becomes lost in advanced fibrosis stages.
Conclusion: The alcohol-induced Glu/Gln signature reflects biphasic zone 3 glutamine synthetase dynamics and may serve as a mechanistic biomarker capturing the transition from metabolic adaptation to failure in MetALD/ALD.

FRI-077

Quantifying biological and clinical modifiers of phosphatidylethanol in treatment-seeking alcohol use disorder

Andrew Palmer[1,2], Jason Connor[1,2], Gerald Holtmann[1,2], John Saunders[1], Paul Clark[1,2]. [1]*The University of Queensland Herston, Herston, Australia;* [2]*Princess Alexandra Hospital, Woolloongabba, Australia*
Email: andrew.palmer@uq.edu.au

Background and aims: Hazardous alcohol consumption and alcohol use disorder (AUD) are leading causes of preventable morbidity and mortality. However, alcohol exposure remains largely quantified by self-report, which is vulnerable to recall bias, social desirability bias, and underreporting. Phosphatidylethanol (PEth) is a sensitive and specific biomarker of recent alcohol intake, yet interpretive thresholds vary across studies and between individuals at comparable intake levels. We aimed to estimate (i) the variance in PEth explained by self-reported intake; (ii) the diagnostic performance of conventional indirect biomarkers at established PEth thresholds; and (iii) the contribution of biological and clinical covariates to PEth variability in a treatment-seeking AUD cohort.
Method: We conducted a prospective cross-sectional study of treatment-seeking adults with moderate to severe AUD recruited between April 2023 and January 2025 from a quaternary hospital alcohol and drug service in Brisbane, Australia. Alcohol intake was assessed using the 30-day Timeline Follow-Back (TLFB; standard drink = 10 g ethanol). The primary outcome was blood PEth 16:0/18:1 measured by LC–MS/MS. Predictors included clinically plausible cohort-derived laboratory variables screened in bivariate analyses (AST, ALT, GGT, ferritin, time since last drink) and a priori variables previously reported to influence PEth (BMI, haemoglobin, advanced fibrosis, age, sex, socioeconomic status).
Results: Seventy-three participants were included; 75% were male, with a mean age of 49 years (IQR 39–56). PEth was strongly correlated with mean daily alcohol intake ($r = 0.82$, $p < 0.001$). Each additional standard drink per day was associated with a 69.6 ng/mL increase in PEth (95% CI 56.4–82.8, $p < 0.001$). A core multivariable model including intake, AST, and ALT explained 79.6% of PEth variance (adjusted $R^2 = 0.780$). Addition of a priori predictors did not significantly improve model performance ($\Delta R^2 = 0.029$, $p = 0.142$). At a PEth threshold >210 ng/mL, ALT demonstrated the strongest discrimination for significant alcohol exposure (AUC = 0.74), followed by AST (AUC = 0.68) and GGT (AUC = 0.67).
Conclusion: In treatment-seeking adults with moderate to severe AUD, PEth closely reflects recent self-reported alcohol intake assessed by TLFB, with liver function tests providing additional biological context.

FRI-078

Long-term mortality under the new steatotic liver disease classification

Parucha Paruchakul[1], Moongmun Anuntasainont[1], Mingkwan Ratanapipop[1], Sakkarin Chirapongsathorn[2]. [1]*Department of Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand;* [2]*Division of Gastroenterology and Hepatology, Department of Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand*
Email: toop.parucha@gmail.com

Background and aims: The 2023 reclassification of steatotic liver disease (SLD) distinguishes metabolic dysfunction–associated SLD (MASLD), MASLD with increased alcohol intake (MetALD), and alcohol-associated liver disease (ALD). However, the long-term mortality implications of this framework, particularly in Asian populations, remain unclear.
Method: We conducted a retrospective longitudinal cohort study of adults diagnosed with SLD by ultrasonography in 2014, reclassified using the 2023 SLD criteria and followed for up to 11 years. All-cause and cause-specific mortality were assessed using Kaplan–Meier analysis and multivariable Cox models, with cancer- and cardiovascular (CVD)-specific mortality evaluated after excluding patients with pre-existing cancer or CVD.
Results: Among 1,279 patients (median age 57 years; 57% male), 88% had MASLD, 3% MetALD, and 3% ALD. During a median follow-up of 10.8 years, 67 deaths occurred. ALD had the highest mortality incidence (58.6 per 1,000 person-years) and the lowest 10-year survival (58.9%). After adjustment, ALD was independently associated with increased all-cause mortality compared with MASLD (adjusted hazard ratio [aHR] 4.0; 95% CI 1.1–14.2), whereas MetALD showed no excess risk. Older age, diabetes, chronic kidney disease, and advanced fibrosis were independent predictors of mortality. Liver- and cancer-related deaths predominated in ALD, while CVD-specific mortality was similar across SLD subtypes. After excluding patients with pre-existing cancer, ALD remained strongly associated with increased overall mortality (64.6 per 1,000 person-years; aHR 7.6; 95% CI 1.9–29.6), the lowest 10-year survival (55.5%), and a median survival of 10.7 years. Significant differences in all-cause, liver-related, hepatocellular carcinoma–related, and cancer-related mortality were observed across SLD subtypes (log-rank $p < 0.001$). Among patients

without pre-existing CVD, ALD was also associated with increased overall mortality (aHR 4.5; 95% CI 1.2–16.3), while CVD-specific mortality did not differ significantly.
Conclusion: In this long-term Asian cohort, the 2023 SLD reclassification provided meaningful prognostic stratification. ALD was associated with markedly higher all-cause, liver-related, and cancer-related mortality and poorer survival than MASLD, whereas MetALD did not increase mortality risk. Cardiovascular mortality was similar across SLD subtypes, supporting the clinical utility of the updated SLD reclassification.

FRI-079-YI
Higher socioeconomic status is associated with alcohol under-reporting: a PEth-based analysis of 6,000 individuals screened for SLD
Helle Schnefeld[1,2], Johanne Kragh Hansen[1,2], Mads Israelsen[1,2], Katrine Tholstrup Bech[1,2], Camilla Dalby Hansen[1,2], Katrine Thorhauge[1,2], Maria Fogt[1], Ea Kyed[1,2], Kathrine Sejer Sørensen[1], Anine Andersen[1,2], Stine Johansen[1,2], Nikolaj Torp[1,2], Ida Villesen[1,2], Peter Andersen[1], Sönke Detlefsen[3], Maja Thiele[1,2], Aleksander Krag[1,2]. *[1]FLASH - Centre for Liver Research, Odense, Denmark; [2]SDU - University of Southern Denmark, Odense, Denmark; [3]Department of Pathology, Odense, Denmark*
Email: helle.schnefeld@rsyd.dk

Background and aims: Steatotic liver disease (SLD) subgrouping relies on current, self-reported alcohol intake and is prone to misclassification due to recall bias. People with low socioeconomic status (SES) have higher alcohol-related morbidity and mortality; however, how SES influences the accuracy of self-reported alcohol intake is less well understood. Phosphatidylethanol (PEth) is a direct biomarker reflecting alcohol consumption over the prior 1–4 weeks. We investigated the association between SES and discordance between self-reported alcohol intake and PEth.
Method: Single-centre, cross-sectional liver fibrosis screening study in the general Danish population and individuals at risk of SLD. SES was assessed by income, education, employment, and living situation. Alcohol use was self-reported (past week and past 3 months) and categorised according to SLD nomenclature. PEth was classified into three categories (<20 ng/mL, 20–199 ng/mL, ≥200 ng/mL). Under-reporting was defined as self-reported intake below the PEth-indicated category. SES trends were evaluated using Cuzick's test and ordinal logistic regression.
Results: We screened 6,364 participants, median age 57 years, 52% female. Alcohol intake was low in 77%, moderate in 16% and high in 7%, while PEth was low in 42%, moderate in 41% and high in 17%. Among 6,082 participants with complete data, 45% under-reported and 4% over-reported their alcohol intake relative to PEth, while 51% showed concordance. Under-reporting increased with higher SES, most notably by income (36% lowest vs 58% highest income; $p < 0.001$), and remained significant after adjustment for age, sex, and education. Full-time employment had the highest adjusted probability of under-reporting (46%) whereas those outside the labour market reported less (36–39%; $p < 0.001$). Individuals living alone under-reported less than those cohabiting (40% vs 46%; $p < 0.001$). Education was not associated with under-reporting.
A cumulative binary SES score (0–4, higher scores indicating higher SES), showed a dose–response relationship based on income, education, labour market attachment, and living alone/other showed a dose–response. Under-reporting decreased from 52% at SES = 0 to 32% at SES = 4 ($p < 0.001$).
Conclusion: SES was strongly associated with discrepancies between self-reported alcohol intake and PEth. Higher-SES individuals substantially under-reported their intake, leading to systematic misclassification. SES-related bias should be explicitly considered when alcohol intake informs SLD assessment.

FRI-083
Type 2 diabetes mellitus and alcohol use disorder amplify both cardio-renal-metabolic and liver related outcomes and mortality risk compared to either disorder alone
Neha Shah[1], Vinay Jahagirdar[1], Kavin Parmar[1], Arun J. Sanyal[1]. *[1]Virginia Commonwealth University School of Medicine, Richmond, United States*
Email: shahn24@vcu.edu

Background and aims: Alcohol use disorder (AUD) and type 2 diabetes mellitus (T2DM) are both highly prevalent and often co-exist in the same person. The impact of T2DM on AUD-related liver outcomes and the impact of AUD on cardio-renal-metabolic (CRM) outcomes is not established in routine clinical practice settings. The aim of this study was the quantify the impact of concomitant T2DM and AUD on CRM and liver outcomes relative to either disorder alone in a large real-world practice setting.
Method: We evaluated mortality, CRM and liver outcomes in those with T2DM + AUD vs propensity score matched (PSM) controls with T2DM (analysis 1) or AUD alone (analysis 2). PSM was done for demographics, BMI, laboratory (bilirubin, AST, ALT, INR, creatinine, A1C), nicotine dependence and statin use. Those on a GLP-1 RA were excluded. Independent analyses by age decile strata from 30 yrs. onwards was performed. The key outcome measures were death, new diagnosis of cirrhosis, ascites, hepatic encephalopathy, alcohol associated hepatitis, 5-point MACE, atrial fibrillation and obesity-related cancers. Absolute risk (AR %) and Hazard ratios (HR) were computed using time-dependent proportional hazards model. Kaplan-Meir analyses were done to assess time to event with cross-group comparisons with logrank test (significance $p < 0.05$).
Results: 131900, 639437 and 2420891 cases of T2DM+AUD, AUD alone and T2DM alone were eligible for analysis prior to PSM. *T2DM +AUD vs T2DM*: In T2DM, coexistent AUD increased mortality (AR 2.2–6.1, HR 1.3–1.6), ascites (HR 2.7–3.3), encephalopathy (HR 6.9–7.9), MACE (HR 1.4–2.0), and atrial fibrillation (HR 1.4–1.8) and sepsis (HR 1.7–2.0) ($p < 0.001$ for all) across all age deciles studied. Cancer risk (HR 1.3, 95% CI 1.2–1.4) was increased in those with age > 60 yrs. *T2DM+AUD vs AUD*: T2DM increased the risk of death (HR 1.4–1.6), new diagnosis of cirrhosis (HR 1.5–1.8) and heart failure (HR 2–3) ($p < 001$ for all) in all age deciles studied. Importantly, the risk of alcohol associated hepatitis was increased in ages 30–59 yrs (HR: 1.1–1.5) ($p < 0.05$ for all).
Conclusion: T2DM +AUD increased mortality and CRM outcomes compared to either one alone. T2DM increases liver-related outcomes including development of alcohol associated hepatitis in those with AUD. AUD increases cardiometabolic outcomes in those with T2DM.

FRI-084
Triangulated alcohol assessment substantially increases identification of MetALD and ALD in a population-based study of steatotic liver disease
Juho Siltanen[1,2], Lara Lehtoranta[3], Annamari Lundqvist[3], Anniina Ojanen[3], Linda Mustelin[3], Lotta Joutsi-Korhonen[4,5], Tuukka Helin[5], Ville Männistö[2], Fredrik Åberg[3,4,6]. *[1]Kuopion yliopisto, Kuopio, Finland; [2]Kuopion yliopistollinen sairaala, Kuopio, Finland; [3]Terveyden Ja Hyvinvoinnin Laitos, Oulu, Finland; [4]University of Helsinki, Helsinki, Finland; [5]Department of Clinical Chemistry, Diagnostic Center, Helsinki University Hospital, Helsinki, Finland; [6]Transplantation and Liver Surgery, Helsinki University Hospital, Helsinki, Finland*
Email: siltanen.juho@gmail.com

Background and aims: Steatotic liver disease (SLD) subclassification is currently based on self-reported average alcohol intake. A triangulated assessment combining self-reports, AUDIT-C and phosphatidylethanol (PEth) was recently proposed to improve subclassification accuracy. In a general population survey, we evaluated how applying triangulated alcohol assessment alters the prevalence and proportion of SLD subclasses.

Method: Of participants in the Finnish Healthy Finland 2023 survey, 1576 adults residing in Uusimaa were invited to a liver substudy. 1090 (69%) participated. SLD was defined as ultrasound-derived fat fraction (UDFF ≥) 5%. Alcohol use was assessed using self-reported 7-day consumption, AUDIT-C, and PEth. Subclassification into MASLD, MetALD and ALD by triangulation was done as previously described (Torp et al. Lancet Gastroenterol Hepatol 2025;10:975). The given method balances allocation to higher risk groups if conflict exists between indicators, emphasizing self-reported consumption. Participants with any missing alcohol consumption data were excluded, leaving 717 individuals for analysis.
Results: Among 717 individuals (mean age 52 years, 45% men, mean BMI 27.3 kg/m2, diabetes 6.5%), 419 (58.4%) had SLD. Mean alcohol use was 56 ± 99.3 g/wk, mean AUDIT-C 3.8 ± 2.1 points, and mean PEth 0.04 ± 0.08 µmol/L. Using mean alcohol use alone, 390 were classified as MASLD (population prevalence 54.4%, proportion of SLD 93.1%), 14 as MetALD (2.0%, 3.3%), 6 as ALD (0.8%, 1.4%) and 9 as other (1.3%, 2.1%), which were omitted from further analysis. Using the triangulated assessment, 160 were classified as MASLD (population prevalence (22.3%, proportion of SLD 38.2%), 236 as MetALD (32.9%, 56.3%), and 14 as ALD (2.0%, 3.3%). Applying a pragmatic "maximum-of-three" indicator subclassified SLD cases into 160 with MASLD (population prevalence 22.3%, proportion of SLD 38.2%), 211 with MetALD (29.4%, 50.4%), and 40 with ALD (5.6%, 9.5%).
Conclusion: Triangulating alcohol assessment substantially alters SLD subclassification in the general population, with major implications for SLD epidemiology and clinical care. Reliance on alcohol self-reports alone likely underestimates, especially MetALD. Accurate evaluation of alcohol consumption should therefore integrate multiple complementary indicators.

Email: lubomir.skladany@gmail.com

Background and aims: Phosphatidylethanol (PEth) is an established erythrocyte-bound biomarker of alcohol exposure. However, its reliability may be influenced by biological factors affecting red blood cell mass and turnover. Anemia is common in patients with advanced chronic liver disease (ACLD) and may alter PEth concentrations independently of alcohol intake. We aimed to evaluate the impact of anemia severity on PEth levels and to identify hemoglobin thresholds associated with systematically reduced PEth concentrations.
Method: In a large cohort of patients with ACLD, PEth concentrations were analyzed across anemia severity categories (none, mild, moderate, severe). Group comparisons were performed, and a data-driven regression tree model was applied to identify hemoglobin (Hb) thresholds associated with altered PEth levels. Clinical severity markers, including MELD score and liver frailty index (LFI), were assessed across anemia strata.
Results: Mean PEth concentrations declined stepwise with increasing anemia severity, with a statistically significant difference across groups (p = 0.028). The most pronounced reduction occurred between non-anemic patients and those with moderate-to-severe anemia. Increasing anemia severity was concurrently associated with worsening clinical status, reflected by higher MELD and LFI values, consistent with advanced disease and malnutrition. Regression tree analysis identified Hb <14 g/dL as the primary threshold associated with markedly reduced PEth concentrations, independent of liver disease etiology. This threshold aligned with the observed stepwise decline across anemia categories.
Conclusion: Anemia is an independent biological modifier of PEth concentrations in patients with ACLD. Reduced erythrocyte mass and shortened red blood cell lifespan likely lead to systematic underestimation of alcohol exposure by PEth in anemic patients. These findings have important implications for the clinical interpretation of PEth and highlight the need to consider hemoglobin levels when using PEth in advanced liver disease.

Email: pablo.a.solis@hotmail.com

Background and aims: Cardiometabolic risk factors (CMRF) have traditionally been overlooked in alcohol-related liver disease (ALD), and their impact on alcohol-relaated hepatitis (AH) remains unexplored. We aimed to assess the influence of CMRF, including number and control, on complications and mortality in patients with AH using the newly proposed steatotic liver disease (SLD) nomenclature and diagnostic criteria.
Method: In this prospective cohort study, we analyzed 100 patients with biopsy-proven AH. Clinical and laboratory data, including obesity, hypertension, diabetes, triglycerides, and HDL cholesterol levels, were collected upon admission, according to the new SLD framework. Patients were followed up for complications during admission and for one year to assess mortality.

Results: Patients with AH and CMRF had higher mortality (46% vs. 25%, p = 0.049) and more complications, notably acute kidney injury (52% vs. 29%, p = 0.030) and infection (31% vs. 9.6%, p = 0.014) than those without CMRF. Logistic regression showed that only patients with ≥3 CMRF had more complications, and mortality, both all-cause (82% vs. 25%, p < 0.001) and liver-related (53% vs. 22%, p = 0.019), while those with 1–2 CMRF had outcomes similar to those of patients without CMRF. These patients also had higher MELD (30 vs. 24, p = 0.010) and Maddrey's mDF (52 vs. 46, p = 0.011) scores than those with 2 or less CMRF. In the multivariable analysis, the MELD score, infections, and diabetes were independently associated with 1-year mortality. Furthermore, patients with poorly controlled CMRF had a higher mortality risk than those with well-controlled CMRF (OR 4.7 [1.4–18]; p = 0.016). A new, intuitive cardiometabolic control (CMC) score integrating the number and degree of CMRF control was also associated with short- and long-term mortality.
Conclusion: The presence, burden, and degree of control of cardiometabolic risk factors significantly influenced outcomes of AH in our cohort. Patients with clustered (≥3) or poorly controlled CMRF had higher risks of complications and mortality, highlighting the potential value of metabolic assessment and management in ALD, particularly in those who later develop AH.

FRI-087-YI
Episodic heavy drinking and implications for steatotic liver disease nomenclature: a national USA study
Yinan Su[1], Jennifer Dodge[2,3], Brian Lee[2]. [1]*Keck School of Medicine, University of Southern California, Los Angeles, United States;* [2]*Division of Gastroenterology and Liver Diseases, University of Southern California, Keck School of Medicine, Los Angeles, United States;* [3]*Department of Population and Public Health Sciences, University of Southern California Keck School of Medicine, Los Angeles, United States*
Email: yinansu@usc.edu

Background and aims: International agencies define heavy drinking by average increased alcohol consumption OR episodic heavy consumption, which do not always coexist. However, SLD nomenclature only captures average alcohol consumption to define subgroups. We assessed prevalence of episodic heavy drinking among SLD subgroups, and differences in liver fibrosis among MASLD with (vs. without) episodic heavy drinking, compared to MetALD and ALD.
Method: We performed a cross-sectional analysis using the nationally-representative US National Health and Nutrition Examination Survey (NHANES) 2017–2023, including adults with vibration-controlled transient elastography (VCTE) data. Episodic heavy drinking was ≥4 drinks (women) and ≥5 (men) on any day, at least once per month. SLD was defined as controlled attenuation parameter ≥248 dB/m and/or liver stiffness measurement (LSM) ≥8 kPA by VCTE. Significant and advanced liver fibrosis were LSM ≥8 and ≥12 kPA by VCTE. Multivariable logistic regression evaluated the association of episodic heavy drinking with liver fibrosis, adjusting for age, gender, and average alcohol consumption. SLD subgroup prevalence was compared using consensus nomenclature vs. if episodic heavy drinking was considered as increased alcohol use under nomenclature.
Results: Among 8,006 adults, 4,571 had SLD: 3,969 had MASLD, 373 had MetALD, and 144 had ALD per consensus nomenclature. Among MASLD, 632 (15.9%) had episodic heavy drinking, which was associated with higher likelihood of significant (aOR 1.69 [95%CI 1.11–2.58]) and advanced (aOR 2.76 [1.58–4.80]) liver fibrosis vs. without episodic heavy drinking. The adjusted weighted-prevalence of significant liver fibrosis among MASLD with episodic heavy drinking (23.6% [17.6–29.6%]) was higher than MASLD without episodic heavy drinking (15.6% [13.5–17.6%]). Reclassifying those with SLD and episodic heavy drinking as MetALD or ALD decreased weighted-prevalence of MASLD (48.0% [46.0–50.0%] to 40.4% [38.5–42.4%]), and increased MetALD (5.3% [5.6–6.1%] to 12.9% [11.9–13.9%]), while ALD was similar (1.9% [1.5–2.3%] to 2.1% [1.7–2.5%]).
Conclusion: Episodic heavy drinking is prevalent in MASLD and associated with 3-fold higher odds of advanced liver fibrosis. Reclassifying these patients to MetALD would more than double the estimated prevalence of MetALD, and highlights the importance of alcohol patterns in clinical risk stratification.

FRI-088
Triglycerides identify a lower-risk phenotype and predict mortality in clinically suspected alcohol-associated hepatitis
Ana Suárez-Saro Fernández[1], Mónica Barreales Valbuena[1], Alvaro Hidalgo[1], Elena Gómez-Domínguez[1], Berta De las Heras[1], Maria Amo[1], Carolina Muñoz Codoceo[1], Irina Calvo[1], Maria Luisa Manzano Alonso[1], Raquel Muñoz Gómez[1], Ana Martin Algibez[1], Maria Inmaculada Fernández Vázquez[1].
[1]*Hospital universitario 12 de octubre, Madrid, Spain*
Email: anasaro1996@gmail.com

Background and aims: Phenotypic heterogeneity is increasingly recognised in alcohol-associated hepatitis (AH). Higher triglyceride (TG) levels may indicate a low-risk phenotype with relatively preserved hepatic function, but this remains insufficiently characterised. We aimed to assess whether admission TG levels predict short and mid-term mortality in clinically suspected AH.
Method: We retrospectively included consecutive patients admitted with clinically suspected AH. TG were analysed categorically (<150, 150–224, ≥225 mg/dL) and as a log-transformed continuous variable. Baseline characteristics, liver severity scores and 28-, 90- and 180-day mortality were compared across TG groups. Associations with mortality were evaluated using logistic regression, Cox models and Kaplan–Meier analysis, adjusting for age, sex, prior cirrhosis and MELD.
Results: TG measurements were available in 185 of 209 patients with suspected AH. Higher TG levels were associated with a milder biochemical profile (lower INR, transaminases, bilirubin, urea, MDF, GAHS and MELD; p < 0.05). Mortality was consistently higher in the low-TG group (<150 mg/dL) compared with patients with TG≥225 mg/dL at 28 days (13.5% vs 2.9%, p = 0.050), 90 days (22.5% vs 4.5%, p = 0.003) and 180 days (28.1% vs 7.3%, p = 0.002). In univariable logistic regression, TG≥225 mg/dL was associated with substantially reduced mortality at all time points (OR: 0.19–0.22). Log-transformed TG showed a similarly protective association (OR: 0.17–0.23). In multivariable models, logTG remained independently associated with reduced 180-day mortality (OR: 0.28; 95% CI 0.10–0.80). Cox regression confirmed these findings, with logTG showing an adjusted HR of 0.34 (95% CI 0.15–0.77). Kaplan–Meier curves demonstrated higher survival in patients with elevated TG (p = 0.002).
Conclusion: Among patients with clinically suspected AH, higher admission TG levels may identify an alcohol foamy degeneration-like phenotype associated with lower biochemical severity and reduced mortality. TG could serve as an inexpensive and accessible biomarker to refine risk stratification and guide clinical decision-making in AH, a finding that warrants prospective validation.

FRI-089
Use of biopsy to diagnose alcoholic hepatitis in a setting a high prevalence of alcohol consumption
Vanessa Trentzsch[1], Cristina Ripoll[1], Andreas Stallmach[1], Alexander Zipprich[1]. [1]*Jena University Hospital, Department of Internal Medicine IV (Gastroenterology, Hepatology, Infectious Diseases and Central Endoscopy), Jena, Germany*
Email: alexander.zipprich@med.uni-jena.de

Background and aims: Criteria for diagnosis of alcoholic hepatitis (AH) have been proposed, however validation in routine clinical practice is scarce. Furthermore, lack of response to corticosteroids leads to doubts regarding the diagnosis if histological confirmation

was not undertaken. The aim of this study was to evaluate the usefulness of biopsy for the diagnosis of AH.
Method: Between 2019 und 2023, 186 patients underwent transjugular liver biopsy, 74 patients because of the clinical suspicion of AH. NIAAA Alcoholic Hepatitis Consortia Criteria were applied to all patients: (1) jaundice < 8 weeks, 2) recent harmful alcohol consumption, 3) AST < 50 IU/ml, 4) AST/ALT 1.5, 5) both AST and ALT < 400 IU/ml, 6) Bilirubin > 3 mg/dL). Comparison of the number of positive criteria, including probable AH (all criteria) and possible AH (not all criteria fulfilled) and histological diagnosis was done. Usefulness of biopsy was evaluated as the proportion of patients who had alternative diagnoses or were non-responders to prednisolone out of the total population who were biopsied with the clinical suspicion of AH. Results are reported as median (IQR) and n (%) as appropriate.
Results: A total of 74 patients underwent liver biopsy with the clinical suspicion of AH (age 54 years (43–64 years) male 45 (61%), MELD 25 (22–30)). These patients fulfilled 4 (n = 6), 5 (n = 21) or 6 (n = 47) of the NIAAA criteria. From these patients, 60 had histological evidence of AH (81%). Among patients with possible AH (n = 27), 37% [n = 3 (50%) with 4 and n = 7 (33%) with 5 criteria] had other diagnoses while among patients with probable AH (n = 47), 9% (n = 4) had an alternative diagnosis. A total of 42 patients received treatment with corticosteroids (10 with possible and 32 with probable AH). Of these, all but one patient had histological confirmation. Among those who were treated, 12 were non-responders at 7 days according to Lille score (including 1 patient without histological confirmation). Taking into account the number of patients in whom the biopsy excluded an AH (n = 14) and in those in whom it was confirmed (despite lack of response to corticosteroids n = 11), the biopsy provided fundamental support for clinical decision-making in 25 (34%) of patients.
Conclusion: Use of biopsy in the diagnosis of AH is useful in all patients since even in patients who fulfil all diagnostic criteria, 9% had no AH. In one third of patients, biopsy provided essential information in clinical decision making against and after non-response to therapy.

FRI-090-YI
AI-based quantitative histologic comparison of disease architecture across steatotic liver disease subclassifications

[1]FLASH - Centre for Liver Research, Odense, Denmark; [2]SDU - University of Southern Denmark, Odense, Denmark; [3]Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; [4]Department of Pathology, Odense University Hospital, Odense, Denmark; [5]GSK Stevenage, Gunnels Wood Road, Stevenage, Hertfordshire, United Kingdom; [6]PathAI Inc., Boston MA, United States
Email: ida.falk.villesen@rsyd.dk

Background and aims: The steatotic liver disease (SLD) nomenclature incorporates both alcohol consumption and metabolic risk factors. Yet, histological differences across the SLD spectrum remain unexplored by novel techniques. We aimed to investigate whether fibrosis distribution, inflammation and cellular composition differed between patients with MASLD, MetALD and ALD when deploying a quantitative histological AI tool.
Method: Single-centre study in Odense, Denmark. Patients were biopsied at first visit. All patients had confirmed MASLD, MetALD or ALD based on metabolic dysfunction and self-reported alcohol intake and phosphatidylethanol measurements. Patients were matched for age and fibrosis stage. A clinical pathologist at Odense performed initial assessment. LiverExplore (PathAI, Boston, Research Use Only; not for use in diagnostic procedures) extracted quantitative histology features from digital H&E whole slide images. The AI-based pathology tool quantitatively differentiated cell subtypes, including distribution and density of immune cells, ballooned and steatotic hepatocytes and fibroblasts. Further, LiverExplore identified different fibrosis subtypes and amount per tissue. We compared the density of cell types and fibrosis distributions using Kruskal-Wallis with p-value correction for multiple testing.
Results: We included 80 patients: 38 MASLD, 20 MetALD, and 22 ALD. Fibrosis stages were distributed as follows (n): F0/1, F1/18, F2/24, F3/27, and F4/10. Mean age was 59 ± 9 years, 72% male. Patients with ALD had substantially more perisinusoidal fibrosis than MASLD and MetALD patients, across both F0–2 and F3–4. Additionally, patients with ALD showed more overall fibrosis, already from earlier stages (F0–2). However, when comparing the densities of injured or healthy hepatocytes and immune cells we found no statistically significant difference between the SLD subgroups. PCA analysis revealed no stratification by fibrosis or SLD subtyping. However, distinct patient clusters emerged according to ballooning, steatosis and lobular inflammation (scored by pathologists) agnostic to SLD subtyping.
Conclusion: Patients with ALD exhibit a greater fibrosis burden than MASLD, particularly within the perisinusoidal compartment, compared across similar fibrosis stages. These architectural differences do not appear to be driven by increased immune cell infiltration or greater hepatocyte injury. PCA analysis suggests distinct histopathological subtypes that are not a function of the driving risk factors of disease.

FRI-091
The gender equity model for liver allocation accurately predicts 90-day mortality and acute kidney injury in alcohol-associated hepatitis
Lankai Xu[1], James Vu[1], Lindsey Immers[1], Jordan Holliday[1], Robert Pecha[1], Lydia Aye[1], Vikrant Rachakonda[1]. *[1]University of California Davis Medical Center, Sacramento, United States*
Email: lcxu@health.ucdavis.edu

Background and aims: The Model for End-Stage Liver Disease (MELD) is commonly used to determine mortality risk in alcohol-associated hepatitis (AH). MELD includes serum creatinine (Cr), which is related to muscle mass, and hence MELD may underestimate disease severity in women due to gender differences in body composition. MELD 3.0 and the Gender Equity Model for Liver Allocation (GEMA) have been developed to address gender disparities in liver disease assessment. The aim of the study was to compare liver disease models for outcome prediction in AH.
Method: This was a retrospective study of 582 patients hospitalized with probable or definite AH from July 2017 to September 2024. Clinical, demographic and laboratory data were obtained at admission. AUROC analysis of logistic regression models was used to compare performance of MELD, MELD-Na, MELD 3.0, GEMA and GEMA-Na for predicting 90-day mortality.
Results: 250 (41.2%) women and 342 (58.8%) men were included. Median age was 45 years, and 267 (45.9%) were Caucasian. 28-day mortality was 19.8%, and 90-day mortality was 32.6%. Compared to men, women exhibited lower BMI [27.0 (IQR 23.4–31.3) kg/m2 vs. 28.0 (IQR 24.2–32.9) kg/m2, $p < 0.035$] with higher serum bilirubin [8.5 (IQR 5.6–17.0) mg/dl vs. 7.6 (IQR 4.6–14.1) mg/dl, $p = 0.023$] and lower serum Cr [0.77 (IQR 0.59–1.15) mg/dl vs. 0.95 (IQR 0.69–1.47) mg/dl, $p < 0.001$]. There were no significant gender differences in MELD, MELD-Na, MELD 3.0, GEMA, and GEMA-Na. GEMA exhibited highest accuracy for predicting 90-day mortality [AUROC: 0.808 (95% CI 0.765–0.851)] with sensitivity of 0.78 and specificity of 0.68 at an optimal cutoff of 23. GEMA exhibited superior performance for 90-day mortality compared to MELD [AUROC: 0.782 (95% CI 0.737–0.827), $p = 0.003$ vs GEMA], MELD-Na [AUROC: 0.776 (95% CI 0.729–0.823)), $p = 0.002$ vs GEMA], MELD 3.0 [AUROC 0.788 (95% CI 0.743–0.833)), $p = 0.028$ vs GEMA] and GEMA-Na [AUROC

0.790 (95% CI 0.744–0.837), $p = 0.013$ vs GEMA]. Acute kidney injury (AKI) developed in 166 patients (28.5%), and GEMA [AUROC:0.858 (95% CI 0.824–0.892)] was superior to MELD [AUROC: 0.797 (95% CI 0.756–0.837), $p < 0.001$], MELD-Na [AUROC: 0.786 (95% CI 0.744–0.828), $p < 0.001$ vs. GEMA], MELD 3.0 [AUROC: 0.800 (95% CI 0.758–0.842), $p < 0.001$], and GEMA-Na [AUROC: 0.844 (95% CI 0.807–0.880), $p = 0.024$].
Conclusion: GEMA demonstrates superior performance for predicting 90-day mortality and acute kidney injury in AH. Prospective studies are planned to assess GEMA to model disease severity in AH.

FRI-092-YI
Integration of polygenic risk score with metabolomics (MetPRS) identifies a protective sphingolipid signature that predicts survival in alcohol-related liver disease
Vaishali Yadav[1], S Muralikrishna Shasthry[1], Mohit Varshney[1], Kanica Kaushal[1], Rishabh Sharma[1], Nirupma Trehanpati[1], Sukriti Baweja[1], Shiv Kumar Sarin[1], Gayatri Ramakrishna[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: rgayatri@ilbs.in

Background and aims: Alcoholic liver disease (ALD) exhibits marked inter-individual variability in disease severity and survival, suggesting an important role for genetic susceptibility and downstream metabolic alterations. We aimed to understand how genetic risk interacts with metabolic pathways to identify patients at higher risk of adverse outcomes.
Method: ALD Patients (n = 84) were genotyped for four gene variants (PNPLA3 rs738409, MBOAT7 rs641738, TM6SF2 rs58542926, and HSD17B13 rs72613567), and a cumulative genetic risk score (CGRS, 1–7) was derived. Untargeted LC–MS based plasma metabolomics was performed. Associations between genetic risk, metabolite profiles, and survival were assessed using correlation and regression-based models to predict mortality.
Results: ALD patients were stratified into low genetic risk (LGR) (score 1–2; $n = 61$) and high genetic risk (HGR) (score 5–7; $n = 23$) groups. The CGRS alone showed moderate predictive ability for one-year survival (AUC = 0.64, p = 0.02). Out of 164 metabolites only five (sphingosine-1-phosphate (S1P), sphinganine-1-phosphate (DHS-1P), 20-oxopregn-5-en-3-yl hydrogen sulfate, hydroxytryptophol (5-HTOL), and dopamine showed strong prognostic performance for survival (combined AUC = 0.89, $p < 0.001$). Among these, S1P was log2 fold higher in survivors and showed the highest predictive value (AUC = 0.79). Genetic risk integration with S1P further improved discrimination between survivors and non-survivors in the low genetic risk (AUC = 0.93). Correlation analysis revealed that in the low-risk group, S1P (r = 0.50, $p = 0.039$), DHS-1P (r = 0.57, $p = 0.018$), and 20-oxopregn-5-en-3-yl hydrogen sulfate (r = 0.66, $p = 0.004$) were positively associated with survival, whereas these associations were attenuated in the high-risk group ($p < 0.001$). In contrast, 5-HTOL and dopamine showed consistent negative associations with survival in both LGR (r ≈–0.50, $p = 0.039$; r = –0.35, $p = 0.017$) and HGR individuals (r ≈–0.36, $p = 0.002$; r = –0.29, $p = 0.015$), indicating poorer outcomes with higher levels.
Conclusion: Integrated genetic–metabolic(Met PRS) profiling significantly outperforms individual markers in predicting ALD survival. We identified a distinct prognostic divergence: LGR individuals exhibit a protective metabolic endotype, characterized by sphingolipids and steroid sulfates while HGR individuals lack this signature. Contrary, the HGR individuals are characterized by decrease of protective lipid metabolites and shifts towards detrimental neuroamines.

FRI-093
Recompensation criteria and clinical outcomes in decompensated alcohol-associated liver disease: a population-based study in Olmsted county
Yigit Yazarkan[1], Diego Drumond Westgeest e Sousa[1], Alberto Calleri[1], Blake Kassmeyer[2], Kamalpreet S. Hara[1], Puru Rattan[1], Tiffany Wu[1], Patrick S. Kamath[1], Vijay Shah[1], Douglas Simonetto[1]. [1]*Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States;* [2]*Division of Clinical Trials and Biostatistics, Mayo Clinic, Rochester, United States*
Email: yyazarkan99@gmail.com

Background and aims: The prevalence of alcohol-associated liver disease (ALD) is increasing, together with increased mortality and need for liver transplantation (LT). Alcohol abstinence may lead to hepatic recompensation; however, reported recompensation rates remain variable and are largely derived from European cohorts, with estimates of 7–18% using the Baveno VII criteria. We aimed to evaluate the impact of broader criteria on recompensation rates and survival in patients with ALD.
Method: Adult residents of Olmsted County, Minnesota (USA), with decompensated ALD diagnosed between 2020–2024 were identified through the Rochester Epidemiology Project using ICD codes and confirmed by chart review. Recompensation required sustained alcohol abstinence, >12 months without decompensation with improved liver function, and was defined using 3 criteria: Baveno VII (no therapy), expanded Baveno (low-dose therapy: spironolactone ≤200 mg/day; furosemide ≤20 mg/day; lactulose/rifaximin), and extended Baveno (medium-dose therapy: furosemide ≤60 mg/day). Recompensation incidence and its association with mortality were assessed using competing-risk models, treating LT, TIPS, and death as competing events.
Results: Among 121 patients with decompensated ALD, 56 (46%) achieved sustained alcohol abstinence (66% biomarker-confirmed). Median age was 55 years (IQR 44–62), 79% were male, and obesity, hypertension, and diabetes were present in 55%, 77%, and 46%, respectively. Ascites was the most common decompensating event (75%). At alcohol cessation, median MELD 3.0 was 19 (15–23). Cumulative incidence of recompensation at 1 and 3 years was 3.7% and 23% (Baveno VII), 3.7% and 42% (expanded Baveno), and 7.4% and 57% (extended Baveno) (Gray's test, p < 0.001). Five-year mortality after the 12-month landmark analysis was 63% in non-recompensated patients and significantly lower in patients meeting Baveno VII (33%), expanded Baveno (28%), or extended Baveno criteria (32%) (Gray's test, p = 0.049). In subdistribution hazard models, expanded and extended Baveno recompensation were associated with reduced mortality (sHR 0.24,95% CI 0.06–1.04; p = 0.057 and 0.23, 95% CI 0.07–0.76; p = 0.016).
Conclusion: In a contemporary US County population with decompensated ALD, broader recompensation definitions captured higher rates of recompensation and were consistently associated with improved survival. These findings support the adoption of expanded recompensation criteria for outcome assessment and highlight the need for confirmation in future studies.

FRI-094
Trends in transplant outcomes for alcohol-related cirrhosis and alcohol-related hepatitis in the United States over 15 years
Maria Stepanova[1], Giacomo Germani[1,2], Robert Wong[1,3], Fatema Nader[1], Rohit Satoskar[1,4], Saleh A. Alqahtani[1], Linda Henry[1], Patrizia Burra[1,2], Ashwani K. Singal[1,5], Zobair M. Younossi[1]. [1]*The global NASH/MASH council, Washington DC, United States;* [2]*Department of Surgery, Oncology and Gastroenterology, University of Padova, Italy, Padova, Italy;* [3]*Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, CA, United States, Palo Alto, United States;* [4]*Georgetown University Medical Center, Washington DC,*

Email: zobair.younossi@cldq.org

Background and aims: Alcohol-related liver disease (ALD) is the leading indication for liver transplantation (LT) in the US and Europe. Within the ALD spectrum, severe alcohol-related hepatitis (AH) has high short-term mortality. We compared characteristics and outcomes of LT patients with ALD cirrhosis (AC) versus AH.
Method: Adult LT candidates and recipients with a primary listing diagnosis of AC or AH were identified from the U.S. Scientific Registry of Transplant Recipients (SRTR), 2006–2022. Demographic and clinical characteristics, waitlist and post-transplant outcomes were compared between two groups.
Results: We included 182,468 adult LT candidates (25% for AC and 0.9% for AH). Over time, LT listing for AC increased from 17% (2006) to 41% (2022). The number of listings with AH were <100 cases per year until 2018 (1.2%) with a subsequent increase to 3.6% (2022). In comparison to candidates with AC, those with AH were younger (44 ± 10 vs. 53 ± 10 years), less commonly male (67% vs. 71%), more commonly covered by a private insurance (63% vs. 53%), with higher MELD scores (32 ± 10 vs. 23 ± 10) (all $p < 0.01$). Of those with ALD, 79% of AH vs. 64% of AC eventually received a LT (77% vs. 47% within 3 months, $p < 0.0001$), 5% vs. 6% died on the list, 3% vs. 5% were removed due to deterioration, and 4% vs. 5% due to improvement. Post-transplant mortality in AH vs. AC was as follows: 1-year 5% vs. 6%, 3-year 10% vs. 13%, 5-year 15% vs. 20% (all $p > 0.01$). In multivariate analysis, being on life support was the only predictor of post-transplant mortality in AH: aHR (95% CI) = 1.77 (1.15–2.73), $p = 0.01$. In patients with AC, post-transplant mortality was higher in those with type 2 diabetes (T2D): 1-year 8% vs. 6%, 3-year 16% vs. 12%, 5-year 24% vs. 19%, 10-year 45% vs. 36%, all $p < 0.0001$. In AC, independent predictors of post-transplant mortality included earlier calendar year (aHR (95% CI) = 0.957 (0.950–0.964) per year), older age (1.027 (1.023–1.030) per year), black race (1.27 (1.11–1.46)), non-Hispanic ethnicity (0.81 (0.75–0.88)), lack of college education (0.88 (0.82–0.94)), Medicaid coverage (1.19 (1.10–1.29)), T2D (1.29 (1.21–1.39)), lower functional status (0.995 (0.993–0.996) per 1 point), the presence of HCC (1.20 (1.08–1.33)), being on life support (1.23 (1.11–1.36)), having received TIPSS (1.20 (1.10–1.31)), and re-transplantation (1.63 (1.34–2.00)).
Conclusion: The share of liver transplantation for both AC and AH is growing, with 5-year survival of >80% in both groups.

FRI-095

Clinician and patient perspectives on stigma, knowledge, and care gaps in alcohol-related liver disease (ALD)

Background and aims: Alcohol-associated stigma, gaps in clinician knowledge about ALD and alcohol use disorder (AUD), and

suboptimal practice patterns may adversely affect ALD management. We evaluated stigma and ALD management from both clinician and patient perspectives.

Method: Two global, web-based anonymous surveys were conducted. Clinicians reported ALD-related knowledge, perceptions (discomfort, empathy, perceived patient responsibility, alcohol underreporting, frustration with care), and practice patterns (alcohol screening, fibrosis assessment, and AUD management). Patients with ALD reported alcohol-related behaviors, and stigma, including self-stigma (cognitive, affective, behavioral domains) and perceived stigma (stereotypes, discrimination, shame, social isolation).

Results: A total of 440 clinicians (290 gastroenterology/hepatology [GI/Hep], 150 non-GI/Hep) and 305 ALD patients completed surveys. GI/Hep clinicians were more often based at tertiary or transplant centers and cared for more ALD patients than non-GI/Hep clinicians (all $p < 0.05$). Despite recognizing the importance of ALD, non-GI/Hep clinicians reported greater discomfort taking care of ALD patients and more frequently attributed responsibility, lack of motivation, and poor self-control to patients (all $p < 0.05$). Overall, 86% of clinicians believed patients underreported alcohol use. Noninvasive fibrosis assessment was commonly recommended (85%). Barriers to care included stigma, limited resources, time constraints, and insufficient addiction medicine training. AUD pharmacotherapy was underutilized, particularly in decompensated cirrhosis. Among patients, 54% reported cirrhosis and 56% had ≥1 chronic condition. Current alcohol use was reported by 36% and 51% had prior AUD treatment (mainly outpatient). Perceived stigma was reported by 92%, including shame (82%), stereotyping (72%), and social isolation (61%). Mean self-stigma score was 27 ± 9 (range 9–45), highest in the cognition domain. Alcohol underreporting due to shame, guilt, or fear was reported by 47%. Among suggested terms, alcohol-related liver disease was considered least stigmatizing by both clinicians (40%) and patients (51%).

Conclusion: ALD-related stigma is prevalent among both clinicians and patients and is associated with clinician discomfort in providing care, reduced disclosure of alcohol use, and suboptimal management of AUD. Findings from this international survey support prioritizing multifaceted stigma-reduction strategies.

Development and validation of a disease-specific health-related quality of life questionnaire (HRQL) for alcohol-related liver disease (CLDQ-ALD)

Zobair M. Younossi[1], Maria Stepanova[1], Leyla de Avila[1], Issah Younossi[1], Andrei Racila[1]. [1]*Center for Outcomes Research in Liver Diseases, Washington DC, USA, Washington DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: Alcohol-related liver disease (ALD) is a leading cause of advanced liver disease and a major indication for liver transplantation. Despite its substantial clinical, humanistic, and societal burden, ALD-specific HRQL instruments are lacking. Accurate HRQL assessment is essential in clinical research and therapeutic trials in ALD. Accordingly, this study aimed to develop and validate an ALD-specific HRQL instrument using a standard protocol for disease-specific HRQL instrument development.

Method: A comprehensive list of HRQL items was generated based on ALD patients' individual interviews and focus groups, existing HRQL instruments, and input from expert healthcare providers. Items were reduced through administration to patients with ALD, calculation of item impact scores, assessment of face validity, exploratory factor analysis, and evaluation of within-domain consistency and redundancy. The final CLDQ-ALD instrument then underwent initial steps for psychometric validation.

Results: The initial questionnaire comprised 90 items. Across two rounds of item reduction, it was completed by 91 patients with ALD (round 1: n = 19 [26% <45 years, 47% male, 5% with type 2 diabetes (T2D), 68% with cirrhosis, 26% current alcohol use]; round 2: n = 72 [32% <45 years, 69% male, 18% with T2D, 39% with cirrhosis, 40% current alcohol use]) and reduced to 40 final items. Exploratory factor analysis identified nine factors explaining >95% of the total variance. Based on factor loadings, items were assigned to nine domains (Fatigue, Alcohol, Function, Physical, Abdominal Symptoms, Itching, Sleep, Emotional, and Worry). Face and construct validity were assessed, along with concordance with the validated CLDQ instrument (CLDQ-MASH). The final CLDQ-ALD demonstrated good to excellent psychometric performance, with high internal consistency (Cronbach's α >0.85 across all domains and >0.90 in 5 of 9 domains). Item-domain correlations exceeded 0.60 for 39 of 40 items and were <0.90 for all items, with each item correlating most strongly with its assigned domain. No substantial floor or ceiling effects were observed. Known-groups validity demonstrated mean score differences >0.5 in relevant domains by sex, presence of T2D, current alcohol use, depression, clinically overt fatigue, and cirrhosis. Additional psychometric analyses are ongoing.

Conclusion: The CLDQ-ALD is a disease-specific HRQL instrument for use in clinical research and therapeutic trials involving patients with ALD.

Cell-free DNA as a biomarker of liver fibrosis in alcohol-related liver disease

Paola Zuluaga Blanco[1], Daniel Fuster[1], Berta Martín[2], Marvin Bueno-Vélez[3], Mireia Torres[3], Mar Muñoz[2], Miguel Angel Peinado[2], Robert Muga[1]. [1]*Hospital Germans Trias I Pujol, Universidad Autónoma de Barcelona-Campus de Bellaterra, Badalona, Spain;* [2]*Igtp Institut Germans Trias I Pujol, Badalona, Spain;* [3]*Hospital Germans Trias I Pujol, Badalona, Spain*
Email: ypzuluaga.germanstrias@gencat.cat

Background and aims: The study of cell-free DNA (cfDNA) methylation in alcohol-related liver disease (ALD) is limited, but there is an emerging interest on it, especially in hepatocellular carcinoma. Most studies have focused on tissue DNA methylation, showing that ALD is associated with aberrant methylation patterns, which may contribute to disease progression. We aimed to describe the global characteristics of cfDNA methylation according to the degree of liver fibrosis (LF) in Alcohol Use Disorder (AUD) patients referred to treatment.

Method: Pilot study of cfDNA methylation microarrays (ILLUMINA) in a cohort of patients with Alcohol Use Disorder (AUD) admitted to detoxification program. We excluded patients with alcohol-related cirrhosis or/and other liver diseases. We quantified cfDNA by fluorometry, we inferred the putative contribution of different tissue to the origin of the cfDNA using cell-type methylation atlas and validated deconvolution standalone program. We also performed an analysis to determine the pace of biological aging using DunedinPACE. We used the Shear Wave Elastography (SWE) to stratify the stage of LF according to the median of ten determinations of kPa value. We stratified in F0-F1 (kPa < 7.0), F2 (kPa 7.1–8) and F3 (kPa > 8). We correlated the results with liver parameters.

Results: We included 47 patients (78% men) with mean age of 49.7 ± 7.6 years and mean alcohol consumption of 173 ± 78 gr/day. The mean biological age was 57 ± 10.8 years with differences from the real age of 7.3 ± 6.29 years ($p < 0.01$). The amount of cfDNA was higher in patients with more advanced stages of LF; 50.41 ± 10.83 ng/µL in F0–F1 (n = 29), 56.39 ± 13.01 ng/µL in F2 (n = 8) and 99.18 ± 100.42 ng/µL in F3 (n = 10); $p = 0.02$. The contribution of liver tissue of the cfDNA was greater in patients with more advanced stages of LF; 2.40 ± 5.06% in F0–F1; 6.17 ± 8.19% in F2 and 4.37 ± 4.70% in F3; $p = 0.04$. The percentage of liver tissue origin was directly correlated with AST ($r = +0.35$, $p < 0.01$) and ALT ($r = +0.20$, $p < 0.01$) and inversely correlated with serum bilirubin ($r = -0.12$, $p = 0.01$) and Lactato Dehydrogenase enzyme ($r = -0.11$, $p = 0.02$).

Conclusion: Cell aging by epigenetic footprint show accelerated ageing in patients with AUD. Cellular aging, the amount of cfDNA, and the contribution of liver tissue to cfDNA were higher in advanced stages of liver fibrosis. CfDNA may have utility in non-invasive diagnosis and staging of liver fibrosis in patients with ALD.

MLCK platelet ignites neutrophil via mitochondrial transfer to trigger liver injury

Juan Wang[1], Xianda Wang[1], Haiyuan Shen[1], Sainan Tang[2], Shuang Wu[3], Yaqun Li[2], Jiayi Zhu[1], Miaomiao Wu[1], Jerrold R. Turner[4], Zi Zuo[2], Hua Wang[1]. *[1]Department of Oncology, the First Affiliated Hospital of Anhui Medical University, Hefei, China, Innovation and Entrepreneurship Laboratory for College Students, Laboratory of Molecular Biology, Department of Biochemistry, Anhui Medical University, Hefei, China, Hefei, China; [2]Innovation and Entrepreneurship Laboratory for College Students, Laboratory of Molecular Biology, Department of Biochemistry, Anhui Medical University, Hefei, China, Hefei, China; [3]School of Pharmacy, Anhui Medical University, Hefei, China, Hefei, China; [4]Department of Pathology, Brigham and Women's Hospital and Harvard Medical School, Boston, Massachusetts, USA, Hefei, China*
Email: wangjuan5102020@163.com

Background and aims: Neutrophil-induced inflammation underlies a wide spectrum of liver pathologies, including alcohol-associated hepatitis (AH), but the triggers of neutrophil activation remain unclear. Platelets are known to contribute to inflammation beyond their roles in hemostasis and thrombosis. This study aims to elucidate the mechanisms of platelet-neutrophil crosstalk in driving NET formation and liver injury, and to explore novel therapeutic targets.
Method: Using single-cell RNA sequencing (scRNA-seq), transmission electron microscopy (TEM), intravital microscopy (IVM), stimulated emission depletion (STED) microscopy, structured illumination microscopy (SIM) and genetic knockout models, we investigated platelet activation, tunneling nanotube (TNT) formation, mitochondrial transfer, and neutrophil extracellular trap (NET) formation in human patients and mouse models of AH, drug-induced liver injury (DILI), and sepsis. In vitro co-culture systems, mitochondrial tracking, pharmacological inhibition, and platelet transfusion experiments were employed to validate mechanistic insights.
Results: We identified a distinct $MLCK^+$ platelet subpopulation that forms TNTs in a Piezo1/Ca^{2+}-dependent manner. These platelets transfer functional mitochondria to CXCR2-high neutrophils via TNTs, fueling oxidative phosphorylation, enhancing glycolytic capacity, and igniting sustained NET formation, which exacerbates liver injury. Genetic ablation of MLCK or pharmacological disruption of the CXCL7-CXCR2 axis abrogated TNT formation, mitochondrial transfer, NET release, and liver injury across multiple models (AH, APAP, GaIN/LPS). Platelet transfusion with *Mylk*-deficient platelets, CXCR2 antagonism (SB225002) or small-molecule inhibitor (T4S1820) attenuated inflammation without increasing bleeding risk.
Conclusion: Our findings establish MLCK-dependent mitochondrial transfer via TNTs as a novel mechanism of platelet-neutrophil crosstalk that drives NET formation and liver injury. Targeting MLCK or the platelet-neutrophil interaction axis offers a promising and safer therapeutic strategy for inflammatory liver diseases by mitigating inflammation without compromising hemostasis.

Inhibition of protein kinase C-η as a strategy to overcome steroid resistance in severe alcohol-related hepatitis

Manisha Yadav[1], Sanju Yadav[1], Neha Sharma[1], Gaurav Tripathi[1], Yash Magar[1], Vasundhra Bindal[1], Jayesh Kumar Sevak[1], Babu Mathew[1], Sushmita Pandey[1], Nupur Sharma[1], Anupama Kumari[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. *[1]Institute of Liver & Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Severe alcohol-related hepatitis (SAH) is a life-threatening condition in which corticosteroids benefit only ~60% of patients, and the molecular mechanisms underlying steroid non-response remain poorly defined. This study identified host signaling pathways and bacterial signatures associated with steroid resistance in SAH.
Method: A total of 71 SAH patients who had undergone transjugular liver biopsy were enrolled. Liver biopsies from 19 prednisolone treated patients (10-responders (R), 9-non-responders (NR)) were analysed via phosphoproteomics and metaproteomics to identify key kinase and microbial signatures associated with steroid non-response. Findings were validated in 20 patients (cohort-2) via immunohistochemistry and in another 32 patients (cohort-3) using RNA-seq. Pathway and kinase associated with steroid resistance were identified. A key glucocorticoid-modulating kinase was functionally validated *in vitro* and *in vivo* using NIAAA animal model.
Results: Metaproteomic identified 257 bacterial species. NR had significantly reduced alpha diversity ($p < 0.01$) with enrichment of *S. pneumoniae, Staphylococcus aureus,* and *Pseudomonas aeruginosa* ($p < 0.05$). Phosphoproteomics identified 372 kinases ($p < 0.05$). NR exhibited significant up-regulation of pathways associated with steroid resistance such as Th17 signalling, CREB phosphorylation, JAK-STAT signalling, and glucocorticoid receptor (GR) inhibitors ($p < 0.05$), and down-regulation of pathways necessary for steroid response such as HSP90 activity, DUSP3, ERK inhibition, and ECM maintenance ($p < 0.05$). Kinome analysis showed increased activity of GR antagonist kinases such as PRKCH (Protein kinase c-eta), MINK1, AURKA in NR with reduced activity of DUSP3 ($p < 0.01$). PRKCH correlated with *P. aeruginosa* abundance (r^2 >0.7) and plasma pyocyanin levels (>2FC, $p < 0.05$) which induces PRKCH. PRKCH partial inhibition using staurosporine significantly restored prednisolone sensitivity in vitro ($p < 0.01$). In NIAAA binge model, staurosporine plus prednisolone therapy significantly reduced inflammatory markers and pathways compared to prednisolone alone documenting benefit of combination therapy ($p < 0.01$).
Conclusion: Bacterial metabolite pyocyanin, drives PRKCH activation and contributes to steroid resistance in SAH. Targeting PRKCH restores steroid sensitivity and enhances anti-inflammatory activity offering a new potential therapeutic strategy for overcoming steroid resistance.

FRI-101

Identification of a $LYVE1^+$ macrophage population associated with vascular remodelling enriched at early stages of alcohol-related liver disease

Laia Aguilar-Corominas[1], Alicia Martínez-Álvarez[2], Javier Vicente-Mora[1], Jordi Gratacós-Ginès[3], Isabel Graupera[3], Pere Ginès[4], Elisa Pose[3], Mar Coll[1]. *[1]University of Barcelona (UB), Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Hospital Clinic of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]University of Barcelona (UB), Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic of Barcelona, Barcelona, Spain*
Email: laguilco22@alumnes.ub.edu

Background and aims: Liver sinusoidal loss and capillarisation, associated with vascular remodelling, increase during the

progression of alcohol-related liver disease (ALD). However, the contribution of immune cells, particularly macrophages, to these processes remains poorly understood. This study aimed to characterize a macrophage population associated with sinusoidal and vascular remodelling during ALD progression.
Method: scRNA-seq analysis was performed on liver biopsies from healthy controls (n = 3) and patients with ALD at early (n = 3) and advanced stages (n = 8). Identified myeloid populations were characterized in silico using signalling pathway databases. Spatial proteomic analysis (CD163, collagen, LYVE1, CD34, PDPN, hepatocyte, actin, CK7, VEGF) was performed using the MACSima™ platform on liver biopsies from healthy controls (n = 6) and patients with ALD without fibrosis (n = 4) or with fibrosis (early F0–F1, n = 6; advanced F3–F4, n = 8). In addition, liver clearing of cirrhotic tissue was performed (CD68, LYVE1). Vascular remodelling signatures were validated by gene set enrichment analysis (GSEA) using bulk transcriptomic data from patients with ALD (healthy controls n = 6; early fibrosis n = 5; advanced fibrosis n = 20).
Results: scRNA-seq identified a distinct LYVE1$^+$ macrophage population enriched at early stages of ALD. In silico functional analysis revealed that LYVE1$^+$ macrophages expressed pathways related to sinusoidal and vascular remodelling. Cell-cell interaction analysis indicated predominant interactions with sinusoidal endothelial cells through CDH5. Spatial proteomic analysis confirmed the presence of this macrophage subpopulation and demonstrated its enrichment in ALD patients with early fibrosis. Analysis of sinusoidal (LYVE1) and classical (CD34) endothelial markers showed increased LYVE1$^+$ sinusoidal structures at early disease stages, followed by a reduction at advanced stages, concomitant with an increase in CD34$^+$ vessels. GSEA revealed increased vascular endothelial proliferation and migration signatures at advanced stages. Liver clearing of cirrhotic tissue demonstrated that LYVE1$^+$ macrophages are in close spatial contact with liver sinusoidal endothelial cells. Importantly, sinusoidal density positively correlated with the abundance of LYVE1$^+$ macrophages along disease progression.
Conclusion: A LYVE1$^+$ macrophage population emerges at early stages of ALD and is associated with sinusoidal and vascular remodelling, suggesting a potential role for LYVE1$^+$ macrophages in sinusoidal integrity.

Hepatic stellate cell-derived Follistatin-like 3 ameliorates alcohol-induced liver injury via inhibition of Activin type II receptor signaling pathway
Gloria Alvarez Sola[1], Sabrina Kogan[2], Russell Goodman[3]. [1]*Liver Center, Division of Gastroenterology. Massachusetts General Hospital, Boston, United States;* [2]*Cornell University, Ithaca, United States;* [3]*Liver Center, Division of Gastroenterology, Massachusetts General Hospital, Endocrine Unit, Massachusetts General Hospital, Boston, United States*
Email: galvarezsola@mgh.harvard.edu

Background and aims: Alcohol-associated liver disease (ALD), characterized by progressive fibrogenesis and loss of hepatic function, has no effective treatments. Activin A, a key profibrogenic factor upregulated in ALD, activates canonical SMAD2/3 signalling in hepatocytes, inducing p21-mediated cell-cycle arrest and senescence. We found that follistatin-like 3 (FSTL3), a secreted antagonist of Activin A, is upregulated in the liver and plasma of ALD patients. We aimed to investigate the role and hepatic cellular origin of FSTL3 in ALD, assess its impact on metabolic function, and evaluate the therapeutic potential of bimagrumab, an anti-Activin type II receptor human monoclonal antibody.
Method: Bioinformatic analyses of human and mouse ALD liver datasets, including single-cell RNA-seq data, were performed to assess FSTL3 expression and its cellular origin. FSTL3 regulation was evaluated in ethanol-treated human liver organoids. The functional role of FSTL3 was investigated in ALD mouse models using AAV-mediated Fstl3 overexpression, global Fstl3 knockout (KO), and treatment with bimagrumab.
Results: FSTL3 was significantly upregulated in human liver biopsies and mouse models of ALD, was induced and secreted in ethanol-treated human liver organoids and was identified as secreted via activated hepatic stellate cells. *In vivo*, Fstl3 overexpression and bimagrumab treatment consistently reduced hepatic fat accumulation, inflammatory markers, and p21 expression in mouse models of ALD. These effects were reversed in ethanol-fed Fstl3-KO mice, which exhibited significantly higher levels of hepatic fat, p21 expression and inflammatory markers compared with wild type. Gene Set Enrichment Analysis revealed repression of hepatic Smad2/3 target gene activation in ethanol-fed mice overexpressing Fstl3. *In vitro*, FSTL3 rescued Activin A-induced loss of Huh7 viability.
Conclusion: Hepatic stellate cell-derived FSTL3 may act as an intrinsic protective factor in ALD by antagonizing Activin A-mediated SMAD2/3 signaling pathway. Enhancing FSTL3 activity or blocking the hepatic Activin type II receptor using antagonists such as bimagrumab may offer a therapeutic approach to limit liver injury and influence early disease mechanisms in ALD.

FRI-103
Impact of fecal microbiota transplant from select human donors on alcohol intake in an immunocompetent alcohol use disorder model is sex-selective
Lauren May[1], Jennifer Wolstenholme[1], Alexander Khoruts[2], Jasmohan Bajaj[1]. [1]*Virginia Commonwealth University, Richmond, United States;* [2]*University of Minnesota, Minneapolis, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Alcohol-related liver disease (ALD) and continuing alcohol use disorder (AUD) needs a concerted effort beyond current therapies to address addiction & liver disease. Altered gut microbiome in ALD is a target. Fecal microbiota transplant (FMT) in human trials with germ-free (GF) translation were successful but focused only on males. GF mice are not immunocompetent. Moreover, the impact of different human FMT donors into immunocompetent recipients is unclear. Aim: In immunocompetent mice determine the impact of sex and FMT donor on alcohol consumption.
Method: Conventional male and female C57BL/6 mice received three courses of oral antibiotics (Abx) using validated techniques to enhance human FMT engraftment while remaining immunocompetent. Male & female groups were (1) no-Abx (2) Abx only (3) Abx with FMT from human donors (1, 2 & 3). Stools from 3 healthy human donors from an accredited stool bank were administered using gavage to the assigned mouse groups. Then voluntary alcohol intake and preference in an intermittent two-bottle choice paradigm were assessed for five weeks. We also performed behavioral tests for anxiety-like & locomotor function (open field & Rotarod) during the same timeframe.
Results: We included 10 mice per subgroup and all survived the testing. Alcohol intake: found notable sex differences in response to cross-species FMT and alcohol intake. Two of the three human FMT donors significantly reduced ethanol intake and preference in female mice, while no significant reductions were found in ethanol intake or preference in male mice. Donor 1 reduced ethanol preference by 30.4% and was significantly different from the no-Abx group ($p = 0.0001$, two-way ANOVA), and donor 2 reduced ethanol preference by 21.3% and was also significantly different from the no-Abx group ($p = 0.008$, two-way ANOVA). Other behavioral tests: Anxiety-like and locomotor behavior in the open field did not differ between groups or by sex following FMT or ethanol drinking ($p > 0.05$, one-way ANOVA).
Conclusion: In a model of immunocompetent mice with antibiotic pre-treatment, female mice were affected by FMT donors, which resulted in reduced alcohol intake. The same donors had no significant impact on male mice. The impact of microbial transfer is unique to alcohol behavior because anxiety &locomotion tests were unaffected. This model provides a foundation for further mechanistic

studies and donor selection via FMT to influence drinking in clinical trials & experimental studies.

FRI-104

Thermoneutral housing alters ethanol metabolism and exacerbates hepatic steatosis in a mouse model of alcohol-associated liver disease

José Fernandez-Checa[1], Monica Barrios[2], Laura Fábrega[2], Denise Pinheiro[3], Susana Nuñez[2], M. Carmen Garcia-Ruiz[2]. [1]*Institute of Biomedical Research of Barcelona, IIBB-CSIC, CIBEREHD, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, Barcelona, Spain;* [2]*Institute of Biomedical Research of Barcelona, IIBB-CSIC, CIBEREHD, Barcelona, Spain;* [3]*Institute of Biomedical Research of Barcelona, IIBB-CSIC, Barcelona, Spain*
Email: checa229@yahoo.com

Background and aims: Alcohol-associated liver disease (ALD) is a major cause of morbidity and mortality. Current models are typically housed at 22°C, the comfort temperature for humans that induce cold stress in rodents, leading to potentially confounding outcomes of relevance for human ALD studies. This study investigates the impact of thermoneutral housing (30°C) on ALD development, hypothesizing that it elicits distinct metabolic and pathological responses compared to standard housing, influencing disease progression.
Method: Male C57BL/6J mice were housed at 22°C or 30°C and subjected to the National Institute on Alcohol Abuse and Alcoholism (NIAAA) acute-on-chronic ethanol feeding model. Hepatic tissue was analyzed for steatosis, inflammation, fibrosis, and ethanol metabolism enzymes. Specifically, we assessed protein expression and activity of cytochrome P450 2E1 (CYP2E1), alcohol dehydrogenase (ADH), and aldehyde dehydrogenase (ALDH), along with blood ethanol and acetaldehyde levels.
Results: Mice housed at 30°C and fed the ethanol diet showed diminished weight gain but exacerbated hepatomegaly and higher quantitative lipid accumulation compared to ethanol-fed mice housed at 22°C. While blood ethanol levels decreased at 30°C, liver acetaldehyde levels significantly increased. Regarding metabolism, 30°C housing resulted in lower CYP2E1 protein expression but significantly higher enzymatic activity, coupled with increased ADH expression and similar ALDH levels, suggesting altered flux through ethanol metabolic pathways. Histopathological analysis further revealed that thermoneutrality significantly exacerbated tissue disorganization and total inflammatory cell infiltration compared to the 22°C group. Notably, specific macrophage infiltration (F4/80) remained comparable between both housing conditions, but thermoneutrality induced increased presence of infiltrating neutrophils. Fibrosis, however, was similar in both housing temperatures.
Conclusion: These data show that thermoneutrality elicits distinct metabolic and inflammatory changes to ethanol response compared to standard housing. This model improves ALD complexity study, offering a more nuanced understanding of environmental factors influence on disease progression.

FRI-105-YI

Exhaled breath condensate bile acid profile correlates with plasma bile acid profile in alcohol related liver diseases

Vasundhra Bindal[1], Gaurav Tripathi[1], Sushmita Pandey[1], Manisha Yadav[1], Neha Sharma[1], Babu Mathew[1], Nupur Sharma[1], Vipul Sharma[1], Yash Magar[1], Sanju Yadav[1], Rakhi Maiwall[1], Shvetank Sharma[1], Jaswinder Maras[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Plasma bile acid levels are closely associated with alcohol-related liver disease (ARLD) and reflect hepatic dysfunction. Exhaled breath condensate (EBC) represents a novel, non-invasive matrix for metabolite assessment. We evaluated EBC for assessing identifying different bile acid farctions and compared with plasma bile acids in ARLD patients.
Method: This study enrolled 360 healthy individuals to establish baseline breath bile acid profiles in EBC, assessing postprandial, age, sex, and weight-related variations. Breath and paired plasma bile acids were then analyzed in 120 patients with alcohol-related cirrhosis (ARC) and 120 with severe alcohol-associated hepatitis (SAH) using high-resolution mass spectrometry.
Results: Altogether, 19 bile acids were identified in plasma of which 16 were identified in the breath samples. The most abundant bile acids in both plasma and breath were glycine- and taurine-modified bile acids. Cholic acid and deoxycholic acid were the most affected bile acids, and correlated with changes in gender, age, weight or diet respectively (FC >1.5, $p < 0.05$). Glycochenodeoxycholic acid (FC >6.5, $p < 0.001$), Glycoursodeoxycholic acid (FC >11, $p < 0.001$), and Glycodeoxycholic acid (FC >9.3, $p < 0.001$) were significantly increased in the EBC samples of SAH patients as compared to ARC or controls. Glycochenodeoxycholic acid, glycoursodeoxycholic acid, and glycodeoxycholic acid exhibited strong diagnostic performance in EBC (AUC >0.85) and plasma (AUC ≈0.82), demonstrating high concordance between breath and plasma bile acid profiles.
Conclusion: Glycochenodeoxycholic acid, Glycoursodeoxycholic acid, Glycodeoxycholic acid levels are significantly elevated in breath and plasma of SAH patients compared with alcohol cirrhosis patients, with a diagnostic efficiency of 85%. Exhaled breath condensate is a novel, non-invasive method for detailed bile acid assessment and early prognostication of poor outcome in ARLD patients.

FRI-106

The glucagon/glucagon-like peptide-1 receptor dual agonist survodutide strongly reduces alcohol intake in the lean golden syrian hamster, a preclinical model with spontaneous alcohol preference

Francois Briand[1], Mohsin Hassan[2], Thomas Klein[2]. [1]*Physiogenex, Escalquens, France;* [2]*Boehringer Ingelheim, Biberach, Germany*
Email: f.briand@physiogenex.com

Background and aims: The glucagon/glucagon-like peptide-1 receptor dual agonist survodutide has demonstrated significant benefits in patients with obesity and metabolic dysfunction-associated steatohepatitis. Since excessive alcohol consumption exacerbates outcomes in these patients, we investigated whether survodutide could provide additional benefits by lowering alcohol intake in the golden Syrian hamster, a preclinical model showing a spontaneous preference for alcohol.
Method: Lean (no overweight), 11-week-old, male golden Syrian hamsters were housed with a free access to either normal tap water or 15% alcohol-supplemented water for 7 weeks. Following a 4-week induction period, hamsters were treated s.c. QD with vehicle, semaglutide 15 nmol/kg (used as a positive control) or survodutide 15 nmol/kg for 3 weeks.
Results: During the 4-week induction period, with free access to water or alcohol, hamsters rapidly halved their water intake while progressively increasing their alcohol consumption by 2-fold. Compared with vehicle, both semaglutide and survodutide treatment induced a significant reduction in food intake for 2 weeks, after which food intake returned to vehicle levels. Compared to vehicle, both semaglutide and survodutide treatments resulted in a strong and sustained reduction in alcohol consumption (−55% in cumulative intake for both), while normal tap water intake gradually increased throughout the treatment period (>2-fold cumulative intake with both drugs). Expressed as total water volume consumed during treatment, alcohol intake decreased from 78% to 29% with semaglutide, and from 82% to 20% with survodutide, at the end of the treatment (both $p < 0.0001$ vs. vehicle). Conversely, normal tap water intake increased from 22% to 71% with semaglutide, and from 18% to 80% with survodutide, as a proportion of total water volume consumed t (both $p < 0.0001$). Since lean hamsters were normolipidemic, no major effect on liver fat content and plasma lipid levels

were observed, however, survodutide slightly reduced plasma triglycerides as well as free fatty acids (p = 0.053 vs. vehicle).
Conclusion: The present study demonstrates that survodutide strongly reduces alcohol intake in a hamster model with spontaneous preference for alcohol. These preclinical findings highlight the potential benefits of the glucagon/glucagon like peptide-1 receptor agonist survodutide for the treatment of patients with significant alcohol consumption.

FRI-107
Gut-derived immunoglobulin A activates hepatic macrophages and exacerbates inflammation in alcohol-related liver disease
Min gu Kim[1,2], Min Su Cha[1,2], Deok Hwa Seo[1,2], Gil Won Lee[1,2], Min Seo Park[1,2], Kwon Yong Tak[1,3], Pil Soo Sung[1,2,3]. *[1]The Catholic University of Korea, College of Medicine, Liver Research Center, Seoul, Korea, Rep. of South; [2]Postech-catholic Biomedical Engineering Institute, Department of Biomedicine & Health Sciences, The Catholic University of Korea College of Medicine, Seoul, Korea, Rep. of South; [3]Seoul St. Mary's Hospital, the Catholic University of Korea, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Seoul, Korea, Rep. of South*
Email: pssung@catholic.ac.kr

Background and aims: Mucosal immunoglobulin A (IgA) protects against gut microbes, but its role in alcohol-related liver disease (ALD) is unclear. We tested whether gut-derived IgA accumulates in the liver, binds hepatic macrophages, and amplifies inflammation.
Method: Patients with ALD and controls (ALD n = 222; control n = 20) were assessed for serum IgA, bilirubin and albumin. Liver sections were immunostained for IgA and immune markers; dissociated liver cells were analyzed by flow cytometry to quantify IgA-bound macrophages; hepatic cytokine transcripts were measured by quantitative PCR (qPCR). Mice underwent chronic-plus-binge ethanol feeding with or without fingolimod (FTY720, 1 mg/kg/day) to block gut-to-liver trafficking; serum aspartate/alanine aminotransferase (AST/ALT), IgA, liver immune profiles (single-cell RNA sequencing and flow cytometry), and gut lymphoid IgA-positive cells were evaluated. In vitro, human CD14-positive monocytes were stimulated with plate-coated secretory IgA (sIgA) with or without lipopolysaccharide (LPS); cytokines were quantified by ELISA and conditioned medium was applied to hepatocytes to assess cell death. Statistics: t-test or Mann-Whitney U test as appropriate; correlations: Spearman; two-sided $p < 0.05$.
Results: Serum IgA was higher in ALD than controls and associated with lower albumin and higher bilirubin. High-IgA patients showed increased hepatic IgA deposition and immune infiltration, higher proportions of IgA-bound macrophages, and increased hepatic inflammatory cytokine transcripts. In mice, ethanol increased interleukin-1 beta-high macrophages and expanded IgA-transcript-high plasma cells. Blocking gut-to-liver trafficking (FTY720) reduced serum IgA and AST/ALT and improved histologic liver injury, with lower hepatic Il1b (qPCR). It also decreased IgA binding to macrophages and hepatic IgA and CD138 staining, while IgA and plasma cells accumulated in Peyer's patches. In vitro, sIgA enhanced LPS-induced cytokine secretion by CD14-positive monocytes, and sIgA plus LPS conditioned medium increased hepatocyte death versus LPS alone.
Conclusion: Gut-derived IgA reaches the liver and engages macrophages, exacerbating ALD. Blocking gut-to-liver trafficking reduced systemic/hepatic IgA and IgA-macrophage interactions and improved liver injury readouts, with decreased AST/ALT, attenuated histologic injury, and decreased hepatic Il1b transcripts. These findings support the IgA–macrophage axis as a therapeutic target.

FRI-108-YI
Methyl group donor supplementation modulates gut microbiota and methylome in a metabolic and alcohol-related liver disease murine model
Carolina Díaz-Canul[1], Ángel Vázquez-Esqueda[1], Rebeca Escutia-Gutiérrez[1], Rebeca Rosas-Campos[1], Mónica Ibarra-Hernández[1], Julio Alonso-Vázquez[1], Marina Galicia-Moreno[1], Juan Armendariz-Borunda[1], Ana Soledad Sandoval-Rodriguez[1]. *[1]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Institute for Molecular Biology in Medicine and Gene Therapy, Guadalajara, Mexico*
Email: anasol44@hotmail.com

Background and aims: Metabolic and alcohol-related liver disease (MetALD) is the combined effects of metabolic dysfunction and alcohol consumption, leading to hepatic inflammation and steatosis. Alterations in intestinal barrier function, dysbiosis, bacterial translocation, and dysregulation of DNA methylation contribute to disease progression. The aim was to evaluate the effects of methyl group donor supplementation as a potential therapeutic strategy for metabolic, intestinal, and epigenetic alterations in a MetALD murine model.
Method: Male C57BL/6J mice (10 wks old, 25 g) were randomly assigned to three experimental groups (n = 8): control group (ND); MetALD (20% ethanol in water +45% fat diet); and MetALD + MetMix (MetALD diet + daily gavage of methionine, betaine, zinc sulfate, choline, B9, B6, and B12), maintained for 20 wks. Weekly body weights were measured. Liver and epididymal weights and biochemical analyses (liver enzymes, lipid profile, and hormones) were determined. Histological evaluation was performed on the liver, adipose tissue, and colon. Liver proinflammatory gene expression was measured using qPCR. Gut microbiota was assessed using 16S rRNA gene sequencing, and barrier function was examined using immunohistochemistry of occludin, claudin-1, and E-cadherin expression. Alcian Blue staining was used to quantify the number of goblet cells. DNA methylation was analyzed using the Infinium Mouse Methylation BeadChip. ANOVA with post hoc tests was used for the statistical analysis, with $p < 0.05$ considered significant.
Results: Methyl group donor significantly reduced body weight, epididymal fat mass, serum cholesterol, and high- and low-density lipoprotein levels compared with the MetALD group ($p < 0.05$). A consistent trend toward reduced AST, ALT, triglyceride, very low-density lipoprotein, adipokine, and hepatic Il6 and Tnfa expression was observed. Histological analyses revealed improvements in steatosis, adipocyte hypertrophy, goblet cell number, and occludin, claudin-1, and E-cadherin expression, supporting improved intestinal barrier integrity. Gut microbiota analysis showed differentiation in beta diversity, whereas alpha diversity and the Firmicutes-to-Bacteroidetes ratio displayed an increasing trend. In addition, MetMix supplementation altered the DNA methylation profile.
Conclusion: Methyl group donor treatment improved metabolic and histological parameters, supported intestinal barrier integrity, tended to enhance gut microbiota diversity, and modulated the DNA methylation profile.

FRI-109
Lifestyle and microbiome modification for the management of MetALD in the preclinical DUAL model
Olga Estévez-Vázquez[1,2,3,4], Alisson Quezada Cuadrado[1], Raquel Benedé-Ubieto[1,3], Hector Leal-Lassalle[1,4], Javier Vaquero[2,3,5], Rafael Bañares[2,3,5], Francisco Javier Cubero[1,2,3,4], Yulia Nevzorova[1,2,3,4]. *[1]Departamento de Inmunología, Oftalmología y Otorrinolaringología, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain; [2]Instituto de Investigaciones Sanitarias Gregorio Marañón (IiSGM), 28009, Madrid, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Instituto de Salud Carlos III, Madrid, Spain; [4]Instituto universitario de investigación en neuroquímica, Facultad de Medicina,*

Universidad Complutense de Madrid, Madrid, Spain; [5]Servicio de Aparato Digestivo, Hospital General Universitario Gregorio Marañón, 28007, Madrid, Spain
Email: olgaeste@ucm.es

Background and aims: MetALD is term that describes patients with MASLD and simultaneous moderate alcohol consumption. Harmful interaction of alcohol and metabolic risk factors increases the development of steatohepatitis, fibrosis and intestinal dysbiosis. As dietary modifications and physical exercise are the most non-pharmacological recommended therapeutic interventions for MetALD management, in this study we emphasise the beneficial effects of gut microbiota modulation plus lifestyle modifications as an attractive therapeutic strategy to improve the clinical outcome of MetALD.
Method: C57BL/6J male mice received 10% alcohol in sweetened drinking water together with a Western diet (DUAL model) for short (10 weeks) and long (23 weeks) periods. Therapeutic modulations of the microbiome were performed by a) application of probiotic mixture containing 8 strains of *Lactobacillus*, or by b) FMT from healthy donor mice during the last 4 weeks of the short- and long-term feeding period. DUAL diet withdrawal (WTD) was performed by c) the replacement with a chow diet and normal water for 21 days alone or d) in combination of WTD with treadmill sessions (WTD+EX).
Results: The use of probiotics in short-term DUAL feeding did not exert any remarkable benefit in terms of hepatic steatosis, inflammation, or liver fibrosis. FMT from a healthy donor induced mild improvement in liver histology and led to the partial reduction of liver injury, steatosis, hepatic inflammation and fibrosis; however, only in short-term DUAL feeding. DUAL diet withdrawal was the best therapeutic option for early MetALD induced by short-term feeding. Nevertheless, after the long-term DUAL feeding, diet replacement resulted in only a slight improvement of steatohepatitis and fibrosis in the liver. Unless the combination of WTD+EXER led to significant reductions in hepatic steatosis, decreased hepatomegaly, liver damage, hepatic inflammation and attenuated activation of HSC in the advanced stage of MetALD.
Conclusion: Overall, for early-stage MetALD, the efficacy of each therapy ranked as follows: diet withdrawal > FMT > probiotics. Microbiome modulation failed to improve advanced liver phenotypes induced by long-term DUAL feeding. Only the combination of WTD +EXERCISE was the best therapeutic option for advanced MetALD. Our data emphasizes the necessity of prompt dietary and lifestyle intervention in MetALD and suggests that microbiota-targeted therapies may aid recovery if introduced before irreversible hepatic changes occur.

Aldehyde dehydrogenase 2 deficiency promotes alcohol-associated liver fibrosis via AMPK/DRP1-dependent oxidized mtDNA

Feiyu Zhang[1], Ying Shi[1], Yanhang Gao[1]. [1]*The First Hospital of Jilin University, Changchun, China*
Email: zhangfeiyu00@163.com

Background and aims: Alcohol-associated liver fibrosis is a critical stage in the development of liver cirrhosis, and the current therapeutic approaches have limited efficacy in its intervention. Therefore, clarifying the mechanism of alcoholic liver fibrosis is of great significance for the development of novel therapeutic strategies. The deficiency of aldehyde dehydrogenase 2 (ALDH2) is closely related to the susceptibility to alcoholic liver fibrosis, but its specific mechanism remains unclear.
Results: This study first found that the liver stiffness of patients with alcoholic liver disease carrying the ALDH2 rs671 mutation was significantly higher than that of ALDH2 wild-type carriers, and the level of oxidized mtDNA (ox-mtDNA) in extracellular vesicles in serum was significantly increased; this result was further verified in an alcoholic liver fibrosis mouse model. Mechanistic studies showed that ALDH2 deficiency could inhibit the phosphorylation of AMPK at Thr172 and enhance the phosphorylation of DRP1 at Ser616, thereby inducing mitochondrial fragmentation and promoting the release of extracellular vesicles rich in ox-mtDNA; these vesicles could activate the cGAS-STING signaling pathway in macrophages, drive the activation of hepatic stellate cells, and further exacerbate the process of liver fibrosis. In addition, inhibiting DRP1 activity in ALDH2 knockout mice could partially reverse mitochondrial fragmentation, reduce the level of ox-mtDNA, and delay the progression of fibrosis.
Conclusion: This study revealed a new mechanism by which ALDH2 deficiency promotes alcohol-associated liver fibrosis through the AMPK/DRP1/ox-mtDNA extracellular vesicle axis, providing a theoretical basis for intervention strategies targeting mitochondrial homeostasis.

Therapeutic potential of mesenchymal stem cells in severe alcoholic hepatitis: integrative analysis of transcriptomic signatures and in vivo validation

Seul Ki Han[1,2], Mi Ra Lee[1,2], HyunJung Chung[1,2], Soon Koo Baik[1,2], Jin Suk Lee[2], Moon Young Kim[1,2]. [1]*Department of Internal Medicine, Wonju Severance Christian Hospital, Wonju, Korea, Rep. of South;* [2]*Regeneration Medicine Research Center, Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and aims: Severe alcoholic hepatitis (SAH) has a high mortality rate, yet effective therapies beyond corticosteroids remain limited. Mesenchymal stem cells (MSCs) are emerging as a potential treatment due to their immunomodulatory properties. This study aimed to identify conserved molecular targets in SAH through meta-analysis of public transcriptomes and to evaluate the therapeutic efficacy and mechanisms of human bone marrow-derived MSCs (hBM-MSCs) in a murine SAH model.
Method: We conducted a meta-analysis of 10 publicly available datasets (8 gene expression and 2 prognostic) to identify robust differentially expressed genes (DEGs) and mortality-related signatures. For validation, an SAH model was established in C57BL/6 mice via 4-week ethanol feeding and thioacetamide (TAA) injection. Mice were treated with vehicle, low-dose (5×10^5), or high-dose (1×10^6) hBM-MSCs. Efficacy was assessed by serum biochemistry and histology. The candidate genes from the meta-analysis were validated using qPCR and Western blotting.
Results: The meta-analysis identified 17 downregulated and 7 upregulated genes consistently associated with SAH. In the mouse model, MSC transplantation significantly ameliorated liver injury, evidenced by reduced ALT, AST, and bilirubin levels, alongside attenuated fibrosis and inflammation. Notably, high-dose MSCs showed superior efficacy. Validation revealed that genes predicted to be upregulated—LYN, TLR2, HDAC9, and MAPK3—were confirmed to be overexpressed in the SAH model at both mRNA and protein levels. Importantly, MSC treatment significantly suppressed the protein expression of these targets, correlating with histological recovery. While some predicted downregulated genes showed discordance between mRNA and protein levels, the suppression of LYN, TLR2, HDAC9, and MAPK3 was consistent and dose-dependent.
Conclusion: This study demonstrates that hBM-MSCs effectively mitigate liver injury, inflammation, and fibrosis in a severe alcoholic hepatitis model, with dose-dependent efficacy. The integration of transcriptomic meta-analysis with in vivo protein-level validation successfully identified LYN, TLR2, HDAC9, and MAPK3 as key pathogenic targets modulated by MSC therapy. These findings suggest that MSCs represent a viable therapeutic strategy for SAH, and the identified gene signatures may serve as potential biomarkers for treatment response.

FRI-115

Ethanol reprograms hepatic lymphatic endothelial cells to promote proinflammatory immune trafficking in alcohol-associated hepatitis

Young-Ri Shim[1], Guqing Luo[1], Yilin Yang[1], Jain Jeong[1], Naotaka Kugiyama[1], Teruo Utsumi[1], Matthew J. McConnell[1], Yasuko Iwakiri[1]. [1]*New Haven, United States*
Email: yasuko.iwakiri@yale.edu

Background and aims: Alcohol intake delays wound healing and exacerbates alcohol-associated hepatitis(AH), yet mechanisms remain incompletely understood. The lymphatic system regulates inflammation through immune trafficking. We hypothesized that ethanol alters lymphatic endothelial cell (LyEC) phenotype, leading to dysregulated immune behavior and worsens AH.
Method: A mouse AH model (NIAAA model) was used to isolate hepatic LyECs for RNA-sequencing and immune profiling. Primary human liver LyECs were used for ethanol exposure and co-culture with human peripheral blood mononuclear cells (PBMCs). Immune phenotypes were analyzed by fow cytometry. Human relevance was assessed using liver scRNA-seq from controls and alcohol-associated cirrhosis (GSE136103).
Results: RNA-seq of LyECs from ethanol-fed mice showed strong induction of stress/detoxification genes (Mt1, Mt2, Aldh1a1; padj $<1 \times 10^{9}$) and inflammatory mediators (Il6, Ccl2, Cxcl1, Cxcl10; padj <0.05), indicating pro-inflammatory reprogramming. In parallel, Ccl21b, which regulates CCR7-dependent immune trafficking, was markedly reduced($>2^{3}$ $\log_2$-fold; padj <0.01), suggesting impaired lymphatic guidance. Ethanol also downregulated junctional/mechanosensory genes (Gja4, Pecam1; padj <0.05), while inducing flow-responsive transcription factors(Klf2, Klf4; 2.4-fold; padj <0.02). In vitro, ethanol (100 mM)-treated human LyECs increased CXCL10 (3.7-fold) and CCL2 (2.4-fold; $p < 0.05$). Ethanol-treated LyECs enhanced PBMC migration, with recruited cells expressing higher CXCR3 (1.42-fold, $p < 0.01$; receptor for CXCL10) and CXCR2 (1.9-fold, $p < 0.0001$; chemokine receptor mediating CCL2-driven chemotaxis). CXCL10 knockdown reduced CD4+ T-cell migration($p = 0.06$). Recruited cells were mainly CD4+ T cells and monocytes, not neutrophils or B cells. Attracted CD4+ T cells showed higher CXCR3 ($p < 0.05$). Human liver scRNA-seq confirmed increased CXCR3 in CD4+ T cells from alcohol-associated cirrhosis. Finally, ethanol-fed mice showed enhanced LyEC - CD3+ T cell interactions, with a 1.43-fold increase in hepatic T-cell accumulation ($p < 0.05$) correlating with lymphatic vessel density ($r^2 = 0.61$, $p < 0.0001$), and increased hepatic CXCR3+CD4+ T cells, including IL-17+ subsets ($p < 0.01$).
Conclusion: Ethanol reprograms LyEC toward a dysfunctional, pro-inflammatory states with impaired immune guidance and selective recruitment of CXCR3+ pathogenic CD4+ T cells. LyEC dysfunction defines a new pathogenic mechanism contributing to impaired tissue repair and AH progression.

FRI-116

Performance of MAF-5 versus FIB-4 for predicting liver fibrosis across alcohol intake levels: NHANES 2017–2023

Nikhil Kalita[1], Luis Antonio Diaz[1], Kaleb Tesfai[1], Rohit Loomba[1]. [1]*University of California San Diego, La Jolla, United States*
Email: nikhil.kalita@gmail.com

Background and aims: The Metabolic-Associated Fatty Liver Disease-5 (MAF-5) score is a recently proposed fibrosis risk index designed to overcome limitations of the Fibrosis-4 (FIB-4) index, particularly in individuals with metabolic dysfunction-associated steatotic liver disease (MASLD). However, its performance across levels of alcohol consumption has not been evaluated. This study aimed to validate the performance of MAF-5 in individuals with increased alcohol intake.
Method: The sample included participants from NHANES 2017–2020 and 2021–2023, aged ≥21 years with vibration-controlled transient elastography data. Participants with chronic liver disease, other than SLD, were excluded. Alcohol intake was quantified in grams per week and categorized into weighted tertiles with equivalent sample sizes. Alcohol intake tertiles were defined as low (0.420–6.44 g/week), moderate (6.78–50.76 g/week), and high ($51.02–4.9 \times 10^{3}$ g/week). Survey weights were applied for all analyses. The risk for significant fibrosis (>8 kPa) was assessed using the numeric MAF-5 and FIB-4 indexes. Associations were evaluated using logistic regression overall and by alcohol intake tertile. Discriminatory performance was assessed using AUROC estimation.
Results: The study population consisted of 11,917 participants and was 49.80% male. Overall, 9.59% of participants had significant fibrosis. Both MAF-5 and FIB-4 scores were associated with significant fibrosis across all logistic regression models in the overall sample and within each alcohol intake tertile ($p < 0.05$). MAF-5 demonstrated consistently higher discriminatory performance than FIB-4 across all alcohol intake strata. Overall AUROCs were 0.78 for MAF-5 and 0.63 for FIB-4 ($p < 0.001$). When comparing MAF-5 versus FIB-4, all AUCs were significantly different ($p < 0.001$): in low intake (0.81 vs 0.57), moderate intake (0.77 vs 0.59) and high intake (0.77 vs 0.65) groups, respectively. MAF-5 had better rule-out performance compared with FIB-4 (NPV 98.26% vs 92.22%, respectively).
Conclusion: In a nationally representative U.S. population, MAF-5 demonstrated superior discrimination for significant liver fibrosis compared with FIB-4, even in individuals with increased alcohol intake. These findings suggest that MAF-5 remains a robust tool for assessing fibrosis risk, irrespective of alcohol consumption, and may offer improved clinical utility for fibrosis screening and referral decisions across heterogeneous exposure profiles.

Background and aims: Alcohol-related hepatitis (AH) is a severe form of alcohol-related liver disease, with high mortality. However, it is hard to distinguish from decompensated alcohol-related cirrhosis without AH (DC). Liver biopsy is the gold standard but is invasive and not always available. Serum bile acids (BAs) are elevated in AH, but faecal BAs are reduced. Fibroblast growth factor 19 (FGF19) is usually produced by ileal enterocytes in response to farnesoid X receptor (FXR) activation by BAs. FGF19 acts on hepatocytes to reduce bile acid synthesis. FGF19 may be elevated in AH, despite cholestasis. We evaluated FGF19 as a diagnostic biomarker of AH.
Method: Baseline (D0) serum FGF19 was measured by enzyme-linked immunosorbent assay (ELISA) in 240 clinically-diagnosed AH patients and 189 DC patients from the MICAH cohort. Serum FGF19 was determined in 46 biopsy-proven AH patients from the ISAIAH clinical trial of canakinumab, at D0 and 28 days after treatment (D28).

Paired D0 and D28 RNA-seq data was available for these patients. Serum FGF19 concentrations were compared by Mann-Whitney U, correlation with hepatic FGF19 expression assessed by Spearman's rank, associations by binary logistic regression, and biomarker performance by area under the receiver operating characteristic curve (AUROC) analysis. Significance tests with Benjamini-Hochberg adjusted p values<0.05 were deemed significant.
Results: Serum FGF19 was higher in AH than DC at D0 (median 1270 [IQR 447–9078] vs 335 [201–919] pg/mL, p < 0.001). In AH, serum FGF19 decreased D0 to D28 (3140 vs 351 pg/mL, p < 0.001). D0 FGF19 distinguished AH from DC (AUROC 0.748, p < 0.001). D0 FGF19 correlated with MELD score (rho = 0.27, p < 0.001), but did not associate with 90-day mortality. Serum FGF19 correlated strongly with hepatic FGF19 expression at D0 (rho = 0.87, p < 0.001), and moderately at D28 (rho = 0.48, p < 0.010). Hepatic FGF19 expression did not correlate significantly with hepatic FXR expression (rho = -0.26, p = 0.051) but correlated with vitamin D receptor (VDR, rho = 0.55, p < 0.001) and retinoic acid receptor alpha (RARA) expression (rho = 0.26, p = 0.045).
Conclusion: Serum FGF19 was significantly higher in AH than DC, and performed moderately as a diagnostic biomarker. In AH, hepatic FGF19 production may compensate for reduced ileal production due to cholestasis. Hepatic FGF19 production may be driven by VDR and RARA activation, known to increase FGF19 transcription in enterocytes. This mechanism warrants further exploration.

FRI-118
Efferocytosis-related biomarkers enable non-invasive identification of at-risk metabolic dysfunction-associated steatohepatitis

Jingjing Jiang[1], Weiwei Lou[2], Weiqian Lou[1], Qing Xie[1], Rongtao Lai[1]. *[1]Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*
Email: xieqingrjh@163.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of chronic liver disease worldwide, and patients with Efferocytosis is increasingly recognized as a critical process linking hepatocellular injury, inflammation, and fibrogenesis. However, efferocytosis-related molecular signatures in at-risk MASH have not been systematically explored.
Method: Bulk RNA-sequencing data from patients with MASLD (GSE135251: n = 110 training) were analyzed to identify efferocytosis-related genes (ERGs) associated with at-risk MASH, defined histologically by a NAFLD activity score (NAS) ≥4 and fibrosis stage ≥2. Differential expression analysis was applied to screen for genes linked to at-risk MASH, which were intersected with ERGs to obtain risk-associated ERGs, followed by functional enrichment analyses. Three machine learning approaches—stepwise regression, least absolute shrinkage and selection operator (LASSO), and support vector machine–recursive feature elimination (SVM-RFE)—were applied to identify robust hub genes. A predictive nomogram was constructed and externally validated in an independent cohort (GSE174478: n = 50 validation). In addition, the translational potential of these biomarkers was evaluated using a circulating serum proteomics dataset.
Results: Seventeen ERGs were identified as being significantly associated with at-risk MASH, from which five hub genes (CD24, CHI3L1, TREM2, PTGS2, and LGR6) were selected. A hub gene–based predictive model demonstrated strong discriminative performance in the training cohort (AUC = 0.866, 95% CI: 0.817–0.915) and remained robust in the external validation cohort (AUC = 0.805, 95% CI: 0.714–0.897). A simplified serum-based model incorporating TREM2 and CHI3L1 achieved acceptable discriminatory ability (AUC = 0.736, 95% CI: 0.664–0.808).
Conclusion: This study identifies an efferocytosis-related molecular signature associated with at-risk MASH and explore its potential utility for non-invasive risk stratification. These findings highlight efferocytosis as a biologically relevant pathway in MASH progression and provide a foundation for future mechanism-oriented and translational studies.

C-X-C chemokine receptor type 4 and C-X-C motif chemokine 12 mediate liver injury by cytotoxic CD8 T-cells in alcohol-associated liver disease

Gil Won Lee[1], Min Seo Park[1], Kwon Yong Tak[2], Hee Sun Cho[2], Ji Won Han[1,2], Pil Soo Sung[1,2]. *[1]Department of Medical Sciences, Graduate School of The Catholic University of Korea, Seoul, Korea, Rep. of South; [2]Division of Gastroenterology and Hepatology, Department of Internal Medicine, College of Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Rep. of South*
Email: pssung@catholic.ac.kr

Background and aims: Alcohol-associated liver disease (ALD) involves chronic immune dysregulation. We hypothesised that CXC chemokine receptor 4 (CXCR4) and its ligand CXC motif chemokine 12 (CXCL12) promote pathogenic CD8 T-cell activation and tissue-directed migration in ALD.
Method: Peripheral blood mononuclear cells (PBMCs) from ALD patients and controls (n = ALD 3, control 3) were analysed by single-cell transcriptomics and flow cytometry to define CXCR4-positive CD8 T-cell states and effector markers. Public transcriptomic datasets were interrogated with gene set enrichment analysis to compare T-cell receptor signalling with cytokine-driven programs (including interleukin 15 and type I interferon). Functional relevance was tested using CXCL12-driven migration assays and hepatocyte co-culture injury assays. Statistics: [tests], two-sided p < 0.05; enrichment was significant at false discovery rate <0.05.
Results: CXCR4-positive CD8 T cells were expanded in ALD and displayed enhanced activation and cytotoxicity, including higher granzyme B and perforin expression than CXCR4-negative cells. Transcriptomic analyses showed preferential enrichment of cytokine-mediated programs (interleukin 15, type I interferon and natural killer-like cytotoxic signatures) with comparatively reduced canonical T-cell receptor signalling, consistent with inflammation-driven activation. CXCL12 selectively promoted migration and enrichment of CXCR4-high CD8 T cells. In hepatocyte co-culture, CXCR4-high CD8 T cells induced greater hepatocyte injury than CXCR4-low/negative cells.
Conclusion: CXCR4-high CD8 T cells represent an activated, cytotoxic population in ALD. The CXCR4-CXCL12 axis couples cytokine-driven activation with directed migration and effector function, supporting this pathway as a potential therapeutic and biomarker target.

FRI-120
Unraveling the progressive remodeling and functional exhaustion of peripheral NK cells in alcohol-related liver disease progression

Young-Sun Lee[1], Ji Hoon Kim[1], Eunho Choi[1], Jong Eun Yeon[1]. *[1]Korea University Guro Hospital, Seoul, Korea, Rep. of South*
Email: lys810@korea.ac.kr

Background and aims: Alcohol-relateded liver disease (ALD) remains a global leading cause of liver-related mortality, yet the immunological drivers of its progression from steatosis to cirrhosis are poorly understood. While Natural Killer (NK) cells are essential for anti-fibrotic surveillance, their functional impairment is a hallmark of chronic liver injury. We sought to elucidate the high-resolution transcriptomic and functional landscape of CD56dim NK cells—the primary cytotoxic subset—across the clinical spectrum of ALD.
Method: We integrated single-cell RNA sequencing (scRNA-seq) and flow cytometry to analyze peripheral blood mononuclear cells (PBMCs) from healthy controls (n = 4), patients with alcoholic fatty liver (AFL, n = 6), and those with alcoholic cirrhosis (n = 3). A

specialized computational pipeline was employed to dissect the CD56dim NK cell compartment, focusing on subset heterogeneity, functional states, and molecular programming.
Results: Analysis of 7,354 high-quality CD56dim NK cells identified four transcriptionally distinct subsets, including a terminally exhausted population. Disease progression was characterized by a profound remodeling of this ecosystem, marked by a massive expansion of exhausted NK cells in cirrhotic patients. These cells exhibited a unique biphasic functional trajectory: a transient hyperactivated state during the AFL stage, followed by a collapse into terminal dysfunction in cirrhosis. Mechanistically, exhausted cells in cirrhosis established a fixed molecular program, upregulating canonical checkpoints (TIGIT, LAG3) alongside novel regulators, specifically the post-transcriptional repressor *ZFP36* and the GPCR-desensitizing protein *ARRB2*.
Conclusion: ALD progression is driven by the systematic expansion and molecular "lockdown" of an exhausted peripheral CD56dim NK cell population. This failure of anti-fibrotic surveillance, defined by a distinct biphasic trajectory, identifies *ZFP36* and *ARRB2* as potential therapeutic targets and offers a robust blood-based molecular signature for disease staging.

FRI-121
Alcohol-induced oxidative stress triggers mitochondrial calcium release through permeability transition pore opening in alcohol-associated steatohepatitis
Kwangwoo Lee[1], Kyurae Kim[1], Jihyo Byun[1], Won-il Jeong[1]. [1]*Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Rep. of South*
Email: wijeong@kaist.ac.kr

Background and aims: Chronic alcohol consumption leads to mitochondrial calcium (Ca^{2+}) accumulation in hepatocytes. The subsequent mitochondrial Ca^{2+} efflux into the cytosol triggers a cascade of glutamate release, and immune activation, ultimately driving the progression of alcohol-associated steatohepatitis (ASH). However, the mechanism underlying mitochondrial Ca^{2+} release remains unclear. One potential mediator is the mitochondrial permeability transition pore (mPTP), a channel known for its activation in response to mitochondrial reactive oxygen species (ROS). Thus, we investigated the relationship between alcohol-induced mitochondrial ROS production and mPTP-mediated Ca^{2+} efflux in ASH.
Method: For ASH induction, mice were fed ethanol (EtOH) for 2 weeks plus a single binge. Mitochondrial ROS and Ca^{2+} levels were measured *in vivo* and *in vitro* by flow cytometry and fluorescence imaging, using MitoSOX, Calcein AM, and Rhod-2 AM. Mito-TEMPO and Cyclosporine A were applied to inhibit ROS generation and mPTP opening, respectively. Mouse hepatocytes and human HCC cells were subjected to EtOH treatment. Bulk RNA sequencing, quantitative RT-PCR, and Western blotting were conducted for additional analyses.
Results: Bulk RNA-sequencing and qRT-PCR analyses revealed the upregulation of mPTP-related genes in EtOH-fed mouse livers and hepatocytes. *In vitro,* low-dose ethanol (20 mM) treatment for 24 hours increased mPTP- and glutamate-related gene expression, primed by the upregulation of *Aldh2*, a key gene for alcohol–mediated mitochondrial ROS production. In mouse hepatocytes, 20 mM EtOH increased mitochondrial ROS and Ca^{2+} accumulation, as measured by MitoSOX and Rhod-2 AM, respectively. Subsequent 100 mM treatment triggered mPTP opening, confirmed by Calcein AM release, which led to mitochondrial Ca^{2+} efflux and enhanced glutamate secretion from hepatocytes. Consistently, intravital live imaging showed that EtOH feeding elevated Rhod-2 AM intensity, which rapidly declined after binge exposure. Notably, treatments of mitochondrial ROS scavenger (Mito-TEMPO) and mPTP inhibitor (Cyclosporine A) blocked mitochondrial Ca^{2+} efflux in hepatocytes, reducing hepatic glutamate release both *in vivo* and *in vitro*. Coincidently, these findings were reproduced in human SNU475 cells.
Conclusion: Our findings reveal the mechanism of mitochondrial Ca^{2+} efflux in ASH development and suggest that targeting mitochondrial Ca^{2+} signaling may provide a therapeutic strategy for ASH.

FRI-122
A Novel murine model of metabolic dysfunction-associated alcoholic liver disease (MetALD) for therapeutic drug evaluation
Hui Li[1], Jiliang Zhang[1], Sitong Zhang[1]. [1]*WuXi AppTec, Shanghai, China*
Email: li_hui0122@wuxiapptec.com

Background and aims: Metabolic dysfunction-associated alcoholic liver disease (MetALD) is a distinct category that represents a large proportion of metabolic dysfunction-associated steatohepatitis (MASH) patients. With the redefinition of "NASH" to "MASH," MetALD, characterized by the presence of metabolic dysfunction coupled with significant alcohol consumption, has garnered increasing attention in clinical practice. The GAN diet-induced MASH model is a widely recognized MASH model, as it effectively simulates both liver pathology and metabolic dysfunction in MASH. However, like other MASH models, it deliberately excludes the influence of alcohol consumption, failing to replicate the alcohol use in MetALD patients. This study aims to develop a MetALD model for preclinical drug evaluation based on the GAN diet and alcohol consumption, incorporating liver pathology, metabolic features, and the factor of alcohol consumption.
Method: Male C57BL/6 mice were assigned to five groups based on diet, ethanol exposure, and treatment regimen: Healthy + Vehicle, MASH + Vehicle, EtOH + Vehicle, MetALD + Vehicle, and MetALD + Semaglutide. The mice were fed either a chow or GAN diet. Additionally, the EtOH and MetALD groups received ethanol in drinking water and via oral gavage. Semaglutide was administered for six weeks, during which body weight and body composition were monitored. After treatment, liver samples were collected for histological analysis, transcriptomics, and clustering analysis with clinical data.
Results: The MetALD model successfully replicated key features of human pathology, including increased liver damage, steatosis, inflammation, and fibrosis, with the NAS score increasing from 1 to 5 and the liver fibrosis score (LFS) increasing from 0 to 2. Semaglutide administration in MetALD mice reduced the NAS score and LFS score to 3 and 1a/b, respectively, demonstrating the model's ability to simulate phenotypes and verify key drugs for MetALD. Moreover, clustering results indicate a high overlap of key liver genes between MetALD model mice and MetALD patients, suggesting reliable simulation of the model at the mechanistic level.
Conclusion: This novel murine model effectively mimics both pathophysiological and mechanistic characteristics of human MetALD in the context of obesity and alcohol consumption. It potentially serves as an essential tool for understanding the molecular mechanisms underlying MetALD pathogenesis and evaluating potential therapeutic strategies.

FRI-123
Hepatocyte SIRT7 regulates PMN-MDSC differentiation via the FXR–bile acid axis in alcohol-related liver disease
Gaoshuang Liang[1], Yicheng Teng[1], Jing Zhang[1], Jinying Peng[1], Zhuan Li[1]. [1]*Hunan Normal University, ChangSha, China*
Email: zhuanli@hunnu.edu.cn

Background and aims: Polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs), a pathologically activated subset of neutrophils, have been increasingly implicated in the progression of alcohol-related liver disease (ALD). However, the mechanisms by which injured hepatocytes shape the hepatic immune microenvironment and influence PMN-MDSC differentiation remain poorly understood.
Method: Hepatocyte-specific SIRT7-deficient mice (Alb-Cre SIRT7 −/−) and wild-type littermates were subjected to a Lieber–DeCarli ethanol diet to model ALD. Hepatic immune cell populations were

characterized using flow cytometry and single-cell transcriptomic analysis. The potential interaction between SIRT7 and FXR was examined using co-immunoprecipitation and chromatin immunoprecipitation assays. Targeted metabolomic analyses were performed to assess alterations in bile acid composition. In vitro differentiation assays were used to evaluate the effects of selected bile acids on bone marrow–derived PMN-MDSC differentiation.

Results: Analysis of clinical samples and experimental ALD models indicated an enrichment of CD300ld^{+} PMN-MDSCs in the diseased liver. Hepatocyte-specific deletion of SIRT7 was associated with attenuated alcohol-induced liver injury and a reduction in hepatic PMN-MDSC accumulation. Mechanistic investigations suggested that SIRT7 may interact with FXR and modulate its acetylation status, thereby influencing FXR transcriptional activity on genes involved in bile acid synthesis and transport, including Cyp7a1 and Cyp27a1. Loss of hepatocyte SIRT7 was accompanied by altered bile acid profiles, characterized by a decrease in deoxycholic acid (DCA) levels. Furthermore, in vitro studies supported a potential role for DCA as a metabolic signal capable of enhancing the differentiation of progenitor cells toward a PMN-MDSC-like phenotype.

Conclusion: These data suggested that hepatocyte SIRT7 is closely associated with the regulation of FXR activity and bile acid homeostasis during ALD. Altered bile acid profiles, particularly changes in deoxycholic acid (DCA) levels, may represent an important metabolic link between hepatocyte injury and PMN-MDSC differentiation. Elucidating SIRT7–FXR–bile acid axis may provide a mechanistic basis for understanding hepatocyte–immune cell communication and identify potential targets for therapeutic intervention for ALD.

FRI-124

CREB1-regulated SLC39A1 attenuates alcoholic liver disease by orchestrating autophagy and mitophagy

Xianwei Liu[1], Rui Li[1], Yijin Wang[1]. [1]*Southern University of Science and Technology, Shenzhen, China*
Email: wangyj3@sustech.edu.cn

Background and aims: Alcoholic liver disease (ALD) represents a major global health burden with incompletely understood molecular underpinnings. Zinc transporter SLC39A1 has been implicated in cellular ion homeostasis, yet its functional role in ALD remains elusive. This study aims to decipher a hitherto unrecognized SLC39A1-dependent pathway that confers protection against ALD.

Method: Liver samples from ALD patients were analyzed by immunofluorescence. Hepatocyte-specific Slc39a1 knockout (CKO) mice were subjected to Lieber DeCarli ethanol feeding. Primary hepatocytes were exposed to ethanol in vitro. Liver injury, steatosis, autophagy, and mitophagy were assessed. ChIP and luciferase reporter assays were employed to evaluate CREB1-dependent transcriptional regulation of SLC39A1. Mechanistic insight into SLC39A1-DRP1 interaction was explored using genetic and pharmacological approaches.

Results: Analysis of human samples and GEO datasets revealed upregulated SLC39A1 in ALD patients. Intriguingly, elevated hepatic SLC39A1 correlated with milder liver injury, including reduced steatosis, inflammation, and fibrosis. Ethanol-fed mice exhibited elevated SLC39A1 and associated with improved survival. Conversely, Slc39a1 CKO mice displayed exacerbated liver injury and steatosis. Mechanistically, SLC39A1 deficiency potentiated autophagy flux, evidenced by increased LC3IIB, Atg5, an effect reversed by chloroquine (CQ). Importantly, CQ administration ameliorated liver pathology and improved survival in CKO mice, underscoring the detriment of excessive autophagy. CREB1 was identified as a direct transcriptional activator of SLC39A1, with enhanced promoter binding upon ethanol exposure. Immunofluorescent staining showed a substantial co-localization of SLC39A1 and CREB1 in ALD patients compared to healthy individuals. Furthermore, SLC39A1 physically interacted with DRP1, promoting mitochondrial fission and Fundc1-mediated mitophagy. Disruption of DRP1 genetically or pharmacologically ablated SLC39A1-driven mitophagy, whereas DRP1 overexpression rescued mitophagy and attenuated apoptosis in SLC39A1- deficient hepatocytes.

Conclusion: We reveal a cytoprotective axis where CREB1-driven SLC39A1 curbs alcohol-induced liver injury via dual regulation of autophagy and DRP1-dependent mitophagy. This delineates a novel ALD pathway, nominating SLC39A1 as a therapeutic target.

FRI-125

Spatial transcriptomics reveals metabolic, immune and regenerative reprogramming during disease resolution in severe alcohol-related hepatitis

Ane Otaegui-Chivite[1], Hiromi Kudo[1], Alastair M. Kilpatrick[2], Daniel Rodrigo-Torres[2], Stuart J. Forbes[2], Luke D. Tyson[1], Nikhil Vergis[1], Robert D. Goldin[1], Stephen R. Atkinson[1], Mark R. Thursz[1], Laura Martinez-Gili[1]. [1]*Imperial College London, London, United Kingdom;* [2]*The University of Edinburgh, Edinburgh, United Kingdom*
Email: l.martinez-gili@imperial.ac.uk

Background and aims: Severe alcohol-related hepatitis (sAH) is associated with high mortality. Clinical trials of assets targeting inflammation have shown limited improved outcomes, necessitating identification of alternate therapeutic pathways. We assessed liver spatial transcriptomics changes between baseline and the resolution phase of sAH.

Method: Paired liver biopsies (day 0 and 28) from five sAH patients recruited to the ISAIAH clinical trial (EudraCT: 2017-003724-79; 80% males; 100% treatment arm) were analysed with CosMx human universal 1000-plex RNA panel. Differential gene expression was determined with linear mixed effects models with subject as random intercept. Benjamini-Hochberg-adjusted p values below 0.1 were considered significant. Spatial metrics were computed with Squidpy.

Results: Activated Kupffer cells, myofibroblasts and ductular reaction cholangiocytes were detected at both timepoints. Kupffer cells were the most abundant at day 0 (d0; 22%), followed by hepatocytes (20%), while a higher hepatocyte proportion trend was observed at d28 (29%; $p = 0.11$). Spatial analysis revealed prominent clustering of B cells, myofibroblasts and stellate cells at d0, while hepatocytes were the most spatially clustered at d28. T cells co-localised with Kupffer cells at d0, and with myofibroblasts and cholangiocytes at d28. Expression of liver X receptor beta (NR1H2), apolipoprotein C1 (APOC1) and selenoprotein P (SELENOP) increased at d28 across multiple cell types. Hepatocytes suppressed stress genes (serum amyloid A 1/2 [SAA1/2], alpha-1 antitrypsin [SERPINA1]), and increased growth factors (insulin-like growth factor 1 [IGF1])). Cholangiocytes increased regenerative genes (WNT7B, notch-related genes, frizzled receptors [FZD]). Endothelial and stellate cells downregulated contractile and fibrogenic programs (transgrelin [TAGLN], collagen type I alpha 2 chain [COL1A2], tissue inhibitor of metalloproteinase 1 [TIMP1]). Kupffer cells downregulated activation genes (CD14, toll-like receptor 2 [TLR2]). T cells upregulated immunomodulatory galectin-9 (LGALS9) and chemokines XCL1/2, and B cells cysteine-rich intestinal protein 1 (CRIP1) and CD81.

Conclusion: Resolution of sAH is associated with spatial and functional remodelling of inflammatory and stromal niches, including changes in lymphocytes spatial organisation that may be relevant to tissue repair. Our findings support immune regulation and metabolic resilience as targets for early combination therapies.

FRI-126

Binge alcohol exposure induces neutrophil extracellular trap associated injury in the proximal small intestine

Scott Minchenberg[1,2], Marti Ortega-Ribera[1,2], Alejandro Hionides-Gutierrez[1,2], Siddharth Ghosh Roy[1], Aditi Datta[1], Viliam Brezani[1], Bruna Santos[1], Subhash Kulkarni[1,2], Prashanth Thevkar Nagesh[1,2], Gyongyi Szabo[1,2,3]. [1]*Beth Israel*

Deaconess Medical Center, Boston, United States; [2]Harvard Medical School, Boston, United States; [3]Broad Institute of Mit & Harvard, Cambridge, United States
Email: sminchen@bidmc.harvard.edu

Background and aims: Acute alcohol binges impair intestinal barrier integrity and promote gut-derived inflammatory signaling implicated in alcohol-related liver disease. The proximal small intestine (PSI) is exposed to the highest luminal alcohol concentrations, yet early site-specific inflammatory mechanisms remain poorly defined. We aimed to characterize the inflammatory response to binge alcohol exposure and to assess the roles of oxidative stress and neutrophil extracellular traps (NETs) in intestinal injury.
Method: Eight- to 12-week-old female C57BL/6J mice received daily oral ethanol gavage (3.5 g/kg) for three days. PSI, distal small intestine (DSI), and colon were collected 3 and 24 hours after the final binge. Intestinal injury was assessed by villus height:crypt depth ratios and neutrophil infiltration by Ly6G immunostaining. Neutrophil activation and NET formation were assessed by measuring neutrophil elastase, lipocalin-2, and citrullinated histone H3. Serum endotoxin was quantified by limulus amebocyte lysate assay. To assess oxidative stress, mice received 500 mg/kg N-acetylcysteine (NAC) with ethanol, and to evaluate NET involvement, mice were pretreated with 5 mg/kg DNase I (intraperitoneal) 1 hour prior to each binge. PSI neutrophil chemotactic factors were also assessed.
Results: Three alcohol binges induced a PSI enteropathy with reduced villus height–crypt depth at 3 hours that persisted at 24 hours, while DSI and colon histology remained unchanged. PSI injury was associated with transient neutrophil recruitment and activation peaking at 3 hours, followed by sustained NET formation. Although tissue neutrophil abundance normalized by 24 hours, NET markers, including citrullinated histone H3, remained elevated. Alcohol increased serum endotoxin at 3 hours, consistent with barrier dysfunction. While alcohol increased PSI reactive oxygen species, antioxidant treatment reduced oxidative stress but failed to prevent PSI injury, neutrophil activation, or endotoxemia. In contrast, DNase I pretreatment reduced PSI neutrophil recruitment, activation, NETosis markers, PSI villus blunting, and decreased serum endotoxin.
Conclusion: DNase I pretreatment protects against alcohol-induced PSI enteropathy and gut-derived inflammatory signaling by suppressing neutrophil activation and NET formation. These findings identify extracellular DNA–driven NETosis as a key upstream mechanism of binge alcohol–induced intestinal injury and a potential therapeutic target in alcohol-related liver disease.

FRI-127
Urinary markers of complement and chronic kidney disease are associated with occurrence of acute kidney injury in patients with severe alcohol-associated hepatitis

Luan Prado[1], Megan McMullen[1], Ryan Musich[1], for The AlcHepNet Investigators[1], Laura Nagy[1]. *[1]Department of Inflammation and Immunity, Cleveland Clinic, Cleveland, United States*
Email: pradol2@ccf.org

Background and aims: Patients with severe alcohol-associated hepatitis (sAH) are at risk of developing acute kidney injury (AKI); however, our understanding of the clinical factors and mechanisms for AKI in patients with sAH is an unmet clinical need. Patients with chronic kidney disease (CKD), associated with renal fibrosis, are at increased risk of AKI. Complement, a critical component of innate immunity, is increased in kidneys, urine and plasma of patients with CKD. Further, complement is perturbed in both plasma and urine from patients with sAH. Here we investigated whether urinary biomarkers of complement, fibrosis and CKD are predictive of AKI in patients with sAH and whether kidney injury and fibrosis develop in murine models of heavy alcohol consumption.
Method: Urine collected from 52 patients with sAH at enrollment in the AlcHepNet Observational study (NCT 3850899) was used for global quantitative proteomics. Patients were stratified by estimated glomerular filtration rate (eGFR <60 or >60) and physician diagnosis of AKI during 24 wk follow-up. Male C57BL/6 mice were exposed to the Lieber-DeCarli ethanol diet for 1–2 d at 6% (v/v) ethanol or 5% (v/v) ethanol for 4 w or pair-fed control diets.
Results: Classical urinary biomarkers of AKI, including urinary lipocalin-2 (LCN2), IL-18, and liver fatty acid-binding protein (L-FABP) were detected in the proteomics analysis but did not distinguish patients who developed AKI from those who did not. Further, biomarkers of renal fibrosis and CKD (DKK3) and complement Factor D (CFD), were detected in patients with sAH and were higher in patients with eGFR<60 + AKI. In murine models, expression of tubular injury markers, as well as complement and inflammatory genes were increased in response to 1–2d of 6% ethanol exposure. Kidney injury was further increased after 4 wk/5% ethanol exposure with mice increased expression of mRNA for fibrogenic genes and DKK3 as well as collagen deposition and mild tubular injury.
Conclusion: Biomarkers of complement activation, fibrosis and CKD were increased in the urine of patients with sAH with lower eGFR and a diagnosis of AKI compared to those without AKI, suggesting that CFD and DKK3 are potential prognostic biomarkers for AKI in patients with sAH and low eGFR. Both short term and chronic heavy ethanol exposure in mice resulted in early stages of kidney injury, providing an important pre-clinical murine model to investigate the relation between alcohol, complement and kidney disease.

Disruption of TCA-glutamine metabolism: α-Ketoglutaric acid as a prognostic marker in alcohol-associated liver disease

Sushmita Pandey[1,2], Khan Shahrukh Khan[1], Shreya Sharma[1], Yash Magar[2], Nupur Sharma[2], Babu Mathew[2], Sanju Yadav[2], Manisha Yadav[2], Gaurav Tripathi[2], Vasundhra Bindal[2], Vipul Sharma[2], Jaswinder Maras[2], Anju Katyal[1]. *[1]Dr. B R Ambedkar Center for Biomedical Research, University of Delhi, New Delhi, India; [2]Institute of Liver & Biliary Sciences, New Delhi, India*
Email: anju_katyal@yahoo.com

Background and aims: Alcohol combined with high-fat consumption drives profound metabolic dysregulation in liver disease. This study aimed to characterize time-dependent metabolic alterations using a Wistar rat alcohol-fat model and validate key findings in patients.
Method: Male Wistar rats were subjected to chronic dietary interventions comprising ethanol, high-fat diet, or their combination, alongside a standard control diet, for a total duration of 10 weeks to induce alcohol-associated liver disease. Animals were euthanized at predefined time points (weeks 6, 8, and 10) to capture temporal metabolic alterations during disease progression. Serum samples were collected and subjected to comprehensive untargeted metabolomic profiling using high-resolution mass spectrometry. Key metabolic signatures were subsequently validated in an independent cohort of patients (SAH; n = 350) with alcohol-associated liver disease to establish translational relevance.
Results: Serum and hepatic metabolomic profiling demonstrated a profound, compartment-specific disruption of glutamine and TCA cycle coupling during alcohol-fat-induced liver injury (FC >1.5; $P < 0.05$). Progressive accumulation of circulating α-ketoglutaric acid and 2-ketoglutaramic acid (FC >1.5; $p < 0.05$), alongside depletion of serum glutamate and glutamine ($p < 0.05$), reflects impaired mitochondrial TCA flux and defective nitrogen handling with advancing disease severity. In contrast, intrahepatic enrichment of α-ketoglutaric acid, glutamate, and glutamine indicates metabolic trapping within the injured liver, consistent with mitochondrial dysfunction and altered anaplerosis. Clinically, elevated serum α-ketoglutaric acid showed a robust and reproducible association with disease severity and adverse outcomes, including in patients with alcohol-associated liver disease (AUROC>0.89; $p < 0.05$, FC >2.0), underscoring its potential utility as a translational biomarker for metabolic decompensation and prognostic stratification in alcohol and fat driven liver injury.

Conclusion: Alcohol and fat induced liver disease is characterized by progressive α-ketoglutaric acid accumulation, reflecting mitochondrial and nitrogen metabolic dysfunction, with translational relevance as a prognostic biomarker in patients.

FRI-133

Morphological differences in mitochondria of patients with and without alcohol related liver disease

Meliz Sahuri Arisoylu[1], Sophie Maliakal[1], Sergio Bozzano[1], Una Rastovic[1], Moyosoreoluwa Feyide[1], Bhavanaa Arunakumar[1], Ane Zamalloa[1], Nigel Heaton[1], Elena Palma[1]. *[1]Roger Williams Institute of Liver Studies, School of Immunology & Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, Foundation for Liver Research and King's College Hospital, London, United Kingdom*
Email: m.arisoylu@researchinliver.org.uk

Background and aims: Changes in hepatocyte mitochondrial morphology and size occur in response to metabolic stressors, including alcohol, in both patients and experimental models. Disproportionate mitochondrial enlargement (megamitochondria) has been described as a maladaptive response but has also been associated with improved clinical outcomes in alcohol-related hepatitis, a form of end-stage alcohol-related liver disease (ALD). However, systematic characterisation of mitochondrial morphology in human liver tissue across health and disease remains limited, partly due to technical constraints and a lack of physiologically relevant models. This study aimed to characterise hepatocyte mitochondrial morphology in patients with different disease backgrounds and to compare these findings with cellular and tissue models to assess their relevance for studying mitochondrial morphology.
Method: For ex vivo analysis, liver samples were obtained from patients with or without ALD. Human precision-cut liver slices (PCLS) were generated from both groups and exposed to acute ethanol at varying concentrations and durations. For in vitro experiments, primary human hepatocytes (PHH) were treated with 100 or 250 mM ethanol for 24 hours. Samples were fixed, mitochondria were visualised by immunofluorescence, and imaging was performed using super-resolution microscopy. Quantitative analyses were restricted to viable hepatocytes, and relative mitochondrial size distributions were compared.
Results: Mitochondrial size distributions varied between patients within each group. Enlarged mitochondria were observed in both groups but were more frequent and larger in ALD patients. In the PCLS model, ethanol exposure increased the frequency of larger mitochondria. Similarly, in the cellular model, enlarged mitochondria were detected in all groups, with both their number and size increasing in a dose-dependent manner following ethanol treatment.
Conclusion: Mitochondrial morphology in human liver tissue is strongly influenced by ethanol exposure and underlying liver health. These findings highlight the need for further research to uncover mechanisms of mitochondrial resilience or vulnerability to alcohol-induced injury. The development of comparable 2D and 3D models to study mitochondrial morphology would not only improve our understanding of the role of this organelle in liver health but also provide a platform for targeting mitochondria in the treatment of liver disease.

Selective farnesoid X receptor agonist INT-787 inhibits ethanol-induced liver injury in mice

David Schöler[1], Sainan Chen[1,2], Marcos Fondevila[1], Aenne Harberts[1], Yanhan Wang[1], Yixin Bai[3,4], Qinghai Liu[3,4], Qihong Yang[3,4], Luciano Adorini[5], Mary Erickson[5], Sanjay Kansra[5], Hidekazu Tsukamoto[3,4,6], Bernd Schnabl[1,7]. *[1]University of California San Diego, La Jolla, United States; [2]Zhujiang Hospital,Southern Medical University, Intensive Care Unit, Guangzhou, China; [3]University of Southern California, Los Angeles, United States; [4]Southern California Research Center for ALPD and Cirrhosis, Los Angeles, United States; [5]Intercept Pharmaceuticals, Inc, Morristown, United States; [6]Department of Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, United States; [7]VA San Diego Healthcare System, San Diego, United States*
Email: beschnabl@health.ucsd.edu

Background and aims: Farnesoid X receptor (FXR) agonists improve bile acid homeostasis and metabolic function, but their role in ethanol-induced liver injury remains unclear. INT-787 is a novel FXR agonist structurally related to obeticholic acid (OCA). We investigated whether INT-787 protects against ethanol-induced liver injury and whether this involves modulation of the gut-liver axis.
Method: INT-787 and OCA were evaluated in 2 mouse models of ethanol-induced liver disease, the oral Lieber-DeCarli chronic-plus-binge ethanol feeding model for 8 weeks and an intragastric hybrid high-cholesterol/high-fat diet plus ethanol plus binge feeding model (intragastric hybrid ethanol feeding model) for 7 weeks. Hepatic injury was assessed by serum/plasma alanine aminotransferase (ALT) levels, while hepatic steatosis was evaluated by hepatic triglyceride content and histological analysis. Bile acid metabolism was assessed by circulating bile acid levels and hepatic CYP7A1 protein expression, and intestinal permeability was evaluated by circulating lipopolysaccharide (LPS) levels. To assess direct intestinal effects of INT-787 and OCA, differentiated Caco-2 monolayers were exposed to LPS, and transepithelial electrical resistance (TER), tight junction protein expression, and cell viability were analyzed.
Results: Across both *in vivo* models, INT-787 reduced ethanol-induced liver injury, as reflected by lower ALT levels, and attenuated hepatic steatosis, as determined by reduced hepatic triglycerides and histological lipid accumulation. These effects were accompanied by suppression of hepatic CYP7A1 protein expression and reduced circulating bile acid levels, consistent with hepatic FXR activation. In the intragastric hybrid ethanol feeding model, INT-787 additionally reduced intestinal permeability and lowered circulating LPS levels, indicating improved gut barrier function. *In vitro*, INT-787 dose-dependently preserved TER and maintained expression of the tight junction protein 1 (TJP1, also known as ZO-1) in LPS-challenged Caco-2 monolayers without inducing cytotoxicity. This barrier-protective effect exceeded that observed with OCA.
Conclusion: INT-787 inhibits ethanol-induced liver injury and steatosis more effectively than OCA in 2 mouse models through modulation of bile acid metabolism and preservation of intestinal epithelial integrity. These findings support INT-787 as a next-generation FXR agonist with therapeutic potential for alcohol-associated liver disease.

FRI-135-YI

Leucine-rich alpha-2-glycoprotein 1 turnover indicates impaired regenerative signaling in alcohol-associated hepatitis

Nupur Sharma[1], Vipul Sharma[1], Sadam Bhat[1], Sushmita Pandey[1], Sanju Yadav[1], Mothe Shravya[2], Yash Magar[1], Babu Mathew[1], Vasundhra Bindal[1], Gaurav Tripathi[1], Manisha Yadav[1], Rimsha Rimsha[1], Neha Sharma[1], Ranjan Nanda[2], Chhagan Bihari[1], Archana Rastogi[1], Shvetank Sharma[1], Viniyendra Pamecha[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]International Centre for Genetic Engineering and Biotechnology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Severe alcoholic hepatitis (SAH) features inflammation, liver dysfunction, and poor regeneration. We assessed protein turnover as a marker of liver injury and repair in SAH patients, and murine ALD and abstinent models.
Method: SAH patients (n = 10), healthy controls (n = 5), and liver donors (n = 5) received 70% D_2O, with plasma collected at baseline and Days 1, 3, 5, and 7. LC-MS/MS quantified turnover of injury- and regeneration-related proteins linked to disease severity. Key

regenerative markers were validated in platelets from SAH patients, controls, and donors (n = 10 each), and in animal models.
Results: SAH patients showed higher plasma protein turnover than controls (0.38/day vs 0.23/day, $p < 0.05$), reflecting accelerated but dysregulated protein dynamics. Specifically, 37 proteins involved in inflammatory, complement, platelet activation, and ECM remodeling pathways had increased while14 proteins associated with HDL assembly and BCR regulation had reduced turnover (FC >1.5, $p < 0.05$). Functional clustering revealed that turnover of ECM and fibrosis-related proteins strongly correlated with histological severity in SAH ($r^2 = 0.98$, $p < 0.05$). When liver donors were analysed, they exhibited increased turnover of 50 proteins linked to platelet degranulation, complement activation, and HDL remodeling, indicating preserved regenerative signaling. Notably, Leucine-rich alpha-2-glycoprotein 1 (LRG1) emerged as a key regenerative marker. Its turnover and regenerative potential were both significantly reduced in SAH patients (35%) compared to liver donors (100%, $p < 0.05$). Supporting this, a preclinical ALD model demonstrated that alcohol abstinence restored hepatic LRG1 expression, its receptors (IL6R, IL4R, TGFβR2, EGFR), and downstream pro-survival and proliferative signaling pathways (FC >1.5, $p < 0.05$). Platelet degranulation, a source of LRG1, was impaired in SAH, contributing to compromised LRG1-mediated signaling and regeneration.
Conclusion: LRG1 turnover supports liver regeneration and may serve as a novel indicator of liver repair and regenerative capacity in alcohol-associated liver disease.

FRI-136
A high-salt diet aggravates alcohol-associated liver diseases by disrupting the functional homeostasis of liver sinusoidal endothelial cells
Haiyuan Shen[1,2,3], Miaomiao Wu[2,4], Juan Wang[1,2], Li Zuo[2,4], Hua Wang[1]. [1]*Department of Oncology, the First Affiliated Hospital of Anhui Medical University, Hefei, China;* [2]*Innovation and Entrepreneurship Laboratory for college students, Anhui Medical University, Hefei, China;* [3]*School of Pharmaceutical Sciences, Anhui Medical University, Hefei, China;* [4]*Department of Biochemistry, Anhui Medical University, Hefei, China*
Email: shenhayyuan@163.com

Background and aims: Alcohol-associated liver disease (ALD), primarily caused by chronic excessive alcohol consumption, is a leading cause of liver-related mortality worldwide. The global burden of ALD remains a significant concern, particularly when compounded by other prevalent lifestyle risk factors such as high-salt diets. This study aims to investigate the impact of high-salt diet on ALD progression and to identify the key cell types and molecular mechanisms involved, thereby elucidating novel pathogenic pathways and potential therapeutic targets.
Method: C57BL/6 mice were subjected to the Gao-binge model of ALD and fed either a high-salt diet or a normal-salt diet. The extent of alcohol-induced liver injury, steatosis, and inflammation was evaluated across groups. Single-cell RNA sequencing was employed to identify liver cell populations significantly affected by high-salt intake. To elucidate the underlying mechanisms, a comprehensive analysis was conducted using 16S rRNA sequencing, metabolomics, proteomics, and genetic engineering approaches.
Results: High-salt diet reshaped the intrahepatic immune microenvironment. Mechanistically, it upregulates salt-inducible kinase 1 (Sik1) in liver sinusoidal endothelial cells (LSECs), leading to increased release of selectins and intercellular adhesion molecule-1 (ICAM-1), which promotes neutrophil infiltration and exacerbates alcohol-induced liver injury in mice. Furthermore, high-salt intake reduced the abundance of beneficial gut bacteria, such as *Akkermansia muciniphila* and *Lactobacillus reuteri*, while promoting the expansion of harmful bacteria, including *Enterococcus faecalis*. Impaired LSEC function facilitated bacterial translocation to the liver, where colonizing bacteria further induced hepatic inflammation and hepatocyte damage.
Conclusion: High-salt intake exacerbates the progression of ALD by impairing LSEC barrier and inflammatory functions. It promotes the expression of selectins and ICAM-1 on LSECs in a Sik1-dependent manner, leading to neutrophil recruitment and increased bacterial invasion into the liver, thereby triggering inflammation and tissue injury. These findings reveal a novel molecular mechanism in alcohol-induced liver injury and suggest that dietary modification and interventions targeting LSECs may offer potential therapeutic strategies for ALD.

FRI-137
Intestinal GPR119 activation improves alcohol-related liver disease via gut-liver axis and mediates the protective effect of its ligand palmitoleic acid
Mengyao Wang[1], Chang Yuan[1], Zhou Zhao[1], Jian Sun[1]. [1]*Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, State Key Laboratory of Multi-organ Injury Prevention and Treatment, Key Laboratory of Infectious Diseases Research in South China, Ministry of Education, Guangdong Provincial Key Laboratory for Prevention and Control of Major Liver Diseases, Guangdong Provincial Clinical Research Center for Viral Hepatitis, Guangdong Institute of Hepatology, Guangdong Provincial Research Center for Liver Fibrosis Engineering and Technology, Guangzhou, China*
Email: sunjianteam@163.com

Background and aims: Alcohol-related liver disease (ALD) is increasingly seen as a systemic metabolic disorder shaped by the gut liver axis. Re analysis of public serum metabolome data indicates that metabolite set enrichment highlights G-protein-coupled receptors (GPCRs), particularly fatty acid activated GPCRs, within the affected pathways. Among these, the specific role and mechanistic contribution of G protein coupled receptor 119 (GPR119) in ALD remain insufficiently explored.
Method: Enrichment analysis was performed on publicly available serum untargeted metabolomics data derived from a published ALD cohort, comprising 32 healthy controls and 100 ALD patients. ALD mouse models were established using the NIAAA protocol, with mice subjected to chronic-plus-binge ethanol feeding regimen. Intestinal epithelium-specific GPR119 overexpression was achieved in wild-type mice via adeno-associated virus (AAV) vector-mediated gene delivery (Vil1-Gpr119Tg). GPR119 was pharmacologically activated with APD688 (10 mg/kg/day, oral gavage) and with palmitoleic acid (50 and 200 mg/kg/day, oral gavage). Caco-2 cell lines were used for in vitro experiments.
Results: In the ALD cohort, serum metabolites differentially enriched versus healthy controls clustered explicitly within GPCR-signalling pathways. Ethanol-fed mice exhibited a selective post-transcriptional loss of intestinal GPR119, as protein levels declined while Gpr119 mRNA remained signifiantly unchanged. Mechanistically, ethanol enhanced ubiquitination of GPR119 and accelerated its proteasomal degradation. Pharmacological activation with APD688, transgenic over-expression of Vil1-Gpr119Tg, or oral supplementation with the endogenous ligand palmitoleic acid all reinstated the GPR119-cAMP-PKA-CREB cascade in the small intestine. This was accompanied by markedly elevated tight-junction proteins Zonula Occludens-1 and occludin, restoration of mucosal barrier integrity, and simultaneous attenuation of ethanol-driven liver injury.
Conclusion: Alcohol impairs intestinal GPR119 through ubiquitin-mediated degradation, whereas Pharmacological activation or intestinal specific overexpression of GPR119 re-programs the gut-liver metabolite axis and ameliorates experimental ALD. Palmitoleic acid functions as an endogenous GPR119 agonist, offering a readily translatable strategy for ALD therapy. These findings establish GPR119 as a guardian of the gut–liver axis and an attractive, druggable target for ALD intervention.

Therapeutic plasma exchange improves short-term survival in acute on chronic liver failure: a randomised controlled trial

Sagnik Biswas[1], Shekhar Swaroop[1], Arnav Aggarwal[1], Ayush Agarwal[1], Poonam Coshic[1], Samagra Agarwal[1], Hem Chandra Pandey[1], Gopal Patidar[1], Rahul Chaurasia[1], Pragyan Acharya[1], Baibaswata Nayak[1], Deepak Gunjan[1], Viren Sardana[2], Ashwani Mishra[1], Shivanand Gamangatti[1], Shalimar[1]. [1]*All India Institute of Medical Science, New Delhi, India;* [2]*Institute of Genomic and Integrative Biology, New Delhi, India*
Email: sagnik_biswas@yahoo.co.in

Background and aims: Therapeutic plasma exchange (TPE) is a promising modality for the management of acute-on-chronic liver failure (ACLF), however, its impact on patient survival is unclear. This randomized controlled trial (RCT) evaluated the efficacy and safety of TPE compared to standard medical therapy (SMT) in ACLF.
Method: In this single-center, open-label RCT (February 2022-March 2025), we randomly (1:1) assigned 194 adult patients (aged 18–60 years) with ACLF (European Association for the Study of the Liver-Chronic Liver Failure Consortium [EASL CLIF-C] Grades 1–3b) to receive SMT plus 5 sessions of TPE (97 patients) or SMT alone (97 patients). The primary outcome was all-cause mortality at 28 days. Secondary outcomes included 90-day mortality, changes in prognostic scores and resolution of organ failures, infections and adverse events.
Results: Baseline characteristics were comparable between the two groups. Alcohol use was the most common cause of underlying liver disease (67.5%) and most patients presented with ACLF Grade 2 (64.5%). Seventy-two (74.2%) patients completed 3 sessions of TPE while 56 (57.7%) received all 5 sessions. Hemodynamic instability was the leading cause for discontinuation of TPE (18/41 patients, 43.9%). The 28-day mortality was significantly lower with TPE (43 patients, 44.3%; 95%CI: 34.2%–54.8%) than SMT (62 patients, 63.9%; 95%CI: 53.5%–73.4%), $p = 0.006$; absolute risk reduction: 19.6% (95% CI: 5.8% to 33.3%), although the 90-day mortality rates between both groups were similar (TPE:66% [55.6–75.3] versus SMT:69.1% [58.9–78]; p = 0.64). Subgroup analysis did not reveal significant heterogeneity across ACLF grade or etiology. TPE resulted in greater reductions in serum bilirubin, international normalized ratio, ammonia, and higher rates of resolution of hepatic and coagulation failure by day 7 as compared to SMT. Infections were more frequent with TPE [20/92 (21.7%) vs 12/102 (11.8%), p = 0.062]. Dyselectrolytemia and shivering were the most common complications after TPE.
Conclusion: TPE significantly improves 28-day survival and organ failure resolution in patients with ACLF, but does not reduce 90-day mortality. Fluid and electrolyte imbalances affect tolerability of TPE in this patient group [CTRI/2022/01/039094].

Continuous terlipressin infusion plus norepinephrine versus norepinephrine alone in acute kidney injury associated with acute-on-chronic liver failure and septic shock: a randomized controlled trial

Jitendra Kumar Singh[1], Rakhi Maiwall[1], Ankit Bhardwaj[1], Harshvardhan Tevethia[1], Rajan Vijayaraghavan[1], Arun Kumar Sood[1], Manoj Kumar[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: jitendra2602kc@gmail.com

Background and aims: Acute kidney injury (AKI) in acute-on-chronic liver failure (ACLF) with septic shock is driven by severe systemic vasodilatation and splanchnic pooling, often limiting the efficacy of norepinephrine (NE) alone. Terlipressin, a vasopressin analogue, may provide complementary splanchnic vasoconstriction and improve renal perfusion. We evaluated whether continuous low-dose terlipressin infusion combined with NE improves renal and hemodynamic outcomes compared with NE alone.
Method: Single-center open-label RCT of 126 ACLF patients with less-severe septic shock (NE <0.05 µg/kg/min) and AKI randomized to NE alone (n = 63) or terlipressin infusion (1 mg/day, escalated to 4 mg/day by Day 4) plus NE (n = 63). MAP ≥70 mmHg targeted; 20% albumin given. Primary endpoint: Day-4 shock reversal with ≥1-stage AKI improvement; secondary endpoints: Day-7 AKI outcomes, NEE, albumin dose, RRT, 28-day mortality, and adverse events.
Results: Baseline characteristics were comparable: age (46.36 ± 10.09 vs 44.21 ± 12.57 years), AARC score (10.53 ± 1.52 vs 10.46 ± 1.17), eGFR (49.92 ± 20.53 vs 51.03 ± 19.49 mL/min/1.73 m^2), MAP (63.47 ± 2.29 vs 62.56 ± 2.22 mmHg; p = 0.085), lactate (2.35 ± 0.62 vs 2.26 ± 0.55 mmol/L; p = 0.502). Pneumonia was the commonest sepsis source (47.2% vs 43.6%), followed by SBP (19.4% vs 33.3%) in NE vs NE+TERLI. Renal biomarkers were similar: urine NGAL (307.3 ± 237.4 vs 246.6 ± 200.1 ng/mL; p = 0.20) and cystatin-C (2.19 ± 1.15 vs 1.90 ± 0.59 mg/L; p = 0.14). Day-4 shock reversal (92.3% vs 52.8%; p < 0.001) and ≥1-stage AKI improvement (74.4% vs 44.4%; p = 0.008) were higher with NE+TERLI. Day-7 AKI resolution was higher (71.8% vs 44.4%; p = 0.004) with lower progression (12.8% vs 16.7%; p = 0.610). Day-4 NEE was lower (0.01 ± 0.03 vs 0.06 ± 0.08; p = 0.001). Albumin dose (100.6 ± 60.7 vs 96.9 ± 62.2 g; p = 0.78), RRT (15.8% vs 20.6%; p = 0.63) and 28-day mortality (22.2% vs 28.2%; p = 0.55) were comparable. AARC score (adjusted HR 3.01, CI 1.76–5.15; p < 0.001) and baseline lactate (adjusted HR 14.39, CI 2.75–75.32; p = 0.002) independently predicted mortality. Adverse events were higher with NE+TERLI (13.3% vs 4.3%; p = 0.2). Baseline eGFR (OR 1.06, CI 1.02–1.11; p = 0.002) and NE+TERLI (OR 3.60, CI 1.04–12.47; p = 0.043) independently predicted Day-7 AKI recovery.
Conclusion: In patients with ACLF, septic shock, and AKI, continuous low-dose terlipressin combined with norepinephrine is safe and significantly improves early shock reversal and renal recovery while reducing catecholamine requirements.

Background and aims: Cirrhosis-associated immune dysfunction plays a central role in the pathogenesis of acute-on-chronic liver failure (ACLF), contributing to organ failure, infection, and death. However, current prognostic models do not incorporate direct measures of immune function. The neutrophil-to-lymphocyte ratio (NLR) reflects both systemic inflammation and immune exhaustion and may serve as a simple, readily available biomarker in clinical practice. We aimed to evaluate the prognostic value of NLR for predicting mortality and infection in patients with ACLF.
Method: We analyzed data from 914 patients with ACLF enrolled in two prospective, multicenter EF-CLIF cohorts: 420 from the PREDICT study and 494 from the ACLARA study. Demographic, clinical, and laboratory data were extracted from the databases. Univariate and multivariate logistic regression models identified independent predictors of mortality and bacterial infection. Kaplan–Meier and Cox regression analyses evaluated survival according to NLR cutoffs. The additive prognostic value of an NLR-defined "immune dysfunction" subscore to standard organ-failure models was also assessed.
Results: Mean age was 57.9 ± 12.2 years, 65.4% were male, and main etiologies included alcohol-related liver disease (57.8%) and MASLD (18.8%). Overall 28-day and 90-day mortality rates were 35.1% and 53.6%, respectively. NLR at ACLF onset was significantly higher in non-survivors than in survivors (median 9 [5–17] vs. 5 [3–9], $p < 0.0001$). In multivariate analysis, NLR independently predicted 28-day mortality (OR 1.02, 95% CI 1.00–1.03, $p = 0.024$) and overall mortality (OR 1.03, 95% CI 1.01–1.05, $p = 0.005$), together with age, MELD score, albumin, acute alcohol-associated hepatitis, and bacterial infection. In Cox regression, NLR remained an independent predictor of death (HR 1.01, 95% CI 1.01–1.02, $p < 0.001$). Incorporating an NLR-defined immune dysfunction marker into standard organ-failure models improved prognostic accuracy (AUC 0.68 vs. 0.65; $p = 0.017$). At ACLF development, 58% of patients presented with bacterial infection, and higher NLR values were consistently associated with infection ($p < 0.01$). In multivariable analysis, only NLR and C-reactive protein independently predicted early infection, highlighting their value in identifying high-risk patients.
Conclusion: Elevated NLR independently predicts mortality and infection risk, and may serve as a simple and widely available biomarker to refine risk stratification in clinical practice.

Machine learning identifies soluble VAP-1 as a promising biomarker to discriminate hepatic and extrahepatic precipitants of decompensation in cirrhosis

Majda El Hassani[1], Johanna Reißing[1], Oluwatomi Ibidapo-Obe[1], Mick Frissen[1], Haedge Frederic[1], Karsten Große[1], Mohamad Murad[1], Andreas Stallmach[2], Philipp Reuken[2], Theresa Hildegard Wirtz[1], Tony Bruns[1]. *[1]University Hospital RWTH Aachen-Department of Internal Medicine III, Aachen, Germany; [2]University Hospital Jena-Department of Internal Medicine IV, Jena, Germany*
Email: melhassani@ukaachen.de

Background and aims: Systemic inflammation drives complications in decompensated cirrhosis. Differentiating sterile inflammatory triggers like alcohol-associated hepatitis (AH) from bacterial infections such as spontaneous bacterial peritonitis (SBP) remains a clinical challenge. We used a machine-learning approach to identify discriminating biomarkers.
Method: In this retrospective case-control study, serum samples and routine laboratory parameters from 70 patients with decompensated alcohol-related cirrhosis (35 AH, 35 SBP) were analyzed. 43 serum biomarkers reflecting inflammation and matrix turnover were quantified by bead-based immunoassay. A Random Forest model was trained to discriminate AH from SBP.
Results: Random Forest models identified Soluble Vascular Adhesion protein-1 (sVAP-1) as a top-ranking feature for discriminating AH from SBP, both in combination with and independent of routine laboratory parameters. Circulating sVAP-1 levels were substantially higher in AH than in SBP (median 759 vs 401 ng/mL, $p < 0.0001$), largely reflecting shedding from hepatic sinusoids. sVAP-1 positively correlated with Soluble Interleukin-1 Receptor type 1 (sIL-1R1) ($r_s = 0.384$, $p = 0.03$) an indicator of intense IL-1 pathway activation in AH but surprisingly not with markers of hepatocyte damage. Patients with AH and highest sVAP-1 concentrations showed a trend towards worse 28-day transplant-free survival compared to those with lower levels in univariate Cox regression (HR = 2.75; 95% CI 0.88–8.62; $p = 0.08$), which was significant after adjustment of Model for End-Stage Liver Disease (MELD) in multivariable analysis (aHR = 5.18; 95% CI 1.19–22.64; $p = 0.03$).
Conclusion: The endothelial-derived amine-oxidase sVAP-1 is a promising serum biomarker for discriminating sterile inflammation in AH from extrahepatic infectious precipitants in cirrhosis. Its independence from traditional markers of hepatocyte injury and its prognostic relevance warrant validation in larger studies.

SAT-449
Alterations in primary hemostasis in patients with liver cirrhosis and bacterial infection

Florentia Athanasaki[1], Larisa Vasilieva[2], Efrosyni Nomikou[3], Efthimia Pavlou[3], Stavros Formozis[3], Krystalia Dimitriou[1], Dimitra Krystallaki[1], Nikolaos-Nektarios Karamanolis[1], Iliana Mani[1], Flora Kontopidou[1], Emilia Hadziyannis[1], Alexandra Alexopoulou[1]. *[1]2nd Department of Internal Medicine and Research Laboratory, Medical School, Hippokration General Hospital, National & Kapodistrian University of Athens, Athens, Greece; [2]Department of Gastroenterology, Alexandra General Hospital, 11528 Athens, Athens, Greece; [3]Blood Bank and Haemophilia Unit, Hippokration General Hospital of Athens, Athens, Greece*

Background and aims: Reduced platelet (PLT) aggregation has been reported in liver cirrhosis (LC) in comparison with healthy controls. The aim was to assess the alterations and the prognostic role of PLT aggregation and von Willebrand factor (vWF)-related parameters in bacterial infection (BI) superimposed on LC.
Method: The alterations of PLT aggregation by thromboelastography (TEG) 6S PLT mapping assay as well as vWF antigen (WF:Ag), vWF activity (vWF Ristocetin cofactor-vWF:RCo) and FVIII levels were studied in patients with decompensated cirrhosis and BI (DC+BI), stable cirrhosis (SC) and those with infection without LC (Control group). The prognostic value of PLT aggregation was explored in the DC+BI group.
Results: 71 patients were enrolled in DC+BI, 42 in SC and 20 in the Control group. Patients in DC+BI had significantly reduced PLT aggregation in response to Adenosine Diphosphate (ADP) compared to those in SC ($p = 0.029$). Significant elevated levels of wWF:Ag%, wWF:RCo% and FVIII counterbalanced the reduced levels of PLT aggregation ($p < 0.001$, $p < 0.001$ and $p = 0.017$, respectively). Patients in DC+BI and SC (cirrhosis groups) had significantly reduced PLT aggregative response to Arachidonic Acid (AA) compared to Control group ($p = 0.003$ and 0.005, respectively). Within the DC+BI group, those with organ failures [sepsis, Acute Kidney Injury (AKI) or acute-on-chronic liver failure (ACLF)] showed lower values of PLT aggregation (ADP) rate ($p = 0.001$, $p < 0.001$, $p < 0.001$, respectively) vs those without. Moreover, wWF:Ag and wWF:RCo levels were higher in patients with AKI than in those without ($p = 0.009$, $p = 0.004$, respectively), while the same parameters along with FVIII were higher in patients with ACLF than in those with acute decompensation (AD) ($p = 0.003$, $p = 0.017$ and $p = 0.031$, respectively). In the survival analysis of the DC+BI group, non-survivors demonstrated reduced PLT aggregation (ADP), which showed high accuracy in predicting mortality (AUROC = 0.851). PLT aggregation (ADP) less than 70.9% *was* independently associated with mortality [HR 6.536 (95%CI 1.296–32.962), $p = 0.023$] after adjustment for cofactors.
Conclusion: ADP-induced PLT aggregation is reduced in liver cirrhosis with infection in a stepwise manner according to the severity of infection. It also plays a prognostic role as it is associated with 30-day mortality. wWF:Ag and wWF:RCo values are elevated compensating PLT hypo-responsiveness. AA-induced PLT aggregation reduction is identified in cirrhosis groups.

SAT-450

Incidence and associated factors of severe chronic kidney disease after liver transplantation in patients with acute-on-chronic liver failure

Anea Augé[1], Hélène Barraud[1], Pauline Houssel-Debry[2], Valentin Coirier[2], Isaure Breteau[1], Eric Levesque[1], Edouard Bardou-Jacquet[2], Adrian Camino[1], Cyprien Gayat[1], Louis Dalteroche[1], Coralie Fleurent[1], Sébastien L'Hermite[2], Philippe Gatault[1], Florent Artru[2], Laure Elkrief[1]. [1]*Hospital Center of Tours, Tours, France;* [2]*Hospital Center of Rennes, Rennes, France*
Email: aneauge@laposte.net

Background and aims: Liver transplantation (LT) is increasingly performed in patients with severe acute-on-chronic liver failure (ACLF), with adequate short- and long-term survival. However, post-LT renal dysfunction is a major concern, particularly in ACLF patients with severe renal impairment at LT. Post-LT renal outcomes in this population remain poorly characterized. We aimed to assess the incidence, determinants and prognostic impact of severe chronic kidney disease after LT in patients with severe ACLF.
Method: We conducted a retrospective cohort study including all patients with severe ACLF (grade 2 or 3) who underwent LT between 2011 and 2021 in two French tertiary centers. The primary endpoint was the incidence of severe chronic kidney disease (CKD) beyond 6 months after transplantation, defined by an estimated glomerular filtration rate <30 mL/min/1.73 m^2, need for renal replacement therapy (RRT) or kidney transplantation. Cumulative incidence was estimated using competing-risk methods with death as a competing event. Factors associated with severe post-transplant CKD were assessed using Fine and Gray subdistribution hazard (sHR) models.
Results: We included 222 patients (median age 57 years, 72% men, median MELD score 36), of whom 20% had diabetes and 14% required RRT at LT. Among the 196 patients (88%) alive at 6 months, 25 (13%) developed severe CKD and 22 (11%) died without reaching the primary endpoint during a median follow-up of 60 months. The cumulative incidence of severe CKD was 6% at 1 year, 9% at 3 years and 13% at 5 years, with no difference between ACLF grade 2 and 3. Diabetes (sHR 2.7, $p = 0.006$) and RRT at LT (sHR 2.8, $p = 0.042$) were independently associated with severe CKD, whereas basiliximab induction ($n = 95$) was protective (sHR 0.33, $p = 0.02$). Severe CKD was associated with increased risks of subsequent mortality (HR 2.3, $p = 0.04$), infections (HR 2.2, $p = 0.006$) and major adverse cardiovascular events (MACE) (HR 7.7, $p < 0.001$).
Conclusion: In this large two-center cohort of patients transplanted for severe ACLF, severe CKD remained relatively infrequent at 5 years, but was associated with a marked increase in long-term mortality, infectious complications and MACE. These findings underscore the central role of post-transplant renal dysfunction in long-term outcomes and support early identification of high-risk patients and implementation of targeted nephroprotective strategies, including basiliximab-based induction therapy.

SAT-451

Validation of consensus liver failure cut offs to predict 30-day mortality in a nationwide inpatient cirrhosis cohort

Scott Silvey[1], Ohm Patel[2], Nilang Patel[1], Jasmohan Bajaj[1]. [1]*Virginia Commonwealth University, Richmond, United States;* [2]*Richmond Va Medical Center, Richmond, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Acute-on-chronic liver failure (ACLF) harmonization is difficult & varying liver failure (LF) cutpoints are proposed. A recent study based on the CLEARED consortium that was put into a multi-stakeholder consensus proposed serum bilirubin >7.5 mg/dL, INR >1.5 with creatinine >1.5 mg/dl, infections & hepatic encephalopathy (HE). Aim: Validate consensus liver failure (LF) definitions in a national cirrhosis cohort.
Method: Cirrhosis inpatients in TriNetX US database from 2009–25 were included. Labs, cirrhosis details & inpatient course were recorded. The primary outcome was 30-day mortality. Prior cut-offs in consensus & CLEARED data (Bilirubin>7.5 mg/dl, creatinine>1.5 mg/dl, INR>1.5 individually or MELD>27 or MELD3.0 > 28 ± HE grade≥2 & infections) were predictive of mortality. Predictive metrics of these thresholds [sensitivity, specificity, positive (PPV) & negative predictive values (NPV)] were calculated. Finally, decision tree models were fit using threshold combinations (1. Bilirubin+INR+Creatinine 2.Bilirubin +INR+Creatinine+HE+Infection, 3.MELD3.0+HE+Infection, 4.MELD3.0 +HE+Infection) to determine relative importance of each component & model AUCs using XGBoost.
Results: 239,482 cirrhosis inpatients were included (60 yrs, 61% men); 9% died at 30-days. Those who died were older, with higher MELD/MELD 3.0 scores & HE/infections. LF thresholds: Individual: Bilirubin>7.5 (sensitivity:30%,specificity:86%, PPV:18%, NPV:92%), INR>1.5 (sensitivity:62%,specificity:66%, PPV:16%, & NPV:94%, Creatinine>1.5 (sensitivity:53%,specificity:74%, PPV:18%, & NPV:94.9%). MELD>27 (sensitivity:37%,specificity:89%,PPV:25%, & NPV:93.1%) & MELD3.0 > 28 had similar metrics (sensitivity:42%, specificity:87%,PPV:25%, & NPV:94%). Finally, 3 individual labs together had sensitivity of 16.2%, specificity of 96.6%, PPV of 33.4%, & NPV of 91.8%. Decision tree analysis: Best-performing model was the three labs+HE/infection (AUC: 0.72 [0.72–0.73]), where creatinine had the highest relative importance (45.0%), then INR (40.3%), bilirubin (9.6%), infection (4.3%), and HE (<1.0%). This was better

than AUCs of individual labs (0.70), MELD+HE/infection (0.68) & MELD3.0+HE/infection(0.69).
Conclusion: Using a threshold of INR>1.5, Bilirubin>7.5 mg/dl & creatinine>1.5 mg/dl at baseline was associated with high inpatient mortality combined with HE and infection in a national cohort of inpatients with cirrhosis. These national data validate prior consensus documents and cohorts, and pave the way for harmonization of ACLF definitions.

SAT-452

Immune failure in ACLF: validation of consensus definitions in two large cohorts of inpatients with cirrhosis

Jasmohan Bajaj[1], Scott Silvey[1], Florence Wong[2], Jacob George[3], Qing Xie[4], Ramazan Idilman[5], Peter Hayes[6], Mario Álvares-da-Silva[7], Aldo Torre[8], Hailemichael Desalegn[9], Mark Topazian[9], Wai-Kay Seto[10], Shiv Kumar Sarin[11], Zhujun Cao[12], Neil Rajoriya[13], Abha Nagral[14], Henok Fisseha[9], Anand Kulkarni[15], Chuanwu Zhu[16], Nabil Debzi[17], Alberto Farias[18], Minghua Su[19], Ashish Goel[20], Sebastián Marciano[21], Robert Livingstone[22], Radha Krishan Dhiman[23], Yanhang Gao[24], René Malé Velazquez[25], Coskun Ozer Demirtas[26], Yongfang Jiang[27], Jose Antonio Velarde-Ruiz Velasco[28], Hiang Keat Tan[29], Caiyan Zhao[30], Maria Sarai González-Huezo[31], Sumeet Asrani[32], Lei Wang[33], Mingqin Lu[34], Matheus Truccolo Michalczuk[35], Zeki Karasu[36], Jacqueline Cordova-Gallardo[37], Cameron Gofton[38], Michael Gounder[39], Jawaid Shaw[1], Xin Zheng[40], Aloysious Aravinthan[41], Ruveena Bhavani[42], Kessarin Thanapirom[43], Dinesh Jothimani[44], Sevda Aghayeva[45], Dinc Dincer[46], Shalimar Shalimar[47], Bin Xu[48], Minghua Lin[49], Xiaoping Wu[50], Chenghai Liu[51], Yan Yue James Fung[52], Helena Katchman[53], Gustavo Pereira[54], Mohamed El Kassas[55], Marie Jeanne Lohoues[56], Dominik Bettinger[57], Hanna Aberra[58], Paul J. Email: jasmohan.bajaj@vcuhealth.org

Background and aims: A recent global consensus on cirrhosis organ failures proposed "immune failure" (IF: SBP, bacteremia, Vibrio, fungal infections and sepsis) and recommended prospective validation. Aim: Validate the impact of IF on 30-day mortality.
Method: We used CLEARED Consortium and Veterans Corporate Data Warehouse (VA-CDW). CLEARED includes cirrhosis inpatients recruited globally where cirrhosis details, country income (high/upper-mid/low income HIC/UMIC/LIC), inpatient course, and infections were recorded. Concurrent VA-CDW data from 2020–24 with data from all Veteran cirrhosis inpatients using validated ICD10 codes was utilized. Patients were divided into IF, non-IF-infections and neither. Logistic regression for 30-day mortality was performed across both cohorts.
Results: CLEARED: 6505 patients (56 years, 64% men) of whom 17% had IF, 17% no-IF infection and 66% neither were included. Highest mortality rate was in IF (38%) versus no-IF-infection (23%) and neither (13%, $p < 0.001$). IF patients had worse cirrhosis severity, comorbidities, and were highest in LICs. Multi-variable regression: IF linked with higher mortality vs neither (OR 2.21:1.83–2.66) and non-IF-infection (OR 2.04:1.06–2.58;both $p < 0.001$) with not being in HIC (LIC: OR-2.34/UMIC:1.7,$p < 0.001$), older age, cirrhosis complications, higher MELD-Na and WBC count. LT listing was protective. VA-CDW: 28,760 patients (68 yrs, 96% men) of whom 13% had IF, 13% and 74% neither. Highest mortality rate was in IF (30%) then no-IF-infections (12%) and neither (8%, $p < 0.001$). Multi-variable regression: IF still showed higher mortality vs neither (OR-2.37:2.13–2.62), and no-IF-infection (OR-2.25:1.96–2.58) both $p < 0.001$; other variables linked with mortality were age, cirrhosis complications, MELD-Na and higher WBC.
Conclusion: Immune failure defined in a recent consensus as presence of SBP, bacteremia, fungal infections and sepsis were linked with high 30-day mortality as compared to other infections in two large independent inpatient cirrhosis cohorts.

SAT-453

Right ventricle- pulmonary artery uncoupling in critically ill decompensated chronic liver disease patients: an exploratory observational stud

Aniruddha Banerjee[1], Deepak Tempe[1], Rakhi Maiwall[2]. [1]*Department of Anaesthesia and Critical Care, Institute of Liver and Biliary Sciences, Delhi, India;* [2]*Department of Hepatology, Institute of Liver and Biliary Sciences, Delhi, India*
Email: banerjeeaniruddha194@gmail.com

Background and aims: Right ventricle-pulmonary artery (RV-PA) uncoupling, a state of right ventricular (RV) dysfunction relative to its afterload, is a known predictor of mortality in various critical illnesses. However, its prevalence and prognostic significance in critically ill patients with decompensated chronic liver disease (CLD) are unknown. This study aimed to determine the prevalence of RV-PA uncoupling in this population and evaluate its association with disease severity and clinical outcomes.
Method: This prospective observational study was conducted in the intensive care unit (ICU) of a tertiary liver institute. We enrolled 250 adult patients with decompensated CLD requiring ICU care. A comprehensive transthoracic echocardiogram was performed within 48 hours of admission. RV-PA uncoupling was defined by a tricuspid annular plane systolic excursion to pulmonary artery systolic pressure (TAPSE/PASP) ratio of ≤0.33 mm/mmHg. Clinical, hemodynamic, and laboratory data were collected, and patients were followed for 28-days in the ICU.
Results: The prevalence of RV-PA uncoupling was 26.8% (67 out of 250 patients). Patients with uncoupling had significantly higher liver disease severity scores on admission (mean model for end-stage liver disease – sodium score: 36.0 ± 8.3 vs 31.0 ± 9.0, $p < 0.01$). The uncoupling group demonstrated greater hemodynamic instability, requiring significantly higher vasopressor support ($p < 0.01$), and had more severe respiratory failure, evidenced by a lower arterial oxygen tension to fraction of inspired oxygen ratio (PF ratio) ($p \leq 0.02$). Persistently elevated serum lactate levels were also significantly associated with uncoupling ($p < 0.01$). Kaplan-Meier survival analysis revealed significanty ($p < 0.01$) shorter survival span in uncoupling group (8.19 vs 17.05 days).
Conclusion: RV-PA uncoupling is common in critically ill patients with decompensated CLD and is a powerful, independent predictor of early mortality. It serves as an integrated marker of advanced liver disease severity and systemic circulatory collapse. The non-invasive bedside assessment of the TAPSE/PASP ratio is a valuable tool for risk stratification, and the identification of uncoupling should prompt aggressive, RV-protective management strategies in this high-risk population.

SAT-457

Beta-blockers for prevention of further decompensation and associated renal outcomes

Brendan Brew[1], Angus Jeffrey[1,2,3], Adam Testro[1], Marie Sinclair[1,4], Penelope Hey[1], Karl Vaz[1], Avik Majumdar[1,4]. [1]*Austin Hospital, Heidelberg, Australia;* [2]*Sir Charles Gairdner Hospital, Nedlands, Australia;* [3]*The University of Western Australia, Crawley, Australia;* [4]*The University of Melbourne, Parkville, Australia*
Email: brewy4@gmail.com

Background and aims: Non-selective beta blockers (NSBBs) are indicated for prevention of decompensation in cirrhosis. This study evaluated the impact of NSBBs initiated after a first decompensating event (ascites, hepatic encephalopathy [HE], or variceal bleeding) on further decompensation, renal outcomes, and mortality.
Method: This retrospective cohort study included adults with cirrhosis admitted with a first decompensation at a single tertiary liver transplant centre in Australia between January 2015 and March 2025. Patients were followed until further decompensation requiring hospitalisation, death, or liver transplant (LT). The primary outcome was further decompensation. Secondary outcomes were liver-related death (LRD) and LT, and acute kidney injury (AKI). Competing risks analysis was performed.
Results: A total of 310 patients were followed for a median of 21.3 months (IQR 6.4–45.5) of which 112 (36.1%) received NSBB therapy (87.5% carvedilol, 12.5% propranolol), of whom 66 (58.9%) achieved target dose. Median age was 61 years (49–69), median MELD 16 (12–20), and a majority 55.4% had alcohol-related liver disease. Median time from first decompensation to NSBB initiation was 2.5 months (IQR –0.04–34.2); three patients were on NSBBs prior to admission. In those who received NSBB therapy compared to not, the cumulative incidence of further decompensation after 5 years was lower in patients who had first decompensation with ascites (53% vs 74%, $p = 0.023$) and variceal bleeding (52% vs 81%, $p = 0.013$). There was no difference seen in HE (67% vs 73%, $p = 0.602$). Cumulative incidence of LRD and LT was also reduced after ascites-related first decompensation (27% vs 49%, $p = 0.007$), but not after variceal bleeding (23% vs 48%, $p = 0.102$) or HE (28% vs 58%, $p = 0.058$). Median creatinine before NSBB initiation was 69 µmol/L (57–86.5) versus 71 µmol/L (59.5–95.5) at follow-up ($p = 0.96$), measured after a median of 31.5 days (IQR 15–116). Only nine AKI events (8%) occurred.
Conclusion: NSBB therapy following a first decompensation with ascites or variceal bleeding was associated with reduced further decompensation and improved clinical outcomes, without adverse renal effects. These findings demonstrate the safety and effectiveness of NSBBs in patients with decompensated cirrhosis, supporting their use in this group.

Email: josune.cabello@ukmuenster.de

Background and aims: Non-selective beta-blockers (NSBB) are commonly used in in patients with chronic liver disease as primary or secondary prophylaxis of variceal bleeding. However, their role on the overall survival of CLD at different disease stages is still under discussion.
Method: This study analyzed 3,622 patients from six multicentre cohorts to evaluate the impact of non-selective beta-blocker (NSBB) use during hospital admissions on short- and long-term survival across CLD stages: non-cirrhotic CLD, stable decompensated cirrhosis (SDC), unstable decompensated cirrhosis (UDC), pre–acute-on-chronic liver failure (pre-ACLF), and ACLF. To account for confounding and healthy survivor bias, propensity score matching 1:1 was applied. Overall mortality was analysed using Fine & Gray competing risk regression with liver transplantation as a competing event. In a subgroup from MICROBPREDICT cohort, a metabolomic analysis was

performed, including manual integration and peak quality assessments.
Results: NSBB use (n = 741; 35.8%) consistently reduced mortality in all CLD stages. ACLF patients profited notably from NSBB with a lower 28-day mortality (19.8% vs. 35.2%, p = 0.02). Pre-ACLF patients also showed reduced short- and long-term mortality (28-day: 19.8% vs. 21.7%, p < 0.05; 1-year: 57.4% vs. 71.4%, p = 0.04). Additionally, NSBB use was independently related to lower overall mortality in all patients (OR: 0.76, 95% CI: 0.60–0.97, p = 0.025), and in pre-ACLF patients when adjusted by other confounders. After propensity score matching, cumulative incidence curves confirmed a significant reduction in mortality for overall cohort, ACLF and pre-ACLF (Gray test p < 0.05). In a metabolomic subgroup analysis, propranolol and carvedilol metabolites were detected in various biosamples, with strongest signals in urine. Metabolites were not detected in all patients with NSBB treatment in the medical history. Patients in which NSBB metabolites were detected showed slightly lower mortality compared to those without detected metabolites, but the difference was not statistically significant.
Conclusion: Patients who received NSBB treatment showed improved survival outcomes, even in the most severe stages, like pre-ACLF or ACLF. However, our metabolomic analysis raises some doubts regarding patient adherence to NSBB therapy. Inadequate compliance may reduce the effectiveness of NSBBs.

SAT-459
Impact of cirrhosis on short- and mid-term outcomes of critically ill patients requiring invasive mechanical ventilation
Gemma Cerezal-Gómez[1,2], Alfonso Muriel[3,4], Mariano Gómez-Rubio[1,5], Fernando Frutos-Vivar[1,6], Óscar Peñuelas[1,5,6]. [1]*Hospital Universitario de Getafe, Getafe, Spain;* [2]*Universidad de Valladolid- Faculty of Medicine, Valladolid, Spain;* [3]*Centro de Investigación en Red de Epidemiología y Salud Pública, Madrid, Spain;* [4]*Universidad de Alcalá de Henares, Madrid, Spain;* [5]*Universidad Europea de Madrid- Faculty of Biomedical and Health Sciences, Villaviciosa de Odón, Spain;* [6]*Centro de Investigación en Red de Enfermedades Respiratorias, CIBERES, Madrid, Spain*
Email: gemmacerezal@gmail.com

Background and aims: Cirrhosis is a significant cause of morbidity and mortality worldwide, with up to 10% of patients requiring admission to an intensive care unit (ICU). Although invasive mechanical ventilation (IMV) has traditionally been associated with a very poor prognosis in this population, contemporary data suggest improving outcomes. The aim of this study was to evaluate clinical practice and outcomes in critically ill patients with cirrhosis requiring IMV.
Method: We performed a subgroup analysis of patients with pre-existing cirrhosis included in a prospective, multicenter, international cohort study enrolling consecutive adult patients admitted to 457 ICUs in 42 countries between October 2022 and June 2024 who required IMV for more than 12 hours (Global Burden of Mechanical Ventilation, GEMINI study). Demographic and clinical variables were collected at baseline, daily during the first ICU week, and until ICU discharge. Outcomes included ICU, in-hospital, and 6-month mortality. Multivariable logistic regression model was applied to evaluate the effect of cirrhosis on mortality and is expressed as odds ratio (OR) with 95% confidence interval (CI).
Results: Of 7,239 patients, 363 (5%) had cirrhosis. Compared with non-cirrhotic patients, those with cirrhosis were younger (59 ± 12 vs. 61 ± 18 years, p = 0.01) and predominantly male (75% vs. 62%, p < 0.001). At ICU admission, they presented greater disease severity, including a higher incidence of sepsis (25.6% vs. 16.5%, p < 0.001) and organ failure. No differences were observed in ICU or hospital length of stay. Mortality was significantly higher in patients with cirrhosis: ICU mortality 42.2% vs. 31.7%, in-hospital mortality 49.5% vs. 37.1%, and 6-month mortality 63.9% vs. 40.3% (all p < 0.001). After adjustment, cirrhosis was independently associated with increased ICU mortality (OR 1.64; 95% CI 1.35–2.08; p < 0.001) and in-hospital mortality (OR 1.67; 95% CI 1.32–2.11; p < 0.001), but not with 6-month mortality (OR 1.25; 95% CI 0.91–1.72; p = 0.164).
Conclusion: In this large cohort of mechanically ventilated ICU patients, cirrhosis was independently associated with increased ICU and in-hospital mortality, while no independent association with 6-month mortality was observed. These findings highlight the sustained prognostic impact of chronic liver disease beyond ICU discharge and support the need for integrated hepatology–ICU management and post-ICU follow-up.

SAT-460
Clinical benefit of artificial liver support system on 90-day survival in patients with acute-on-chronic liver failure
Xiao Che[1], Jingran Jiao[2], Shuang Li[3], Rui Zhao[1], Manman Xu[1], Yu Chen[1]. [1]*Fourth Department of Liver Disease (Difficult & Complicated Liver Diseases and Artificial Liver Center), Beijing You'an Hospital, Capital Medical University, Beijing Key Laboratory of Liver Regeneration and Artificial Liver Transformation Research, Beijing You'an Hospital, Capital Medical University, Beijing, China;* [2]*Beijing Key Laboratory of Liver Regeneration and Artificial Liver Transformation Research, Beijing You'an Hospital, Capital Medical University, Beijing, China;* [3]*Blood Purification Center, Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: chechexx@163.com

Background and aims: Acute-on-chronic liver failure (ACLF) is a clinical syndrome with high mortality. This study evaluated the effect of artificial liver support systems (ALSS; dual plasma molecular adsorption system combined with plasma exchange, DPMAS + PE) on 90-day transplant-free survival in patients with ACLF.
Method: Consecutive hospitalized patients with ACLF who received ALSS or standard medical therapy (SMT) were prospectively enrolled at Beijing You'an Hospital, Capital Medical University, between January 2022 and June 2025. ALSS and SMT patients were compared using 1:1 propensity score matching (PSM) based on key baseline covariates. Survival outcomes were assessed using Kaplan-Meier analysis and multivariable Cox regression.
Results: A total of 624 patients were included (ALSS group, n = 235; SMT group, n = 390). After PSM, 235 pairs were analyzed. The 90-day survival was higher in the ALSS group than in the SMT group (58.3% vs. 43.4%, $P < 0.05$). Survival benefit was observed in patients with ACLF 0–1 (64.5% vs. 47.6%, $P < 0.05$) and in those with MELD-Na ≥25 (53.3% vs. 28.6%, $P < 0.05$), but not in ACLF grade 2–3 or MELD-Na < 25 (In patients with 15 ≤ MELD-Na <25, survival curves intersected). In interaction analysis, patients with ACLF 0–1 and 15 ≤ MELD-Na <25, showed improved 90-day survival with ALSS (59.8% vs. 43.0%, $P < 0.05$) and independently reduced 90-day mortality (HR 0.56, 95% CI 0.37–0.89; $P < 0.05$). Older age (HR 1.02 per year; $P < 0.05$) and decompensated cirrhosis (HR 1.97, $P < 0.05$) were associated with increased mortality.
Conclusion: ALSS conferred a survival benefit in patients with EASL-CLIF ACLF 0–1 and intermediate MELD-Na scores.

Dynamic innate immune trajectories assessed by SeptiLoop identify immunoparalysis associated with nosocomial infection in decompensated cirrhosis
Juan Manuel Diaz[1,2,3], José Alcaraz[4], Richie Alexander Inge-Cox[1,2,3], Natalia Jimenez-Esquivel[1], Sandra Blaya[1], Ignacio Retta[1], Loredana Cosmina Sabau[4], Juliana Zapatero[1], Enrique Hernández Jiménez[5], Eduard Guerrero[5], Queralt Caus-Capdevila[5], Vanessa Roman[5], Joan Clària[3,6], Javier Fernández[1,3]. and Molecular Genetics, Hospital Clínic, Barcelona, Spain; [5]Loop Dx, StartUB! - University of Barcelona, Barcelona, Spain; [6]Biochemistry and Molecular Genetics Service, Hospital Clínic, IDIBAPS, University of Barcelona and CIBERehd, Barcelona, Spain
Email: juanmanuel.diaz@efclif.com

Background and aims: Patients with decompensated cirrhosis and acute-on-chronic liver failure (ACLF) develop immune dysfunction that increases susceptibility to nosocomial infections. Immunoparalysis, a key driver of infection risk in this setting, cannot currently be monitored dynamically at the bedside. SeptiLoop, a rapid in vitro assay of stimulated tumor necrosis factor (TNF) alpha production, may allow assessment of innate immune competence. We aimed to characterize longitudinal SeptiLoop trajectories in acute decompensation (AD) and ACLF and to evaluate whether early changes are associated with nosocomial infection.
Method: Prospective observational study including consecutive patients nonelectively hospitalized for AD of cirrhosis and admitted to the intensive care unit or regular ward at Hospital Clínic of Barcelona (September 2024–November 2025). Patients were classified as AD or ACLF at baseline according to EASL-CLIF criteria. SeptiLoop was measured at baseline and on days 1, 3, 7, 15 and 28 (404 tests in 91 patients). Delta SeptiLoop 0–7 was defined as the change from day 0 to day 7. Longitudinal trajectories were analyzed using mixed-effects models. Fine–Gray competing-risk analyses evaluated the association between delta SeptiLoop 0–7 and nosocomial infection, adjusted for ACLF and MELD-Na.
Results: Baseline SeptiLoop measurements showed no association with disease severity, infection or mortality. In contrast, trajectories differed markedly: AD showed an upward pattern consistent with immune recovery, whereas ACLF showed persistently low values and a progressive decline (days 3 to 7; $p < 0.001$). Patients who developed nosocomial infection had a downward SeptiLoop trajectory, whereas those without infection showed an increase (group by time $p < 0.01$). An early decline in delta SeptiLoop 0–7 was associated with a higher risk of nosocomial infection (sHR 0.45, 95% CI 0.23–0.92; $p = 0.028$). SeptiLoop did not independently predict 28-day mortality, which was driven by ACLF.
Conclusion: Baseline SeptiLoop measurements have limited prognostic value, but dynamic trajectories identify a clinically relevant immune phenotype. An early decline reflects functional immunoparalysis and is associated with an increased risk of nosocomial infection, supporting the use of SeptiLoop for immune monitoring in AD and ACLF.

SAT-464

Bilirubin trajectory phenotypes in patients with cirrhosis admitted to intensive care: an externally validated joint latent class mixed model with implications for future definitions of acute-on-chronic liver failure

Thomas Dixon[1], Tasneem Pirani[1], William Bernal[1], Mark Mcphail[1].
[1]*Liver Intensive Therapy Unit, King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: thomasdixon@nhs.net

Background and aims: Patients with cirrhosis admitted to the Intensive Care Unit (ICU) show heterogeneous organ failure trajectories. In acute-on-chronic liver failure (ACLF), bilirubin is variably expressed, and high bilirubin trajectories may capture distinct phenotypes with different survival. We aimed to identify early, reproducible, outcome-relevant bilirubin trajectory phenotypes during the first week of ICU admission using latent class mixed modelling.
Method: We analysed ICU patients with cirrhosis at our institution who had ≥2 bilirubin results during the first 7 days of ICU admission (n = 870). To identify latent trajectories in bilirubin levels while accounting for informative dropout, we fitted a joint latent class mixed model. We evaluated 2–5 class solutions, prioritising model fit, clinical interpretability, and bootstrap stability for model selection. The three-class model was selected and applied to an external MIMIC-IV cohort.
Results: The derivation cohort comprised 870 patients (61.0% male, 37.9% in-hospital mortality). A three-class solution was optimal, yielding three bilirubin trajectories: low-stable, high-improving, and high-worsening. Assignment certainty was high (mean posterior probability ≥0.87). In-hospital mortality was 32.5% (233/717) for low-stable, 51.1% (24/47) for high-improving, and 68.9% (73/106) for high-worsening. At ICU admission, higher bilirubin trajectories were associated with greater organ failure burden: the mean number of organ failures (SOFA subscore ≥3 per organ component) was higher in the high-worsening (2.3) and high-improving (2.2) classes compared with the low-stable class (1.6).
In external validation (n = 3,264), in-hospital mortality was 18.3% (545/2,971) for low-stable, 35.7% (10/28) for high-improving, and 57.7% (153/265) for high-worsening; the preserved mortality gradient and high assignment certainty (mean posterior probability ≥0.89) support reproducibility of these trajectory phenotypes across cohorts.
Conclusion: Longitudinal bilirubin phenotyping yields reproducible, survival-linked subgroups and is associated with organ failure burden. This supports trajectory-informed interpretation of routine bilirubin measurements for risk stratification in critically ill patients with cirrhosis. These findings suggest that significant hyperbilirubinaemia and/or early bilirubin dynamics warrant consideration as potential eligibility criteria in future iterations of ACLF definitions.

SAT-465

Assessing the effectiveness of an educational intervention to improve BASL bundle compliance and optimise care in the first 24 hours for patients with acute decompensation of cirrhosis in a district general hospital

Osama Elshabasy[1], Emily Hebden[1], Yousuf Ismail[1], Patrick Robinson[1].
[1]*Yeovil District Hospital, Yeovil, United Kingdom*
Email: Osama.elshabasy@gmail.com

Background and aims: Morbidity and mortality from chronic liver disease in the UK have risen markedly over the past 50 years. The National Confidential Enquiry into Patient Outcome and Death (NCEPOD) reported that fewer than 50% of patients admitted with alcohol-related liver disease received good-quality inpatient care (1). To address this, the British Association for the Study of the Liver (BASL) developed a care bundle to standardise management within the first 24 hours for patients with decompensated cirrhosis (2). However, uptake remains low, with bundle use reported in only 11.4% of admissions (2). This study aimed to assess baseline BASL bundle compliance and evaluate the impact of a targeted educational intervention in a district general hospital.
Method: An audit of patients admitted with DC was undertaken to evaluate adherence to key elements of the BASL care bundle, including early diagnostic ascitic tap and timely recognition and management of sepsis. Baseline compliance was assessed retrospectively over four months, during which no patients had a complete bundle performed.The educational intervention was targeted at resident doctors most frequently responsible for clerking patients with DC. Post-intervention compliance was subsequently reassessed over a two month period.
Results: Following the educational intervention, overall compliance improved, with 45% of patients admitted with decompensated cirrhosis receiving the full BASL care bundle. Improvements were noted in timely diagnostic ascitic tap on admission. Some areas which included requesting cultures and CXR continued to show poor adherence.
Conclusion: Baseline compliance with the BASL care bundle was poor, consistent with findings from national audits. A focused, low-cost educational intervention targeting resident doctors led to a clinically meaningful improvement in bundle compliance. This demonstrates that teaching resident doctors can effectively improve

early care for cirrhotic patients. Ongoing educational initiatives and further streamlining of bundle implementation is required to sustain and improve compliance.

Email: kymentie.ferdinande@studenti.unipd.it

Background and aims: Patients with acute-on-chronic liver failure (ACLF) are at high risk of non-portal hypertensive (NPH) bleeding. Although rotational thromboelastometry (ROTEM) assesses whole-blood haemostasis, interpretation is limited by isolated parameters. The area under the ROTEM curve (AUC), integrating clot kinetics and strength, is no longer routinely reported. We aimed to develop a reproducible method to estimate AUC INTEM/EXTEM and to evaluate its predictive value for major NPH bleeding in ACLF.
Method: In a prospectively followed multicentre ACLF cohort (n = 95), INTEM and EXTEM AUCs were estimated using AUC = 176.47–0.579×(time to MCF)-0.346 × CT+0.802 × CFT+ 100.12 × MCF. Agreement with device-reported AUCs was assessed using Lin's concordance correlation coefficient (CCC). NPH bleeding was defined as acute spontaneous or post-procedural bleeding, excluding PH–related bleeding. Discrimination was assessed by ROC analysis with Youden-derived cut-offs. Independent predictors were identified using MELD-adjusted LASSO-penalised logistic regression including bacterial infection, acute kidney injury, platelet count and fibrinogen.
Results: Patients were predominantly male (62%), with alcohol-related liver disease as the main aetiology (61%) and a median MELD of 25. 30/95 patients (31.6%) developed major NPH bleeding after a median of 13 days, most commonly mucosal, procedure-related, soft-tissue or intracranial bleeding. Estimated AUCs showed excellent agreement with device-reported values (INTEM CCC 0.952; EXTEM CCC 0.955; $p < 0.001$). AUC INTEM/EXTEM and a combined score integrating AUC INTEM/EXTEM and MCF FIBTEM decreased stepwise with increasing ACLF severity, with significant differences between ACLF grade I and III. Discrimination for NPH bleeding was good for AUC INTEM (AUROC 0.803; cut-off 3597; sensitivity 0.70, specificity 0.82; $p < 0.001$), AUC EXTEM (AUROC 0.787; $p < 0.001$), MCF FIBTEM (AUROC 0.763; $p < 0.001$), and the combined score (AUROC 0.802; cut-off 7239; sensitivity 0.70, specificity 0.83; $p < 0.001$). In MELD-adjusted models, AUC INTEM below the cut-off independently predicted bleeding (λ.min OR 4.82, 95% CI 1.67–13.17; λ.1se OR 1.95, 95% CI 1.03–4.81), as did the combined AUC score (λ.min OR 5.38, 95% CI 1.91–15.24; λ.1se OR 2.16, 95% CI 1.04–5.33).
Conclusion: An extrapolation-based method accurately estimates ROTEM-derived AUCs in ACLF; low AUC INTEM and the composite score independently predict major NPH bleeding. Prospective validation is needed to define actionable thresholds.

SAT-467-YI

Geographical variation in rifaximin use, gut microbiota composition, and outcomes in european patients with decompensated cirrhosis

Email: s.e.fischer@lumc.nl

Background and aims: Cirrhosis causes substantial morbidity and mortality, with outcomes potentially varying across European regions due to differences in healthcare systems, demographics, and treatment strategies. This study investigated the association between geographical region and the clinical phenotype among hospitalized European patients with acutely decompensated cirrhosis (AD). As a secondary objective, regional variation in gut microbiota composition and its association with mortality was investigated.
Method: Clinical data on disease phenotype and mortality from 2,377 hospitalized patients with AD enrolled in three European prospective cohorts (CANONIC, PREDICT, FCRB) across 16 countries were collected. Patients were grouped into Northern/Western (n = 962, N/W), Eastern (n = 181, E), and Southern Europe (n = 1234, S). Disease phenotypes were classified as acute-on-chronic liver failure (ACLF, at admission and pre-ACLF combined), unstable decompensated cirrhosis (UDC), and stable decompensated cirrhosis (SDC). In a subcohort of patients with stool samples available (n = 248), gut microbiota composition was assessed by shotgun metagenomic sequencing with taxonomic profiling and multivariable microbiome analyses adjusting for antibiotic (AB) exposure and clinical variables.
Results: Disease phenotype distribution differed between regions, with lower UDC and higher SDC in Eastern Europe ($p < 0.001$). The prevalence of ACLF/pre-ACLF at admission was similar across regions (N/W 30%, E 34%, S 29%; $p = 0.339$). 28- and 90-day mortality did not differ, while 1-year mortality was higher in Eastern Europe (40% vs. 33% N/W and 30% S; $p = 0.035$). Baseline gut microbiota composition differed significantly by region and was strongly influenced by AB exposure. Rifaximin use was highest in Southern Europe (35% vs. 26% N/W and 10% E; $p < 0.001$). Overall microbiota structure was dominated by *Bacteroides*, while Southern Europe showed a distinct shift toward an *Enterococcus*-enriched microbiota. Bacterial infections were more common in Eastern Europe (44% vs. 27% N/W and 28% S; $p = 0.029$). These regional microbiota differences persisted after adjustment for AB use, but were not associated with disease phenotype or mortality.

Conclusion: ACLF prevalence and mortality were largely comparable across European regions in patients with decompensated cirrhosis. Regional variation in gut microbiota composition does not independently determine survival outcomes.

SAT-468

Clinical impact of bacterial infections in acutely decompensated cirrhosis: insights from 4.97 million admissions

Email: yacine.hajji@genfit.com

Background and aims: Acute decompensation (AD) of cirrhosis is defined by an acute development or worsening of ascites, hepatic encephalopathy (HE), and/or variceal bleeding (VB). It is unclear whether bacterial infections (BI) should be considered as an AD event "per se" or a precipitating/aggravating decompensation factor. Using real-world data, we evaluated the impact of BI on patient outcomes either alone or combined with other AD events.

Method: All hospitalizations (hosp) of patients with cirrhosis recorded between April-2016 and February-2025 in Komodo's Healthcare Map US real-world database and associated with at least one AD or BI event were included. Hosp were categorized by types of AD events (ascites, HE, VB) reported regardless of initial or subsequent AD event. BI were considered community-acquired if they were reported within 48 h after admission, and nosocomial if they occurred thereafter. Length of hosp stay (LOS), AD re-hospitalization rates, and mortality within 28/90/180d were compared between hosp with or without BI using fold changes (FC).

Results: A total of 4,974,364 hosp from 1,620,164 patients were extracted (male: 58%, mean age at admission: 63 ± 13 years, median LOS: 6 days [IQR: 4, 10]). Presence of ascites was reported in 46% of hosp, HE in 24%, and VB in 11%. A total of 40% of hosp reported community-acquired infections (CAI) without AD, 40% had AD without CAI, and 20% had both CAI and AD. Among hosp with ascites, HE, or VB, CAI was observed in 36%, 37%, and 24% of cases, respectively. VB and CAI alone showed the lowest 28/90/180d mortality (2/5/8% and 4/8/11%, respectively) while HE and ascites alone had higher mortality rates (4/10/15% and 5/13/19%, respectively). The 28-d mortality in hosp with VB, HE, or ascites increased when CAI was present (7, 10, 12% respectively). In hosp with at least 1 AD event, the median LOS (4–7 d) and 28-d mortality (2–8%) consistently increased with bacterial infection, either community-acquired or nosocomial (FC ranging 1.4–1.9 and 2.8–3.1 for LOS; 2.3–3.5 and 2.4–4.5 for mortality). Re-hospitalization rates at 28-d (15–35%) were modestly affected by CAI and nosocomial infections with FC ranging 0.9–1.3 and 1.0–1.5 across groups.

Conclusion: While BI alone was associated with low mortality and re-hospitalization rates, infections precipitating or complicating any AD event consistently increased mortality and prolonged LOS. These findings support the view that BI acts mainly as an aggravating factor in decompensated cirrhosis.

SAT-473

Examining the newly proposed consensus organ failure thresholds for acute on chronic liver failure

Jonas Ho[1], Sakktivel Elangovan[1], Jeanette Ng[1], Yan Ling Ong[1], Jessica Tan[1], Eugene Wong[1], Hiang Keat Tan[2], Chanda Ho[2], Marianne De Roza[3], Jason Pik Eu Chang[2], Prema Raj[2], Rahul Kumar[1]. *[1]Changi General Hospital, Singapore, Singapore; [2]Singapore General Hospital, Sinagapore, Singapore; [3]Sengkang General Hospital, Singapore, Singapore*
Email: rahul.kumar@singhealth.com.sg

Background and aims: Recently, efforts have been made to harmonize the heterogeneous definitions of acute-on-chronic liver failure (ACLF). New organ-specific thresholds have been proposed for defining organ failure (OF)[1,2]. These individual cut-offs and their implications for mortality require further exploration. The study aims to examine the specific OF cut-off and its impact on 28- and 90-day mortality.

Method: This prospective study was conducted as part of the multicentre SoLiDaRity collaborative, designed to predict decompensation, ACLF, and mortality in cirrhosis. A total of 396 consecutive hospital admissions for acute decompensation were included in the analysis. OFs, encompassing liver (LF), kidney (KF), circulatory (CF), respiratory (RF), immune (IF), and acute encephalopathy (AE), were defined as per the new criteria[2]. Standard statistical tests, along with Cox regression, were used to assess the risk of death associated with the proposed OF cut-offs.

Results: Majority were male (67.2%), and the mean age was 64.4 ± 11.5 years. Alcohol (43%) and MASLD (30%) were predominant aetiologies. The mortality was 11.1% and 25% at 28 and 90 days. Individually, LF was present in 14.1%, KF in 5.6%, AE in 14.6%, CF in 9.6%, RF in 5.8% and IF in 9.3%. On Cox regression, LF (HR:2.11; 95%CI: 1.07–4.17), KF (HR:5.39; 95%CI: 2.59–11.23), CF (HR:5.87;95%CI:3.13–10.92), and RF (HR: 4.90; 95%CI: 2.35–10.21) were individual predictors of 28-day mortality, but IF (HR: 0.983; 95%CI:0.35–2.74) and AE (HR: 1.29; 95%CI:0.63–2.79) were not. Furthermore, in the multivariable Cox regression (MVA), while KF, CF, and RF were independent predictors of 28-day mortality, LF was not. Similar results were observed for 90-day mortality, except that LF was also an independent predictor in MVA. Although IF did not predict 28- or 90-day mortality, a neutrophil-to-lymphocyte ratio of ≥9 was a predictor

at both time points. Kaplan-Meier analysis showed that the pooled mortality of patients with any OF by the new definition was 19.7% at 28 days and 33.7% at 90 days, compared with 5.6% and 18.7%, respectively, in those without any OF.
Conclusion: The new organ-specific cut-offs stratify mortality, with kidney, circulatory, and respiratory failures as the strongest independent predictors. Immune failure and encephalopathy require further refinement, supporting the prognostic relevance of objective inflammatory markers such as the neutrophil-to-lymphocyte ratio.

Exploring rhabdomyolysis in critically ill decompensated cirrhotic patients – a retrospective analysis of a german transplant centre

Lukas Hofmann[1], Romy Winkler[1], Janett Fischer[1], Florian van Bömmel[1], Sirak Petros[2], Lorenz Weidhase[2], Thomas Berg[1], Jonas Schumacher[1]. *[1]Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany, Leipzig, Germany; [2]Medical ICU, University Hospital Leipzig, Leipzig, Germany, Leipzig, Germany*
Email: jonas.schumacher@medizin.uni-leipzig.de

Background and aims: Rhabdomyolysis, characterized by excessive skeletal muscle breakdown and elevated serum myoglobin levels, is a potentially life-threatening condition frequently complicated by acute kidney injury (AKI). In patients with decompensated liver cirrhosis (dLC), AKI commonly results from hypovolemia or hepatorenal syndrome. Yet the contribution of rhabdomyolysis to renal dysfunction and mortality remains poorly defined.
We aimed to determine the real-world incidence, etiology, and clinical impact of rhabdomyolysis in critically ill patients with dLC.
Method: dLC-patients admitted to the intensive care unit (ICU) between June 2024–May 2025 were included and screened for signs of rhabdomyolysis defined by myoglobin serum levels ≥1000 ng/ml. Clinical and laboratory data were obtained at admission and from rhabdomyolysis-diagnosis for 10 consecutive days. Patients were followed for 90 days.
Results: Among 117 dLC-patients 25 (21.4%) presented with rhabdomyolysis. 28- and 90-Day transplant-free survival rates differed significantly between patients with and without rhabdomyolysis (8/25 (32%) vs 55/92 (59.8%), $p = 0.014$; and 4/25 (16%) vs. 44/92 (47.8%), $p = 0.005$). Outcomes in Statin-associated rhabdomyolysis (SAR) were even worse with transplant-free survival rates of 22.2% and 11.1%, respectively. SAR was the leading cause of rhabdomyolysis (9/25, 36%). Plasma myoglobin levels were significantly higher in SAR compared to non-SAR ($p < 0.001$). Nearly all affected patients 24/25 (96%) presented with acute-on-chronic liver failure, and 22/25 (88%) developed concomitant AKI.
Conclusion: Rhabdomyolysis and specifically SAR might represent an underestimated contributor to AKI and mortality in patients with dLC. Elevated myoglobin levels may serve as a prognostic marker of poor outcome and warrant systematic evaluation in future studies.

SAT-475

Serological responses COVID-19 vaccination: a potential biomarker to predict liver-related complications in patients with compensated advanced liver disease (cACLD)

Email: r.jalan@ucl.ac.uk

Background and aims: Patients with compensated advanced chronic liver disease (cACLD) have dysregulated innate and adaptive immunity, worsening with the stage of the disease. This is referred to as cirrhosis-associated immune dysfunction (CAID) and is characterized by a variety of abnormalities in immune profiles. However, there are no specific biomarkers of CAID that have been validated to be associated with future complications of cACLD. As immune response to vaccines provides a composite perspective on immune function, we hypothesized that serological response to COVID-19 vaccine may serve as a biomarker to identify cACLD patients at risk of developing liver-related complications.
Method: cACLD patients were included from the COBALT study, a prospective, observational cohort study. Participants with liver transplantation (LT) before study inclusion or those without serological or follow-up data were excluded. Serum concentrations of IgG directed against COVID-19 Spike and IgM against COVID-19 S1 receptor binding domain (RBD) were measured at week-7 following vaccination. Participants were followed up after the second vaccination dose for 1-year or until the third vaccine dose. The liver-related complications were evaluated using competing risk analysis, in which LT was treated as a competing event.
Results: A total of 95 cACLD patients were included in this study. The median age was 62 (IQR: 56–69) years, and 67.4% patients were male. Alcohol-associated liver disease (40%) was predominant. Over a

median follow-up time of 151 (IQR: 107–289) days, 16 patients developed liver-related complications, 13 patients received LT, and 8 patients had non-liver-related complications (including 5 COVID-19 infections). The levels of anti-S1-RBD IgM and anti-spike IgG were both comparable between different clinical outcome groups (both p > 0.05). We then used tertiles of vaccine response among the healthy population (n = 41) as the cut-off points of the cACLD populations. cACLD patients with a lower level of anti-S1-RBD IgM developed significantly greater liver-related complications compared to those with medium or high levels (sHR: 0.37, 95%CI: 0.14–0.98, p = 0.042).
Conclusion: Impaired serological response after COVID-19 vaccination was associated with the development of liver-related complications suggesting that serological responses to vaccination could serve as a composite biomarker of immune function to predict future liver-related complications in cACLD patients.

SAT-476

ATANGO organ failure (OF) score performs better than EASL-CLIF, NACSELD and APASL scores for the diagnosis of acute-on-chronic liver failure (ACLF) in the independent COSSH cohort

Email: humeiqian@zju.edu.cn

Background and aims: ACLF is a complex syndrome associated with high short-term mortality, with no agreement between continents on its diagnostic criteria. In order to try and harmonize the definitions, the ATANGO score was developed and validated in over 8000 patients from Europe, Latin America, India and China. In order to determine the comparative value of the ATANGO score, the performance of all models for the diagnosis and prognosis of ACLF was tested in an independent cohort–the Chinese (COSSH) cohort, developed in Hepatitis B patients.
Method: Data from 3,370 hospitalized cirrhosis patients with acute decompensation in the COSSH cohort were analyzed. Five ACLF diagnostic models were compared, including A-TANGO, EASL-CLIF (European), COSSH-ACLF (Chinese), the APASL (Asia), and NACSELD (USA). Prognostic performance was assessed using net reclassification improvement (NRI), C-indices, and integrated discrimination improvement (IDI).
Results: Among 3,370 patients, the A-TANGO and COSSH-ACLF models identified the largest numbers of ACLF patients (1,134 and 1,155), compared with the EASL-CLIF (706), APASL-ACLF (437), and NACSELD-ACLF (93) models. The 28-/90-day mortality rates were 32.5%/49.0% for A-TANGO model and 31.6%/48.6% for COSSH-ACLF framework, whereas NACSELD-ACLF framework identified the fewest patients but with the highest mortality (62.9%/67.9%). Only 39-patients met criteria for diagnosis of ACLF in all five models and these patients had extremely high mortality (87.5%/93.3%). The A-TANGO model showed the best reclassification using NRI compared with EASL-CLIF, COSSH-ACLF, APASL-ACLF, and NACSELD-ACLF models (11.81%, 7.71%, 37.4%, and 45.9%). Using the CLIF-organ failure (OF) score as the reference, the COSSH-ACLF II, COSSH-ACLF, and A-TANGO OF scores demonstrated improved discrimination (IDI: 4.09%, 0.62%, and 0.81%). C-index analyses further confirmed that COSSH-ACLF II, COSSH-ACLF, and A-TANGO OF scores provided the best discrimination for 28-day mortality (0.857, 0.848, and 0.832).
Conclusion: The A-TANGO models performs as well as the COSSH model in the COSSH cohort for the diagnosis of ACLF and for prediction of short-term mortality. The other 3-models underestimate the diagnosis of ACLF markedly. As further attempts are made to harmonize definitions for the diagnosis and prognosis of ACLF, the data from this study would support the use of ATANGO score for non-HBV patients whilst COSSH score be used for HBV patients.

SAT-477

Prognostic value of minimal hepatic encephalopathy assessment in patients with acute and chronic liver disease

Nicholas Zeuzem[1], Yu Ri Im[1], Samuel Scholl[1], Alina Bauschen[1], Timo Lehr[1], Katharina Merk[1], Julian Allgeier[1], Christian M. Lange[1], Christiana Graf[1]. *[1]LMU University Hospital, München, Germany*
Email: christiana.graf@med.uni-muenchen.de

Background and aims: Minimal hepatic encephalopathy (mHE) may predict overt hepatic encephalopathy (oHE). However, the prognostic value of different mHE assessment tools across various stages of liver disease remains unclear. The aim of this study was to evaluate the predictive value of mHE testing for clinical outcomes.
Method: Patients with liver cirrhosis or severe acute liver injury without overt HE at inclusion were prospectively enrolled. mHE was assessed using the Psychometric Hepatic Encephalopathy Score (PHES), Critical Flicker Frequency (CFF), Animal Naming Test (ANT), and EncephalApp Stroop test. mHE was defined as ≥2 of 3 tests abnormal using age- and education-adjusted norms. Serial mHE assessment was performed in a subgroup. Primary endpoints were the development of oHE and liver transplantation-free survival.
Results: A total of 121 patients were included: 46% male, median age 56 years, median MELD was 17. Disease stages comprised compensated cirrhosis (20%), stable decompensated cirrhosis (13%), unstable decompensated cirrhosis (17%), pre-ACLF (18%), ACLF (13%), and severe acute liver injury (19%). Main etiologies were alcohol-related (40%) and autoimmune/cholestatic liver diseases (29%). At baseline, mHE was present in 14% (17/121). During median follow-up of 9 months, 24 patients (20%) developed oHE, 25 (21%) underwent liver transplantation, and 11 (9%) died. CFF as continuous variable was significantly associated with oHE (HR 0.91 per Hz, 95% CI 0.84–0.98, p = 0.011), remaining significant after MELD adjustment (aHR 0.91, p = 0.015). Serial assessment was available in 58 patients. Unfavorable mHE trajectory (new onset or persistently abnormal) was associated

with higher oHE rates (60% vs 16%, p < 0.001). In MELD-adjusted regression, unfavorable trajectory strongly predicted oHE (aHR 5.62, 95% CI 2.06–15.39, p < 0.001). Sensitivity analysis restricted to patients with cirrhosis (n = 98) confirmed these findings.
Conclusion: CFF as continuous variable predicts oHE development in patients with acute and chronic liver disease. Serial mHE assessment identifies high-risk patients independent of MELD score, supporting integration of mHE testing into clinical practice.

Email: jennifer.jaravargas@genfit.com

Background and aims: Overt hepatic encephalopathy (HE) carries high risk of hospitalization (hosp), recurrence and mortality. While lactulose (L) remains the cornerstone of HE management, evidence suggests adding rifaximin (R) enhances clinical outcomes. This study aims to characterize treatment patterns of L and/or R and assess their impact on clinical outcomes in hospitalized patients (pts) with HE.
Method: All hosp from 04/2016–02/2025 of pts with cirrhosis and HE defined by ICD codes, treated with L and/or R were extracted from the Komodo's Healthcare Map U.S. real-world database. Three treatment options during hospitalization were evaluated: L monotherapy (L_m), R monotherapy (R_m), L and R dual therapy (LR_d). Further sub-categorization was based on L and/or R prescription the month prior to hosp to describe pharmaceutical patterns. Evaluated clinical outcomes were 28d mortality and length of stay (LOS).
Results: The study cohort included 211,171 pts with 414,305 hosp. Mean age at admission was 61y, 56% were male. Only 44% had one hosp, 23% had two and 33% had three or more. Treatment during hosp was L_m in 50% of cases, R_m in 19%, and LR_d in 31%. Pharmaceutical patterns varied across hosp: the most common being L_m with prior L (27%), LR_d with prior LR (21%) and L_m without prior L/R (19%). Hosp with L_m without prior L/R were predominantly first admissions (72%), showing an overall 28d mortality rate of 4.1% and a median LOS of 7d. Hosp with LR_d without prior L/R were also mainly first hosp (64%), and were associated with a slightly higher 28d mortality (5%), the longest median LOS (11d) and the highest proportion of cases with bacterial infection and/or other type of acute decompensation reported on top of HE (76%). Hosp with L_m or LR_d and prior L were typically second or later hosp (>64%), with higher 28d mortality for L_m (9.3%) vs LR_d (6%) [$p < 0.001$]. Prior treatment with LR was predominantly associated with third hosp onwards (>60%), with lower 28d mortality for LR_d (7.3%) compared with L_m (8.1%) [$p < 0.001$] and R_m (9.1%) [$p < 0.001$].
Conclusion: In this large US-based cohort, treatment patterns for hospitalized pts with HE reveals substantial heterogeneity. L monotherapy still predominates, indicating potential to possibly reduce LOS and mortality with earlier dual therapy. Over half of pts were readmitted with high readmission rates persisting even under dual therapy, highlighting the need for optimized strategies and novel therapies to improve outcomes.

SAT-480

Beyond MELD: machine learning mortality prediction in cirrhotic patients with sepsis

Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: lawinsteve.ls@gmail.com

Background and aims: Sepsis remains a leading cause of mortality in cirrhotic patients, with ICU mortality rates exceeding 40–50%. Traditional prognostic scores (MELD, MELD-Na, SOFA, CLIF-SOFA) were developed for different clinical contexts and may not optimally capture the unique pathophysiology of sepsis superimposed on chronic liver disease. We developed and validated machine learning (ML) models for predicting ICU mortality in cirrhotic patients with sepsis and compared their performance against established clinical scores.
Method: This retrospective cohort study used the MIMIC-IV (v3.1) database to identify adult patients (≥18 years) with cirrhosis and concurrent sepsis requiring ICU admission (2008–2022). Cirrhosis and sepsis were identified using ICD-9/10 codes. Predictors included demographics, liver function tests, renal parameters, sepsis markers, hemodynamics, neurological status, cirrhosis complications, and ICU interventions collected within 24 hours of admission. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, Gradient Boosting) were trained using 80/20 train-test splits with stratified sampling. Performance was evaluated using AUC-ROC, AUPRC, and Brier score with five-fold cross-validation. ML models were compared against MELD, MELD-Na, SOFA, and CLIF-SOFA scores using bootstrap resampling (n = 1000) for confidence intervals.
Results: Among 1,612 patients (mean age 60.1 years; 56.2% male), hospital mortality was 45.7%. Random Forest and Logistic Regression achieved the highest discrimination (AUC 0.787, 95% CI 0.740–0.834), significantly outperforming CLIF-SOFA (0.710), SOFA (0.710), MELD (0.708), and MELD-Na (0.708). Random Forest achieved sensitivity 65.3%, specificity 77.8%, PPV 71.1%, and NPV 72.9%. Top predictors integrated sepsis severity markers (lactate, pH, temperature) and

liver-specific dysfunction (bilirubin, INR, creatinine), reflecting the intersection of both disease processes.
Conclusion: ML models significantly outperform traditional scoring systems for predicting ICU mortality in cirrhotic patients with sepsis, achieving an 11% relative improvement in AUC. Key predictors capture both sepsis severity and hepatic dysfunction, supporting development of cirrhosis-specific sepsis prognostic tools.

SAT-481
Machine learning model for non-sodium predictors of ICU mortality drivers in cirrhotic hyponatremia
Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: lawinsteve.ls@gmail.com

Background and aims: Hyponatremia is common in cirrhosis and incorporated into MELD-Na to improve mortality prediction. However, in patients with established hyponatremia, the prognostic value of sodium level itself remains unclear. We hypothesized that once hyponatremia develops, factors beyond sodium drive ICU mortality. We aimed to identify key mortality predictors using machine learning (ML) and evaluate whether MELD-Na provides incremental value over MELD in this pre-selected population.
Method: This retrospective cohort study used MIMIC-IV (v3.1) to identify adults with cirrhosis and hyponatremia requiring ICU admission (2008–2022). Predictors from the first 24 hours included liver function, renal parameters, metabolic markers, hemodynamics, sodium values, and cirrhosis complications. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, Gradient Boosting) were trained using 80/20 splits with five-fold cross-validation. Performance was compared against MELD, MELD-Na, SOFA, and sodium alone using bootstrap DeLong testing (n = 2000).
Results: Among 1,437 patients (mean age 58.4 years; 61.2% male; mean sodium 128.3 mEq/L), hospital mortality was 26.7%. Random Forest achieved superior discrimination (AUC 0.784, 95% CI 0.721–0.841), significantly outperforming MELD (0.672, $p < 0.001$) and MELD-Na (0.665, $p < 0.001$) which is 18% relative improvement. Critically, MELD-Na provided no advantage over standard MELD (p = NS), and sodium alone showed no prognostic value (AUC 0.503, equivalent to random chance). Feature importance analysis revealed non-sodium factors dominated prediction: bilirubin, INR, anion gap, lactate, and hemodynamic parameters ranked highest, while all sodium parameters fell outside the top 20 predictors.
Conclusion: In cirrhotic patients with established hyponatremia, ML significantly outperforms traditional scores while revealing that sodium loses prognostic value once hyponatremia is present. Liver synthetic function (bilirubin, INR) and metabolic-hemodynamic status and not sodium level were found to be the drivers of mortality risk. These findings suggest clinicians should focus prognostic assessment on hepatic and metabolic parameters rather than sodium correction in this population.

SAT-482
Single-nucleus RNA sequencing identifies a GATA4+ liver sinusoidal endothelial cell subpopulation in acute-on-chronic liver failure
Xiayao Li[1], Xiaohan Qian[1], Wenxin Zhoudi[1], Yangfan Shen[1], Xiaowei Xu[1]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: lixiayao2001@163.com

Background and aims: Liver sinusoidal endothelial cell (LSEC) dysfunction is a persistent feature of liver diseases, yet its phenotypic regulation in acute-on-chronic liver failure (ACLF) remains poorly understood. This study aimed to delineate the heterogeneity and functional characteristics of LSECs in ACLF using single-nucleus RNA sequencing, and to identify key molecules and signaling pathways involved in liver inflammation and repair.
Method: We performed snRNA-seq on explanted liver tissues from five HBV-ACLF patients underwent liver transplantation. Public snRNA-seq datasets of healthy human livers were integrated as controls using Harmony. Following quality control and normalization, LSECs were extracted and re-clustered. Pathway enrichment was assessed using AddModuleScore, developmental trajectories were inferred by Monocle, intercellular communication was analyzed by CellChat and gene regulatory network was analyzed by pySCENIC.
Results: After analyzing 5,247 LSECs which were re-clustered into 7 subpopulations, we identified a distinct GATA4$^+$ LSEC subpopulation that was expanded in the liver of patients with HBV-ACLF. These GATA4$^+$ LSECs present in all ACLF samples, characterized by high expression of GATA4, ENG, IL33 but low expression of STAB2, LYVE1, suggesting the dysfunction and remodeling of LSECs in ACLF. Pathways related to cell migration, morphogenesis, and cytoskeletal organization were enriched in this subpopulation, reflecting a liver pro-repair signature. In a trajectory analysis, GATA4$^+$ LSECs located at the branch after healthy LSECs, indicating the endothelial phenotypic transition in ACLF. Cell-cell interaction analysis revealed enhanced interactions between GATA4$^+$ LSECs and hepatocytes, cholangiocytes and hepatic stellate cells via the BMP-SMAD axis. Notably, GATA4, a transcription factor, is the master regulator of LSEC differentiation, which may drive endothelial dysfunction by regulating the expression of its target gene ENG.
Conclusion: GATA4$^+$ LSECs constitute a distinct subset enriched in ACLF livers and exert LSEC dysfunction and liver pro-repair effects, suggesting potential therapeutic targets targeting LSECs for ACLF.

SAT-483
The GCS paradox: machine learning shows glasgow coma scale has no prognostic value in hepatic encephalopathy
Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. [1]*New York Medical College, Valhalla, United States;* [2]*Rutgers University-Newark Arch, Newark, United States*
Email: jeril.lasington@gmail.com

Background and aims: Hepatic encephalopathy (HE) is a major cirrhosis complication requiring ICU admission, with mortality rates of 30–50%. Traditional prognostic tools including MELD, SOFA, and Glasgow Coma Scale (GCS) are commonly used, but their performance in HE remains unclear. Importantly, GCS interpretation is confounded by the potentially reversible nature of HE-related mental status changes. We developed machine learning (ML) models to predict ICU mortality in HE and evaluated whether GCS provides independent prognostic value.
Method: This retrospective cohort study used MIMIC-IV (v3.1) to identify adults with HE requiring ICU admission (2008–2022). Predictors from the first 24 hours included demographics, liver function, renal parameters, GCS components, HE precipitants (sepsis, AKI, GI bleeding, hyponatremia), and cirrhosis complications. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, Gradient Boosting) were trained using 80/20 splits with five-fold cross-validation. Performance was compared against MELD, MELD-Na, SOFA, and GCS using bootstrap DeLong testing (n = 2000).
Results: Among 1,314 HE patients (mean age 57.2 years; 64.8% male), hospital mortality was 32.3%. Logistic Regression achieved highest discrimination (AUC 0.801, 95% CI 0.740–0.856), significantly outperforming MELD (0.669, +20%, p = 0.0001), MELD-Na (0.647, +24%, $p < 0.0001$), and SOFA (0.645, +24%, $p < 0.0001$). Strikingly, GCS alone showed no prognostic value (AUC 0.531), performing no better than random chance. Feature importance revealed sepsis as the dominant predictor, followed by lactate, creatinine, sodium, and INR. The underlying precipitant, rather than HE severity or GCS, determined outcomes.
Conclusion: ML significantly outperforms traditional scores for HE mortality prediction. Critically, GCS alone has no prognostic value in HE, reflecting the reversible nature of HE-related encephalopathy. Clinicians should not use GCS for prognostication in HE; instead,

focus should be on identifying precipitants, particularly sepsis and AKI which drive mortality risk. These findings support precipitant-focused risk stratification rather than reliance on neurological assessment alone.

SAT-484

Incidence and risk factors for acute-on-chronic liver failure in outpatients with cirrhosis–a prospective multicenter cohort study

Isadora Bombassaro[1], Angelo Mattos[2], Luciana Goncalves[3], Gustavo Pereira[4], Mario Álvares-da-Silva[5], Carlos Antonio Rodrigues Terra Filho[6], Liliana Mendes[7], Patrícia Goncalves[8], Juliana Maya[4], Gabriel Guerreiro[5], Daniel Meohas[6], Angelo Z. Mattos[1]. *[1]Federal University of Health Sciences of Porto Alegre, Irmandade Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, Brazil; [2]Ufcspa- Fund Univ Federal De Ciências Da Saúde De Porto Alegre, Porto Alegre, Brazil; [3]Universidade Federal do Espírito Santo, Vitória, Brazil; [4]Hospital Geral de Bonsucesso, Rio de Janeiro, Brazil; [5]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [6]Universidade Do Estado Do Rio De Janeiro, Hospital da Lagoa, Rio de Janeiro, Brazil; [7]Hospital de Base, Brasília, Brazil; [8]Hospital Universitário Cassiano Antônio Moraes, Vitória, Brazil*
Email: angmattos@hotmail.com

Background and aims: Acute-on-chronic liver failure (ACLF) has been extensively studied in hospitalized patients, but its incidence and risk factors in outpatients remain poorly defined. This study evaluated the incidence and independent risk factors for ACLF in an outpatient cohort of individuals with cirrhosis.
Method: This is a prospective multicenter cohort study, in which baseline data were collected at the first outpatient visit of individuals with cirrhosis, who were then followed until the development of ACLF or the competing outcomes (liver transplant and death). ACLF was defined according to the Chronic Liver Failure Consortium criteria. Cumulative incidence functions for ACLF were calculated, and multivariable analyses were performed using the Fine–Gray competing risk model, in which subdistribution hazard ratios (HRs) and their 95% confidence intervals (CIs) were estimated.
Results: A total of 881 patients were included (78.1% - Child-Pugh A, 19.9% - Child-Pugh B, 2% - Child-Pugh C). The cumulative incidence of ACLF was 4.7% (n = 36) in 12 months and 5.9% (n = 45) in 36 months. Independent risk factors for ACLF at 12 months included lower levels of hemoglobin (HR = 0.80; 95% CI = 0.69–0.93, p = 0.003) and albumin (HR = 0.45; 95% CI = 0.26–0.76, p = 0.003), higher levels of creatinine (HR = 1.44; 95% CI = 1.08–1.91, p = 0.013), and the presence of ascites (HR = 2.12; 95% CI = 1.03–4.33, p = 0.040) at the baseline.
Conclusion: ACLF incidence was relatively low, consistent with the predominance of compensated cirrhosis at the beginning of the follow-up. Anemia and baseline markers of impaired liver and kidney function were independently associated with the development of ACLF.

SAT-489

Body composition is a predictor of treatment response and survival in hepatorenal syndrome (HRS-AKI)

Sina Oesinghaus[1], Julian Pohl[1], Dominik Geisel[2], Nick-Lasse Beetz[2], Frank Tacke[1], Cornelius Engelmann[1]. *[1]Charité Campus Virchow, Department of Gastroenterology and Hepatology, Berlin, Germany; [2]Charité Campus Virchow, Department of Radiology, Berlin, Germany*
Email: sina.oesinghaus@charite.de

Background and aims: Advanced liver cirrhosis is characterized by systemic complications, including hepatorenal syndrome (HRS-AKI) and sarcopenia. Despite their co-occurrence, the interplay between body composition, pharmacotherapy response and survival remains poorly defined. While terlipressin plus albumin is the standard of care, 30–40% of patients do not respond. AI based CT body composition analysis (BCA) offers a novel approach to identify risk factors in these vulnerable patients. This study investigated BCA-derived predictive markers for terlipressin response and 90-day transplant-free survival.
Method: 106 HRS-AKI patients receiving terlipressin at Charité Centers (2018–2022) were retrospectively included in this study. Treatment response after 7 days was defined based on the reduction of peak serum creatinine by ≥25%. Using BCA, the tissue area at the L3 level was measured and standardized by height [cm^2/m^2] to calculate skeletal muscle index (SMI), subcutaneous fat index (SFI) and visceral fat index (VFI). A Sarcopenic Visceral Obesity Index was defined as SVI = SMI × SFI/VFI. Regression and competing risk analyses identified independent predictors of treatment response and 90-day mortality.
Results: Out of 106 patients 77% were male and 33% female with a median age of 63 years. Overall, 39.6% presented with ACLF grade I, 20.8% with grade II, 4.7% with grade III and 34.9% without ACLF at diagnosis of AKI. The median MELD score was 25. Mean SMI was 40.2 ± 8.7 cm^2/m^2 in men and 35.8 ± 5.8 cm^2/m^2 in women. At 90 days, 57.5% of patients had died and 2.8% had undergone liver transplantation. The overall terlipressin response rate was 25.5%. In a multivariate competing risk model, day 7 treatment response was a significant protective factor for 90-day mortality (sHR 0.42; 95% CI 0.20–0.90; p = 0.026). While SMI, SFI, and VFI alone showed no association with transplant-free survival, a lower SVI was associated with a higher 90-day mortality (sHR 0.64; 95% CI 0.41–1.00; p = 0.050). Multivariate Cox models identified low SMI (HR 1.52; 95% CI 1.06–2.19; p = 0.03) and low SVI (HR 1.40; 95% CI 1.071.82; p = 0.01) as robust independent predictors of terlipressin non-response.
Conclusion: Reduced muscle mass (SMI) and altered muscle-to-fat distribution (SVI) are independent predictors of terlipressin non-response which is a critical determinant of 90-day transplant free survival. BCA-based stratification may help guide early treatment strategies in HRS-AKI.

SAT-490

Acute kidney injury in decompensated cirrhosis without underlying chronic kidney disease represents a distinct high-risk phenotype compared to acute-on-chronic kidney disease

Rahul Thakkar[1], Kavish Patidar[2], Olivia Walker[1], Gerald Ogola[1], Patrick S. Kamath[3], Sumeet Asrani[1]. *[1]Baylor Scott & White Health, Dallas, United States; [2]Houston Methodist, Houston, United States; [3]Mayo Clinic, Rochester, United States*
Email: rahul.thakkar@bswhealth.org

Background and aims: Acute kidney injury (AKI) is a critical prognostic factor in decompensated cirrhosis and acute-on-chronic liver failure (ACLF). The 2025 Consensus on Organ Failures in Cirrhosis has formalized the definition of acute-on-chronic kidney disease (AoCKD), but data characterizing the prognostic divergence between AoCKD and *de novo* AKI remain limited. This study evaluated the mortality impact of acute serum creatinine (sCr) change across baseline renal function and chronic kidney disease status.
Method: We conducted a retrospective cohort study of adult patients with decompensated cirrhosis admitted to intensive care units across 54 hospitals in a large integrated healthcare system (2019–2022). The primary outcome was 30-day all-cause mortality. Patients were stratified based on admission sCr (admit sCr), maximum absolute change in sCr during their stay (delta sCr), and presence or absence of chronic kidney disease (CKD). Mortality trajectories were analyzed as a function of Delta sCr across distinct admission baselines, stratified by CKD status.
Results: Mortality increased with larger delta sCr in all patients across admission sCr values, but the steepness of this increase differed between non-CKD and CKD cohorts. For most admit sCr/delta sCr combinations, non-CKD patients exhibited higher mortality rates than their CKD counterparts. The maximum absolute mortality difference between non-CKD and CKD patients followed a bell-shaped pattern across admission sCr values, peaking at an admit sCr of 2.5 mg/dL (22% difference) and narrowing at the extremes (10–11% at admit sCr of 1.0 and 4.0 mg/dL). At an admission sCr of 2.5 mg/dL,

patients without pre-existing CKD exceeded 60% mortality with a delta sCr of 1.0 mg/dL, whereas patients with CKD required a delta sCr of 3.0 mg/dL to reach comparable mortality.
Conclusion: Acute rises in serum creatinine were associated with a greater increase in 30-day mortality among patients without pre-existing CKD compared to those with CKD in decompensated cirrhosis, supporting *de novo* AKI as a distinct high-risk phenotype from acute-on-chronic kidney disease. These findings suggest that prognostic frameworks and renal endpoints in ACLF intervention trials should account for baseline kidney status, as equivalent creatinine changes may not confer equivalent mortality risk.

SAT-491

Long-term efficacy of double plasma molecular adsorption system with sequential low-volume plasma exchange for intermediate-stage HBV-ACLF: a randomized controlled trial

Chan Xie[1], Jia Chen[1], Wenxiong Xu[1], Liang Peng[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: xchan@mail.sysu.edu.cn

Background and aims: The mortality rate of hepatitis B virus (HBV)-related acute-on-chronic liver failure (ACLF) remains high despite standard care. Artificial liver support systems are widely used, but long-term data remains limited. This study aimed to investigate the safety and long-term efficacy (up to 2 years) of the double plasma molecular adsorption system combined with sequential low-volume plasma exchange (DPMAS+LPE) specifically in patients with intermediate-stage HBV-ACLF.
Method: In this randomized controlled trial, patients diagnosed with intermediate-stage HBV-ACLF were enrolled and randomly assigned (1:1) to either a trial group or a control group. Both groups received standard medical treatment (SMT), including antiviral therapy and comprehensive supportive care. Patients in the trial group additionally received three sessions of DPMAS+LPE, administered once every two days. The primary endpoint was 2-year transplantation-free survival (TFS), the second endpoints included treatment safety, 2-year cumulative overall survival (OS).
Results: A total of 56 patients (28 per group) completed the 2-year follow-up, with no severe treatment-related adverse events recorded in the trial group. The trial group achieved significantly superior short-term outcomes compared to the control group, evidenced by higher cumulative TFS (53.6% vs. 25.0%, $p = 0.029$) and OS (64.3% vs. 35.7%, $p = 0.033$) at 3 months. Notably, this survival advantage was sustained over the long term; the trial group maintained numerically higher survival rates at 2 years (OS: 50.0% vs. 28.6%; TFS: 35.7% vs. 21.4%) compared to the control group, although the difference did not reach statistical significance in this cohort ($p > 0.05$).
Conclusion: DPMAS+LPE is a safe intervention that significantly improves short-term survival in intermediate-stage HBV-ACLF. Importantly, this early therapeutic efficacy translates into a clinically meaningful trend toward better long-term prognosis, with survival benefits persisting up to 2 years. Therefore, DPMAS+LPE is recommended as an effective strategy for management in this population.

Individualised nutrition support improves outcomes in hepatitis B virus-related acute-on-chronic liver failure patients at nutritional risk: a randomised controlled trial

ZhiPeng Li[1,2], Yeqiong Zhang[1], Qiumin Luo[1], Chan Xie[1], Liang Peng[1]. [1]*Department of Infectious Diseases Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China;* [2]*Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: lizhp28@mail.sysu.edu.cn

Background and aims: Patients with acute-on-chronic liver failure (ACLF) are at high nutritional risk, which adversely affects prognosis, yet robust evidence for nutritional interventions is scarce. This study evaluated the safety and efficacy of individualised nutritional support for hepatitis B virus-related ACLF (HBV-ACLF).
Method: In this single-centre, investigator-initiated, open-label randomised controlled trial, HBV-ACLF patients meeting COSSH criteria with NRS-2002 ≥3 were randomised 1:1 to individualised nutritional support (energy target 1.2 × REE; protein 1.2 g/kg/day) or control (standard dietary advice). Assessments were performed at baseline, day 30, and day 90. Primary endpoints were 30- and 90-day transplant-free mortality. Secondary endpoints included safety, the incidence of adverse clinical outcomes, liver severity scores (MELD, COSSH-ACLF IIs), anthropometry (mid-arm circumference), muscle function (handgrip strength, gait speed, SPPB), and quality of life (EQ-5D).
Results: Between December 2023 and March 2025, 572 patients with HBV-ACLF were screened, 80 were randomised, and 78 (39 in the control group and 39 in the intervention group) were analysed in the modified intention-to-treat population. Individualised nutrition significantly reduced transplant-free mortality at day 30 (2.6% vs. 20.5%, $p = 0.033$) and day 90 (17.9% vs. 38.5%, $p = 0.044$) compared to controls. Adverse clinical outcome rates were also lower (day 30: 25.6% vs 56.4%, $p = 0.006$; day 90: 33.3% vs 74.4%, $p < 0.001$), with no excess in serious events, gastrointestinal reactions, complications, or hyperglycemia. The intervention group achieved greater improvements in MELD and COSSH-ACLF II scores, anthropometric indices, muscle function, adverse clinical outcomes and EQ-5D scores (all $p < 0.05$).
Conclusion: In HBV-ACLF patients at nutritional risk, individualised target-driven nutritional support is safe, lowers 30- and 90-day transplant-free mortality, reduces adverse clinical outcomes, and improves hepatic function, muscle performance, and quality of life. These findings provide prospective, randomised evidence supporting early, goal-driven, and function-oriented nutrition treatments with dynamic assessments as a practical strategy in ACLF care.

SAT-493

A phase I clinical trial evaluating the safety and efficacy of the QH-1A combination bio-artificial liver support system incorporating ex-vivo mesenchymal stem cells for the treatment of acute-on-chronic liver failure patients

Liang Peng[1], Chan Xie[1], Wenxiong Xu[1], Jia Chen[1], Xiyao Chen[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*
Email: pliang@mail.sysu.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) has high mortality, and artificial liver support is a key therapeutic approach. Compared with mechanical artificial liver systems, bio-artificial liver support better mimics native hepatic function. This study evaluated the safety and preliminary efficacy of the QH-1A bio-artificial liver support system incorporating ex vivo mesenchymal stem cells (MSCs) in ACLF patients.
Method: This single-center, open-label Phase I clinical trial (approved by NMPA China) assessed QH-1A's safety and preliminary efficacy. All patients received standard medical treatment, including antiviral therapy and comprehensive supportive care. Patient plasma was separated with a plasma separator and perfused through an MSC-seeded hollow-fiber cartridge, allowing MSC-derived extracellular vesicles (including exosomes) and other bioactive factors to return to the patient. Participants were sequentially enrolled into 4-hour (n = 3), 6-hour (n = 3), and 8-hour (n = 3) cohorts with escalating durations. Follow-ups were conducted post-treatment, on Days 3, 7, and 28. Escalation decisions were made by an independent Safety Evaluation Committee based on 28-day safety data.
Results: Nine patients were enrolled from May to October 2025. The 28-day liver transplantation-free survival rate was 88.89% (one patient underwent liver transplantation on Day 26 due to unimproved condition). For safety, 25 related adverse events occurred; only 1 patient had a serious adverse event, with no treatment discontinuation. At Day 28, clinical parameters improved across all cohorts. TBIL decreased from baseline levels of 324.40 (248.10, 361.90), 424.00 (393.20, 462.00), and 265.60 (224.20, 333.10) μmol/L

to 83.20 (63.20, 192.30), 313.60 (151.70, 531.80), and 51.10 (43.20, 116.50) μmol/L in the 4-, 6-, and 8-hour groups, respectively. INR improved significantly in the 4- and 8-hour groups, dropping from 1.89 (1.53, 2.10) and 2.23 (1.65, 2.31) to 1.44 (1.18, 1.68) and 1.23 (1.20, 1.59), respectively. Correspondingly, their COSSH-ACLF II scores decreased from 6.40 (6.00, 6.80) and 7.40 (6.90, 7.40) to 5.40 (4.50, 5.50) and 5.50 (4.90, 6.50), respectively.
Conclusion: The QH-1A bio-artificial liver support system exhibited good safety and tolerability in ACLF patients, improving liver function, coagulation parameters, and clinical severity scores. It may be a promising ACLF treatment, with further studies needed to validate its safety and efficacy.

SAT-494
Elevated plasma aldosterone predicts liver-related mortality in decompensated cirrhosis
Clemens Renhardt[1,2,3], Benedikt Simbrunner[1,2,3,4], Mathias Jachs[1,2,3], Benedikt Hofer[1,2,3,4], Georg Kramer[1,2,3], Christian Sebesta[1,2,3], Marlene Hintersteininger[1,2,3], Paul Thöne[1,2,3], Paula Hoefinger[1,2], Lorenz Balcar[1,2,3], Georg Semmler[1,2,3], Rodrig Marculescu-Ferrari[5], Michael Trauner[1,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3,4], Lukas Hartl[1,2,3]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [3]Clinical Research Group MOTION, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [4]Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [5]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria*
Email: n12028120@students.meduniwien.ac.at

Background and aims: Portal hypertension (PH) - as the main driver of hepatic decompensation - is associated with circulatory dysfunction that triggers the compensatory activation of the renin-angiotensin aldosterone system. However, the prognostic value of plasma aldosterone concentration (ALDO) in contemporary patients with compensated (cACLD) and decompensated (dACLD) advanced chronic liver disease remains unknown.
Method: Patients with ACLD undergoing hepatic venous pressure gradient (HVPG) measurement between 05/2018 and 08/2024 within the prospective VICIS study (NCT03267615) and available ALDO were included. Patients were followed up for 2 years; the event of interest was decompensation in cACLD and liver-related death in dACLD patients.
Results: Overall, 595 patients (cACLD: n = 210; dACLD: n = 385; median age: 58 years; 69.6% male; median MELD: 14 points; median HVPG: 17 mmHg) were included. While only 18 cACLD patients (8.6%) were treated with mineralocorticoid receptor antagonists (MRA), 302 dACLD patients (78.4%), were treated with MRA. ALDO (was significantly increased in dACLD (246 vs. cACLD: 76 pg/mL; p < 0.001). In dACLD patients, HVPG (per mmHg; B: 0.032; 95%CI: 0.012–0.053; p = 0.002), MELD (per point; B: 0.045; 95%CI: 0.021–0.070; p < 0.001) and sodium (per mmol/L; B: –0.133; 95%CI: –0.155 ––0.111; p < 0.001) were strongly linked to ALDO (log-transformed) in univariate analysis of linear regression, however, only sodium (per mmol/L; B: –0.131, 95%CI: –0.155 ––0.107; p < 0.001) remained independently linked to ALDO on multivariate analysis. In cACLD patients (median follow-up 18.3 months), ALDO was not associated with first decompensation in competing risk regression analysis. In dACLD (median follow-up 23.2 months), ALDO predicted liver-related mortality (aSHR: 1.062, [97.5%CI: 1.001–1.125]; p = 0.044) independently of sex, age, MELD-Na and albumin.
Conclusion: ALDO levels substantially increase in dACLD and are strongly linked to low plasma sodium levels. ALDO is an independent risk factor for liver-related death in dACLD.

SAT-495
Predictors of reversibility of acute-on-chronic liver failure at 6 months: a prospective study
Shreyas Sarvesh[1], Rajan Vijayaraghavan[1], Ashok Kumar Choudhury[1], Rakhi Maiwall[1], Chitranshu Vashitshtha[1], Ankur Jindal[1], S. Muralikrishna Shasthry[1], Vinod Arora[1], Harshvardhan Tevethia[1], Satender Pal Singh[1], Guresh Kumar[1], Ankit Bhardwaj[1], Vikram Bhatia[1], Manoj Kumar[1], Shiv Kumar Sarin[1]. *[1]Institute of Liver & Biliary Sciences, New Delhi, India*
Email: rajanvf40@gmail.com

Background and aims: Acute-on-chronic liver failure (ACLF) is a rapidly progressive condition and carries a high short-term mortality. Although a proportion of patients achieve reversal of key elements that define ACLF, only a few have been analysed prospectively under defined timelines. We aimed to determine baseline factors that could predict reversal of ACLF within 180 days.
Method: ACLF patients, admitted either in the ward or in the ICU, were prospectively enrolled and followed for 365 days. Reversal of ACLF was defined as: bilirubin <5 mg/dL and INR <1.5, with no hepatic encephalopathy, and either resolution of ascites or no ascites. The objective was to determine the proportion of patients achieving reversibility by 180-days and 'early reversal' by 90-days, and baseline factors predicting reversibility at 6-months.
Results: A total of 475 patients were enrolled, of whom 44.6% required ICU admission. Alcohol was the predominant acute insult (75.6%), followed by drug-induced liver injury (12%) and hepatitis B (7.16%). Overall, ACLF reversal at 180 days was achieved in 52.4% (n = 249) patients, while early reversal at 90 days occurred in 33.5% (n = 183). Among patients surviving beyond 28 days, reversal rates increased to 62.9% at 90 days and 69.8% at 180 days.Patients achieving reversal had significantly lower baseline BMI, Child–Turcotte–Pugh score, MELD-Na score, and AARC score (all p < 0.001). On multivariable analysis, higher serum albumin (HR 1.74, 95% CI 1.11–2.74, p = 0.016), HDL cholesterol (HR 1.03, 95% CI 1.00–1.06, p = 0.025), and platelet count (HR 1.92, 95% CI 1.16–3.19, p = 0.011) were independently associated with increased likelihood of reversibility. Alcohol as the acute insult was associated with a nearly threefold higher probability of reversal compared with other etiologies (HR 2.83, 95% CI 1.60–5.01, p < 0.001). Conversely, higher ferritin levels (HR 0.60, 95% CI 0.45–0.79, p < 0.001), shock (HR 0.53, p = 0.008), SBP(HR 0.46, p = 0.002), HE, and need for RRT were associated with poorer reversibility. Prolonged rifaximin or norfloxacin was independently associated with improved reversal (HR 2.27, p < 0.001).
Conclusion: More than half of patients with ACLF achieve reversal by 6 months, whereas early reversal within 90 days is uncommon. Baseline inflammatory burden, organ failures, and metabolic reserve strongly influence reversibility. Extending the assessment window to 180 days may better define meaningful recovery and therapeutic endpoints in ACLF.
Clinical trial registration: NCT-06387160.

Email: e1354047@u.nus.edu

Background and aims: Statins possess pleiotropic effects beyond lipid lowering that may beneficially modify the course of liver cirrhosis. However, their use in compensated cirrhosis remains limited due to safety concerns and the paucity of large-scale data. We evaluated the association between statin use and the risks of hepatic decompensation and all-cause mortality in patients with compensated liver cirrhosis.
Method: We performed a retrospective, multinational, longitudinal cohort study within the Cirrhosis Outcome and Research Endeavour (CORE) consortium, including consecutive adults with compensated cirrhosis across 13 tertiary centers in eight countries. Compensated cirrhosis was defined by liver stiffness measurement ≥10 kPa and absence of prior decompensation. Statin exposure was defined at baseline. Outcomes were hepatic decompensation and all-cause mortality, analyzed using Fine–Gray competing-risk regression. Multivariable models adjusted for demographic, metabolic, and liver disease–related covariates. Inverse probability of treatment weighting (IPTW) was used to support causal inference.
Results: Among 2,564 patients (median follow-up 3.09 years), 901 (35.1%) were statin users. Statin use was associated with a significantly lower risk of hepatic decompensation in multivariable analyses (adjusted subdistribution hazard ratio [SHR] 0.70, 95% CI 0.57–0.86). Findings were consistent across moderate- and high-risk cirrhosis strata. Statin use was associated with lower all-cause mortality in partially adjusted models, though this association was attenuated after full adjustment. In IPTW-weighted analyses, statin use was associated with reduced risks of hepatic decompensation (SHR 0.55, 95% CI 0.37–0.80) and all-cause mortality (SHR 0.65, 95% CI 0.46–0.91).
Conclusion: In this large multinational cohort, statin use was associated with reduced hepatic decompensation and improved survival in compensated cirrhosis, supporting a potential disease-modifying role warranting prospective evaluation.

SAT-497

Optimizing linezolid therapy in acute-on-chronic liver failure through interprofessional therapeutic drug monitoring in the ICU

Georgios Athanasoulas[1], Alexander Kratzer[1], Sophia Rusch[1], Sophie Schlosser-Hupf[1], Patricia Mester-Pavel[1], Vlad Pavel[1], Martina Müller-Schilling[1], Stephan Schmid[1]. [1]*Universitätsklinikum Regensburg, Regensburg, Germany*
Email: stephan.schmid@ukr.de

Background and aims: Acute-on-chronic liver failure (ACLF) is a rapidly progressive syndrome associated with severe infections and high mortality. Linezolid is a key reserve antibiotic for the treatment of multidrug-resistant infections but is characterized by a narrow therapeutic window and high pharmacokinetic variability, particularly in critically ill patients with liver dysfunction. Therapeutic drug monitoring (TDM) may optimize efficacy while reducing toxicity. This study aimed to evaluate the clinical impact of an interprofessional TDM-based approach for individualized linezolid therapy in ICU patients with and without ACLF.
Method: This prospective study was conducted on a medical intensive care unit with hepatology specialization. Fifty-one critically ill patients receiving linezolid therapy, with and without ACLF, were included. Linezolid was administered as a continuous infusion following an initial loading dose. Weekly TDM was performed using high-performance liquid chromatography (HPLC). Serum concentrations, implementation of interprofessional recommendations, linezolid consumption, and clinical course were analyzed. Outcomes were compared between ACLF and non-ACLF patients.
Results: Initial TDM revealed marked variability in linezolid exposure: 29% of patients were within the therapeutic target range (2–10 mg/L), 21% were below target (<2 mg/L), and 50% exceeded the upper limit (>10 mg/L), including extreme concentrations >20 mg/L. Therapy adjustments were recommended in 20 cases, with full adherence by the treating teams. Subsequent measurements demonstrated improved target attainment. Notably, more than 80% of patients with supratherapeutic concentrations (>10 mg/L) had ACLF. No hematological or other relevant adverse events were observed under TDM-guided therapy. The structured involvement of medical students supported interprofessional learning and reinforced antibiotic stewardship principles in the ICU.
Conclusion: An interprofessional TDM-based strategy enables safe and individualized linezolid therapy in critically ill patients with ACLF. High rates of supratherapeutic exposure in ACLF patients underscore the need for systematic TDM in this population. This approach enhances patient safety, promotes rational use of reserve antibiotics, and represents an effective model for integrating precision medicine and interprofessional education in intensive care.

SAT-498

Machine learning based prediction of early organ failure in acute-on-chronic liver failure

Garima Singhal[1], Ashok Kumar Choudhury[1], Vinod Arora[1], Shiv Kumar Sarin[1] AARC APASL ACLF Research Consortium[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: doctor.ashokchoudhury@gmail.com

Background and aims: Acute-on-chronic liver failure (ACLF) is a dynamic syndrome characterized by rapid progression to multiorgan failure and high short-term mortality. However, predictive models to identify patients at risk of developing organ failure (OF) after presentation—particularly among those without OF at baseline—remain limited. We aimed to develop and validate machine-learning models to predict early development of organ failure.
Method: We analysed data from the AARC registry, including detailed clinical, laboratory, and organ failure assessments. After data preprocessing, the cohort was randomly divided into derivation (70%) and validation (30%) datasets. Multiple machine-learning models—XGBoost, Random Forest, Decision Tree, and Logistic Regression—were used. Model performance was assessed using area under the receiver operating characteristic curve (AUROC), accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) to predict development of new-onset organ failure by day 4.
Results: A total of 8,683 patients were included (mean age 44.6 ± 11.6 years; 87% male), with alcohol as the predominant etiology (56.8%). At presentation, 92.85% had at least one organ failure, while 621 patients (7.15%) had no organ failure. Among these, 16.4% developed new-onset organ failure by day 4, which was associated with significantly increased 90-day mortality (HR 1.37; 95% CI 1.32–1.43; p = 0.001). After feature selection, 25 variables were retained for model development. The Random Forest model demonstrated the best performance (accuracy 0.92, AUROC 0.87, sensitivity 0.70, specificity 0.96, PPV 0.77, and NPV 0.94). The most influential predictors were baseline serum albumin, PT-INR, serum lactate, hepatic encephalopathy, and new-onset sepsis by day 4. Decision tree analysis accurately stratified patients into high-risk (lactate >1.62 mmol/L and albumin <2.2 g/dL), intermediate-risk (lactate

<1.62 mmol/L and albumin >2.2 g/dL or lactate >1.62 mmol/L with INR >2.0), and low-risk (INR <2.0 and lactate <1.62 mmol/L) categories, with corresponding risks of early organ failure of 58.4%, 15.3%, and 8.1%, respectively.
Conclusion: Among ACLF patients without organ failure at baseline, nearly one-sixth develop new-onset organ failure within 4 days, conferring a higher mortality risk. A simple combination of serum lactate, albumin, and PT-INR provides effective early risk stratification and may aid prognostication, intensive monitoring, and transplant decision-making in ACLF.

SAT-499
Presence of sarcopenia or chronic kidney disease does not influence the level of venous ammonia in outpatients with stable cirrhosis
Rajit Soni[1], Pooi Ling Loi[1], Hiang Keat Tan[2], Marianne De Roza[3], Chanda Ho[2], Jason Pik Eu Chang[2], Prema Raj S/O Jeyaraj[4], Rahul Kumar[1]. [1]*Changi General Hospital, Singapore, Singapore;* [2]*Singapore General Hospital, Singapore, Singapore;* [3]*Sengkang General Hospital, Singapore, Singapore;* [4]*Duke-Nus Medical School, Singapore, Singapore*
Email: rajit.soni94@gmail.com

Background and aims: Hyperammonaemia in cirrhosis is multifactorial. Although skeletal muscle and kidneys are thought to play a key role in extrahepatic ammonia clearance, the influence of sarcopenia and chronic kidney disease (CKD) on circulating ammonia levels in stable outpatients with cirrhosis has not been systematically evaluated. We aimed to determine whether sarcopenia or CKD affects venous ammonia concentrations in this population.
Method: This prospective study was conducted as part of the multicentre SoLiDaRity collaborative, designed to predict decompensation, acute-on-chronic liver failure, and mortality in cirrhosis. Consecutive outpatients with cirrhosis attending hepatology clinics were enrolled. Sarcopenia was assessed using the right psoas muscle index (PMI), calculated from available computed tomography scans at the level of the third lumbar vertebra. CKD was defined by an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 for ≥3 months, together with loss of corticomedullary differentiation on renal ultrasonography, and further staged. Venous ammonia and routine biochemical parameters were measured at enrolment. Standard statistical methods were used to compare ammonia levels across groups. The study was approved by the institutional review boards of participating centres and conducted in accordance with the Declaration of Helsinki.
Results: A total of 280 patients were included. The median venous ammonia level at enrolment was 25.5 µmol/L (Interquartile range [IQR] 18–43.5). Median ammonia levels were 29 µmol/L (IQR 19–52) in patients without sarcopenia and 24.5 µmol/L (IQR 15–39) in those with sarcopenia ($p = 0.054$). Across CKD stages, median ammonia levels were 30 µmol/L (IQR 19–53) in stage 0, 24 µmol/L (IQR 17–39) in stages 1–2, 26 µmol/L (IQR 15–51) in stage 3, and 34 µmol/L (IQR 18.5–68) in stages 4–5, with no significant difference observed ($p = 0.068$). In contrast, ammonia levels increased significantly with worsening liver disease severity: 21 µmol/L (IQR 16–29) in Child–Turcotte–Pugh (CTP) class A, 46 µmol/L (IQR 27–69) in class B, and 57 µmol/L (IQR 42–77) in class C ($p < 0.001$).
Conclusion: In stable outpatients with cirrhosis, venous ammonia levels are primarily driven by the severity of hepatic dysfunction and are not independently influenced by sarcopenia or chronic kidney disease. These findings highlight liver disease severity, rather than extrahepatic ammonia clearance, as the dominant determinant of circulating ammonia in stable cirrhosis.

SAT-500
Fairness-aware machine learning predicts 30-day mortality in vietnamese patients with decompensated cirrhosis
Hien Tran[1]. [1]*School of Biomedical Engineering - Vietnam National University HCMC International University, Ho Chi Minh, Vietnam*
Email: doctor.tranhuuhien@gmail.com

Background and aims: Decompensated cirrhosis carries high short-term mortality and existing scores (Child-Pugh, MELD) may underperform in Asian populations. We aimed to build fairness-aware machine learning (ML) models to predict 30-day mortality in a Vietnamese cohort and to compare them with established scores.
Method: We prospectively enrolled 100 adults hospitalized for decompensation at a tertiary center. After standard preprocessing, hybrid feature selection and synthetic oversampling addressed class imbalance. The primary model was a regularized logistic regression within a stacked ensemble; performance was evaluated on a held-out test set using area under the receiver operating characteristic curve (AUROC) and decision curve analysis (DCA). Benchmarks included Child-Pugh, MELD, MELD-Na, MELD 3.0, ALBI and PALBI. Interpretability used Shapley additive explanations (SHAP).
Results: Median age was 53 years (IQR 46–63); 21.4% were female. Major etiologies were alcohol-related (53.0%) and viral hepatitis (42.3%). Logistic regression achieved the highest test AUROC of 0.990 with accuracy 94.1%, outperforming all prognostic scores (AUROC 0.751–0.912; $p < 0.05$ for pairwise comparisons). DCA showed greater net benefit across clinically relevant thresholds (e.g., net benefit 0.441 at 50% risk vs 0.324 for MELD 3.0). SHAP ranked international normalized ratio and total bilirubin as the most influential predictors.
Conclusion: A fairness-aware ML framework, particularly logistic regression, improved discrimination and clinical utility for 30-day mortality prediction in decompensated cirrhosis. External validation in independent populations is warranted for generalizability.

SAT-501
Myeloid cell 5-lipoxygenase activation and its metabolite product 5-HETE promote systemic inflammation and hepatocyte ferroptosis in acute-on-chronic liver failure
Huilan Tu[1], Xinyi Xu[1], Ruoqi Zhou[1], Xia Yu[1], Xianbin Xu[1], Jiyang Chen[1], Xiuding Zhang[1], Xinxin Liu[1], Ying Hu[1], Jifang Sheng[1], Yu Shi[1]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: 12318425@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by profound systemic inflammation, yet upstream inflammatory circuits remain incompletely defined. We investigated whether myeloid 5-lipoxygenase (5-LOX) activation and its oxylipins (5-HETE, leukotrienes) drive inflammation in ACLF and associate with hepatocyte ferroptosis.
Method: We enrolled 145 participants (26 healthy controls, 31 chronic liver disease, 33 decompensated cirrhosis, 55 ACLF). We performed bulk RNA-seq (whole-blood leukocytes, neutrophils, liver) and liver scRNA-seq, quantified plasma 5-LOX products by targeted oxylipin metabolomics, and calculated a 5-LOX pathway score in deconvoluted leukocyte subsets. Intrahepatic 5-LOX^+ myeloid cells were assessed by multiplex immunofluorescence. Oral zileuton was tested in LPS/D-GalN and ConA murine liver failure. Iron and ferroptosis markers were assessed in patients and mice, including a high-iron diet model. 5-HETE effects were tested in THP-1–derived macrophages and THLE-2 hepatocytes.
Results: 5-LOX/leukotriene pathway transcripts increased stepwise across disease stages and peaked in ACLF, which were enriched in neutrophils and monocytes/macrophages, and correlated with inflammatory activation and ACLF severity. Plasma 5-HETE and leukotrienes were markedly elevated in ACLF and associated with liver injury and systemic inflammation. Liver omics and tissue validation showed heightened hepatic 5-LOX activation with increased 5-LOX^+ macrophages and neutrophils. In both murine

models, hepatic 5-HETE increased; zileuton reduced 5-HETE and liver injury. In vitro, 5-HETE robustly activated the ATF4/CHOP integrated stress response and the NR4A/KLF2/4-driven immunometabolic program in THP-1–derived macrophages, accompanied by increased glycolysis and lipid peroxidation. Patients with ACLF and murine liver failure exhibited increased serum and hepatic iron and ferroptosis-associated changes, which were mitigated by 5-LOX inhibition. A high-iron diet model supported an association between hepatic ferroptosis and 5-LOX pathway activation. In THLE-2 cells, 5-HETE exposure induced ferroptosis-related alterations.
Conclusion: Myeloid 5-LOX activation is tightly linked to systemic inflammation and severity in ACLF, and 5-HETE associates with hepatocyte ferroptosis, supporting 5-LOX as a therapeutic target.

Email: xavier.verhelst@uzgent.be

Background and aims: Acute on chronic liver failure (ACLF) is a clinical syndrome of acute decompensation observed in patients with cirrhosis characterized by very high morbidity and mortality. The aim of this project was to describe the clinical characteristics and outcomes of patients with autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) compared to non-autoimmune related liver disease.
Method: Patient data collected by the EF CLIF consortium in 3 prospective studies (CANONIC, PREDICT and ACLARA) were used to study patient characteristics, the development of ACLF (within 28 days of admission) and patient outcome (28- and 90-day mortality) in patients with AIH, PBC and PSC, compared to patients with non-autoimmune related liver disease.
Results: Patients with AIH (n = 122), PBC (n = 114), PSC(n = 56) and 3179 controls were included (Alcohol: n = 2271; MAFLD: n = 541; HepC: n = 711; and HepB: n = 182). AIH and PSC patients were younger compared to the controls (46.8 and 48.1 vs. 58.2; $p < 0.01$). Immunosuppressants were significantly more used in AIH, PBC and PSC versus controls (resp. 63%, 21%, 21% vs. 1%; $p < 0.01$). As a precipitating factor more bacterial infections were observed (AIH 53%, PBC 38%, PSC 58% versus 32%; $p < 0.01$, $p = 0.28$, $p < 0.01$). AIH patients showed a higher prevalence of ACLF at admission (OR 1.71; 34% vs 23%; $p = 0.01$). In PBC and PSC a trend was observed towards a higher prevalence of ACLF at admission (31% and 33% versus 23%, $p = 0.07$ and $p = 0.12$). There was no difference in the severity of ACLF at presentation. PSC patients tended to have a higher incidence of ACLF development (OR 2.22; 28.1% vs 15%, $p = 0.07$). At admission higher values of bilirubin were present in AIH, PSC and PBC ($p < 0.01$), a higher INR in AIH and PSC ($p < 0.01$), higher CRP (28.8 and 54.2 versus 20.8; $p < 0.01$) and serum TNF-alpha levels (44.54 and 40.49 vs. 27.05; $p < 0.01$) in AIH and PSC patients. Levels of IL-8 were decreased in AIH (4.21 vs. 7.06; $p < 0.01$). There was however no significant difference in 28-day and 90-day mortality between patients with AIH, PBC or PSC and controls.
Conclusion: Patients with AIH hospitalised for an acute decompensation of cirrhosis have a higher incidence of ACLF at admission compared to other aetiologies. PSC patients tended to develop more ACLF after admission, without significant impact on mortality. Clinical, biochemical and immunological characteristics of AIH, PBC and PSC patients with ACLF require further research.

SAT-506-YI

Elevated serum concentrations of Angiopoietin-2 link endothelial dysfunction, vascular destabilization, and poor outcomes across stages of cirrhosis

Lea von Ehren[1], Johanna Reißing[1,2,3], Mohamed Ramadan Mohamed[1], Haedge Frederic[1], Mick Frissen[1], Oluwatomi Ibidapo-Obe[1], Majda El Hassani[1], Andreas Stallmach[4], Philipp Reuken[4], Theresa Hildegard Wirtz[1], Tony Bruns[1]. *[1]University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany; [2]Aachen, Aachen, Germany; [3]University Hospital RWTH Aachen, Department for Internal Medicine III, Aachen; [4]Friedrich Schiller University Jena, Jena University Hospital, Department of Internal Medicine IV, Jena, Germany*
Email: lvonehren@rwth-aachen.de

Background and aims: Endothelial dysfunction is a hallmark of advanced cirrhosis, driving portal hypertension and potentially aggravating organ failure. We aimed to characterize the relationship between Angiopoietin-2 (ANGPT2), a key regulator of vascular stability, and a comprehensive network of inflammatory, endothelial, and angiogenic mediators across the spectrum of liver disease severity.
Method: Serum concentrations of ANGPT2 and a panel of 20 related biomarkers were quantified by multiplex immunoassay in cohorts of healthy controls (n = 20), patients with compensated cirrhosis (n = 20), decompensated cirrhosis without acute-on-chronic liver failure (n = 20) and with acute-on-chronic liver failure (ACLF, n = 40). Angiopoietin-2 mRNA was analyzed in gut and liver from two murine models of fibrosis (CCl4 and bile duct ligation) and in cultured human endothelial cells.
Results: Angpt2 was upregulated in liver, colon and small intestine in both animal models of cirrhosis with comparable expression of ANGPT2 between human liver sinusoidal and macrovascular endothelial cells. In patients, circulating ANGPT2 levels increased progressively with the severity of liver disease, being highest in ACLF. Serum ANGPT2 correlated with upstream inflammatory drivers and cell death pathways (IL-6, sCD163, FasR, progranulin) and was tightly associated with downstream markers of endothelial activation and injury (ICAM-1, Thrombomodulin). Higher ANGPT2 serum concentrations indicated poor transplant-free survival, particularly in patients with decompensated cirrhosis ($p < 0.0001$, log-rank test).
Conclusion: Circulating ANGPT2 levels are an indicator of systemic inflammation and endothelial dysfunction in cirrhosis. ANGPT2 may provide a mechanistic link that translates the inflammatory insult into vascular destabilization and poor outcomes associated with clinical decompensation and ACLF.

SAT-507

Definition of renal failure with stage ≥2 acute kidney injury and final serum creatinine ≥2 mg/dL has the best prognostication for mortality in a global cirrhosis cohort

Email: florence.wong@utoronto.ca

Background and aims: Acute kidney failure (AKF) in cirrhosis has variably been defined as serum creatinine (sCr) ≥2.5 mg/dL (International Ascites Club), or sCr ≥2 mg/dL (EASL-CLIF), or stage ≥2 AKI ± RRT (Consensus paper 2025). It is unclear which provides the best prognostic value. Aim: To identify an AKF definition that provides the strongest prediction of 30-day mortality in patients with cirrhosis & AKF.

Method: The global CLEARED Consortium enrolled non-electively admitted patients with cirrhosis from 127 sites in 37 countries. Patients with AKI with sCr of >0.3 mg/dL were allotted into one of 3 definitions of AKF: A) stage ≥2 AKI & final sCr <2 mg/dL (modified Consensus) (n = 219), B) AKI with sCr ≥2 mg/dL but no doubling (modified EASL-CLIF) (n = 430), C) stage ≥2 AKI & final sCr ≥2 mg/dL (overlap Gp) (n = 740) and compared with D) all other AKI cases (No AKF) (n = 816). Demographics, cirrhosis details, inpatient course and 30-day mortality were collected. Multivariable logistic regression model was fitted to identify factors independently associated with the strongest AKF definition.

Results: 2205 (age = 57 yrs, 65% men) of 8143 enrolled patients had AKI and sCr and outcome data for analysis. At enrolment, Group (Gp) B had high prevalence of diabetes (44%) or hypertension (38%) ($p < 0.05$ vs. other 3 Gps), and most cirrhosis complications with ascites (79%), prior AKI/HRS (55%), hypoNa (32%), and 68% admitted in past 6 Ms ($p < 0.05$ vs. other 3 Gps). However, Gp C had the highest median admission MELD-Na of 30 ($p < 0.001$ vs. other 3 Gps) and became the sickest with their AKI, triggered commonly by infection (35.3%) ($p < 0.001$ vs. other 3 Gps). More Gp C patients developed encephalopathy (44.5%) and electrolytes imbalance (38.5%) with their AKI ($p < 0.001$ vs. other 3 Gps for both). Median peak sCr were 1.53 mg/dL, 2.85 mg/dL and 3.84 mg/dL for Gps A, B, & C respectively ($p < 0.001$). 33% of Gp C received terlipressin ($p = 0.023$ vs. Gps A & B) and 89% received albumin ($p < 0.001$ vs. Gps A & B). AKI was unresolved in 44% in Gp C vs. Gp B = 34%, and Gp A = 21% ($p < 0.001$). In-hospital and 30-day mortality were 45% & 55% for Gp C, vs. 25% & 35% for Gp B, vs. 18% & 25% for Gp A ($p < 0.001$ for both). SBP as the AKI trigger, electrolyte imbalance, high WBC or high MELD-Na at admission were factors associated with AKF as defined in Gp C ($p < 0.05$ for all).

Conclusion: In a global cirrhosis cohort, stage ≥2 AKI with final sCr ≥2 mg/dL links with the worst 30-day mortality after AKI, especially when triggered by SBP.

SAT-508

Exploratory study of early diagnostic markers for hepatitis B-related acute-on-chronic liver failure based on plasma cell-free deoxyribonucleic acid methylation sequencing

Wenxin Zhoudi[1], Yangfan Shen[1], Xiayao Li[1], Zhangya Pu[1], Xiaowei Xu[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, College of Medicine, The First Affiliated Hospital, Zhejiang University, Hangzhou, China, Hangzhou, China*
Email: di.zhou@zju.edu.cn

Background and aims: Acute-on-Chronic Liver Failure (HBV-ACLF), characterized by acute hepatic decompensation in chronic liver disease patients, is predominantly triggered by hepatitis B virus (HBV) reactivation in China and carries high short-term mortality. Circulating cell-free DNA (cfDNA) has emerged as a prognostic non-invasive biomarker in HBV-ACLF. To address the need for early detection, this study profiles cfDNA methylation in HBV-ACLF and validates findings in ACLF animal model to identify potential early diagnostic markers.
Method: This study enrolled 110 HBV-ACLF patients, 25 patients with HBV-related liver cirrhosis, 25 patients with chronic HBV infection, and 107 healthy controls. Plasma cfDNA methylation was profiled by Reduced Representation Bisulfite Sequencing RRBS, and bioinformatics identified pathways and differentially methylated genes (DMGs) relevant to early ACLF diagnosis. Selected DMGs were validated in an ACLF mouse model, assessing promoter methylation and its effect on gene expression.
Results: Elevated plasma cfDNA levels in HBV-ACLF patients correlated with disease severity and survival, declining during recovery. Methylation analysis highlighted immune pathway involvement, including LYVE1-associated regulation of macrophages, neutrophil responses, and $CD8^+$ T cell differentiation, with survival-linked differences in NOD2 and TGF-β/IL-6 signaling. Disease progression showed increasing promoter methylation of RAB8A and MGLL, and decreasing methylation of DUSP22, MPG, MIB2, FKBP5, and PSENEN. In ACLF mouse model, reduced MPG and FKBP5 promoter methylation correlated with elevated gene and protein expression, supporting their methylation-dependent role in pathogenesis.
Conclusion: This study characterized the methylation landscape of HBV-ACLF across disease stages (CHB, cirrhosis, ACLF), severity, outcome, and recovery. Seven genes (DUSP22, MGLL, MPG, RAB8A, MIB2, FKBP5, PSENEN) were identified as potential early diagnostic markers. Mouse model validation implicated MPG and FKBP5 in ACLF pathogenesis via promoter methylation regulation, providing a basis for further mechanistic investigation.

SAT-509

Timing of diagnostic paracentesis from first physician contact and in-hospital outcomes in cirrhosis with ascites

Alexander Zhu[1], Meghan Cloutier[1], Ikjot Singh[1], Edward Tamale[1], Inioluwa Dada[1], Anthony Martinez[1,2]. [1]*Department of Internal Medicine, University at Buffalo, Buffalo, United States;* [2]*Department of Gastroenterology and Hepatology, University at Buffalo, Buffalo, United States*
Email: alexander.b.zhu@gmail.com

Background and aims: Timely diagnostic paracentesis is recommended for hospitalized patients with cirrhosis and ascites, and earlier performance has been associated with improved outcomes. Prior studies predominantly define timing relative to hospital admission, which may not accurately reflect delays from initial clinical evaluation. We aimed to examine associations between timing of diagnostic paracentesis, measured from the first physician contact, and in-hospital outcomes among patients with cirrhosis and ascites.
Method: We conducted a retrospective cohort study of adults with cirrhosis and ascites hospitalized at a tertiary care safety-net hospital between 2023 and 2024 who underwent diagnostic paracentesis. Time to diagnostic paracentesis was measured from the first physician contact, defined using the timestamp of the initial physician evaluation. Early diagnostic paracentesis was defined as occurring within 24 hours of first physician contact. Outcomes included in-hospital mortality, acute kidney injury (AKI), hepatic encephalopathy (HE), and length of stay (LOS). Associations between the timing of diagnostic paracentesis and in-hospital outcomes were examined using multivariable regression models adjusted for MELD-Na and age.
Results: Among 192 hospitalizations, 89 (46.4%) received early paracentesis, and 103 (53.6%) received delayed paracentesis. AKI occurred less frequently in the early paracentesis group compared with the delayed group (31.5% vs 53.4%; $p = 0.002$), as did HE (20.2% vs 37.9%; $p = 0.008$). After adjustment for MELD-Na and age, early paracentesis remained associated with lower odds of AKI (adjusted OR 0.31, 95% CI 0.15–0.62; $p = 0.001$) and HE (adjusted OR 0.43, 95% CI 0.22–0.83; $p = 0.012$). Median LOS was shorter in the early paracentesis group (7 days [IQR 3–12]) compared with the delayed group (13 days [IQR 7–21.5], $p < 0.0001$). In-hospital mortality was numerically lower among patients who received early paracentesis (13.5% vs 21.4%), although this difference did not reach statistical significance ($p = 0.154$).
Conclusion: Diagnostic paracentesis performed within 24 hours of the first physician contact was associated with lower rates of acute kidney injury and hepatic encephalopathy, and with shorter length of stay, among hospitalized patients with cirrhosis and ascites. Measuring paracentesis timing from first physician contact may provide a more clinically meaningful quality metric than admission-based timing and better identify modifiable delays in care.

SAT-510-YI

Reduced thrombin generation capacity in decompensated cirrhosis and acute-on-chronic liver failure is associated with short-term mortality

Alexander Zubko[1], Jonathan Frederik Brozat[2], Rana Ismail[2], Julian Pohl[2], Hannah Schwarz[2], Philipp Enghard[3], Jan Kruse[3], Frank Tacke[2], Christoph Sucker[4], Cornelius Engelmann[2]. [1]*Charité - Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, CCM and CVK, Augustenburger Platz 1, 13353 Berlin, Berlin, Germany;* [2]*Charité - Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, CCM and CVK, Augustenburger Platz 1, 13353 Berlin, Berlin, Germany;* [3]*Department of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin, 13353 Berlin, Berlin, Germany, Berlin, Germany;* [4]*Medical Care Center (Medizinisches Versorgungszentrum), COAGUMED Gerinnungszentrum, Berlin, Germany*
Email: Alexander.Zubko@charite.de

Background and aims: In liver cirrhosis, haemostasis is rebalanced through concomitant alterations of pro- and anticoagulant pathways, limiting the clinical interpretability of conventional coagulation tests such as INR and platelet count. We evaluated thrombin generation assay (TGA) profiles in acute decompensation (AD), acute-on-chronic liver failure (ACLF) compared with healthy controls and explored associations with organ failure and short-term outcome.
Method: In 136 participants (AD n = 74; ACLF grade I–III n = 49; controls n = 13), TGA was performed at baseline from platelet-poor plasma and quantified by tLag, tPeak, peak thrombin (Peak), velocity index (VI) and area under the curve (AUC). Cox proportional hazards models were used to estimate hazard ratios (HR) for 90-day mortality. Elastic-net regression (lambda.min) was applied to derive a composite TGA score based on Peak, VI and AUC.
Results: Compared with AD, ACLF patients showed more pronounced laboratory abnormalities (INR, bilirubin and creatinine, all $p < 0.01$) and had higher disease severity scores (MELD 25 vs. 14; CLIF-C OF 9

vs. 5; p < 0.001). Onset of thrombin generation was delayed in ACLF (median tLag 5.0) compared with AD (3.85) and controls (3.6) (p = 0.007), while time to peak remained comparable (p = 0.148). Quantitative thrombin capacity (AUC) was preserved in AD and controls (p = 0.784) but substantially reduced in ACLF (all p < 0.001 vs. AD/controls). Higher INR and bilirubin correlated with lower Peak, VI and AUC (all p < 0.001). Across AD and ACLF, reduced thrombin capacity (Peak, VI and AUC) correlated with 28-day and 90-day mortality (all p < 0.05). In univariable Cox models, higher Peak, VI and AUC were each associated with a lower risk of 90-day mortality. The elastic-net-derived composite TGA score showed robust prognostic performance (HR 0.546, 95% CI 0.403–0.739; p = 0.001) and remained independently associated with mortality after adjustment for either platelet count, INR, age, sex category or aetiology (platelets HR 0.539 [0.398–0.732], p = 0.001; INR HR 0.645 [0.451–0.921], p = 0.016, respectively).

Conclusion: While the concept of rebalanced haemostasis applies in AD, the development of ACLF represents a turning point characterized by profound alterations in quantitative thrombin generation. The predictive performance of single and composite TGA parameters support TGA as a global coagulation marker for risk stratification in acutely ill patients with cirrhosis.

Cirrhosis and its complications – Experimental and pathophysiology

Targeting the sEH–EET axis with DPP-4 inhibitor and ARNI ameliorates portal hypertension in experimental cirrhosis

Masafumi Oyama[1], Kosuke Kaji[1], Hitoshi Yoshiji[1]. [1]*Department of Gastroenterology, Nara Medical University Hospital, kashihara, Japan*
Email: k184066@naramed-u.ac.jp

Background and aims: Portal hypertension (PH) is a major complication of cirrhosis, and non-selective beta-blockers (NSBBs) are recommended as the standard therapy; however, in some cases, their use may be limited due to systemic hypotension and renal dysfunction. Epoxyeicosatrienoic acids (EETs) improve hepatic microcirculation but are rapidly inactivated by soluble epoxide hydrolase (sEH), whose expression is increased in cirrhotic livers. Inhibition of sEH increases EET levels and has been reported to reduce portal pressure and fibrosis. Dipeptidyl peptidase-4 inhibitors (DPP-i) and angiotensin receptor–neprilysin inhibitors (ARNI) are suggested to maintain EETs through sEH suppression, but their combined effects remain unclear. This study aimed to evaluate the effects of DPP-i and ARNI on portal pressure and liver fibrosis in experimental models of cirrhosis.

Method: F344 rats were fed a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for six weeks to induce cirrhosis. Thereafter, rats received oral administration of vehicle, vildagliptin (10 mg per kg), sacubitril/valsartan (30 mg per kg), combined vildagliptin and sacubitril/valsartan, or carvedilol (10 mg per kg) for an additional six weeks. Portal pressure and systemic hemodynamics were measured, and hepatic sEH activity, EET levels, endothelial function, vascular remodeling, and liver fibrosis were assessed by enzyme-linked immunosorbent assay, quantitative polymerase chain reaction, Western blotting, and immunohistochemistry.

Results: In CDAHFD rats, portal pressure elevation was significantly attenuated by DPP-i or ARNI, and combination therapy showed a reduction comparable to NSBB. Unlike NSBB, DPP-i and ARNI did not alter mean arterial pressure, heart rate, or cardiac output. Both drugs increased vasodilatory markers (Gch, Ddah1), enhanced eNOS phosphorylation, and reduced moesin phosphorylation. Sinusoidal capillarization (CD34), pathological angiogenesis (Vegfa, Ptgs2, Pigf, Vwf), Hedgehog pathway activation, and profibrotic gene expression (Acta2, Col1a1, Tgfb1, Ctgf) were suppressed. sEH expression and activity were elevated in CDAHFD rats and were reduced by both agents, with concomitant increases in hepatic EETs.

Conclusion: DPP-i and ARNI improved portal hypertension and liver fibrosis and demonstrated additive benefits when combined. This therapeutic strategy may represent a novel treatment option for cirrhosis-associated portal hypertension.

TOP-439

Oxidized mitochondrial DNA released from injured hepatocytes drives macrophage STING activation in acute-on-chronic liver failure

Qiankun Hu[1], Xueyun Zhang[2], Yuxian Huang[1,2]. [1]*Shanghai Public Health Clinical Center, Fudan University, Shanghai, China;* [2]*Huashan Hospital, Fudan University, Shanghai, China*
Email: yxhuang@fudan.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by a systemic inflammatory response leading to multi-organ failure and high short-term mortality. Although mitochondrial injury is a prominent feature of ACLF, whether mitochondria-derived danger signals initiate innate immune activation remains poorly defined. We aimed to determine whether oxidized mitochondrial DNA (ox-mtDNA) released from injured hepatocytes acts as a pathogenic trigger of macrophage-driven inflammation in ACLF.

Method: Clinical samples, murine ACLF models, and hepatocyte-macrophage systems were integrated to characterize mtDNA release, oxidative modification, and activation of cytosolic DNA-sensing pathways. Transcriptomic, histological, and molecular analyses were performed to delineate activated innate immune pathways and cell-specific immune responses. The role of cGAS-STING signaling was evaluated using myeloid-specific STING-deficient mice ($STING^{fl/fl}$-$LyzM^{cre}$) and pharmacologic inhibition of cGAS or STING.

Results: In both patients with ACLF and experimental murine models, hepatocellular mitochondrial damage was accompanied by a marked increase in circulating mtDNA copy numbers, with ox-mtDNA representing the dominant form. The accumulation of ox-mtDNA preceded maximal cytokine induction and coincided with early activation of innate immune pathways in the liver. Among cytosolic DNA sensors, cGAS-STING signaling was robustly activated in hepatic macrophages in both murine and human ACLF. In vitro, ox-mtDNA exhibited enhanced immunostimulatory capacity compared with non-oxidized mtDNA, potently activating macrophage cGAS-STING signaling and downstream TBK1-IRF3 and NF-κB pathways. In vivo, intraperitoneal administration of ox-mtDNA in combination with D-galactosamine induced acute liver injury and inflammatory cell infiltration, recapitulating key pathological features of ACLF. Importantly, myeloid-specific deletion of STING or pharmacologic inhibition of cGAS or STING markedly attenuated macrophage activation, reduced hepatic necroinflammation, and improved survival in ACLF mice.

Conclusion: Ox-mtDNA released from injured hepatocytes functions as an upstream pathogenic driver of ACLF by activating macrophage cGAS-STING signaling. Targeting oxidized mtDNA-driven innate immune activation represents a promising therapeutic strategy for attenuating inflammation-driven liver failure.

L-Homoarginine as a novel prognostic biomarker and therapeutic target in cirrhotic dilutional hyponatremia: an integrated study from clinical cohort to mechanistic exploration

Xue Mei[1], Hai Li[2], Guohong Deng[3], Xian-Bo Wang[4], Xin Zheng[5], Yan Huang[6], Jinjun Chen[7], Zhong-Ji Meng[8], Yanhang Gao[9], Feng Liu[10], Yu Shi[11], liujuan Ji[1], Yuyi Zhang[1], Wei Yuan[1], Zhi-Ping Qian[1]. Email: meiw258@163.com

Background and aims: Dilutional hyponatremia (DH) is a life-threatening complication of cirrhosis with no effective therapy, driven by arginine vasopressin-mediated renal aquaporin-2 (AQP2) upregulation. We aimed to identify key pathogenic metabolites through metabolomics and validate their mechanistic role in AQP2 dysregulation.
Method: We analyzed data and plasma from a multicenter prospective cohort (CATCH-LIFE) of cirrhotic patients (n = 1013; 253 with hyponatremia). Untargeted metabolomics was performed to screen differential metabolites. Key findings were validated by targeted metabolomics, in a bile duct ligation (BDL) rat model of cirrhotic DH, and in human renal tubular epithelial (HK-2) cells under hypotonic stress.
Results: Clinical Cohort: Serum sodium was an independent predictor for 90-day adverse outcomes (per 1 mmol/L increase: OR 0.95, 95% CI 0.93–0.97, $p < 0.001$). Patients with uncorrected hyponatremia at day 7 had a 46% increased risk (HR 1.46, 95% CI 1.05–2.02, $p < 0.001$) compared to those corrected, and exhibited higher rates of cirrhosis complications ($p < 0.05$). Metabolomics Discovery: Among 514 significantly altered plasma metabolites in hyponatremic patients, the arginine biosynthesis pathway was most enriched. L-homoarginine (L-hArg) was the most significantly depleted metabolite in the refractory hyponatremia subgroup and demonstrated superior predictive value for 28-day outcomes (AUC = 0.702, 95% CI 0.61–0.79, $p < 0.0001$) compared to other candidates. In Vivo Validation: In BDL-induced cirrhotic rats with DH, L-hArg supplementation significantly downregulated both renal AQP2 mRNA and protein expression ($p < 0.05$) compared to saline-treated controls, paralleling a trend toward higher serum sodium levels. Notably, L-hArg treatment restored AQP2 expression to levels comparable to non-hyponatremic controls. In Vitro Mechanistic Insight: In HK-2 cells, L-hArg potently inhibited the upregulation of AQP2 protein on the cell membrane induced by hypotonic stress ($p < 0.05$). Furthermore, L-hArg treatment enhanced cellular antioxidant capacity, evidenced by increased levels of nitric oxide (NO), superoxide dismutase (SOD), and glutathione (GSH) ($p < 0.05$), without affecting cell proliferation.
Conclusion: L-hArg depletion as a novel hallmark of refractory cirrhotic DH. L-hArg effectively suppresses renal AQP2 expression *in vivo* and *in vitro*, positioning it as a potent dual-purpose biomarker for prognosis and a promising therapeutic candidate for this high-mortality condition.

FRI-382

Neurofilament light chain proteins are a sensitive biomarker of neuronal damage in hepatic encephalopathy

[1]Università Degli Studi Di Messina, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy, Division of Medicine and Hepatology, University Hospital of Messina, Messina, Italy, Messina, Italy; [2]Università Degli Studi Di Messina, Messina, Italy; [3]Università Degli Studi Di Palermo, Division of Medicine and Hepatology, University Hospital of Messina, Messina, Italy, Palermo, Italy; [4]Università Degli Studi Di Messina, Division of Medicine and Hepatology, University Hospital of Messina, Messina, Italy, Department of Clinical and Experimental Medicine, Messina, Italy
Email: clelia.asero@gmail.com

Background and aims: Hepatic encephalopathy (HE) is a severe complication of liver cirrhosis. Although traditionally considered reversible, growing evidence suggests that HE episodes may lead to persistent neuronal damage. This study aimed to evaluate the potential role of neurofilament light chain proteins (NfL) as biomarkers for detecting neuronal injury associated with HE.
Method: Between May 1st, 2024, and April 30th, 2025, 133 patients were consecutively enrolled at the Liver Unit of the University Hospital of Messina. Exclusion criteria included active alcohol use and/or illicit drug consumption, and the presence of neurological disorders. For each patient serum NfL concentrations were measured using Single Molecular Array Technology. The study design included two phases: 1) evaluation of NfL concentration differences across the study population, 2) analysis of correlations between NfL levels and clinical/biochemical parameters routinely used for HE diagnosis [West Haven criteria, ammonia levels, Animal Naming Test (ANT)], as well as anthropometric and nutritional indicators [body mass index (BMI), handgrip strength, calf circumference].
Results: The study population (56.4% males; median age 69 years) included 28 non-cirrhotic (21.1%) and 105 cirrhotic patients (78.9%), 34 of them (32.3%) with a diagnosis of HE. Statistical analysis revealed significant differences in NfL levels across the three groups ($p = 0.001$), with a progressive increase in NfL levels from non-cirrhotic patients (mean rank = 43.13) to cirrhotic patients with HE (mean rank = 78.94). ROC curve analysis demonstrated good discriminative ability of NfL for HE detection with an AUC of 0.753 (95% C.I. 0.630–0.876, $p = 0.001$). Significant negative correlations were observed between NfL levels and ANT scores (Rho = –0.320, $p = 0.001$), suggesting that higher neurofilaments levels were related to poorer cognitive performance, while positive associations were detected for West Haven grades (Rho = 0.168, $p = 0.05$) and ammonia levels (Rho = 0.222, $p = 0.021$), indicating that higher NfL concentrations corresponded to more severe HE grades. Also, higher NfL levels were associated with lower BMI ($p = 0.009$), reduced handgrip strength ($p = 0.008$) and calf circumference < 31 cm ($p = 0.043$), reflecting the impact of sarcopenia on HE development.
Conclusion: NfL is a promising biomarker for HE. Its use in clinical practice may improve early detection and stratification of HE severity in cirrhotic patients.

FRI-383

Effect of nitazoxanide on organ failures in disease models of alcohol-mediated acute-on-chronic liver failure (ACLF)

Sabine Klein[1], Marie Bobowski-Gerard[2], Frank Erhard Uschner[1], Camille Vanbésien[2], Philippe Delataille[2], Simon Debaecker[2], Dean Hum[2], Bart Staels[3], Jonel Trebicka[1], Sakina Sayah Jeanne[2].
[1]Hospital of the Goethe University Frankfurt, University Hospital Münster, Germany, Munster, Germany; [2]GENFIT SA, Loos, France; [3]Univ. Lille, Institut Pasteur de Lille, CHU Lille, Inserm U1011, Lille, France
Email: marie.gerard@genfit.com

Background and aims: Acute-on-chronic liver failure (ACLF) in patients with cirrhosis is characterized by multiple organ failures and is associated with high short-term mortality. Acute alcohol hepatitis is a common ACLF precipitant, triggering immune dysfunction and cell death. We previously demonstrated the beneficial effect of nitazoxanide (NTZ) on systemic inflammation as well as liver and kidney function in lipopolysaccharide-induced ACLF models. The aim of this study was to assess the efficacy of NTZ on cell death and multiple organ failure in alcohol-induced disease models.
Method: To assess the effect of NTZ on organ failure, Sprague-Dawley rats were administered with CCl_4 (1 mg/kg, i.p.) combined with 0.06 g/L phenobarbital and 4 to 16% ethanol in drinking water for up to 16 weeks. When rats reached the decompensated stage (i.e., appearance of ascites), a binge of ethanol at 6 g/kg was given orally to precipitate ACLF. NTZ (150 mg/kg, p.o.) was administered one hour after ethanol binge, then twice daily for 3 days. Markers for organ failure were assessed using blood analysis, pulse oximetry and animal behaviour testing. To assess the *in vitro* effect of NTZ on alcohol-mediated cell death, immortalized human hepatocytes were stimulated with 0.6 mM ethanol and treated with tizoxanide (TZ), NTZ's circulating active metabolite. Cell death was evaluated through measurement of caspase 3 activation and cleavage.
Results: In ACLF rats, NTZ administered post-alcohol binge significantly improved brain dysfunction as shown by a reduction of neurological behaviour scoring: 2.7 vs 1 in the NTZ vs the vehicle group ($p = 0.02$). Peripheral blood oxygenation also improved upon NTZ treatment as shown by an increase of oxygen saturation rate (88% vs. 60% in the vehicle group, $p < 0.001$). NTZ also reduced serum levels of blood urea nitrogen (−29%, $p = 0.05$) and AST (−43%, $p = 0.008$) relative to vehicle in ACLF rats, indicating improvement of liver and kidney function. In human hepatocytes, TZ blunted ethanol-induced apoptosis in a dose-dependent manner as shown by a reduction of caspase 3/7 activity and caspase 3 cleavage ($IC_{50} = 1.9$ µM).
Conclusion: NTZ protects from multiple organ failure (brain, respiratory, liver and kidney) in alcohol-induced ACLF models, which could be explained in part by a direct anti-cell death effect. These findings further support the development of NTZ (investigational drug G1090N) as a new therapeutic approach for ACLF.

FRI-384
Differential activity of nitazoxanide vs rifaximin in lipopolysaccharide-induced disease models

Marie Bobowski-Gerard[1], Philippe Delataille[1], Simon Debaecker[1], Camille Vanbésien[1], Athéna Crespin[1], Bart Staels[2], Jonel Trebicka[3], Sakina Sayah Jeanne[1]. [1]*GENFIT SA, Loos, France;* [2]*Univ. Lille, Institut Pasteur de Lille, CHU Lille, Inserm U1011, Lille, France;* [3]*Hospital of the Goethe University Frankfurt, University Hospital Münster, Germany, Munster, Germany*
Email: marie.gerard@genfit.com

Background and aims: Nitazoxanide (NTZ), an antimicrobial compound with large spectrum activity, has shown promising effects on HE in 3 clinical studies. Moreover, we demonstrated anti-inflammatory and organ protective activities of NTZ in disease models of acute-on-chronic liver failure, a severe complication of chronic liver disease associated with multi-organ failure. Rifaximin is a poorly absorbed antibiotic, indicated for the prevention of hepatic encephalopathy (HE) recurrence in cirrhotic patients. The primary mechanism of rifaximin is thought to occur through is effects on the gut microbiome, although other potential beneficial activities, such as anti-inflammatory effects, have been reported. To better understand the mechanisms of action of NTZ vs rifaximin, we compared their activities on lipopolysaccharide (LPS)-induced inflammatory response *in vivo* and *in vitro*.
Method: Endotoxemia was induced in healthy rats by intraperitoneal (i.p.) injection of LPS (1 mg/kg). A single oral dose of NTZ (300 mg/kg) or rifaximin (50 mg/kg) was administered 15 min after LPS. Serum was collected at 3 and 5 hours post-LPS stimulation and cytokine levels and hepatic function parameters analyzed. TZ, the active metabolite of NTZ, or rifaximin (0.3 to 30 µM) were applied *in vitro* for 6 hours to human PBMCs concomitant with LPS stimulation. Cytokine secretion in the supernatant was measured using a Luminex.
Results: In rats with endotoxemia, NTZ lowered LPS-induced serum cytokine release by 26% for IL-6 ($p = 0.03$), 45% for IL-10 ($p = 0.04$), and 43% for TNF-alpha ($p = 0.14$), in comparison with the vehicle group. LPS-induced levels of hepatic markers were also reduced upon NTZ administration: total bile acids by 100% ($p < 0.001$) and AST by 70% ($p = 0.06$). Finally, NTZ restored albumin levels by 50% ($p = 0.007$). In contrast, rifaximin had no effect on LPS-induced serum levels of inflammatory cytokines and hepatic markers (AST, ALT, albumin, total bile acids), in comparison with the vehicle group. In LPS-stimulated PBMC, TZ dose-dependently inhibited cytokine secretion IL-6 ($IC_{50} = 6.9$ µM; Emax = −88%) and TNF-alpha ($IC_{50} = 0.7$ µM; Emax = −39%), whereas rifaximin showed no effect.
Conclusion: Although both NTZ and rifaximin exhibit broad-spectrum antibiotic activity, these findings highlight NTZ's superior ability to rapidly mitigate systemic inflammation and liver injury/function in LPS-induced disease models.

FRI-385-YI
Serum-conditioned nanoplastics trigger hepatocyte injury and inflammation in human liver tissue

Email: paula.boeira@plymouth.ac.uk

Background and aims: Hepatic accumulation of micro- and nanoplastics (MNPs) has increased over the past decade in parallel with the surge in global plastic pollution and has been reported in patients with cirrhosis. While animal studies demonstrate MNP induced hepatotoxicity, inflammation, and fibrogenesis, mechanistic human data is lacking, identifying a poorly understood risk factor.
Method: Human precision-cut liver slices (hPCLS) preserving native architecture, multicellularity, and immunocompetence from macroscopically normal liver tissue adjacent to resected metastases ($n = 10$) were cultured for 48 h with fluorescent 54 nm polypropylene nanoplastics (PP-NP; 2–25 µg/mL), directly or following pre-incubation with autologous human serum (untreated/heat-inactivated). Hepatotoxicity was assessed by histology (evaluation by histopathologist), cytotoxicity assays, biochemistry, apoptosis/necrosis, confocal microscopy, transmission electron microscopy and flow cytometry. RNA analysis was used to define transcriptional pathways of injury. Immortalized human hepatocytes (IHH) were used to validate key findings.
Results: Subcellular and endosomal accumulation of PP-NPs was observed in >85% of hepatocytes, accompanied by marked hepatotoxicity ($n = 10$; LDH/ALT/AST rise $p < 0.01$) and histological/transcriptional evidence of cellular damage resembling drug-induced liver injury. Serum pre-conditioning significantly exacerbated

toxicity (n = 10; LDH, ALT, AST rise p < 0.001), whereas heat-inactivated serum abolished this effect. IHH recapitulated responses observed in hPCLS. High levels of necrosis were observed and subjects with a significant alcohol history exhibited increased susceptibility to plastic-induced liver injury, suggesting that pre-existing hepatic stress may amplify MNP toxicity.
Conclusion: This study provides mechanistic evidence of plastic-induced liver injury in human tissue. Serum-conditioned nanoplastics, but not heat-inactivated controls, triggered injury at real-world exposure levels, demonstrating that heat-labile serum proteins are mediators of MNP toxicity. Integrated transcriptomic and histological analyses revealed inflammatory and cell-death pathways, establishing a causal mechanism for hepatotoxicity. The heightened susceptibility in patients with alcohol history supports a second-hit model in which nanoplastics exacerbate pre-existing liver stress. These data position MNPs as a clinically relevant environmental risk factor with implications for liver disease progression and exposure regulation.

FRI-386
Monocyte distribution width predicts infection and mortality in acutely decompensated cirrhosis

Robert G Brenig[1,2], Lukas Jutzi[1], Anne Geng[1], Kelly Da Silva[2], Patrizia Künzler-Heule[3], Beatrice Frauchiger[4], Laura Infanti[4,5], Mark J W McPhail[6], Julia Wendon[6], David Semela[3], Christine Bernsmeier[1,2,6]. *[1]Department of Biomedicine, University of Basel, Basel, Switzerland; [2]University Centre for Gastrointestinal and Liver Disease Basel, University Hospital Basel, Basel, Switzerland; [3]Department of Gastroenterology and Hepatology, HOCH Health Ostschweiz – Cantonal Hospital St.Gallen, St. Gallen, Switzerland; [4]Regional Blood Transfusion Center Swiss Red Cross Northwestern Switzerland, Basel, Switzerland; [5]Division of Haematology, University Hospital Basel, Basel, Switzerland; [6]Institute of Liver Studies, King's College Hospital, King's College London, London, United Kingdom*
Email: robert.brenig@unibas.ch

Background and aims: Innate immune dysfunction is a hallmark of advanced cirrhosis and is associated with susceptibility to infection, acute decompensation (AD) and adverse prognosis. Monocyte distribution width (MDW), a measure of monocyte size heterogeneity reflecting cellular activation, has shown diagnostic value in sepsis but remains poorly characterised in cirrhosis. We aimed to evaluate MDW as a biomarker of preserved innate immune activity and to assess its association with disease severity, susceptibility to infection, and short-term prognosis from compensated to acutely decompensated cirrhosis.
Method: Patients with compensated or AD cirrhosis were recruited at two Swiss tertiary centres, along with healthy controls (HC) (Cantonal Hospital St.Gallen [SG]: HC/ Child A/B/C, n = 13/33/25/12; University Hospital Basel [BS]: n = 23/40/29/4). An independent cohort of patients with AD (n = 25) was included from King's College London (KCL). Peripheral blood monocytes were identified by flow cytometry using a CD14/CD16/HLA-DR gating strategy. MDW was analysed retrospectively defined as the standard deviation of forward scatter width.
Results: In the SG cohort, MDW correlated with diverse cirrhosis severity scores (Child: r = 0.24, p = 0.03; MELD: r = 0.24, p = 0.03; ALBI: r = 0.27, p = 0.02), albumin (r = –0.24, p = 0.04), portal hypertension (HVPG: r = 0.41, p = 0.01), and immune markers (CD16: r = 0.23, p = 0.04; HLA-DR: r = -0.25, p = 0.03). Associations with severity scores were confirmed in the BS cohort (Child: r = 0.23, p = 0.05; MELD: r = 0.26, p = 0.04), here MDW also correlated with CRP (r = 0.32, p = 0.01) and INR (r = 0.30, p = 0.02). In AD patients from the BS cohort, MDW increased significantly within 24 hours of AD onset (d0-d1 = 1277, p = 0.01). MDW at AD onset predicted primary infection (AUROC 0.90, p = 0.03), secondary infection within 14 days (AUROC 0.88, p = 0.04), and 1-month mortality (AUROC 0.91, p = 0.02). In AD patients from the BS and KCL cohorts, failure of the MDW to increase within the first 1–3 days after AD onset (d0-d1–3 = –1389) was a strong predictor of transplantation or death within 28 days (AUROC 0.93, p = 0.02).
Conclusion: MDW was associated with cirrhosis severity, infection risk and short-term mortality. Notably, early dynamic changes in MDW within 1–3 days after AD onset predicted 28-day transplant-free survival. Despite small cohorts, these findings support MDW as a simple, inexpensive biomarker for risk stratification and immune monitoring in AD.

Apical sodium-dependent bile acid transporter (ASBT) inhibition improves hepatic and extrahepatic manifestations in a mouse model of cirrhosis

Francisco Javier Caballero-Camino[1,2], Noelia Pastor de los Toyos[1], Mireia Tena-Garitaonaindia[1], Santiago Iturbe-Rey[1], Beatriz Val[1], Maider Huici-Izagirre[1], Laura Izquierdo-Sánchez[1,2], Maria Jesus Perugorria[1,2], Pedro Rodrigues[1,2,3], Luis Bujanda[1,2,4], Peter Åkerblad[5], Erik Lindstrom[5], Jesus M Banales[1,2,3,6]. *[1]Department of Liver and Gastrointestinal Diseases, Biogipuzkoa Health Research Institute - Donostia University Hospital - University of the Basque Country (UPV/EHU), San Sebastian, Spain; [2]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, "Instituto de Salud Carlos III"), Madrid, Spain; [3]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain; [4]Department of Medicine, Faculty of Medicine and Nursing, University of the Basque Country (UPV/EHU), San Sebastian, Spain; [5]Ipsen, Gothenburg, Sweden; [6]Department of Biochemistry and Genetics, School of Sciences, University of Navarra, Pamplona, Spain*

Background and aims: Liver cirrhosis is estimated to cause about one million deaths worldwide each year. In addition to the pathological changes within the liver, extrahepatic complications including, portal hypertension and persistent systemic inflammation, are major drivers of disease progression and clinical outcomes. Disrupted bile acid (BA) homeostasis, particularly increased BA concentrations, is a hallmark of cirrhosis; however, its pathological contribution remains poorly understood. Here, we evaluated the role of the sodium-dependent bile acid transporter (ASBT) in a mouse model of cirrhosis, using either a gut-restricted ASBT inhibitor (elobixibat) or a systemic ASBT inhibitor (ritivixibat).
Method: A mouse model of advanced fibrosis with cirrhotic features was established through chronic (12-week) administration of carbon tetrachloride (CCl_4). Starting from the 3rd week of CCl_4 administration, elobixibat or ritivixibat were provided in chow at doses of 2.5 and 12 mg/kg/day respectively. Liver histology was assessed blindly by an expert pathologist. Serum BA species were quantified using UHPLC-MS.
Results: Mice exposed to chronic CCl_4 administration developed advanced liver fibrosis, inflammation, steatohepatitis and splenomegaly, along with increased serum transaminases, bilirubin, and iron levels compared with healthy controls. Consistent with previous findings in cirrhotic patients (Sauerbruch T, *et al*. Front. Physiol. 2021), total serum bile acid (TBA) levels were elevated in CCl_4-challenged mice, accompanied by a higher proportion of primary and conjugated BAs. Chronic treatment with either ritivixibat or elobixibat reduced serum TBA levels and restored the balance of primary/secondary and conjugated/unconjugated BAs in CCl_4-exposed mice. These improvements were accompanied by significant reductions in liver fibrosis, steatohepatitis and transaminases, as well as normalization of splenomegaly, serum iron levels, and perivenous hepatic iron deposition. Importantly, serum TBA concentrations—as well as the proportions of primary and conjugated BAs—positively correlated with the histopathological liver phenotype, biochemical serum markers of hepatic injury (transaminases and bilirubin), and spleen size across all study groups.
Conclusion: ASBT inhibition restores bile acid homeostasis and significantly improves hepatic and extrahepatic features of advanced

fibrosis, supporting its potential as a therapeutic strategy for advanced liver disease.

FRI-388-YI

Maladaptive emergency myelopoiesis (EM) is already activated in patients with the less severe forms of acutely decompensated cirrhosis (ADC), and its amplification drives progression towards severity

Email: richard.moreau@efclif.com

Background and aims: Whether maladaptive EM (i.e., amplified myelopoiesis with immunosuppressive features), which is associated with acute-on-chronic liver failure (ACLF) and pre-ACLF, is also seen in less severe forms of ADC is unknown. The dynamicity of maladaptive EM with disease progression is also unknown. We addressed these questions here.

Method: We analyzed whole-blood RNA-seq data obtained in 25 healthy subjects (HS) and on admission from 501 patients who were classified as AD (ADC without ACLF by day-28, n = 299), pre-ACLF (ADC developing ACLF by day-28, n = 79), and ACLF (n = 123). In addition, we performed multivariable ordinal regression with the adjacent categories logit model to analyze the association between transcriptional changes and the progression of disease from HS to ACLF through AD and pre-ACLF.

Results: Compared to the group of HS, each patient's group presented with features of activated EM, including neutrophilia, monocytosis, upregulation of the *STAT3* gene and its target *CEBPB* (which encodes a master transcription factor driving EM), together with upregulation of genes related to immature and mature neutrophils and monocyte subsets. Each patients group also had upregulation of genes related to low-density neutrophils and myeloid suppressor cells (known to suppress lymphocyte functions), features indicating that EM was maladaptive. Flow cytometry analysis confirmed the presence of maladaptive EM in AD. Using weighted gene co-expression network analysis, we identified 24 gene programs, of which one was representative of maladaptive EM (member genes included, e.g., transcription factor *CEBPA*, granule genes [*RETN, NAPRT, NEU1, RNASE2, CTSC*], and immunosuppressive genes [*IL10, CD163, C1QA/B, MERTK, MARCO, HMOX1*]). Multivariable ordinal regression with the adjacent categories' logit model revealed that amplifying the maladaptive EM gene program was associated with a higher risk of disease progression to the next most severe stage (common odds ratio [cOR], 1.83; 95% CI, 1.59–2.11), after adjustments for differences in age, sex, BMI, and clinical precipitants.

Conclusion: Maladaptive EM is already activated among patients who present with the less severe forms of ADC. Moreover, amplification of the maladaptive EM gene program per se may drive progression to severe forms of ADC, findings suggesting that this program should be a target for future therapies aiming to prevent disease progression.

Background and aims: Cirrhosis and hepatocellular carcinoma (HCC) are long-term complications of chronic liver disease (CLD). We aimed to study the genetic basis of cirrhosis and HCC relative to CLD risk factors and clinical risk prediction.
Method: Multi-ancestry genome-wide association studies (GWAS) for cirrhosis and HCC included cohorts from North America, Europe and Asia with: 1) 35,481 all-cause cirrhosis cases vs 2.36M population controls; 2) replication cohort of 8,806 cirrhosis cases vs 328,061 population controls; 3) 35,481 all-cause cirrhosis cases vs 191,491 CLD controls; 4) 6,680 HCC cases vs 1.76M population controls; 5) 4,995 HCC cases vs 706,432 population controls; 6) 6,680 HCC cases vs 191,491 CLD controls. Genome-wide significance (GWS) was defined by p-value < 5×10^{-8}. We also conducted coding variant, gene burden, immunogenetic, causal mediation, multi-state survival, risk prediction, drug target discovery and treatment response analyses in a subset of the cohorts.
Results: All-cause cirrhosis GWAS with population controls identified 27 GWS cirrhosis-associated loci, including 10 novel loci of which three (*FGF21*, *RPTOR*, and *IFNL3/4)* were replicated in independent cirrhosis cohorts. Cirrhosis GWAS using CLD controls showed 6 GWS loci (*PNPLA3, SERPINA1, HLA, TM6SF2, HKDC1*), of which *CD81* was novel. HCC GWAS with population controls identified 11 GWS HCC-associated loci of which three were novel (*EPHA2, CD81, TENM4*), without GWS loci for HCC GWAS with cirrhosis controls. In causal mediation analyses, 15 cirrhosis loci showed differential effects on cirrhosis risk via underlying etiologies (e.g. alcohol, metabolic, viral) and 6 HCC loci influenced HCC risk through cirrhosis. In a gene-burden analysis of rare variants from whole-genome sequencing data in the VA Million Veteran Program (n = 102,677), we identified *GSTA5* as a novel cirrhosis-associated gene, while *APOB* and *ATP9B* were associated with and replicated for HCC. Furthermore, a high genetic risk score for cirrhosis was associated with a nearly doubled risk of CLD progression to cirrhosis (HR = 1.94, $P = 2 \times 10^{-68}$) and cirrhosis progression to HCC (HR = 1.65, $P = 7 \times 10^{-8}$). Finally, among individuals with chronic hepatitis C, cirrhosis risk following therapy was modified by *PNPLA3*, *IFNL3/4*, and *CD81* variants for PEG-IFN, and by *APOE* lead variant for DAA.
Conclusion: These findings define genetic basis of HCC and cirrhosis, with distinct interplays with underlying CLD causes and potential prognostic implications.

FRI-394-YI
Reduced cardiorespiratory fitness and its physiological determinants in patients with cirrhosis: evidence of cirrhosis-induced myopathy

Alexis Couret[1], Fabrice Rannou[2], Bruno Pereira[2], Camille Marcantei[1], François Le Calvez[1], Valérie Julian[2], Martine Duclos[2], Fréderic Costes[2], Leon Muti[3], Benjamin Buchard[3], Sarah Arbogast[3], James King[4], Delphine Weil-Verhoeven[5], Armand Abergel[3], Gael Ennequin[1].

Email: Alexis.couret@uca.fr

Background and aims: Cirrhosis induces multi-organ dysfunction, yet the specific physiological determinants underlying reduced cardiorespiratory fitness (CRF) remain poorly defined. This study aims to compare patients with cirrhosis to healthy controls to assess and identify the main contributors to CRF.
Method: Forty-five patients with cirrhosis and 45 age- and sex-matched controls underwent incremental cardiopulmonary exercise testing (CPET) on a cycle ergometer. The pulmonary, cardiac, vascular, and muscular components of CRF were measured, including peak oxygen uptake (VO_{2Peak}), ventilatory efficiency (VE/VCO_2), oxygen uptake efficiency slope (OUES) and chronotropic response. Non-invasive hemodynamic monitoring (Physioflow®) was used to estimate cardiac output and arteriovenous oxygen difference (a-vO_2). In pre-transplantation settings, a sub-group of twenty-five patients with cirrhosis did plethysmography and diffusing capacity evaluation.
Results: Patients with cirrhosis exhibited markedly reduced CRF compared with controls (VO_{2Peak}: 15.4 ± 5.5 vs 29.3 ± 7.5 $ml.min^{-1}.kg^{-1}$, $p < 0.001$) and the decline correlated to Child-Pugh score. Kinetic parameters (OUES: 1467 ± 544 vs 2216 ± 584, Lowest VE/VCO_2: 35.3 ± 9.3 vs 27.6 ± 4.5, Wilkoff index: 0.50 ± 0.28 vs 0.95 ± 0.19; $p < 0.001$) were also significantly impaired and chronotropic incompetence was highly prevalent (89%). Cardiac output during exercise was preserved but a-vO_2 was decreased (10.7 ± 3.0 vs 14.1 ± 1.1 $mlO_2.dl^{-1}$, $p = 0.002$), indicating a defective peripheral oxygen extraction in patients with cirrhosis. Multivariate regression analysis ($r^2 = 0.79$) identified maximal heart rate and muscle performance (5-sit to stand) as independent predictors of $VO_{2Peak.}$
Conclusion: Reduced CRF in cirrhosis appears to result mainly from impaired skeletal muscle oxygen utilisation, compounded by chronotropic incompetence. Muscle function has shown to be the most important determinant of CRF impairment with evidence of cirrhosis-induced myopathy. These findings emphasize the value of integrative functional evaluation in cirrhosis management.

FRI-395-YI
Recapitulating cirrhosis in vitro using a primary liver microphysiological system and patient plasma profiling

Laura de Jong[1], Luuk de Haan[2,3], Vincent van Duinen[2], Iris Schilt[2], Tomás Coimbra[2], Sander de Ruiter[2], Lenie van den Broek[2], Minneke Coenraad[1]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]MIMETAS BV, Oegstgeest, Netherlands; [3]Leiden Academic Centre for Drug Research, Leiden, Netherlands*
Email: l.m.de_jong@lumc.nl

Background and aims: Liver cirrhosis is the end stage of chronic liver disease and a major cause of liver-related mortality. Progress in understanding its pathophysiology and developing therapies is hampered by the lack of preclinical models that mimic the multicellular architecture and complexity of the cirrhotic liver. This study aims to develop a human liver microphysiological system (MPS) that mimics key features of cirrhosis and to investigate how patient plasma from different stages of cirrhosis affects liver phenotype in the MPS.
Method: Plasma from patients with compensated cirrhosis, decompensated cirrhosis, and acute-on-chronic liver failure (ACLF) was profiled using targeted lipidomics and Olink Reveal proteomics. In parallel, we developed a primary human liver model using OrganoPlate Graft technology by embedding primary hepatocytes, liver-derived endothelial cells, stellate cells, and Kupffer cells in hydrogel under unidirectional flow. Cirrhosis-like features were induced through combined LPS/TGF-β exposure with controlled lipid loading.
Results: Lipidomics on plasma showed widespread lipid suppression with selective accumulation of free fatty acids, lactosylceramides, and phosphatidic acids in decompensated and ACLF patients, but not in compensated disease. Proteomic profiling revealed stage-specific remodeling, with clear separation by principal component analysis (PC1 30%, PC2 15%) and 519, 717, and 758 proteins altered in compensated, decompensated, and ACLF patients, respectively. IL-6, HAVCR, CA9 and MUC13 were among the most consistently altered hits. To evaluate the impact of disease-stage specific plasma on liver phenotype, we developed a human liver MPS containing four cell types, which maintained core hepatic functions, including stable albumin production (>5 µg/mL/day) and CYP activity for 19 days. The model was immunocompetent, with a 4-fold IL-6 increase after LPS

stimulation, and showed a perfusable vascular network. The 10-day cirrhosis trigger induced lipid accumulation and inflammatory and pro-fibrotic mediator release, recapitulating steatosis and fibrosis. Plasma exposure experiments on the MPS model are ongoing.
Conclusion: Plasma profiling revealed disease stage-specific lipid and proteomic alterations. To explore the functional impact of these changes, we developed a human liver MPS that maintained hepatic function and recapitulated cirrhosis-like steatosis and fibrosis, establishing a platform with the potential to link patient plasma profiles to liver phenotype.

FRI-396
Dyslipidemia is associated with impaired fibrinolysis in patients with cirrhosis
Fynn Elvers[1], Jelle Adelmeijer[1], Marilena Stamouli[2], William Bernal[3], Vishal C Patel[2], Ton Lisman[1]. *[1]Surgical Research Laboratory and Section of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Roger Williams Institute of Liver Studies, School of Immunology & Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, Foundation for Liver Research and King's College Hospital, London, United Kingdom; [3]Liver Intensive Therapy Unit, Institute of Liver Studies, Kings College Hospital, London, United Kingdom*
Email: fynn.l.elvers@gmail.com

Background and aims: Patients with cirrhosis frequently show abnormalities in lipid profiles and circulating proteins of clot breakdown (fibrinolysis). Recent studies suggest that fibrinolytic proteins regulate lipid metabolism and that dyslipidemia is associated with fibrinolytic abnormalities. However, these mechanisms have not yet been studied in experimental models of liver disease or patients with cirrhosis. We aimed to study the relationships between fibrinolytic parameters and lipid profiles across stages of cirrhosis.
Method: Plasma and serum samples were collected from patients admitted to King's College Hospital, United Kingdom. We studied 33 patients with stable cirrhosis (SC), 42 with decompensated cirrhosis (DC), 43 with acute-on-chronic liver failure (ACLF) and 29 with sepsis without liver disease (as a reference for systemic inflammation), and compared them to reference values from 38 healthy controls. We quantified fibrinolysis by clot lysis time (CLT), plasminogen (PLG), plasminogen activator inhibitor 1 (PAI-1), and tissue-plasminogen activator (tPA), and assessed serum lipids through apolipoprotein-A1 (ApoA1), very low-density lipoprotein (VLDL), LDL, high-density lipoprotein, lipoprotein (a) (Lp(a)), triglycerides and total cholesterol.
Results: CLT was shortened in SC and DC, and prolonged in ACLF and sepsis. PLG decreased, while PAI-1 and tPA increased progressively with cirrhosis severity and in sepsis. Triglycerides were similar to controls in cirrhosis but high in sepsis. All other lipids decreased progressively with cirrhosis severity and in sepsis. In multiple-testing adjusted correlation analysis for cirrhosis, we found statistically significant ($p < 0.05$) associations for ApoA1 with CLT ($r = -0.24$), PAI-1 ($r = -0.29$), tPA ($r = -0.22$) and PLG ($r = 0.39$, $p < 0.001$), for triglycerides with CLT ($r = 0.32$), and for LDL ($r = 0.29$) and Lp(a) ($r = 0.28$) with PLG. In sepsis, LDL ($r = 0.53$), VLDL ($r = 0.44$), Lp(a) ($r = 0.48$), total cholesterol ($r = 0.52$) and triglycerides ($r = 0.44$) correlated with PLG.
Conclusion: Progressive cirrhosis was characterized by a shift toward impaired fibrinolysis and declining lipid levels. ApoA1 showed inverse, and triglycerides, LDL, and Lp(a) positive, associations with fibrinolytic parameters, consistent with prior experimental and non-cirrhotic human studies. Our findings suggest that dyslipidemia is linked to impaired fibrinolysis in cirrhosis which may contribute to thrombosis risk, warranting further mechanistic studies.

FRI-397-YI
Increased ceftriaxone exposure in hospitalised patients with decompensated cirrhosis compared to patients without cirrhosis revealed by population pharmacokinetic modelling (TACTILE study)
Solaiman Ezzafzafi[1], Reinier van Hest[1], Ron Mathôt[1], Midas B. Mulder[2], Brenda De Winter[3], Joost PH Drenth[1], Raoel Maan[3], Marten Lantinga[1]. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]Haaglanden MC, Den Haag, Netherlands; [3]Erasmus MC, Rotterdam, Netherlands*
Email: s.ezzafzafi@amsterdamumc.nl

Background and aims: Bacterial infections are a leading cause of decompensation and mortality in patients with cirrhosis. Guidelines recommend adequate antibiotic treatment, but pathophysiological changes in decompensated cirrhosis alter drug pharmacokinetics (PK), potentially resulting in unpredictable and complex drug behaviour. Ceftriaxone (CFX) is widely used in decompensated cirrhosis, however liver-related alterations may affect the PK despite predominant renal clearance. There is limited PK data to inform proper dosing in liver cirrhosis. This study investigated whether CFX exposure was changed in patients with cirrhosis compared to hospitalised patients without cirrhosis. Funding: Gastrostart (24-2023).
Method: The TACTILE study is a multicentre observational study in hospitalised patients with decompensated cirrhosis and ascites treated with intravenous CFX 2 g/day. Waste material blood samples were collected to measure unbound (pharmacologically active) CFX plasma concentrations (CFX_u). A published population PK (popPK) model developed in non-cirrhosis patients was used to predict CFX_u in patients with cirrhosis. Measured CFX_u were compared with model-predicted CFX_u, and bias (mean prediction error, MPE) and precision (normalised root mean squared error, NRMSE) were assessed as measures of predictive performance. In case of significant bias and/or imprecision, the popPK model would be refitted with the obtained CFX_u to assess differences in PK.
Results: The analysis included 75 CFX_u measurements from 19 patients with cirrhosis (median age 62 years [IQR 50–71], eGFR 84 mL/min/1.73 m^2 [IQR 51–106], MELD-Na score 18 [IQR 16–25], n = 7 Child-Pugh B and n = 12 Child-Pugh C). Measured CFX_u in patients with cirrhosis (range 1–76 mg/L) were significantly underestimated by the popPK model in non-cirrhosis patients, with a MPE of −25% [95% CI −38 to −11] and substantial imprecision of 79% (NRMSE; 95% CI 68–89). Refitting the popPK model revealed CFX_u clearance in patients with cirrhosis to be 4.2 L/h (95% CI 3.5–5) compared to 7.2 (95% CI 6.3–8.2) L/h in the population of non-cirrhosis patients that served as a basis for development of the original popPK model.
Conclusion: CFX exposure is higher in hospitalised patients with decompensated cirrhosis when compared to patients without cirrhosis. This finding reveals that renally cleared drugs warrant cirrhosis-specific dosing recommendations and challenges the assumption that drugs independent of liver metabolism are unaffected by advanced chronic liver disease.

FRI-398
Comparing the intrahepatic effects of carvedilol and simvastatin in experimental liver cirrhosis
Yeldos Nulan[1,2,3], Eric Felli[2,3], Cong Wang[2,2], Sonia-Emilia Selicean[2,3], Manuel Prampolini[1,2,3], Annalisa Berzigotti[2,3], Jordi Gracia-Sancho[2,3,4], Jaime Bosch[2,3]. *[1]Graduate School for Cellular and Biomedical Sciences (GCB), University of Bern, Bern, Switzerland; [2]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [3]Department for BioMedical Research, Hepatology, University of Bern, Bern, Switzerland; [4]Liver Vascular Biology Research Group, CIBEREHD, IDIBAPS Research Institute, Barcelona, Spain*
Email: nulan.yeliduosi@unibe.ch

Background and aims: Portal hypertension (PH) arises primarily due to increased intrahepatic vascular resistance (IHVR) driven by structural alterations, such as architectural remodeling due to hepatic stellate cells (HSCs) activation, and elevated hepatic vascular tone resulting from liver sinusoidal endothelial cells (LSECs) dysfunction. Non-selective-beta-blockers (NSBBs) lower PH through extrahepatic actions. Recently, in experimental cirrhosis, we found that carvedilol, a newer generation NSBB with additional anti-alpha1-adrenergic activity, achieves a superior reduction in portal pressure (PP) compared to traditional NSBBs by decreasing IHVR. Simvastatin, a type of HMG-CoA reductase inhibitor, is well established in reducing IHVR by 1) improving LSECs phenotype and increasing NO release, and 2) deactivating HSCs, both through the Krüppel-like factor 2 (KLF2) transcription pathway. This study aims to evaluate the potential synergistic effects of carvedilol and simvastatin in reducing HSCs and LSECs activation and dysfunction both in vitro and in vivo in a rat model of cirrhosis.
Method: *In vitro*: LSECs and HSCs were isolated from cirrhotic rats (i.p. thioacetamide 12 weeks) and then cultured with carvedilol (C)/simvastatin (S)/carvedilol plus simvastatin (C+S) for 24 hours. Endothelial function was assayed by NO bioavailability. Cell contraction assays were performed in cirrhotic HSCs. (n = 3–5). *In vivo*: hepatic hemodynamics were assessed in cirrhotic rats treated with carvedilol (10 mg/kg/day) or simvastatin (25 mg/kg/day) or carvedilol plus simvastatin for 2 weeks (n = 6–9). Hepatic remodeling was evaluated by measuring the collagen proportionate area (CPA), and HSCs activation were assessed via immunofluorescence detection of alpha-smooth muscle actin (α-SMA) in liver sections.
Results: In vitro: NO release was increased in all experimental groups vs vehicle, by 2.2, 2.3 and 2.2 fold-change respectively. HSCs cell contraction was reduced by 49% in C,78% in S, and 84% in C+S. In vivo: All treatments reduced PP by 29.7% (C), 16.9% (S), and 29.5% (C+S). CPA-positive area in liver tissue slides was reduced by 35.1%, 35.0% and 26.4% respectively. αSMA-positive area was reduced by 33.5%, 32.7%, and 32.5% respectively (all $p < 0.05$).
Conclusion: These results indicate that combined carvedilol and simvastatin treatment is comparable to their individual effects, ameliorating endothelial function and reducing hepatic stellate cell activation and support further characterization of their synergistic effects.

FRI-399

Neutrophil-derived miR-223 suppresses inflammasome activation and ameliorates pyroptotic cell death in peritoneal macrophages during spontaneous bacterial peritonitis

Mick Frissen[1], Majda El Hassani[1], Karsten Große[1], Philipp Reuken[2], Stefanie Quickert[2], Johanna Reißing[1], Oluwatomi Ibidapo-Obe[1], Tony Bruns[1]. *[1]University Hospital RWTH Aachen - Department of Internal Medicine III, Aachen, Germany; [2]University Hospital Jena - Department of Internal Medicine IV, Jena, Germany*
Email: mfrissen@ukaachen.de

Background and aims: Spontaneous bacterial peritonitis (SBP) is a frequent complication of decompensated cirrhosis often precipitating acute-on-chronic liver failure. While the peritoneal influx of neutrophils is a hallmark of peritonitis, the regulatory signaling between infiltrating cells and resident peritoneal macrophages (PMφ) remains poorly defined. We hypothesized that microRNAs (miRNAs) serve as local mediators in this peritoneal immune crosstalk.
Method: We performed multiplex microRNA profiling on paired serum and ascitic fluid samples from patients with decompensated cirrhosis before and during SBP, and candidate miRNAs were validated using qRT-PCR. To dissect cellular origin and functional impact, we utilized primary human neutrophil and PMφ *ex vivo* models as well as mechanistic studies using miRNA mimic technology.
Results: miRNA profiling revealed a distinct peritoneal miRNA landscape during SBP, characterized by a significant enrichment of miR-223 in ascites but not in serum. We identified infiltrating neutrophils as the primary source of extracellular miR-223. *In vitro*, isolated PMφ exposed to conditioned medium from circulating neutrophils of patients with SBP exhibited robust inflammatory gene expression and inflammasome activation, which was ameliorated by a synthetic miR-223 mimic, which suppressed *NLRP3* expression and abrogated Caspase-1-mediated pyroptosis.
Conclusion: Our findings define an intercellular resolution circuit in SBP, wherein infiltrating neutrophils release miR-223 to act as a molecular brake on resident macrophages. By dampening NLRP3 inflammasome activation and preventing pyroptosis, this paracrine transfer limits excessive peritoneal inflammation.

FRI-400

IGF1r receptor is involved in the Th17-mediated response in chronic liver disease

Ani Gasparyan[1,2,3], Oriol Juanola[1,2], Paula Boix[1,2], Isabel Gómez-Hurtado[1,2], Manuel Sánchez[1], Albina Espana[1], Esther Caparrós[1,2], Rubén Francés[1,2]. *[1]Laboratorio de Inmunobiología Hepática e Intestinal, Departamento de Medicina Clínica, UMH, San Juan, Spain; [2]ISABIAL Investigación en Inmunobiología Hepática e Intestinal, Alicante, Spain; [3]Departamento de Farmacología, UMH, San Juan, Spain*
Email: rfrances@umh.es

Background and aims: The immune system plays a key role in the development of chronic liver disease (CLD) orchestrating the transition from compensated to decompensated disease. One of the main factors involved in the regulation of Th17-Treg balance is the insulin-like growth factor (IGF) system. However, the exact role of the IGF1-IGF1r pathway in CLD remains unclear. Therefore, the main goal of this study was to further explore the role of the IGF1-IGF1r duo in regulating the functionality and maintenance of Th1y cells, as well as the interaction with other liver damage-associated ligands in a model of experimental cirrhosis.
Method: Two experimental approaches were used. Firstly, an animal model of experimental cirrhosis by CCL4 administration was carried out in a total 20 C57BL/6J male mice (6–8 weeks of age). And, secondly, an in vitro model was used to stimulate naïve T cells differentiation into Th17 cells simulating the pro-inflammatory microenvironment in the liver. These cells were used to co-culture with hepatocyte and to evaluate Th17-mediated response under different experimental conditions. Flow cytometry, relative RNA gene expression, western blotting and ELISA were used.
Results: Flow cytometry studies revealed higher expression of IGF1r receptors in Th17 cells from spleens of cirrhotic mice vs controls (12.7 ± 1.4 vs. 1.4 ± 0.7 units, $p < 0.0001$) and a higher percentage of IGF1r+ cells ((24.9 ± 0.2 vs. 16.1 ± 0.7%, $p = 0.0009$). An increase in the gene expression of Igf1r (6.1 ± 3.9 vs. 1.1 ± 0.5 units, $p = 0.0003$) and Igf1 (2.2 ± 0.7 vs. 1.1 ± 0.3 units, $p = 0.0001$) were observed in co-cultured lymphocytes and hepatocytes, respectively. In addition, higher IGF1 ligand levels were observed in the co-culture supernatant (0.32 ± 0.01 vs. 0.27 ± 0.02 units, $p = 0.0001$). Ligand-exposure studies revealed a synergistic action between IGF1r and TLR4 in Th17, as IGF1 ligand increased IL-17 expression but even higher IL-17 was observed with the combination of IGF1 and HMGB1 ligands (19.7 ± 0.9 vs. 14.65 ± 1.0 units, $p = 0.0003$). The use of IGF1r antagonist reduced IL-17 expression compared to controls (5.17 ± 1.64 vs. 16.8 ± 5.0 units, $p = 0.012$).
Conclusion: Blocking IGF1r reduces the activity of primary differentiated Th17 lymphocytes. Given the synergistic activity of IGFr1 with other innate receptors, its modulation may constitute a new tool for reducing Th17 expansion present during advanced CLD.

Email: humeiqian@zju.edu.cn

Background and aims: Overt hepatic encephalopathy (OHE) is a severe neuropsychiatric complication of decompensated cirrhosis. Beyond hyperammonemia, increasing evidence suggests that systemic immune dysregulation and metabolic alterations contribute to its pathogenesis. We aimed to characterize the immune-metabolic landscape associated with OHE using integrative multi-omics analyses.
Method: Transcriptomic profiling was performed in 78-patients with decompensated cirrhosis from the PREDICT cohort, comparing patients with OHE and age- and sex-matched non-OHE controls (1:2). Differential expression, pathway enrichment (GO and KEGG), and gene set enrichment analyses were conducted. In a subset of 37-patients with paired transcriptomic and metabolomic data, integrative analyses were used to explore immune-metabolic interactions. Transcriptomic data from microglia and astrocytes isolated from bile duct ligation (BDL) and sham-operated mice were analyzed for supportive validation.
Results: Whole blood transcriptomics revealed that OHE was characterized by robust activation of type I interferon signaling and innate antiviral responses, including upregulation of interferon-stimulated genes, RIG-I-like receptor signaling components, and chemokines involved in immune cell recruitment. Genes related to tryptophan metabolism (IDO1, IL4I1) were significantly upregulated. Gene set enrichment analysis further confirmed enhanced innate immune and interferon responses, accompanied by downregulation of pathways related to glial and astrocyte differentiation. Metabolomic profiling identified distinct metabolic alterations in OHE, with prominent enrichment of pathways related to carnitine synthesis, ammonia recycling, amino-acid and purine metabolism. Integrative correlation analysis demonstrated significant associations between interferon-related genes and metabolites involved in carnitine metabolism and the tryptophan-kynurenine pathway. In keeping with the systemic data, interferon-stimulated genes, including Mx1, were markedly upregulated in microglia and astrocytes from BDL mice.
Conclusion: OHE is associated with a systemic type I interferon-driven immune activation coupled with metabolic reprogramming. These alterations may contribute to impaired glial homeostasis and neuroinflammation, providing important mechanistic insights into the pathogenesis of OHE and potential therapeutic targets related to type 1 interferon and tryptophan metabolism pathways.

FRI-402

A peritoneal macrophage-Th1/Th17 axis drives inflammation in spontaneous bacterial peritonitis

Oluwatomi Ibidapo-Obe[1], Majda El Hassani[1], Johanna Reißing[1], Mick Frissen[1], Haedge Frederic[1], Mohamad Murad[1], Karsten Grosse[1], Tony Bruns[1]. *[1]Department of Internal Medicine III, University Hospital RWTH, Aachen, Germany*
Email: oibidapo@ukaachen.de

Background and aims: Bacterial infections like spontaneous bacterial peritonitis (SBP) are a major cause of morbidity and mortality in cirrhosis. We investigated the phenotype and function of peritoneal T helper cells in ascitic fluid (AF) and their interaction with peritoneal macrophages during SBP.
Method: We profiled blood and AF T helper cells from cirrhosis patients with and without SBP using unsupervised mass cytometry (CyTOF) and flow cytometry. Cytokines and chemokines were quantified in plasma and AF by Luminex and ELISA. Sorted AF T helper cell subsets were analysed by sequencing. To mimic peritoneal infection, we co-cultured AF CCR6$^+$ CD4$^+$ T cells with autologous macrophages and heat-killed *E. coli*.
Results: Peritoneal, resident-like CD69$^+$ T helper cells were abundant in AF compared to blood and showed heterogeneous CD127 expression. Unlike their CD127lo counterparts, CD4$^+$ CD69$^+$ CD127$^+$ cells displayed an activated effector phenotype, co-expressing CCR6 with CD161, CD49a, and CXCR3. Upon stimulation, these cells produced both IL-17 and IFN-γ, and gene profiling confirmed a pathogenic Th1/Th17 signature distinct from circulating T cells. During SBP, these Th1/Th17 cells (CD4$^+$ CXCR3$^+$ CCR6$^+$) were enriched in AF but not blood. Peritoneal levels of the CCR6 ligand CCL20 correlated with the severity of local and systemic inflammation. In vitro, *E. coli*-exposed macrophages produced CCL20 and pro-inflammatory cytokines, which enhanced IFN-γ and IL-17 production by co-cultured CCR6$^+$ T cells.
Conclusion: Our findings reveal a macrophage-Th1/Th17 inflammatory circuit in SBP, driven by CCL20-mediated recruitment and sustained by macrophage-derived cytokines. Peritoneal CCR6$^+$ T helper cells represent a key driver of peritoneal inflammation and a potential target for modulating immunity in cirrhosis-associated infections.

FRI-403

Ascites bactericidal capacity in patients with decompensated cirrhosis

Isanka Ratnasekera[1], Min-Duy Phan[2,3], Nhu Nguyen[2,3], Eline Jessen[1], Sahar Keshvari[1], Yvette Ong[4], Timothy Kidd[5], Steven Hancock[2,3], David Hume[1], Elizabeth Powell[6], Matthew Sweet[2,3], Mark Schembri[2,3], Katharine Irvine[1,3]. *[1]Mater Research - The University of Queensland, Brisbane, Australia; [2]Institute for Molecular Bioscience, The University of Queensland, Brisbane, Australia; [3]Australian Infectious Diseases Research Centre, The University of Queensland, Brisbane, Australia; [4]School of Biomedical Sciences, Queensland University of Technology, Brisbane, Australia; [5]School of Chemistry and Molecular Biosciences, The University of Queensland, Brisbane, Australia; [6]QIMR-Berghofer Medical Research Institute, Brisbane, Australia*
Email: katharine.irvine@uq.edu.au

Background and aims: Patients with decompensated cirrhosis are at high risk of developing bacterial infections. The most common infection is spontaneous bacterial peritonitis (SBP) in ascites fluid, caused by gut bacterial translocation. We aimed to investigate the bactericidal activity of cell-free ascites fluid and ascites macrophages.
Method: We performed bacterial killing assays using cell-free ascites fluid or ascites macrophages from patients with decompensated cirrhosis without active infection. We performed a genetic screen for EXPEC and K. pneumoniae genes that confer resistance to ascites fluid killing and validated novel targets in patient samples and in vivo in a mouse model.

Results: Non-pathogenic *Escherichia coli* K12 was rapidly killed in cell-free ascites fluid, associated with complement deposition, but ExPEC and *K. pneumoniae* strains were completely resistant to killing. A transposon-based genome-wide screen identified a requirement for genes involved in O-antigen biosynthesis for survival of both organisms in cell-free ascites fluid, including the transcription factor RfaH, which controls expression of surface polysaccharides. Although ExPEC were resistant to fluid-mediated killing, ascites macrophages, especially VSIG4^{Hi} cells, phagocytosed and killed ExPEC and non-pathogenic *E. coli* with similar efficacy. Mice with toxin-induced cirrhosis had higher bacterial burdens in the liver than control mice when infected with ExPEC, but rapidly cleared an *rfaH* mutant attenuated for capsule and O-antigen biosynthesis.
Conclusion: Together, these data identify critical roles for capsule and O-antigen in host evasion by SBP-associated pathogens. While pathobionts may cause infections in some patients with decompensated cirrhosis, especially those with impaired cellular immunity, many patients may be able to effectively defend against translocating intestinal commensal bacteria. Targeting bacterial virulence factors and/or host macrophage functions may reduce the risk of SBP in cirrhosis.

FRI-404

Lymphatic vessel dilatation with Rspo3-Wnt dysregulation drives impaired intestinal regeneration in cirrhosis-associated portal hypertensive duodenopathy

Deepika Jakhar[1], Pinky Juneja[1], Aarti Sharma[1], Simran Sharma[1], Ahona Roy[1], Phool Chand[1], Archana Rastogi[1], Vikram Bhatia[1], Savneet Kaur[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: savykaur@gmail.com

Background and aims: Portal hypertensive duodenopathy (PHD), a common complication of portal hypertension and cirrhosis, involves mucosal and vascular alterations, with largely undefined pathogenic mechanisms. Emerging evidence has identified intestinal lymphatic vessels (LVs) as critical regenerative niche; however, their role in PHD remains ambiguous. This study aimed to investigate the association between duodenal LVs and intestinal regeneration in patients with cirrhosis and PHD.
Method: A total of 30 patients with liver cirrhosis and 15 control subjects (dyspepsia) were recruited. All subjects underwent upper gastrointestinal endoscopy and were assessed for PHD. Intestinal stem cells marker (Lgr5), LV density and diameter (podoplanin score-sum of intensity and density of pdpn+ vessels), along with gene expression of regeneration factors were analyzed in biopsies from the second part of duodenum (D2) by IHC and RT-PCRs.
Results: Controls had normal endoscopic findings and among cirrhosis patients, 50% showed ulcers, red and/or white spots, erythema, and mucosal edema. Cirrhosis patients had higher dilated pdpn+ LV histological score versus controls (5.9 ± 1.1 vs 2.1 ± 0.5. p = 0.04). As compared to controls, cirrhotics showed thickened mucosa and decreased villi:crypt ratio (2.4 + 0.24 vs 0.8 ± 0.2, p = 0.02). Endoscopically, most patients (but not all) with higher pdpn score showed D2-lymphangiectasia spots. We did not observe any other correlation between pdpn score and endoscopy findings in patients. Expression of the intestinal stem marker, Lgr5 was decreased in patients with cirrhosis as compared to controls (3 fold, p = 0.05). Gene expression of intestinal repair and injury factors secreted by Paneth cells, Notch-2 (18 fold, p = 0.02), BMP-2(20 fold, p = 0.01), EGF(2 fold, p = 0.05) were increased in cirrhotics vs controls. However, expression of lymphangiogenic factors, Rspo3 (6 fold, p = 0.02) and Wnt2b (6 fold, p = 0.02) was decreased in patients as compared to controls.
Conclusion: A high duodenal LV density is a common feature in patients with cirrhosis, irrespective of the endoscopic findings. Despite activation of Notch signaling, impaired lymphangiocrine Rspo3–Wnt signaling likely drives mucosal injury and defective intestinal stem cell–mediated regeneration leading to PHD in some of these patients.

FRI-409-YI

Insulin-like growth factor 1 suppression worsens with cirrhosis severity and mortality, and therapeutic restoration improves outcomes in decompensated cirrhosis: a clinical-experimental study

Parminder Kaur[1], Wenting Tan[2], Pratibha Garg[1], Abeba Habtesion[2], Pinaki Dutta[1], Cornelius Engelmann[2], Gaurav Sharma[1], Alexandra Phillips[2], Naveen Kalra[1], Rui Zhang[3], Takayuki Kondo[2], Guohong Deng[3], Yunjie Dan[3], Sunil Taneja[1], Fausto Andreola[2], Ajay Kumar Duseja[1], Rajeshwar Prosad Mookerjee[2], Virendra Singh[1], Rajiv Jalan[2], Nipun Verma[1]. [1]*Post Graduate Institute of Medical Education and Research, Chandigarh, India;* [2]*Institute for Liver and Digestive Health, University College London, Royal Free Campus, London, United Kingdom, London, United Kingdom;* [3]*Department of Infectious Diseases, Southwest Hospital, Third Military Medical University, Chongqing, Chongqing, China*
Email: r.jalan@ucl.ac.uk

Background and aims: Insulin-like growth factor 1 (IGF-1) is reduced in advanced cirrhosis but its role in mediating hepatic inflammation, senescence and liver regeneration is unknown. This clinic-experimental study explores the role of IGF-1 in disease progression and evaluated outcomes of restoring IGF-1 axis.
Method: This study has 4 study parts. 1. Circulating IGF-1 was measured in 2-patient cohorts - (China; n = 221) (India; n = 257) and related to disease severity and mortality. 2. 2-models of cirrhosis (bile-duct ligation and CCL4) and lipopolysaccharide (LPS)-induced acute-on-chronic liver failure (ACLF) were used to test TLR4 (YAQ005) and RIPK1 inhibition (necrostatin-1) and impact on IGF-1 axis. 3. Effect of rhIGF-1 restoration on liver function, fibrosis, survival, liver and muscle transcriptomics was assessed. 4. Decompensated cirrhosis patients were randomized to standard medical therapy (SMT) or adjunct growth hormone (GH) 2 IU/day, titrated to normal IGF-1; primary endpoint: complication-free survival (CFS).
Results: 1. In both cohorts, IGF-1 levels declined stepwise from chronic hepatitis to stable cirrhosis to acute decompensation (AD) (all p < 0.05), and lower IGF-1 independently predicted 28-, 90-, 180-, and 365-day mortality.
2. In animal-models, hepatic IGF-1 expression decreased in ACLF (3.4-fold and 2.3-fold; p < 0.05); TLR4 or RIPK1 inhibition reduced mortality significantly and restored hepatic IGF-1.
3. rhIGF-1 improved reduced fibrosis (p < 0.05), lowered ammonia (p = 0.045), and improved coma-free survival (85.7% vs 33.3%; p = 0.048). Hepatic transcriptomics confirmed downregulation of injury, senescence and inflammatory pathways; muscle transcriptomics identified pathways related to cellular stress responses, inflammatory signalling, and muscle development.
4. At 12-months, CFS improved with GH vs SMT (HR 0.57; 0.34 to 0.96; p = 0.035). Patients who normalized IGF-1 on GH (responders; n = 22) had higher CFS vs SMT (77.0% vs 22.2%; HR 0.19; p = 0.001). GH prevented AD or ACLF occurrence (sHR 0.47; p = 0.010) with highest benefit in IGF-1 responders (sHR 0.04; p = 0.002). GH also improved the skeletal muscle index, liver frailty, myostatin, cell death, and neutrophil phagocytic capacity with maximal effects in IGF-1 responders. Fewer serious adverse events were noted in GH vs SMT group (23.9% vs 50.0%; p = 0.018).
Conclusion: Downregulation of IGF-1 axis is a pathophysiologically relevant feature of decompensated cirrhosis and data supports later phase clinical trials of IGF-1 in this condition.

FRI-410-YI

Circulating bile-acid profiles delineate disease severity and identify a metabolic fingerprint of ACLF

Georgios Konstantis[1], Moritz Passenberg[1], Maiju Myllys[2], Zaynab Hobloss[2], Jörg Reinders[2], Ahmed Ghallab[2,3], Andreas Schütte[1], Nargiz Nuruzade[1], Clara Guntlisbergen[1], Björn Jung[1], Benedikt Hild[1], Jan Best[1], Katharina Willuweit[1], Hartmut Schmidt[1], Jan G. Hengstler[2], Jassin Rashidi-Alavijeh[1]. Email: georgios.konstantis@uk-essen.de

Background and aims: Bile-acid (BA) synthesis, conjugation and microbiome-dependent transformation are tightly linked to liver function and become progressively disrupted with advancing chronic liver disease. However, comprehensive data on circulating BA patterns across the full spectrum of cirrhosis remain limited. We aimed to characterize BA profiles across compensated and decompensated stages and to determine whether they delineate disease severity and define an ACLF-specific metabolic signature.
Method: Circulating BA were quantified across compensated cirrhosis (194), non-acute decompensation (111), acute decompensation (AD, 48), and acute-on-chronic liver failure (ACLF, 41). Between-group differences were assessed with false discovery rate (FDR) control. Global metabolic structure was explored using unsupervised dimensionality reduction and clustering. Supervised models were applied to derive phenotype-specific BA signatures and to evaluate discrimination of ACLF and ACLF grades using ROC analyses. Pathway enrichment was assessed using established metabolomics tools.
Results: Multiple BA differed significantly across disease stages after FDR correction, indicating progressive BA remodeling with worsening cirrhosis. The dominant signal was a marked depletion of secondary BA with progression to decompensation, reaching lowest levels in ACLF (e.g. DCA, LCA, GDCA, GLCA). In parallel, conjugated primary BA were relatively enriched in ACLF, most notably TCDCA and TCA. Unsupervised analysis revealed a strong structure (PC1–2 ~ 54% of variance) and identified two metabolically distinct clusters associated with clinical stage (Cramér's V = 0.39), separating compensated from decompensated disease. Supervised modeling yielded the strongest discrimination for ACLF (AUROC 0.79), defining an interpretable ACLF-specific fingerprint combining increased conjugated primary BA and reduced secondary BA. Discriminatory performance increased with ACLF grade for key BA (e.g. TCDCA AUROC 0.63 for ACLF-1 vs AD and 0.88 for ACLF-3 vs AD). Infection status did not modify the ACLF-associated BA pattern. Pathway analysis identified primary BA biosynthesis as the only significantly enriched pathway.
Conclusion: Circulating BA profiles exhibit a strong, severity-aligned pattern across the cirrhosis spectrum. ACLF is characterized by a distinct metabolic fingerprint marked by loss of secondary and enrichment of conjugated primary BA, reflecting ACLF disease biology and severity.

Systemic markers of fibroblast- and immune cell activity in post-TIPS endotyping within patients with severe clinical evolution

Alejandro Mayorca Guiliani[1], Christian Labenz[2], Eva Maria Schleicher[2], Paul Schneider[2], Jasmin Soehngen[2], Michael Bernhard Pitton[3], Julia Weinmann-Menke[2], Peter R. Galle[2], Simon Johannes Gairing[2], Myriam Meineck[2], Diana Julie Leeming[1], Morten Karsdal[1]. [1]*Nordic Bioscience A/S, Herlev, Denmark;* [2]*Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, Mainz, Germany;* [3]*Department of Radiology, University Medical Center of the Johannes Gutenberg-University Main, Mainz, Germany, Mainz, Germany*
Email: christian.labenz@unimedizin-mainz.de

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is an established treatment for cirrhosis complications, such as ascites or variceal bleeding. Circulating extracellular matrix (ECM) biomarkers may aid in identifying patients with poor post-TIPS prognosis by endotyping patients according to ECM remodeling activity.
Method: 89 patients living with cirrhosis undergoing TIPS at the University Hospital Mainz were enrolled and followed for further decompensation, hepatic encephalopathy (HE), ascites, variceal bleeding and death/liver transplantation. Serum collected at TIPS placement and outpatient visits was analyzed for white blood cell count, IL-6, IL-8, C-reactive protein, ammonia, bilirubin, creatinine, fibroblast activity (nordicPRO-C3, nordicPRO-C6), neutrophil activity (CPa9-HNE), macrophage activity (VICM), and ECM degradation biomarkers of type III and IV collagen (nordicC3M, nordicC4M, nordicCTX-III). Unsupervised k-means clustering was applied to baseline variables to define patient clusters, subsequently assessed for associations with post-TIPS outcomes using Kaplan–Meier survival analysis and multivariable Cox proportional hazards models
Results: Median age was 62 (52–67 yo), predominant etiology was alcohol related liver disease (ALD) (56%) and predominant indication was ascites (88%). We identified 3 clusters (1 = 29, 2 = 35, 3 = 25). Cluster 1, (*fibrogenic*), was characterized by high PRO-C3, C3M and PRO-C6, suggesting high fibroblastic activity. Cluster 2 (*quiescent*) had lower ECM biomarkers but high ammonia, albumin and bilirubin. Cluster 3 (*fibrolytic*) had a high ECM degradation and immune activation profile. Kaplan–Meier analysis showed a significantly lower and delayed HE incidence in the fibrolytic cluster compared with the other two (log-rank p = 0.013); in contrast, Cox regression identified the fibrogenic cluster as having a significantly higher risk of further decompensation (p = 0.016). In Cox regression analysis adjusted for MELD score and age, the quiescent cluster was not significantly associated with post-TIPS hepatic encephalopathy (HR 0.50, 95% CI 0.17–1.41; p = 0.20)
Conclusion: ECM biomarkers identified three endotypes, fibrogenic, quiescent, and fibrolytic. Patients in the fibrogenic cluster demonstrated an elevated risk of further decompensation and post-TIPS HE. The fibrolytic cluster was protective for developing HE. These findings suggest that ECM remodeling reflects post-TIPS disease activity and pathophysiology.

FRI-412

Balancing immune dysfunction in ACLF: ASK1 inhibitor SRT-015 mitigates inflammatory responses while enhancing immune antibacterial defenses

Vanessa Legry[1], Ophélie Hanot[1], Berta Romero-Grimaldo[2], Cristina López-Vicario[2], Bryan J. Contreras[2], María Belén Sánchez-Rodríguez[2], Carlos Rojano-Alfonso[2], Ines Vanhille-Campos[2], Richard Moreau[3], Jean-Marie Brusq[1], Bart Staels[4], Sakina Sayah Jeanne[1], Joan Clària[2]. [1]*GENFIT SA, LOOS, France;* [2]*Hospital Clinic-IDIBAPS, Universitat de Barcelona, European Foundation for the Study of Chronic Liver Failure (EF CLIF), Barcelona, Spain;* [3]*European Foundation for the Study of Chronic Liver Failure (EF CLIF), Barcelona, Spain;* [4]*Université de Lille, Institut Pasteur de Lille, INSERM U1011, CHU Lille, Lille, France*
Email: vanessa.legry@genfit.com

Background and aims: Patients with cirrhosis develop significant immune dysfunction, characterized by the simultaneous presence of systemic inflammation, which correlates with disease progression, and immune paralysis, which increases the susceptibility to bacterial infections leading to complications such as acute-on-chronic liver failure (ACLF). Currently, there are limited therapeutic options addressing the underlying pathogenic mechanisms of ACLF. Given that systemic inflammation contributes to tissue damage in ACLF,

anti-inflammatory agents should halt disease progression, without exacerbating immune paralysis. SRT-015, an investigational Apoptosis Signal-Regulating Kinase 1 (ASK1) inhibitor, has demonstrated efficacy in reducing systemic inflammation and liver injury in preclinical models of liver failure and ACLF. This study aimed to further characterize the effect of SRT-015 on the functions of innate and adaptive immune cells using healthy donor blood cells as a proof-of-concept.

Method: The effects of SRT-015 (2–10 μM) on cytokine production and B cell and monocyte immunophenotype were assessed in peripheral blood mononuclear cells (PBMCs), while its actions on bacterial phagocytosis, degranulation and migration were tested in polymorphonuclear leukocytes (PMNs). The effects of SRT-015 on cytokine secretion and polarization were evaluated in monocyte-derived macrophages (MDM).

Results: In PBMCs, SRT-015 significantly reduced LPS-induced production of pro-inflammatory cytokines (IL-6, IL-1β, CXCL10, and TNFα), while shifting B-cell composition toward a memory phenotype, increasing memory B cells by 60% and decreasing naïve B cells by 34%. No changes in the composition of classical, intermediate or non-classical monocytes were observed. In PMNs, SRT-015 increased *E. coli* phagocytosis (+52%, p = 0.02) without negatively affecting complementary antibacterial effector functions, including degranulation and cell migration. In MDMs, SRT-015 significantly attenuated LPS-induced production of pro-inflammatory cytokines (IL-6, IL-1β, MIP-1α), while preserving IL-4 -driven macrophage M2 polarization.

Conclusion: This proof-of-concept study demonstrates the potential of the investigational drug SRT-015 to reduce systemic inflammation while enhancing antibacterial activity and preserving immune cell function, supporting its further development for advanced liver disease and ACLF.

FRI-413

Modulation of the gut microbiome by Yaq-001 ameliorates fecal microbiome transplant (FMT) induced liver injury from cirrhotic specific pathogen-free mice to germ-free mice

Jinxia Liu[1], Jose G Guevara[2], Haifeng Wu[3], Qin Jin[4], Huoyan Ji[5], Saeed Shoaie[2], Rajiv Jalan[6]. *[1]UCL Institute for Liver and Digestive Health, Upper third floor, Royal Free Campus, Rowland Hill Street, Hampstead, London, NW3 2PF, Nantong, China; [2]Centre for Host-Microbiome Interactions, Faculty of Dentistry, Oral & Craniofacial Sciences, King's College London, SE1 9RT, UK, London, United Kingdom; [3]Department of Gastroenterology, Affiliated Hospital of Nantong University, Nantong, 226001, China, Nantong, China; [4]Department of Pathology, Affiliated Hospital of Nantong University, Nantong, 226001, China, Nantong, United Kingdom; [5]Department of Laboratory Medicine, Affiliated Hospital of Nantong University, Nantong, 226001, China, Nantong, China; [6]UCL Institute for Liver and Digestive Health, Upper third floor, Royal Free Campus, Rowland Hill Street, Hampstead, London, NW3 2PF, London, United Kingdom*
Email: r.jalan@ucl.ac.uk

Background and aims: The gut microbiome is critically involved in the pathogenesis of liver diseases. Yaq-001, a non-absorbable, gut-restricted microbiome therapeutic, has demonstrated potential in restoring microbiome balance, mitigating endotoxemia, systemic inflammation, hepatic fibrosis, and liver cell death in specific pathogen-free (SPF) mice with liver cirrhosis. This study aims to investigate the mechanisms through which Yaq-001 modulates the liver-gut axis using FMT from SPF to germ-free (GF) mice.

Method: Two mouse models of cirrhosis were utilized: (a) SPF mice: carbon tetrachloride (CCl4)-induced cirrhosis for 6-weeks in SPF mice; *4 groups: control (n = 6), control-Yaq-001 (n = 6), CCl4 (n = 12), and CCl4-Yaq-001 (n = 12)*, and (b) GF mice: Fecal samples from SPF mice were used for FMT in GF mice for 9-weeks, combined with CCl4 administration for 3 weeks; *4 groups: FMT from SPF control (n = 6), FMT from SPF control-Yaq-001 (n = 6), FMT from SPF CCl4 (n = 10), and FMT from SPF CCl4-Yaq-001 (n = 10)*. Yaq-001 (0.4 g/100 g body weight per day) was administered to SPF mice for 6-weeks. Blood and tissue samples were collected for subsequent analysis of biochemistry, colonic and liver bulk RNA sequencing, and fecal samples for I6S RNA microbiome analysis.

Results: GF mice that received FMT from Yaq-001-pretreated, CCl4-exposed SPF mice donors exhibited markedly attenuated liver damage, as evidenced by significantly reduced serum ALT, hepatic fibrosis (CPA), apoptosis (TUNEL), and endotoxemia, compared to those receiving microbiota from untreated SPF-CCl4 donors. Microbiome analysis confirmed that Yaq-001 pretreatment reshaped microbial communities, enriching for beneficial taxa negatively correlated with injury biomarkers and depleting harmful taxa positively correlated with damage. Transcriptomic profiling revealed that Yaq-001's effects extended to host gene expression, modulating pathways involved in metabolism and stress response in both the liver and intestine. A key finding was the upregulation of intestinal Cyp2e1 following Yaq-001, which correlated negatively with injury markers.

Conclusion: The core mechanisms underlying the protective effect of Yaq-001 on inflammation and liver injury involves restructuring the gut microbiome, which in turn regulates host gene expression programs both locally and also in distant organs such as the liver. The data support its future development as a microbiome therapeutic for diverse diseases associated with dysbiosis.

FRI-414

Dual molecular targeting of Pttg1 and NO delivery restores hemodynamics, halts fibrogenesis and decreases liver steatosis in advanced liver disease

Manuel Macías-Herranz[1], Rocío García-Pérez[2], Andrea Díaz-Tendero[3], María Calvo[4], Gregori Casals[5], Cristina Fornaguera[6], Salvador Borrós[3], Wladimiro Jiménez[1], Guillermo Fernández-Varo[7]. *[1]Biochemistry and Molecular Genetics Service, Hospital Clínic of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, CIBEREHD, ISCIII, Madrid, Spain, Department of Biomedicine, University of Barcelona, Barcelona, Spain; [2]Hepatopancreatobiliary Surgery & Transplantation, General & Digestive Surgery Service, Digestive & Metabolic Disease Institute (ICMDM), Hospital Clínic of Barcelona, Barcelona, Spain; [3]Grup d'Enginyeria de Materials (Gemat), Institut Químic de Sarrià (IQS), Universitat Ramon Llull (URL), Barcelona, Spain; [4]Advanced Optical Microscopy-Clinic Campus, Scientific and Technological Center, University of Barcelona, Barcelona, Spain; [5]Biochemistry and Molecular Genetics Service, Hospital Clínic of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, CIBEREHD, ISCIII, Madrid, Spain, Department of Fundamental and Clinical Nursing, Faculty of Nursing, University of Barcelona, L'Hospitalet de Llobregat, Barcelona, Spain; [6]Grup d'Enginyeria de Materials (Gemat), Institut Químic de Sarrià (IQS), Universitat Ramon Llull (URL), Barcelona, Spain, Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain; [7]Biochemistry and Molecular Genetics Service, Hospital Clínic of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, CIBEREHD, ISCIII, Madrid, Spain*
Email: gfvaro@recerca.clinic.cat

Background and aims: Advanced liver fibrosis is a critical stage in chronic liver disease progression, characterized by severe hemodynamic impairment, extracellular matrix accumulation, and increased risk of cirrhosis and hepatocellular carcinoma. Pituitary tumor transforming gene 1 (*Pttg1*) regulates fibrogenic and oncogenic pathways, while nitric oxide (NO) modulates vascular tone and cellular activation. We investigated the therapeutic potential of combining *Pttg1* silencing with NO delivery using poly(β-amino ester) nanoparticles functionalized with retinol (ret-pBAE NPs) for specific liver targeting in a rat model of advanced fibrosis.

Method: Twenty-three Wistar rats with CCl_4-induced fibrosis (plus phenobarbital for 17 weeks) were randomized to receive either *Pttg1* siRNA + NO donor-loaded ret-pBAE NPs (n = 12) or vehicle (n = 11).

Hemodynamic parameters (mean arterial pressure [MAP], portal pressure [PP]), serum liver function markers, hepatic collagen and steatosis, and expression of profibrogenic genes were assessed.
Results: Combined therapy significantly improved MAP (110 vs. 115 mmHg, $p < 0.001$) and reduced PP (10 vs. 7 mmHg, $p < 0.001$). ALT, AST and total bilirubin levels decreased markedly (225 vs. 85 U/L, $p < 0.01$; 445 vs. 199 U/L, $p < 0.01$; and 0.45 vs. 0.10 mg/dl, $p < 0.05$, respectively), indicating improved hepatic function. Hepatic collagen content and steatosis were reduced by 47% and 48%, respectively ($p < 0.001$). Molecular analysis revealed strong downregulation of *Pttg1* and key profibrogenic genes (*Col1alpha2, alpha-SMA, Dlk1, Pdgfrb, Timp1*). It is important to emphasize that the combined therapy elicited a significant upregulation of *Mmp2* and *Mmp9* expression, accompanied by a concomitant downregulation of *Timp1*. This modulation resulted in a substantial increase in the *Mmp2/Timp1* gene expression ratio, and an even more pronounced elevation in the *Mmp9/Timp1* ratio. Collectively, these findings indicate a perturbation in the transcriptional equilibrium governing extracellular matrix (ECM) turnover, thereby facilitating its accelerated degradation.
Conclusion: Dual targeting of *Pttg1* and NO delivery via ret-pBAE NPs exerts robust antifibrotic and hepatoprotective effects in advanced liver fibrosis. These findings support the translational potential of combined RNA interference and NO modulation strategies as innovative therapies for chronic liver disease.

FRI-415-YI

Bone marrow mitochondrial dysfunction drives pathogenic myelopoiesis and monocyte–macrophage dysfunction in cirrhosis

Manisha Manisha[1], Deepanshu Maheshwari[1], Nidhi Nautiyal[1], Sandeep Kumar[1], Sunidhi Diwakar[1], Rajni yadav[1], Vaibhav Tiwari[1], Anupama Kumari[1], Dinesh Mani Tripathi[1], Shiv Kumar Sarin[1], Anupam Kumar[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: dr.anupamkumar.ilbs@gmail.com

Background and aims: Cirrhosis is characterized by sustained recruitment of dysfunctional monocytes/macrophages that drive chronic inflammation, fibrosis progression, and failure of hepatic repair. Although demand-driven myelopoiesis is required to meet increased immune needs in chronic liver injury, the mechanisms by which this process becomes pathogenic at the level of the bone marrow(BM) remain unclear. We investigated whether dysfunction of BM hematopoietic stem and progenitor cells (HSPCs) underlies the generation of pathogenic monocyte–macrophages in cirrhosis, and whether correcting this dysfunction can reprogram pathogenic myelopoiesis toward a reparative phenotype.
Method: Proteomic and metabolomic profiling of cirrhotic HSPCs were performed to identify bioenergetic defects. Mitochondrial integrity and ultrastructure were characterized via flow cytometry and electron microscopy. Bone marrow derived Macrophages (BMDMs) functionality was evaluated using phagocytosis and efferocytosis assays. Therapeutic potential of Mesenchymal Stem Cells (MSCs) was investigated using in vitro and in vivo cirrhotic models. Efficacy was determined by assessing HSC expansion, macrophage functional restoration, and histological quantification of liver fibrosis and regeneration.
Results: Proteomic and metabolic profiling reveals significant bioenergetic defect in cirrhotic HSCs, characterized by the down-regulation of ETC,TCA enzymes and the coactivators PGC-1α and TFAM($p < 0.01$). Cirrhotic HSPCs exhibit elevated ROS levels, reduced mitochondrial mass and membrane potential($p < 0.01$).Electron microscopy revealed mitochondrial fragmentation in cirrhotic HSPCs. BMDMs from cirrhotic HSPCs exhibited dysfunctional phenotype with significantly impaired phagocytosis and efferocytosis($p < 0.05$). In vitro co-culture of MSCs and HSCs improves HSPCs bioenergetics through mitochondria transfer. In-Vivo, MSC infusion significantly expanded the HSC pool($p < 0.05$). BMDMs derived from rescued HSPCs showed increased phagocytosis($p < 0.001$) and efferocytosis ($p < 0.001$). Finally, Restoring BMDMs function via reprogramming of HSPCs led to a significant reduction in liver fibrosis ($p < 0.001$) and promotes hepatic regeneration ($p < 0.001$).
Conclusion: Bone marrow mitochondrial dysfunction drives pathogenic myelopoiesis and impaired monocyte–macrophage responses in cirrhosis. MSC-mediated restoration of hematopoietic mitochondrial health reprograms myelopoiesis toward a reparative state, reducing liver fibrosis and promotes hepatic regeneration.

FRI-416-YI

Treg metabolic dysfunction precedes cirrhosis-associated immune dysfunction: implications for therapeutic intervention

Diana Marin-Correa[1], Celio Xavier Da Costa Dos Santos[2], Ravi Kumar[2], Yoana Arroyo[3], Ada Sera Kurt[1], Jorge Torres[1], Alison Taylor[1], Mzamo Mbelle[1], Roberto Savoldelli[1], Evangelos Triantafyllou[4], Timothy Tree[3], Ajay Shah[2], Alberto Sanchez-Fueyo[1], Niloufar Safinia[1]. Email: diana.marin_correa@kcl.ac.uk

Background and aims: Chronic liver injury drives fibrosis through inflammation and oxidative stress, leading to cirrhosis. Advanced cirrhosis features cirrhosis-associated immune dysfunction (CAID), marked by systemic inflammation, innate immune paralysis, multi-organ failure, and increased mortality. We have shown that cirrhotic Tregs are functionally impaired due to dysregulated nuclear factor erythroid 2-related factor 2 (NRF2) signaling, a master regulator of antioxidant and metabolic responses. We hypothesize that NRF2 dysfunction in cirrhosis impairs Treg metabolic plasticity, preventing maintenance of immunosuppressive capacity within the pro-oxidant, metabolically dysregulated systemic milieu of CAID.
Method: Peripheral blood was obtained from healthy volunteers and patients stratified by Baveno VIII criteria: fibrosis (F3–4), compensated and decompensated advanced chronic liver disease (cACLD and dACLD). Acute-on-chronic liver failure (ACLF) samples served as positive CAID controls. After PBMC isolation, we measured: 1) monocyte phenotypic and functional profiling by flow cytometry; 2) Treg suppressive capacity by micro-suppression assays; 3) bulk RNA sequencing; 4) targeted metabolomics of cellular lysates and serum by LC-MS; and 5) metabolic profiling by SCENITH.
Results: ACLF monocytes displayed the classic CAID phenotype: upregulated inhibitory receptors (PD1, PDL1, MERTK), downregulated HLA-DR and CD86, and impaired phagocytosis and cytokine production. In contrast, cACLD monocytes were phenotypically and functionally equivalent to controls, confirming intact innate immunity. Despite preserved monocyte function, cACLD Tregs showed significantly reduced suppression, identifying an early Treg-intrinsic defect preceding innate dysfunction. Transcriptomic analysis revealed reprogrammed gene networks regulating suppressive function, stability, and metabolism. SCENITH showed diminished glycolytic capacity with compensatory increases in fatty acid oxidation and amino acid catabolism, consistent with metabolic stress adaptation in a chronic inflammatory milieu.
Conclusion: Treg dysfunction constitutes an early event in disease progression. Transcriptional and metabolic Treg reprogramming occurs during compensated disease when innate immunity remains otherwise intact, establishing Treg metabolic dysregulation as a early driver of CAID. These findings position metabolic intervention as a rational strategy to restore Treg function and limit immune-mediated hepatic injury in early-stage cirrhosis.

FRI-418

Inflammation and viscoelastic haemostasis assessment in a wistar rat model of cirrhosis and peritonitis

Iuliana Nenu[1], Andra Tichindeleanu[1], Ioan Topor[1], Serban Trella[1], Rares Craciun[2], Horia Ștefănescu[3], Bogdan Procopet[2], Zeno Sparchez[2]. [1]"Iuliu Hatieganu" University of Medicine and Pharmacy, Physiology Department, Cluj-Napoca, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, 3rd Medical Clinic, Department 4 - Internal Medicine; "Prof. Dr. O. Fodor" Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, Romania; [3]"Prof. Dr. O. Fodor" Regional Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania
Email: iuliana.nenu@gmail.com

Background and aims: In cirrhosis with spontaneous bacterial peritonitis, inflammation and coagulation are tightly linked. Fresh frozen plasma (FFP) is often administered for coagulopathy, but may not reduce inflammatory burden and could promote hypercoagulability. We compared FFP support with adjuvant simvastatin in Wistar rats.
Method: Cirrhosis was induced in Wistar rats by bile duct ligation and allowed to develop for 16 weeks. Abdominal ultrasound was used to confirm advanced liver disease. Peritonitis was induced by intraperitoneal Escherichia coli inoculation (1.0 × 10^8 colony-forming units, CFU). Infected rats received 14-day antibiotics: ceftriaxone 100 mg/kg/day or meropenem 25 mg/kg/day, subcutaneously once daily. Simvastatin was given by oral gavage (25 mg/kg/day) for 14 days. Plasma support consisted of FFP transfusion every 2 days for 14 days from healthy donor rats. Tissue tumor necrosis factor alpha (TNF-a), interleukin 6 (IL-6) and interleukin 1 beta (IL-1b) were quantified. Coagulation was assessed by ClotPro EX-test and IN-test measuring clotting time (CT), clot formation time (CFT) and maximum clot firmness (MCF). Group comparisons for inflammation tests was made with one-way ANOVA test.
Results: In peritonitis treated with meropenem, simvastatin was associated with lower inflammatory cytokines versus FFP: TNF-a: 8.864 versus 13.241 pg/g protein, IL-6: 4.864 versus 8.307 pg/g protein, and IL-1b: 20.629 versus 42.938 pg/g protein. No statistically significant differences were observed between groups ($p > 0.05$). Across the other groups (ceftriaxone-treated peritonitis and non-infected cirrhosis groups with or without simvastatin), cytokine levels varied by group without a consistent reduction associated with FFP. Across infected cohorts receiving FFP (with either antibiotic), ClotPro showed faster clot build-up and higher firmness consistent with a hypercoagulable profile (EX-test CFT about 22 s with MCF 66.5 to 69.3 mm; IN-test CT 93 to 109.7 s with MCF 69 to 71.3 mm). Simvastatin-treated infected cohorts tended to show closer-to-reference viscoelastic profiles.
Conclusion: In Wistar rats with cirrhosis and peritonitis, repeated FFP transfusion showed no anti-inflammatory signal and was associated with a consistent hypercoagulable viscoelastic pattern, suggesting lack of benefit and potential prothrombotic imbalance. Adjuvant simvastatin showed lower inflammation and comparatively more balanced coagulation profiles.

FRI-419

Beyond status markers: profound disruption of vitamin d metabolism in decompensated cirrhosis and its clinical implications

Anika Nier[1], Julia Kühn[1], Stefanie Quickert[2], Christian Weißenborn[2], Philipp Reuken[2], Tony Bruns[3], Alexander Zipprich[2], Alexander Kluttig[4], Rafael Mikolajczyk[4], Marko Damm[5], Gabriele Stangl[1]. [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany; [2]Jena University Hospital, Jena, Germany; [3]University Hospital RWTH Aachen, Aachen, Germany; [4]Institute of Agricultural and Nutritional Sciences, Halle (Saale), Germany; [5]University Clinic Halle (Saale), Halle (Saale), Germany
Email: Anika.Nier@landw.uni-halle.de

Background and aims: Vitamin D (VD) deficiency is common in chronic liver disease (CLD), but the clinical relevance of disturbed VD metabolism remains unclear. In advanced disease, routine 25-hydroxyvitamin D (25(OH)D) assessment may underestimate clinically relevant metabolic failure. Thus, we performed a comprehensive, pathway-wide analysis of VD metabolism across CLD stages and assessed clinical associations.
Method: Patients with decompensated cirrhosis and ascites from University Hospital Jena (n = 39) and German National Cohort (NAKO) participants with (n = 57) or without (n = 48) steatosis were included, matched for age, sex and sampling season; vitamin D supplementation was present in a subset. Plasma and ascitic vitamin D_3 (VD_3), 25$(OH)D_3$, 24,25-dihydroxyvitamin D_3 [24,25$(OH)_2D_3$, catabolism], precursor sterol 7-dehydrocholesterol (7-DHC), 1,25-dihydroxyvitamin D [1,25$(OH)_2D$, active hormone], vitamin D binding protein (DBP) and fibroblast growth factor 23 (FGF23, 1,25$(OH)_2D$ suppressor) were quantified by HPLC–MS/MS or ELISA. Free metabolites were calculated. 90-day survival was analysed by MELD-adjusted Cox regression stratified by median DBP or 25$(OH)D_3$ and predefined 1,25$(OH)_2D$ cut-offs; spontaneous bacterial peritonitis (SBP) in the preceding 3 months was analysed as binary.
Results: VD metabolism was preserved in NAKO groups but globally disrupted in decompensated cirrhosis, independent of VD supplementation (plasma total 25$(OH)D_3$ – 70%, total 1,25$(OH)_2D$ – 60% $p < 0.0001$; free 25$(OH)D_3$ – 35%, free 1,25$(OH)_2D$ – 28%, $p = 0.002$). Plasma VD_3 was detectable in <50% and 24,25$(OH)_2D_3$ in <20% of patients. Plasma 7-DHC (−45%) and DBP (−54%) were reduced, while FGF23 was elevated (+60%, all $p < 0.0001$). Seasonal variation of plasma 25$(OH)D_3$ and 1,25$(OH)_2D$ was lost in cirrhosis. Plasma and ascitic metabolites correlated (25$(OH)D_3$ $r = 0.5$, $p < 0.006$; 1,25$(OH)_2D$ $r = 0.8$, $p < 0.0001$). While plasma 25$(OH)D_3$ was not outcome-associated, low plasma 1,25$(OH)_2D$ showed a trend toward impaired survival (HR 5.1, 95%CI 0.7–39.3; adjusted HR 5.6, 95%CI 0.7–43.4). Low plasma DBP independently predicted 90-day mortality (HR 4.9, 95%CI 1.3–17.9; adjusted HR 4.8, 95%CI 0.9–20.2) and SBP (OR 7.0, 95%CI 1.3–38.4; adjusted OR 8.9, 95%CI 1.3–59.7).
Conclusion: Steatosis does not substantially impair VD metabolism, while decompensated cirrhosis shows profound, supplementation-resistant disruption. DBP emerges as a MELD–independent biomarker for mortality and SBP, extending its role beyond VD transport and underscoring limits of current supplementation.

FRI-420

Acute-on-chronic liver failure is associated with impaired function of mitochondria in the liver

Lena Oeckl[1], Mona-May Langer[1], Helena Stadler[1], Severin Jacobi[2], Dionysios Koliogiannis[2], Markus Guba[2], Hans Zischka[3], Christian M. Lange[1]. [1]Department of Internal Medicine II, LMU University Hospital, Munich, Germany; [2]Department of Visceral Surgery, LMU University Hospital, Munich, Germany; [3]Institute of Molecular Toxicology and Pharmacology, Helmholtz, Institute of Toxicology and Environmental Hygiene, Technical University, Munich, Germany
Email: lena.oeckl@med.uni-muenchen.de

Background and aims: In patients suffering from advanced liver cirrhosis, the development of Acute-on-chronic liver failure (ACLF) is a very frequent syndrome with a high short-term mortality. It is characterized by an intense systemic inflammation associated with different combinations of organ failure. Mitochondrial dysfunction is known to play a crucial role in ACLF, contributing to the development of organ failure and immune dysfunction. This study aims to further characterize mitochondrial dysfunction with progression of liver cirrhosis in the context of a severe inflammatory environment and identify pathophysiological pathways.
Method: Liver tissue was collected from patients undergoing liver transplantation and further processed for Oroboros high resolution respirometry. Mitochondrial morphology was assessed by performing electron microscopy and immunofluorescence staining using

mitochondrial markers. Serum from healthy specimens (= control group) and patients suffering from ACLF was collected for stimulation of HepG2-cells prior to Oroboros analysis as well as cell viability and ATP-assays.
Results: Morphological impairments such as mitochondrial swelling, cristae rarefication and membrane rupture were clearly visible in EM of ACLF patients. Intensity of TOM20 staining was decreased in advanced cirrhosis, indicating loss of mitochondrial mass. The respirometry analysis performed with liver tissue showed a clearly higher mitochondrial membrane instability in ACLF and a significant downregulation of the glycerophosphat pathway ($p = 0.03$), correlating negatively with increasing MELD score. Malat-stimulated complex I respiration, however was higher in ACLF ($p = 0.01$), correlating positively with the MELD score. Non-mitochondrial respiration by oxidative side-reactions was significantly upregulated in patients suffering from ACLF ($p = 0.03$). HepG2s stimulated with ACLF-serum for 3 h showed a significantly higher respiration than the control ($p = 0.02$). Especially, serum from patients with high cytokine levels and inflammatory markers led to an increased mitochondrial respiration, however with a lower viability and less ATP-production compared to the control group.
Conclusion: We suggest that the pro-inflammatory environment in ACLF leads to a significant overstimulation of mitochondria which is not only ineffective regarding energy supply, but may also harm the cells, ultimately causing cell death.

FRI-421
GLP-1 agonist lowers portal pressure by modulating hepatic vascular tone in a toxin-induced cirrhotic rat model
Maria Andres-Rozas[1], Peio Aristu[1], Tomas Jelenik[2], Jenny Egecioglu Norlin[3], Morten Fog-Tonnesen[4], Jordi Gracia-Sancho[5], Anouk Oldenburger[6]. *[1]Barcelona Liver Bioservices, Barcelona, Spain; [2]Diabetes Pharmacology Novo Nordisk A/S, Bagsværd, Denmark; [3]Late translational Medicine Novo Nordisk A/S, Bagsværd, Denmark; [4]CC TA Early project Novo Nordisk A/S, Bagsværd, Denmark; [5]IDIBAPS - Hospital Clínic Barcelona - CIBEREHD, Barcelona, Spain; [6]Early Translational Medicine Novo Nordisk A/S, Bagsværd, Denmark*
Email: auog@novonordisk.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) promotes fibrosis and vascular dysfunction that increases intrahepatic resistance, leading to portal hypertension and cirrhosis complications. GLP-1 agonists improves MASH in clinical trials and preclinical models, but data on their effects on hemodynamic parameters in advanced or late-stage cirrhosis is limited. We evaluated portal haemodynamics and liver endpoints in a thioacetamide (TAA) rat cirrhosis model and tested the effects of a GLP-1 agonist.
Method: Male Sprague–Dawley rats received TAA (250 mg/kg, i.p., twice weekly) for 10 weeks to induce cirrhosis and portal hypertension, followed by a 3-week TAA-free period during which animals were administered vehicle or a GLP-1 agonist (15 nmol/kg/day, s.c.). End-point measurements included haemodynamic parameters like portal pressure, portal blood flow and intrahepatic vascular resistance (IHVR), organ weights, and histological analyses.
Results: TAA caused portal hypertension due to increased IHVR, and splenomegaly. A 3-week TAA-free interval partially restored haemodynamics but the key pathological features remained impaired: portal pressure and IHVR were increased by 38% and 40%, respectively, compared to healthy controls. Liver fibrosis and spleen weight were increased after TAA treatment and remained unchanged after its removal. Thus, a 3-week washout preserves a cirrhotic model suitable for haemodynamic intervention studies. The GLP-1 agonist significantly lowered portal pressure (10%), which was accompanied by trend to an increased portal flow (23%) and reduced IHVR (22%). These effects are independent of modest body-weight loss (6%). The GLP-1 agonist lowered mean arterial pressure and modestly raised heart rate; fibrosis was unchanged.
Conclusion: The TAA model recapitulates key features of compensated cirrhosis and portal hypertension and is well suited for translational haemodynamic studies. The GLP-1 agonist rapidly lowered portal pressure by reducing IHVR, an effect independent of fibrosis and of weight loss. Fibrosis is in this model not affected by the GLP-1 agonist probably due to the short treatment period. Overall, the GLP-1 agonist appears to reduce portal hypertension through mechanisms that are distinct from effects on body weight or fibrosis. However, human haemodynamic data remain limited, and translational confirmation is required. Future studies should define the vascular-tone pathways that mediate the observed decreases in portal pressure.

Email: tsarcina@unisa.it

Background and aims: Hepatic cirrhosis represents the final stage of most chronic liver diseases and is commonly driven by viral, alcoholic, metabolic or mixed etiologies. In recent years, both the epidemiology and clinical presentation of cirrhosis have been rapidly evolving; however, contemporary national data characterizing this scenario are lacking. To describe the current epidemiological profile and initial clinical presentation of hepatic cirrhosis in Italy during 2024.
Method: In this prospective, multicenter study, 1195 patients with cirrhosis were consecutively enrolled from 11 tertiary hepatology centers across Italy. Eligible participants included individuals with a new diagnosis of cirrhosis or those presenting for the first time to participating centers in 2024. Demographic, socioeconomic, etiological, clinical and laboratory data were collected at baseline. The

relative contribution of individual risk factors was assessed using Pareto chart analysis.
Results: Among 1195 enrolled patients, MASLD was the most prevalent etiology (28.8%), following by viral etiology (20.5%), Alcohol Liver Disease (ALD) (19.4%) and other causes (10.2%), but 251 patients (21%) had a mixed etiology (Met-ALD, Met- virus, ALD-virus, Met-ALD-virus). In the Pareto analysis of individual risk factors, arterial hypertension ranked first, followed by type 2 diabetes mellitus, alcohol abuse, obesity, HCV infection, HBV infection. Despite the growing metabolic burden, viral hepatitis remains a major contributor, representing 41.2% (202 patients of 490) of etiology, among patients at their access to the centers, but with cirrhosis already known, confirming its persistent epidemiological impact despite antiviral therapies and vaccination programs.
Conclusion: This study highlights the evolving epidemiology of cirrhosis, characterized by an increasing contribution of MASLD and a predominance of early-stage, compensated disease (Child-Pugh A) at diagnosis. The comorbidity profile associated with cirrhosis is also emphasized: arterial hypertension was the most prevalent risk factor, although diabetes and obesity appear to exert a more direct pathogenetic impact on liver injury. Viral hepatitis continues to impose a substantial clinical burden, underscoring the need to strengthen vaccination, screening and linkage-to-care strategies. Overall, the frequent overlap of hepatic risk factors, observed in approximately one-fifth of patients, reflects the increasing complexity of cirrhosis management and contributes to a higher disease burden.

FRI-426

Inhibition of VCP alleviates inflammatory injury in acute-on-chronic liver failure through STING-dependent enhancement of macrophage efferocytosis

Zhangya Pu[1], Wenxin Zhoudi[2], Yangfan Shen[3], Qingqing Hu[4], Xiaohan Qian[1], Lingxiao Zhu[1], Zhongyang Xie[5], Xiaoxin Wu[1], Shangci Chen[1], Xiayao Li[1], Xiaowei Xu[1]. *[1]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, H, China; [3]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Han, China; [4]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangz, China; [5]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicinev, Hangzhou, China*
Email: Fleur.puzhangya@outlook.com

Background and aims: Acute-on-chronic liver failure (ACLF) is a severe clinical syndrome characterized by systemic inflammation and immune dysregulation, which leads to high short-term mortality. The valosin-containing protein (VCP), a member of the AAA-ATP family, participates in multiple cellular functions and has been implicated in the progression of various diseases. This study aimed to elucidate the role and underlying mechanisms of VCP in the progression of ACLF, with the goal of identifying potential therapeutic targets for future intervention.
Method: To assess VCP expression, liver samples from patients and mice model of ACLF were analyzed. The functional role of macrophage-specific VCP and its underlying molecular mechanisms in ACLF were investigated in mice model using the VCP small-molecule inhibitor and adeno-associated virus (AAV). Additionally, validation of these mechanisms was performed in an in-vitro macrophage cell model.
Results: We found that VCP expression is markedly upregulated in the liver tissues of both patients and mice model of ACLF. In the CCl4/LPS-induced mice ACLF model, inhibition of VCP significantly attenuated liver injury, as evidenced by reduced serum levels of liver enzymes, decreased hepatic inflammation, and improved histopathological outcomes. Mechanistically, VCP inhibition exerted its protective effects through a dual regulatory mechanism: it suppressed the activation of the STING signaling pathway while concurrently enhancing macrophage efferocytosis. Importantly, the administration of a STING agonist effectively reversed these protective effects in vivo, which was further validated in an in-vitro macrophage cell model.
Conclusion: The findings demonstrate that inhibition of VCP expression in ACLF protects against liver injury by enhancing macrophage-mediated efferocytosis of damaged cells. Overall, these results suggest that VCP may represent a potential therapeutic target for the treatment of ACLF.

SIRT5 rs12216101 T > G variant is associated with hepatic encephalopathy and impaired ammonia metabolism in patients with cirrhosis

Federico Salomone[1], Antonio Gil-Gómez[2], Federica Barreca[3,4], Miriam Longo[5], German Soriano[6], Rubén Francés[7], Rocío Gallego-Durán[2], Javier Ampuero Herrojo[2], Marco Tafani[3], Paola Dongiovanni[5], Manuel Romero-Gómez[2]. *[1]Azienda Sanitaria Provinciale di Catania, Catania, Italy; [2]Instituto de Biomedicina de Sevilla, IBiS/Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, Spain; [3]Dipartimento di Medicina Sperimentale, Università di Roma "La Sapienza", Roma, Italy; [4]La Sapienza University of Rome, Medicina Sperimentale, Roma, Italy; [5]Medicine and Metabolic Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [6]Department of Gastroenterology, Hospital de la Santa Creu y Sant Pau, Barcelona, Spain; [7]Department of Clinical Medicine, Miguel Hernandez University, Alicante, Spain*
Email: federicosalomone@rocketmail.com

Background and aims: Hepatic encephalopathy (HE) arises from impairment of ammonia homeostasis. Genetic factors conferring susceptibility to HE are poorly understood. SIRT5 regulates the activity of key enzymes involved in ammonia metabolism by desuccinylating lysine residues. In this study, we aimed to examine the impact of SIRT5 rs12216101 T > G variant on HE and ammonia homeostasis in patients with cirrhosis.
Method: The rs12216101 was genotyped in a retrospective cohort of 598 outpatients followed at four liver units in Spain. Multivariate regression analysis, Kaplan-Meyer curves and Cox regression analysis were performed to assess the predictive value of rs12116101 for HE and decompensating events. Immunoprecipation on liver samples was performed to assess the impact of rs12216101 T > G on succinylation levels of target proteins. To evaluate the role of SIRT5 in intestinal and liver ammonia metabolism, CaCo2 and HepG2 were treated with 50 μM of the SIRT5 activator MC3138 for 24 and 48 h under glucose deprivation.
Results: Patients were followed-up for 30.1 ± 23.1 months. At multivariate regression analysis, adjusted for age, sex and MELD score, rs12216101 T > G variant was associated with the development of decompensation during the follow-up [aHR 1.374

(1.118–1.688); p = 0.002]. At Cox regression analsys, the presence of the G allele was independently associated with the development of hepatic encephalopathy [HR 1.533 (1.153–2.036); p = 0.003]. In a subcohort of patients (n = 219), G-allele carriers displayed an impaired response to the glutamine overload test having a higher ammonia increase at 60 min (58.3 ± 52.6 vs 41.6 ± 35.5 umol/L; p = 0.005). Liver samples from subjects with the GG genotype displayed higher levels of succinyl lysines, indicating reduced SIRT5 activity. Treatment of CaCo2 and HepG2 with MC3138 led to a reduction of ammonia in the medium due respectively to higher desuccinnylation of Glutaminase C (inhibition) and of Carbamoyl-Phosphate Synthase 1 (activation).
Conclusion: SIRT5 rs12216101 T > G variant confers susceptibility to HE in cirrhosis by disrupting intestinal glutaminolysis and urea cycle in the liver.

FRI-428-YI
Endothelial forkhead box O1 (FoxO1) signalling in acute decompensation and acute-on-chronic liver failure: evidence from in vivo models and in vitro exposure to patient plasma
Fabian Schachteli[1], Sabine Klein[1,2], Maximilian Joseph Brol[1,2], Robert Schierwagen[1,2], Pia Lembeck[1], Sara Zarei[1], Sara Noemi Reinartz Groba[1], Wenyi Gu[1,2], Christoph Welsch[2], Jonel Trebicka[1,2,3], Frank Erhard Uschner[1,2]. Email: fabian.schachteli@ukmuenster.de

Background and aims: Endothelial dysfunction is a hallmark of acute decompensation (AD) and acute-on-chronic liver failure (ACLF). Forkhead box O1 (FoxO1) regulates endothelial metabolic and growth programmes and could link inflammatory triggers to impaired endothelial repair. We investigated the role of FoxO1 signalling in AD/ACLF *in vivo* and *in vitro*.
Method: In rats, AD was induced by bile duct ligation (BDL) or carbon tetrachloride (CCl4) injections, with or without Western diet or ethanol. ACLF was triggered by lipopolysaccharide injections, alcohol binge or transnasal stool inoculation. For *in vivo* FoxO1 inhibition, the FoxO1 inhibitor AS1842856 was administered intravenously to AD rats. Hepatic FoxO1 pathway activity was assessed in liver tissue by complementary RNA (cRNA) microarray, Western blot and quantitative PCR (qPCR). Human umbilical vein endothelial cells (HUVECs) were incubated with the FoxO1 inhibitor AS1842856 or with plasma from healthy controls and patients with AD/ACLF. Endothelial function was assessed *in vitro* (angiogenesis, proliferation, viability, apoptosis, autophagy, senescence) using tube formation, scratch and MTT assays.
Results: Compared with AD and healthy controls, ACLF induction reduced hepatic FoxO1 signalling *in vivo*. In AD rats, FoxO1 inhibition increased mean arterial pressure (MAP) and decreased the international normalised ratio (INR), while increasing the neurological severity score (NSS). *In vitro*, only ACLF plasma (but not AD plasma or control plasma) significantly downregulated FoxO1. Both AS1842856 and ACLF plasma significantly reduced angiogenesis and proliferation, without increasing autophagy, senescence or apoptosis.
Conclusion: In ACLF, FoxO1 signalling seems to be inhibited in humans and in experimental models and thereby to impair angiogenesis and proliferation, inducing endothelial dysfunction in ACLF.

Background and aims: Liver cirrhosis follows complex and heterogeneous trajectories that may shift between distinct clinical states of compensation (CC), decompensation (DC) and acute-on chronic liver failure (ACLF). Deciphering intrahepatic signalling pathways associated with distinct disease stages may identify therapeutic targets to modulate disease progression.
Method: A total of 100 human liver samples from non-cirrhotic (NC) controls (marginal tissue obtained during liver surgery) and liver explants from patients with CC, DC, or ACLF due to alcohol-related liver disease (ARLD), primary sclerosing cholangitis (PSC), or hepatitis C virus (HCV) were subjected to quantitative bulk Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS) analysis.
Results: Out of over 4,500 proteins profiled across all conditions, between 5–12% were differentially expressed between NC and CC, 0–0,8% between CC and DC, and 0,3–4% between DC and ACLF livers across all etiologies. Principal component analysis revealed robust stage-dependent clustering in ARLD and HCV, but much less in PSC livers, possibly related to cholestasis-associated hyperbilirubinemia in this condition. NC-to-CC transition was expectedly marked by a high abundance of fibrogenic and extracellular matrix proteins, and a downregulation of proteins related to detoxification and metabolism in CC. DC-to-ACLF transition was dominated by perturbations of metabolic homeostasis and inflammatory responses, characterized by downregulation of PPAR signalling, glycolysis–gluconeogenesis, fatty acid metabolism, detoxification and expression of CYP450 family members. Inflammation-related proteins (e.g. resistin, neutrophil elastase, myeloperoxidase) were amongst the most abundantly expressed proteins in ACLF livers. Regulator activity analysis inferred signatures compatible with SMAD3 overactivation during NC-to-CC transition, whereas DC-to-ACLF progression was compatible with inhibition of HNF4α and PPAR-α/γ activity.
Conclusion: Chronic liver disease progression is associated with distinct, stage-dependent hepatic proteomic signatures. While fibrosis-related proteins predominate across cirrhosis stages, an overabundance of inflammatory proteins and metabolic decline characterize DC–ACLF progression. The contribution of stage-specific hepatic cellular composition remains to be clarified. Modulation of dysregulated protein networks may carry therapeutic potential in advanced chronic liver disease.

and Wildlife, University of Veterinary and Animal Sciences, Lahore, Pakistan
Email: qamar.niaz@uvas.edu.pk

Background and aims: Cirrhotic cardiomyopathy (CCM) is a myocardial dysfunction in advanced liver disease with chronotropic dysfunction. Vasodilator agents and diuretics are not recommended in CCM due to decreased vascular resistance and electrolyte imbalance. Nintedanib (Nin), "a tyrosine Kinase inhibitor," is used to treat idiopathic pulmonary fibrosis. Thus, we evaluated Nin against liver inflammation and fibrosis to alleviate the chronotropic dysfunction in CCM in bile duct ligation (BDL)-induced cirrhotic rats.
Method: A total of 64 rats of body weight 250–280 g were selected and grouped as Sham-Saline, Sham-Nin 30, Sham-Nin 60, Sham-Lac (lactulose) 1.5, and BDL-Saline, BDL-Nin 30, BDL-Nin 60, and BDL-Lac 1.5. Sham (control) and BDL surgery (experimental) wa performed to induce liver cirrhosis for 28 days. The Nin 30 and 60 mg/kg and Lac 1.5 g/kg were used to treat the liver cirrhosis for 14 days. Post-treatment, liver and heart histopathology, in vivo chronotropic study, QTc interval, liver function tests (AST, ALT, ALP, albumin, and bilirubin), heart IL-6, TNF α, BNP, and MDA, and serum troponin-I (trop-I) were evaluated.
Results: The average heart rate was decreased with higher doses of adrenaline and noted irregular in the BDL-Saline group, and was increased in BDL-Nin 30 (regular-irregular) and BDL-Nin 60 (regular) groups. The QTc interval was increased in the BDL-Saline group, and was decreased equally in the BDL (Nin 30 and 60) groups. The liver histopathology showed severe inflammation and fibrosis in the BDL-Saline group and moderate and mild in BDL (Nin 30 and 60) groups. The heart showed coagulative and degenerative necrosis in all BDL groups. The BNP, MDA, TNF-α, and IL-6 in heart tissue were increased in the BDL-Saline group and decreased BNP in BDL (Nin 30 and 60) groups, MDA and IL-6 in BDL-Nin 60 group, TNF-α in BDL [Nin 30 (less) and 60 (more)] groups. The serum ALT, AST, ALP, bilirubin, and trop-I increased and albumin reduced in the BDL-Saline group, and decreased AST, ALP, and trop-I more in the BDL-Nin 60 group relative to the BDL-Nin 30, decreased bilirubin with no difference in the BDL (Nin 30 and 60) groups, increased albumin evenly in the BDL (Nin 30 and 60) groups, and increased ALT only in the BDL-Nin 60 group.
Conclusion: Nin 60 mg/kg is more effective in alleviating the chronotropic dysfunction in CCM by improving the liver inflammation and fibrosis, liver function tests (AST, ALP, and bilirubin), myocardial injury (trop-I), and cardiac stress (MDA and BNP) in BDL rats.

FRI-431-YI

LSECtin attenuation in cirrhosis correlates with disease severity and inflammation and can be experimentally recovered by IL-10/IL-13 administration

Email: benedikt.simbrunner@meduniwien.ac.at

Background and aims: Liver sinusoidal endothelial cell (LSEC) C-type lectin (LSECtin) is a key regulator of hepatic immune homeostasis and reduced in cirrhosis. Experimental studies showed that LSECtin overexpression restores LSEC immunoregulatory function, mediated by anti-inflammatory cytokines IL10 and IL13. This study investigated the relationship between LSECtin and portal hypertension and disease severity in patients with cirrhosis and explored the cytokine-driven regulation of LSECtin expression in experimental cirrhosis.
Method: This translational project combined human data from patients with cirrhosis and experimental mouse studies from two centers. In the human cohort (n = 86), hepatic LSECtin mRNA expression was quantified in liver biopsies and correlated with clinical stage, biomarker profiles, and hepatic IL10 and IL13 expression. In CCl_4 and CDAHFD mouse models of cirrhosis (induction period 12 weeks, respectively), hepatic single-cell RNA sequencing (scRNA-Seq) assessed LSECtin regulation in LSECs at peak fibrosis and during regression (3, 7, 14 days after cessation of injury). Interventional studies in the CCl_4 model examined whether exogenous IL-10 or IL-13 administration induces LSECtin expression.
Results: In patients with cirrhosis, hepatic LSECtin mRNA decreased across disease stages (log-fold median vs compensated cirrhosis [CC]: first decompensation −0.88 [−2.25;−0.05]; further decompensation −2.86 [−3.31;−1.45]; $p < 0.001$), similar to hepatic IL10 mRNA expression (−0.31 [0.77] and −0.67 [0.98] vs CC; $p = 0.045$). LSECtin mRNA expression correlated negatively with HVPG (Spearman's r = −0.553), MELD (r = −0.634), and biomarkers ELF (r = −0.718), VWF (r = −0.388), and IL-6 (r = −0.534); and correlated positively with hepatic IL10 mRNA (r = 0.352) and IL13 mRNA (r = 0.351, $p < 0.05$ for all analyses). In hepatic scRNA-Seq analyses, LSECtin expression in LSECs was downregulated at peak fibrosis, followed by upregulation during fibrosis regression in both CCl_4 and CDAHFD models. In the CCl_4 model, IL-10 and IL-13 injections increased the proportion of LSECtin-positive LSECs (CIR-VEH: 25.6%; CIR-IL10: 45.5%; CIR-IL13: 48.5%; $p = 0.035$) indicating partial restoration of LSECtin expression.
Conclusion: Downregulation of LSECtin expression in patients with cirrhosis correlates with clinical disease stage, portal hypertension, and inflammation. In murine models, LSECtin is recovered during fibrosis regression and cytokine administration,supporting IL10/IL13–dependent pathways as regulators of LSECtin in cirrhosis.

FRI-432

Characterization of the toll-like receptor ligandome across the clinical spectrum of alcohol-related cirrhosis

Benedikt Simbrunner[1,2,3,4,4], Raphaela Staltner[5], Benedikt Hofer[1,2,3,4,6], Lorenz Balcar[1,2,3], Vlad Taru[1,3,4,6], Lukas Hartl[1,2,3], Georg Kramer[1,2,3], Georg Semmler[1,2,3], Kerstin Zinober[1,3,4], Katharina Regnat[1,3,4], Michael Trauner[1,2], Mattias Mandorfer[1,2,3], Ina Bergheim[5], Thomas Reiberger[1,2,3,4,6].

Email: benedikt.simbrunner@meduniwien.ac.at

Background and aims: Disruption of the intestinal barrier in alcohol-related (ALD) cirrhosis facilitates translocation of microbial products, most commonly exemplified in literature by

lipopolysaccharide (LPS). Recent evidence indicates that a broader spectrum of pathogen-associated molecular patterns (PAMPs) reaches the circulation in cirrhosis that may trigger inflammation through different Toll-like receptors (TLR). This study aimed to characterize the circulating "TLR ligandome" across the disease severity spectrum of ALD cirrhosis.

Method: Concentrations of TLR1–9 ligands in serum samples were estimated using an assay employing HEK-293 cells stably transfected with the respective human TLRs. Cells were stimulated with 20 μL serum from patients with compensated (CC, n = 20), stable decompensated cirrhosis (SDC, n = 17), or acute decompensation with and without acute-on-chronic liver failure (AD ± ACLF, n = 20), and healthy controls (n = 12). Secreted Embryonic Alkaline Phosphatase (SEAP) reporter activity was quantified on a microplate reader. Each assay included positive and negative controls.

Results: Disease severity as reflected by MELD (CC 11.5 [9.0–14.0], SDC 12.0 [10.0–16.0], AD-ACLF 19.0 [18.0–24.5]; $p < 0.001$) and IL-6 levels (5.85 [4.12;9.40], 12.9 [6.84–22.7], and 27.6 [24.1–41.8]; $p < 0.001$) increased across cirrhosis stages. All TLR assays showed significantly increased activity in cirrhosis stages compared to healthy controls, with modest activation in CC and SDC; but a pronounced activation peak in AD-ACLF. SEAP reporter activity reflecting TLR ligand concentration correlated strongly among all TLRs, indicating either shared TLR recognition or simultaneous presence of various circulating ligands (Spearman's rho >0.500 for all). Positive correlations with inflammatory biomarkers (IL-6, C-reactive protein: CRP) were observed for TLR2, TLR4, TLR7, TLR8, and TLR9. Notably, TLR4 ligand concentration additionally correlated with LPS-binding protein (LBP) levels.

Conclusion: Cell-based TLR reporter assays detect a broad repertoire of circulating TLR ligands in patients with ALD cirrhosis, extending beyond canonical TLR4 activation. The marked activation spike in AD-ACLF and correlations with systemic inflammation support the concept of various circulating PAMPs in cirrhosis peaking in AD-ACLF. The findings highlight the importance of further studies on TLR-activating ligands that shape inflammatory trajectories in cirrhosis.

FRI-433

Integrated metaproteomics reveals parasitic protein signatures associated with inflammation, oxidative stress, regeneration, and mortality in acutely decompensated cirrhosis

Shreya Singh[1], Rohit Nadda[1], Pratibha Garg[1], Sunil Taneja[1], Ajay Kumar Duseja[1], Sumeeta Khurana[1], Trayambak Basak[2], Nipun Verma[1]. *[1]Postgraduate Institute of Medical Education and research, Chandigarh, India; [2]Indian Institute of Technology, Mandi, Himachal Pradesh, Mandi, India*
Email: drnipun29j@gmail.com

Background and aims: The role of circulating parasite-derived proteins in modulating host biological pathways and clinical outcomes in acutely decompensated cirrhosis remains poorly defined. We investigated parasite protein signatures in acute decompensation (AD) and evaluated their associations with host pathway activity and mortality.

Method: In a prospective cohort of 100 patients with AD and 10 healthy controls, plasma proteomic profiling was performed using LC-MS/MS. Parasite-derived peptides were assigned using Unipept version 3.0.1, and diversity metrics were assessed. Differentially expressed parasite proteins (DEPs) between survivors and non-survivors, were identified through inferential statistics, discriminant analysis and machine learning. Associations with inflammatory markers, clinical outcomes, and host pathway enrichment scores (ssGSEA) were evaluated.

Results: Parasite diversity was higher in AD vs. healthy controls, and in non-survivors vs. survivors, reflected by increased alpha diversity and beta diversity ($p < 0.05$). Ten mortality-associated DEPs were identified. *Plasmodium falciparum* reticulocyte-binding homolog 1 (PfRH1) emerged as the strongest predictor of mortality (VIP > 2.2) and correlated with systemic inflammation (NLR, $r = 0.36$, $p = 0.004$). Helminth-derived proteins, *Necator americanus* histone-H4 (NECAME_16786), was enriched in survivors and associated with lymphocyte predominance and total protein levels. PfRH1 showed positive correlations with host Toll-like receptor signalling, MAPK signalling, and inflammatory response pathway, all enriched in non-survivors, and negative correlation with regulatory TGF-beta signalling. Conversely, NECAME_16786 was positively associated with p53 signalling which was enriched in survivors and negatively associated with reactive oxygen species (ROS) pathway which was enriched in non-survivors. Helminth, *Fasciola gigantica* DUB-like protein, FGIG_02690 had negative correlations with ROS pathway.

Conclusion: Circulating parasite proteins are detectable in AD cirrhosis and are systematically associated with host inflammatory, stress, and regulatory pathways, with prognostic relevance. PfRH1 is linked to heightened systemic inflammation and mortality, whereas helminth-derived proteins are associated with a more regulatory host response. These findings raise the possibility of unrecognised low-density parasite exposure in hepatic and immune dysfunction and suggests that helminth-derived immune modulators warrant further therapeutic investigation.

FRI-434

Targeting disrupted immunometabolism-induced mitochondrial bioenergetic failure using YAQ006 and YAQ005 reduces mortality in ACLF

Supachaya Sriphoosanaphan[1,2,3], Annarein Kerbert[1], Tingting Qi[1], Abeba Habtesion[1], Fausto Andreola[1], Jan-Willem Taanman[4], Francesco De Chiara[5], Rajiv Jalan[1]. *[1]Liver Failure Group, Institute for Liver and Digestive Health, University College London, London, United Kingdom; [2]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Centre of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand; [4]Department of Clinical and Movement Neurosciences, Queen Square Institute of Neurology, University College London, London, United Kingdom; [5]Institute for Bioengineering of Catalonia, Barcelona, Spain*
Email: r.jalan@ucl.ac.uk

Background and aims: Hyperammonemia contributes to morbidity and mortality in advanced liver disease and has significant impact on immune function and metabolism, particularly in patients with ACLF. Integrated multiomic profiling demonstrated that ammonia triggers hepatic mitochondrial bioenergetic collapse through a specific, Toll-like receptor 4 (TLR4)-dependent immunometabolic axis[1]. Although ammonia lowering using ornithine phenylacetate (YAQ006) successfully reverses hepatic encephalopathy, it does not improve survival in ACLF. Given the underlying mechanism of ammonia-induced organ injury in ACLF, we aimed to evaluate whether YAQ006 is synergistic with YAQ005 (a TLR4 antagonist) in reducing mortality in ACLF.

Method: We studied two distinct rodent models: 1) A rat model of ACLF induced by bile duct ligation (4 weeks) followed by lipopolysaccharide (LPS) challenge (0.025 mg/kg, i.p.); and 2) A mouse model of ornithine transcarbamylase deficiency ($Otc^{spf\text{-}ash}$) fed a high-protein diet for 7 days acting as hyperammonemic controls. In the ACLF model, YAQ005 (10 mg/kg, i.p.) was administered 3 hours before LPS, and YAQ006 (0.3 g/kg, oral gavage) was given twice daily for 5 days. In the $Otc^{spf\text{-}ash}$ model, YAQ005 and YAQ006 were administered during the final 4 days. Endpoints included ammonia levels, ALT and 6-hour coma-free survival.

Results: In the ACLF model, BDL-LPS rats developed severe hyperammonemia (280.5 ± 38.7 μmol/L) and all animals died. Monotherapy with either YAQ006 or YAQ005 reduced plasma ammonia to 130–145 μmol/L ($p < 0.001$ vs. BDL-LPS). Combination therapy provided synergistic benefit, further reducing ammonia to 73.4 ± 11.5 μmol/L ($p < 0.001$ vs. monotherapies) and reducing liver

injury (ALT 115.1 vs. 321.0 U/L, $p < 0.001$). Notably, the combination achieved 100% coma-free survival, significantly higher than YAQ006 (62.5%) or YAQ005 (75.0%) alone (both $p < 0.01$). In contrast, in the $Otc^{spf\text{-}ash}$ mice, while YAQ006 and YAQ005 significantly reduced ammonia and ALT (both $p < 0.001$), the combination provided no additive benefit, suggesting that the synergy is specific to the inflammatory context.
Conclusion: Combined ammonia scavenging with YAQ006 and TLR4 inhibition with YAQ005 provides synergistic survival benefit in ACLF. The therapeutic synergy observed in inflammatory models of hyperammonemia but not in congenital urea-cycle deficiency highlights disease-context specificity and suggests a novel therapeutic framework for ACLF.

Background and aims: The pathogenesis of ammonia-induced hepatotoxicity remains incompletely understood. While hyperammonemia causes mitochondrial dysfunction, the molecular events linking ammonia to organelle failure are undefined. We previously identified Toll-like receptor 4 (TLR4) as a critical mediator of ammonia-induced liver injury *in vivo* and showed that YAQ005, a TLR4 inhibitor, could significantly reduce ammonia[1,2]. Here, we aimed to explore the mechanisms and define the role of TLR4 in this pathway.
Method: In AML12 murine hepatocytes, we assessed gene expression (qPCR), mitochondrial respiration (Seahorse XF) and oxidative phosphorylation (OXPHOS) enzyme activities (spectrophotometry and Blue Native PAGE). Mitochondrial reactive oxygen species (ROS) and membrane potential were quantified by live-cell confocal imaging. TLR4-mitochondrial co-localisation was assessed by immunofluorescence. Ultrastructural changes were examined by transmission electron microscopy (TEM).
Results: Ammonia (NH_4Cl) exposure induced profound mitochondrial dysfunction, characterised by suppressed basal and maximal respiration ($p < 0.001$) and a specific inhibition of Cytochrome c oxidase (OXPHOS Complex IV). This bioenergetic collapse was accompanied by a mitochondrial ROS surge and membrane depolarisation. Mechanistically, ammonia significantly upregulated *Tlr4* mRNA expression ($p = 0.002$), an effect mitigated by treatment with YAQ005 ($p = 0.001$). Inhibition of TLR4 with YAQ005 also prevented the functional defects, restoring OXPHOS Complex IV activity and respiratory capacity without altering extracellular ammonia levels, confirming a direct protective effect. Notably, ammonia increased TLR4 protein abundance and its spatial association with the mitochondrial network (Pearson's r 0.76; $p = 0.046$). This recruitment was associated with mitochondrial stress and structural remodelling, including cristae effacement and mitophagy, which were attenuated by TLR4 blockade.
Conclusion: These findings identify TLR4 as a direct, cell-autonomous mediator of ammonia-induced mitochondrial dysfunction. We propose a novel mechanism whereby ammonia triggers the transcriptional upregulation and mitochondrial recruitment of TLR4, leading to specific Complex IV inhibition and bioenergetic failure. This provides a mechanistic rationale for the use of TLR4 inhibitor (YAQ005) to protect hepatocyte mitochondrial function in hyperammonemia.

Peritoneal remodeling in patients with liver cirrhosis and ascites: a possible pathogenic link to impaired fluid homeostasis and altered peritoneal immunity
Helena Stadler[1], Mona-May Langer[1], Quan Yin[1], Lena Oeckl[1], Marc Weiß[1], Alina Bauschen[1], Severin Jacobi[2], Christian M. Lange[1]. *[1]Department of Medicine II, University Hospital LMU, Munich, Germany; [2]Department of General- Visceral- and Transplant-Surgery, University Hospital LMU, Munich, Germany*
Email: helena.stadler@med.uni-muenchen.de

Background and aims: In homeostasis, the peritoneum plays a central role in maintaining fluid homeostasis and local immune surveillance within the abdominal cavity. Previous studies have shown structural remodeling in the peritoneum of patients with liver cirrhosis, including fibrosis, dilated lymphatics and increased vascularization. Despite the potential impact of peritoneal remodeling on permeability and immune responses, the underlying mechanisms and consequences in the context of liver cirrhosis and ascites remain poorly understood. Therefore, this study aims to characterize the structural and cellular remodeling in the peritoneum of patients with liver cirrhosis.
Method: Specimens of parietal peritoneum were obtained in non-cirrhosis-related elective abdominal interventions and during liver transplantations. H&E and Masson's trichrome staining were performed for histological evaluation, while real-time PCR, spatial transcriptomics and immunofluorescence was used to assess molecular and cellular remodeling. Single-cell sequencing was performed on ascites samples collected during routine paracentesis.
Results: The collagen-positive area in the peritoneum was found to be greater in patients with liver cirrhosis than in controls, with significantly higher collagen content in patients with massive versus moderate ascites ($p = 0.02$). In line with that, spatial transcriptomic analysis revealed an increased abundance of fibroblasts ($p = 0.01$) and myofibroblast ($p = 0.045$) in peritoneum of patients with decompensated liver cirrhosis compared to controls. Additionally, peritoneal mesothelial cells, as well as detached mesothelial-like cells in ascites showed signs of mesothelial-to-mesenchymal transition. This fibrotic and remodeling environment in the peritoneum of patients with decompensated liver cirrhosis was further characterized by a predominance of anti-inflammatory M2 macrophages in the peritoneum. Moreover, lymphatic and vascular endothelium showed an upregulation of activation and inflammatory markers, which may contribute to altered fluid homeostasis and lymphatic drainage.
Conclusion: We suggest that the pro-inflammatory environment in the peritoneal cavity of patients with liver cirrhosis promotes fibrotic remodeling of the peritoneum. The altered peritoneal microenvironment may contribute to development and persistence of ascites and abdominal infections by affecting fluid homeostasis and immune cell polarization and trafficking.

Background and aims: Endotoxemia aggravates portal hypertension (PHT) in cirrhosis, fundamentally driven by dysfunctional LSECs. In cirrhosis, metabolic reprogramming of LSECs under influence of endotoxemia remains unexplored. We hypothesized that metabolic shift toward 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3) driven glycolysis disrupts LSEC mitochondrial function, vascular integrity, leading to coagulation, thrombosis and contributing to PHT. We aimed to investigate the role of PFKFB3 and its pharmacological modulation in restoring LSEC bioenergetics and mitigating PHT during sepsis in cirrhosis.
Method: Sepsis was induced in non-cirrhotic (Caecum ligation puncture) and with LPS(1 mg/kg) in CCL_4 cirrhotic rats treated with PFKFB3-inhibitor 3PO (50 mg/kg, i.p). Hemodynamics, LSECs functionality and remodeling were assessed. Metabolomics and bioenergetics of LSECs were analysed. Endothelial integrity was quantified using Trans-endothelial electrical resistance (TEER), vascular permeability (Lucifer yellow, Dextran 40 kDa), tube formation and leukocyte adhesion assays. Molecular validation [gene/protein profiling of PFKFB3, HMGB1 endothelial junctional markers (VE-cadherin/Claudin-5)] was performed and survival was studied.
Results: PFKFB3 inhibition significantly attenuated portal pressure and hyperdynamic circulation in both cirrhotic and non-cirrhotic groups. Treatment reversed the glycolytic shift, evidenced by reduced ECAR($p < 0.001$) and restored mitochondrial respiration (OCR) ($p < 0.01$). LSECs treated with 3PO showed significant improvement in mitochondrial biomass (MTG), potential (MTR) and oxidative stress. Electron microscopy revealed marked increase in diameter and number of LSEC fenestrae. TEER and permeability assays demonstrated restored endothelial barrier integrity ($p < 0.01$) upon treatment. PFKFB3 blockade in LSECs markedly reduced monocyte/neutrophil adhesion, and promotes tube formation ($p = 0.01$). Mechanistically, Glycolytic (PFKFB3, HK1, LDHA) and inflammatory mediators (IL-1β, HMGB1, ICAM-1) were reduced significantly in both cells and tissue. Improved endothelial junction proteins (VE-cadherin/Claudin-5) expression conferred improved barrier integrity upon treatment. Consequently, cellular inhibition of PFKFB3 improved liver injury markers and overall survival (28%).
Conclusion: Targeting PFKFB3 reverses glycolytic reprogramming and rescues LSEC mitochondrial function, thereby ameliorating vascular dysfunction and portal hypertension during sepsis in cirrhosis.

Email: j.vaquero@iisgm.com

Background and aims: Thrombocytopenia is a hallmark of chronic liver disease (CLD), largely due to hypersplenism and reduced thrombopoietin (TPO) production. Here, we investigated peripheral and bone marrow (BM) determinants of platelet production across stages of experimental cirrhosis.
Method: Male SD rats receiving oral carbon tetrachloride (CCl4) for 2–12 weeks were classified into early, intermediate, and advanced stages based on liver-to-body weight (L/BW) ratio. We examined systemic, hepatic, and hematologic parameters, including TPO across vascular beds, hepatic and BM Tpo/Mpl mRNA, portal pressure, and BM megakaryocyte (MGK) counts (H&E). Liver (n = 27) and BM (n = 31) RNA-seq were analyzed with LIMMA or DESeq2, and GSEA. Separate rat cohorts received the TPO-receptor agonist romiplostim to assess BM responsiveness.
Results: CCl4 induced progressive fibrosis, portal hypertension, and hepatic dysfunction. Platelet counts varied widely but correlated with L/BW ratio, not with plasma TPO, portal pressure, or hepatic function. The normal association of transhepatic venous TPO gradient with platelet count was lost in cirrhosis. In cirrhotic rats, BM Tpo and Mpl mRNA expression decreased, and MGK numbers rose early but failed to increase at advanced stages despite thrombocytopenia. BM RNA-seq showed limited differential expression (64 genes) in rats treated with CCl4, with enrichment of inflammation-related and suppression of metabolic pathways. Of note, stage-resolved analyses revealed distinct programs: early stage had proliferative/stress and ribosome-biogenesis signatures with reduced differentiation and energy metabolism; intermediate stage had persistent metabolic stress with increased immune/antimicrobial pathways and reduced proliferation; advanced stage had exacerbated inflammatory activation with dysregulated ribosome biogenesis and suppression of stress-response and differentiation pathways. GSEA focused on platelet/MGK-related gene sets showed a shift from enrichment to suppression at advanced stage. Romiplostim increased platelet counts in controls ($p < 0.001$) and in cirrhotic rats ($p < 0.05$), without worsening liver injury or portal hypertension. BM transcriptomic responses to romiplostim were preserved in cirrhosis.
Conclusion: Liver disease induces complex, dynamic, and stage-dependent changes in both peripheral and central regulators of platelet production. The preserved response to romiplostim supports that BM progenitors remain functional despite disease-related transcriptional reprogramming.

Whole blood ex vivo targeted lipidomic profiling as an immunometabolic target screening tool in decompensated liver disease

Joseph D Wilson[1,2], Roosey Sheth[1,2], Francesca Trovato[1,2], Mark J W McPhail[1,2]. [1]*Roger Williams Institute of Liver Studies, King's College London, London, United Kingdom;* [2]*King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: joseph.wilson10@nhs.net

Background and aims: Lipidomic analysis of patients with decompensated cirrhosis and acute-on-chronic liver failure (AD/ACLF) has revealed targets of potential therapeutic and/or biomarker potential. The AD/ACLF lipidome has significant immune dysfunction implications. Currently, lipidomic analysis is performed on plasma or serum, thus negating the impact of metabolically active cells on the observed lipidome. We devised a whole blood, scalable, *ex vivo* platform for targeted lipidomic profiling and assessing therapeutic modulation. We assessed the lipidomic response to autotaxin (ATX) inhibition given the immunomodulatory importance of the lysophosphatidylcholine-autotaxin-lysophosphatidic acid (LPC-ATX-LPA) axis.
Method: Whole blood from AD/ACLF patients (n = 8) and healthy controls (HCs) (n = 4) was cultured *ex vivo* in a RPMI media and foetal bovine serum mixture for 18–24 h with or without the ATX inhibitor HA130 at 100 nM. Supernatants, generated from whole blood centrifugation, were subject to flow injection analysis-tandem mass

spectrometry (FIA-MS/MS) on the Biocrates LxQuant platform. A total of three hundred and twenty-five lipid species were measured. Lipid concentrations were normalised to the median, log-transformed, and pareto-scaled, prior to multivariate analysis by principal components analysis (PCA) and orthogonal least squares discrimant analysis (OPSL-DA).
Results: PCA and OPSL-DA demonstrated distinct whole blood lipidomic profiles of HC and AD/ACLF ($R^2Y = 0.920$; $Q^2 = 0.807$), indicative of good model fit, and predictive performance verified using permutation testing (n = 1000). Sixteen lipid species had a variable importance of projection (VIP) value >2, the majority of which were phosphatidylcholines (38%), acyl carnitines (25%), and cholesteryl esters (19%). They were dominated by phosphatidylcholine O-38:1, phosphatidylcholine 32:1, phosphatidylcholine 32:0, cholesteryl ester 20:5, and hexadecenoylcarnitine. ATX inhibition reduced phosphoenalomine concentrations in both HCs and AD/ACLF.
Conclusion: We demonstrate that our whole blood *ex vivo* lipidomic profiling successfully discriminates between AD/ACLF and HCs, with phosphatidylcholines being highly discriminatory in OPLS-DA analysis. A previously unknown off target effect of ATX inhibition was identified with potentially important immunomodulatory and therapeutic relevance. This model should be further explored to expand this platform and investigate promising drug targets prior to human experimental medicine studies.

Data-driven biomarker phenotypes refine risk stratification in advanced chronic liver disease
Adrian Wunderbaldinger[1], Benedikt Simbrunner[1], Lorenz Balcar[1], Lukas Hartl[1], Benedikt Hofer[1], Mathias Jachs[1], Georg Kramer[1], Paul Thöne[1], Christian Sebesta[1], Bernhard Scheiner[1], Philipp Schwabl[1], Albert Friedrich Stättermayer[2], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1], Georg Semmler[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria; [2]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria*
Email: adrian.wunderbaldinger@meduniwien.ac.at

Background and aims: Traditionally, patients with advanced chronic liver disease (ACLD) are categorized based on their clinical appearance, but their outcomes within specific disease stages like compensated cirrhosis, decompensated cirrhosis and further decompensation are highly heterogeneous. Here, data-driven clustering based on pathophysiological biomarker profiles may unravel prognostically relevant phenotypes.
Method: We prospectively analyzed ACLD patients at the time of first hemodynamic characterization (baseline) at a tertiary care center between 2017 and 2021. We assessed the subsequent clinical course including first and further decompensation and liver-related death (LRD). Unsupervised clustering was performed using partitioning around medoids on a biomarker panel capturing portal hypertension (hepatic venous pressure gradient [HVPG]), endothelial dysfunction (von Willebrand Factor [VWF] antigen), fibrosis (enhanced liver fibrosis [ELF] test), liver function (MELD, albumin, bile acids), systemic inflammation (C-reactive protein [CRP], interleukin-6 [IL-6], procalcitonin [PCT]), and circulatory dysfunction (N-terminal pro-brain-type natriuretic peptide [NT-proBNP], copeptin).
Results: A total of 451 patients (72% male, alcohol-related liver disease as main aetiology [36%]) were included. Distribution of disease stages were as follows: 168 (37%) patients had compensated, 166 (37%) patients had decompensated cirrhosis, and 117 (26%) patients were further decompensated. Within the ACLD spectrum (i.e., not considering clinical stages), we identified two clusters with the following key variable contribution in descending order: Albumin > HVPG > VWF > ELF > others. In total 29% of cACLD, 72% of decompensated cirrhosis and 86% of further decompensation were allocated to the more advanced disease cluster. This cluster identified compensated patients at significantly higher risk of first decompensation (HR: 4.57 [95%CI: 2.31–9.076], p < 0.001), even when adjusted for presence of clinically significant portal hypertension (aHR: 3.75 [95% CI: 1.86–7.57], p < 0.001). In decompensated cirrhosis, this cluster was associated with further decompensation (HR: 1.86 [1.02–3.38], p = 0.042) and LRD (HR: 2.84 [1.09–7.39], p = 0.032).
Conclusion: Patient clustering based on key biomarker profiles reduces the complexity and pathophysiological heterogeneity of ACLD, identifies patients at risk for further disease progression and may serve as an enrichment strategy for clinical trials.

FRI-445
Updated natural history of contemporary compensated advanced chronic liver disease patients
Adrian Wunderbaldinger[1], Lorenz Balcar[1], Lucie Simonis[1], Jan Embacher[1], Georg Kramer[1], Benedikt Simbrunner[1], Mathias Jachs[1], Lukas Hartl[1], Bernhard Scheiner[1], Michael Trauner[1], Thomas Reiberger[1], Mattias Mandorfer[1], Georg Semmler[1]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria*
Email: adrian.wunderbaldinger@meduniwien.ac.at

Background and aims: Due to significant improvements in non-invasive diagnosis and clinical management, the natural history of contemporary patients with compensated advanced chronic liver disease (cACLD) is unclear, especially regarding the multistate disease course of cACLD. Similarly, data on prognostic factors for specific clinical transitions remain limited.
Method: We studied 1140 consecutive cACLD patients presenting at a hepatology outpatient clinic from 2015 (i.e., following the introduction of interferon-free therapies) to 2022. The occurrence of first and further decompensation, acute-on-chronic liver failure (ACLF), and death were recorded. Baseline profiles were obtained at baseline and longitudinally (32,789 individual time points for laboratory values, 1,617 LSMs) and incorporated in a multistate modelling framework.
Results: 61% were male, median age was 55 years, 42% had steatotic liver disease, and 37% viral hepatitis. Median LSM at baseline was 16.0 kPa, median MELD 7, median albumin 43.1 g/dL. The median follow-up was 3.9 years. The probability to remain compensated was 94% at 1 year, 89% at 2 years, and 74% at 5 years, and the probability of having experienced (only) first decompensation was low with 2.6% at 1, 3.8% at 2, and 3.5% at 5 years. At the same time, 0.3% experienced further decompensation at 1, 2.1% at 2, and 3.1% at 5 years while 3.1% had died at 1, 6.6% at 2 and 20% at 5 years, respectively. Within 5 years, patients starting in compensated state were estimated to spend 51.9 months in compensated compared to only 2.7 months in decompensated and further decompensated state. Baseline information on LSM, albumin, MELD and platelet count was associated with first decompensation and further decompensation (LSM, platelet count, MELD), but not any subsequent endpoints (adjusted for age, sex and aetiological cure). Using updated biomarker profiles significantly enhanced the associations of MELD (associated with all subsequent stage transitions) and C-reactive protein (non-liver-related death from cACLD and liver-related death from first decompensation).
Conclusion: The prognosis of cACLD patients in the era of aetiological therapies is improved as compared to historic data and should inform trial design. However, the disease course gets accelerated as soon as first hepatic decompensation has occurred. Baseline biomarkers provide little information for subsequent events other than first decompensation. In contrast, updated biomarkers provide incremental stage-specific information.

FRI-452-YI

Intrahepatic low shear–induced mitochondrial redox dysfunction in liver sinusoidal endothelial cells drives microvascular dysfunction and contributes to acute portal hypertension

Rajni Yadav[1], Vaibhav Tiwari[1], Himanshi Himanshi[1], Aishwarya Bhatnagar[1], Manisha Manisha[1], Savneet Kaur[1], Anupam Kumar[1], Shiv Kumar Sarin[1], Dinesh Mani Tripathi[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: dineshmanitripathi@gmail.com

Background and aims: Physiological shear regulates LSEC mediated hepatic vascular homeostasis, whereas disturbed shear promotes microvascular dysfunction. However, the consequences of acute reduction in intrahepatic shear below physiological level remain less explored. We investigated how low shear remodels the sinusoidal microenvironment and initiates early vascular complications.
Method: Intrahepatic low shear model was developed by 50–60% portal vein ligation. Intrahepatic blood Flow was assessed by hemodynamics, intra-vital imaging in sham, D1, D2 post PPVL. Liver tissue and isolated LSECs at D2 metabolomics and proteomics was performed. Bioenergetics of LSECs was analysed using Seahorse Extracellular Flux Assay and mitochondrial biomass and potential was measured using MitoTracker dye. Electron microscopy was performed.
Results: Marked reduction in PBF (−42%, −48% at D1, D2 respectively) post PPVL indicate intrahepatic low shear, further confirmed by intravital imaging of portal-vein. Rise in PP (+110%, +135% at D1, D2 respectively) indicating intrahepatic flow resistance. Mechanistically, early alterations dominated by mitochondrial remodelling in LSECs revealed enhanced glycolytic flux- pyruvate levels (log2FC +1.7), reduced mitochondrial fatty-acid β-oxidation, accumulation of L-palmitoylcarnitine (Log2FC- 1.53) indicating carnitine shuttle dysfunction, decrease maximal respiration indicating impaired oxidative phosphorylation. Increased NAD^+ levels (log2FC 2.1) indicate disrupted mitochondrial redox balance. Reduced mitochondrial mass, membrane potential, increased ROS (Sham- 12% vs D2-76% at D2) confirm mitochondrial injury. This altogether disrupts redox sensitive actin protein cdc42 (FC+3), actin-related protein-2 (FC +4.3) and gelsolin (FC −3.5) indicating increased actin polymerisation. Consequently, lead to defenestration (porosity- 18% sham vs 7.9% at D2), while TEM revealed elongated LSECs with increased cytoplasmic-to-nuclear ratio (≥2.1:1 at D2 vs sham = 1:1.5). These endothelial alterations coincided activation of immune and complement-coagulation cascade, establishing a thrombo-inflammatory microenvironment, as evidenced by increased S100A8/A9 expression, elevated serum vWF, reduced ADAMTS13. Together these processes aggravate sinusoidal microvascular dysfunction culminating in acute portal hypertension.
Conclusion: Low shear induces glycolytic uncoupling and mitochondrial redox dysfunction in LSECs, driving cytoskeletal remodelling, thrombo-inflammation, and acute portal hypertension.

Email: namrata.pandey@plymouth.ac.uk

Background and aims: Large plastic products degrade during use and after disposal into small particles described as microplastics (<5 mm, MP) and nanoplastics (<1 µm, NP). These MP/NPs accumulate in the environment and can enter the human body via ingestion and inhalation. Several studies have reported MP/NP in human tissue, raising concerns about potential adverse health outcomes. Existing research on NP toxicity is variable and lacks sufficient understanding of the liver-associated pathophysiology. To understand the impact of NP on the liver, we determined the uptake and effects of commercially available carboxylate-modified 20 nm polystyrene nanoparticles (PS NPs) in three hepatic models: human carcinoma hepatocytes (HepG2), immortalised human hepatocytes (IHH), and human precision-cut liver slices (hPCLS).
Method: We visualised and quantified PS NPs uptake in all three hepatic models using confocal microscopy and flow cytometry. We analysed post-exposure cytotoxicity by assessing cell viability, and measuring hepatic injury markers. We also examined the subtle physiological effects of PS NPs in the HepG2 cells by estimating relative reactive oxygen species (ROS) production using the DCFHDA assay and by comparing mitochondrial respiration in cells using the Agilent Seahorse XFe96 analyser.
Results: Exposure experiments show a model and dose-dependent uptake of PS NPs after 24 and 48 hours of exposure in all three hepatic models. 63.0 ± 31.5% IHH cells showed uptake at a concentration of 0.1 µg/mL, which is considerably lower than the measured plastic concentration in human blood (1.8–4.7 µg/mL). Cell viability of IHH cells decreased from 95.2 ± 2% in the control group to 9.7 ± 7.1% at 100 µg/mL after 48 hours of exposure. Early signs of cell injury were observed with high levels of AST enzyme in the media of IHH and hPCLS at high PS NPs concentrations. HepG2 cells showed no changes in cell viability, redox state, or mitochondrial respiratory parameters after exposure to PS NPs.
Conclusion: The study demonstrates that PS NPs can readily accumulate in hepatocytes, even at a concentration as low as 0.1 µg/mL in IHH cells, and cause cell damage and reduce cell viability at high doses. The effect of PS NPs is model-dependent, highlighting the need for physiologically relevant toxicity models to study the underlying mechanisms of NP cytotoxicity. These findings emphasise the urgent need to investigate the health effects of NP pollution on human liver health using humanised toxicity models.

Impact of apixaban on hepatic decompensation in cirrhosis (ApiHep): a randomized controlled trial

Ayush Agarwal[1], Samagra Agarwal[1], Sagnik Biswas[1], Arnav Aggarwal[1], Sarthak Saxena[1], Hem Singh[1], Shivani Pandey[1], Jasmita Dass[1], Sonu Kumar[1], Shubham Jain[1], Shekhar Swaroop[1], Vishal Chauhan[1], Ankit Agarwal[1], Mukul Aggarwal[1], Ashwani Mishra[1], Ankur Goyal[1], Shivanand Gamangatti[1], Raju Sharma[1], Deepak Gunjan[1], Baibaswat Nayak[1], Shalimar Shalimar[1]. [1]*All India Institute of Medical Sciences, New Delhi, New Delhi, India*
E-mail: drshalimar@gmail.com

Background and aims: Evolving data suggest that anticoagulation is safe in patients with cirrhosis and may improve decompensation-free survival in selected patients with hepatic dysfunction. This study aimed to assess the efficacy and safety of the direct oral anticoagulant apixaban in patients with cirrhosis.

Method: In this single-center, parallel-group, open-label randomized controlled trial, patients aged 18–60 years with cirrhosis (Child–Pugh B7–C10) without splenoportal axis thrombosis were randomized (1:1) to receive apixaban (5 mg daily) and standard of care (SOC) or SOC alone for 12 months. The primary outcome was proportion of patients with new-onset or further hepatic decompensation (as defined by Baveno VII) at 1 year. Secondary outcomes included frequency of liver-related events, overall and liver-related mortality, and adverse events. Analyses were performed using modified intention-to-treat and per-protocol approaches.
Results: 134 patients were randomized (67 apixaban; 67 control). Baseline characteristics were comparable between the groups (mean age 43.4 ± 9.5 years; 91.0% males; 51.5% alcohol-related cirrhosis, 30.6% viral and 10.5% MASLD related; CTP 8 [7–9]; MELD-Na 17.1 ± 4.4). Over a median follow up of 12 months, apixaban significantly reduced new-onset or further decompensation compared to control (32.8% vs. 52.2%; absolute risk difference −19.4 [−35.8 to −3.0]; p = 0.036), confirmed in per-protocol analysis (31.2% vs 53.3%, p = 0.01). Secondary outcomes showed trends toward reduced ascites (6.0% vs. 16.4%; p = 0.06), hepatic encephalopathy (20.9% vs. 34.3%; p = 0.08) and variceal bleeding (7.5% vs 13.4%; p = 0.3) with apixaban. Overall and liver-related mortality at 1 year were similar between the groups. Adverse events (55.2 vs 53.7%: p = 0.86), any bleeding (41.8 vs 46.3%; p = 0.6) and major bleeding (9.0% vs. 11.9%; p = 0.57) did not differ between the two groups.
Conclusion: In patients with Child-Pugh B/C cirrhosis without portal venous thrombosis, apixaban significantly reduced new-onset or further hepatic decompensation without increasing hemorrhagic events.
(CTRI/2023/09/058018).

E-mail: enrico.pompili2@studio.unibo.it

Background and aims: Long-term albumin (LTA) therapy has been shown to improve survival and reduce cirrhosis-related complications in patients with cirrhosis and uncomplicated ascites. To identify the patients deriving the greatest benefit from LTA, this study aimed to evaluate whether baseline serum albumin (SA) levels can predict clinical response to treatment.
Method: This is a post-hoc analysis of the ANSWER trial including 431 patients with cirrhosis and uncomplicated grade 2 or 3 ascites randomized to Standard Medical Treatment (SMT) alone or SMT + LTA up to 18 months. To identify the most discriminatory baseline SA threshold, cut-offs between 2.5 and 4.2 g/dL (0.1 g/dL increments) were tested. For each value, 18-month survival was compared between treatment arms using the log-rank test, and the cut-off with the lowest p-value was selected. The threshold was internally validated using a bootstrap resampling technique with 1000 replicates. The primary endpoint was 18-month survival; secondary endpoints included the incidence rates (IR) of cirrhosis-related complications. Each endpoint was compared between the two subgroups stratified by baseline SA concentration.
Results: Patients did not differ in baseline SA concentration (SMT 3.1 ± 0.5 vs SMT+LTA 3.1 ± 0.6 g/dL, p = 0.86). The baseline SA cut-off associated with the greatest survival benefit was 3.2 g/dL, which was confirmed by the internal validation via bootstrap analysis. Overall, 275 patients (64%) had baseline SA ≤ 3.2 g/dL (132 SMT, 143 SMT+LTA). The 18-month survival was significantly higher in SMT +LTA than SMT in patients with baseline SA ≤ 3.2 g/dL (HR 0.47, 95%CI 0.29–0.77, p = 0.002), while it was similar in patients with SA > 3.2 g/dL (HR 1.04, 95%CI 0.41–2.63, p = 0.93), who show a low mortality rate in both treatment groups. Conversely, the cumulative incidence of paracentesis was significantly lower in the SMT+LTA group compared to SMT, both in patients with SA ≤ 3.2 g/dL (HR 0.45, 95% CI 0.31–0.65, p < 0.001) and in those with SA > 3.2 g/dL (HR 0.52, 95% CI 0.32–0.87, p = 0.010). Similarly, both subgroups showed a significant reduction in complications (i.e., spontaneous bacterial peritonitis [SBP], non-SBP infections, grade III/IV hepatic encephalopathy).
Conclusion: LTA provides survival and morbidity benefits in patients with at least mild-to-moderate hypoalbuminemia, whereas in those with normal SA levels, its advantages are confined to reducing morbidity. Baseline SA may therefore help for prioritizing LTA therapy when resources are constrained.

E-mail: tergast.tammo@mh-hannover.de

Background and aims: Cardiac decompensation (CD) after implantation of transjugular intrahepatic portosystemic shunts (TIPS) for treatment of portal hypertension related complications is a frequent complication. Thus far, only few studies evaluated prognostic relevance of CD, as well as its potential risk factors. Recently, the Toulouse algorithm or pathological E/A have been proposed to predict post-TIPS CD. However, validation in large independent cohorts are lacking. Here, we aimed to investigate the impact and predictors of post-TIPS CD in a large multicenter cohort.
Method: All patients that received TIPS between 2009 and 2025 for portal hypertension derived complications were retrospectively included in this study across 15 tertiary care centers. All included patients received qualified transthoracic echocardiography (TTE) before TIPS implantation. Primary outcome of this study was development of CD within 365 days post-TIPS implantation as defined by current guidelines of the European Society of Cardiology. Fine and Gray competing risk analyses were used to determine association between risk factors and endpoints, treating death and liver transplantation as competing events.
Results: Overall, 1410 patients were included. Median age was 59 years, ascites was the leading factor for TIPS implantation (76%), most patients were male (65%) and alcohol-related liver disease was the main underlying cause of the liver disease (61%). Cardiac decompensation was documented in 14% of all patients and was associated with significantly increased mortality (HR: 1.90, 95%CI 1.23–7.74; P <0.001). Pathological elevated BNP/proBNP and moderate/severe aortic stenosis were significantly linked to CD (HR 3.08, 95%CI 1.23–7.74, P = 0.02 and HR: 2.79, 95%CI 1.02–7.69, P = 0.04). Patients stratified as "high risk" according to the Toulouse algorithm had significantly higher risk for CD (incidence: 11% vs. 21%; HR: 1.91; 95% CI 1.048–3.49; P = 0.04), while pathological E/A, i.e. <0.8 or >2, was numerically associated with CD (HR: 1.43, 95%CI 0.97–2.10, P = 0.07). CD was rare in patients with normal E/A and BNP/proBNP levels (incidence 3% vs. 17%, HR: 5.29 95% CI 1.28–21.96, P = 0.02).
Conclusion: CD is associated with mortality after TIPS implantation. The Toulouse algorithm predicts CD, however some patients are missed. Basic TTE values in combination with BNP/proBNP indicate those with a low risk of post-TIPS CD.

Remote patient monitoring reduces liver-related hospital readmissions in patients with acutely decompensated cirrhosis

Alberto Calleri[1], Yihong Deng[2], Gabriel Prusch Fernandes[1], Kamalpreet S. Hara[1], Mindy Mickelson[2], Katherine Williams[3], Sara Kloft-Nelson[3], Angela Leuenberger[3], Lindsey Sangaralingham[2], Patrick S. Kamath[1], Vijay Shah[1], Daniel Penrice[1], Douglas Simonetto[1]. *[1]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, United States; [2]Robert D and Patricia E Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, United States; [3]Center for Digital Health, Mayo Clinic, Rochester, United States*
E-mail: alberto.calleri.md@gmail.com

Background and aims: Patients with decompensated cirrhosis experience frequent, costly, and often preventable hospitalizations. Despite benefits of remote patient monitoring (RPM) in several chronic diseases, evidence in advanced liver disease remains limited. This study assessed the impact of a cirrhosis-specific RPM program (CiRPM) on post-hospitalization outcomes for patients with acutely decompensated (AD) cirrhosis.
Method: A three-cohort observational study was conducted including adults hospitalized for AD cirrhosis. Patients enrolled in CiRPM (2021–2024) were compared with contemporary controls (C-control) and historical controls (H-control, 2018–2019). CiRPM consisted of 90 days of home monitoring of vitals, body weight, and symptom questionnaires with virtual nurse assessment and hepatologist consultation. This analysis focused on the cumulative incidence of 90-day liver-related hospitalization (LRH). Subgroup analyses evaluated effects by cause of decompensation, liver disease etiology, and disease severity (CLIF-C AD). Confounding was addressed using IPTW with multiple imputation; time-to-event analyses used Cox regression.
Results: Of 430 patients (156 CiRPM, 152 H-control, 122 C-control), the mean age was 59 years, with 41% female, 65% alcohol-associated liver disease (ALD) etiology and mean CLIF-C AD of 56. The 90-day cumulative incidence of LRH was lower in the CiRPM group (39%, 95% CI 29–48) compared to H-control (52%, CI 41–61) and C-control (58%, CI 46–67). CiRPM was associated with a lower risk of LRH relative to C-control (HR 0.57, CI 0.37–0.87; p = 0.01) and H-control (HR 0.67, CI 0.43–1.03; p = 0.07), with a number needed to treat of 5–8 patients. In patients with ALD, CiRPM significantly reduced hospitalizations due to fluid imbalance compared to H-control (OR 0.40, CI 0.25–0.63; p < 0.001) and C-control (OR 0.37, CI 0.24–0.58; p < 0.001). Among patients with non-ALD etiologies, CiRPM was associated with fewer encephalopathy-related hospitalizations compared to H-control (OR 0.29, CI 0.13–0.67; p = 0.004) and C-control (OR 0.36, CI 0.15–0.85; p = 0.02). Patients with CLIF-C AD ≥ 60 experienced the greatest reduction in 90-day LRH (HR 0.43, CI 0.24–0.77; p = 0.005 vs H-control and HR 0.51, CI 0.29–0.91; p = 0.02 vs C-control).
Conclusion: CiRPM significantly reduced liver-related hospitalization, particularly among patients with ALD, fluid imbalance, and advanced disease severity (CLIF-C AD ≥ 60), supporting targeted remote monitoring as scalable post-discharge strategy for this high-risk population.

Longitudinal trajectories of IL-6 and vWF predict clinical outcomes in advanced chronic liver disease independent of liver function

Georg Kramer[1,2,3,4], Dalila Costa[2,5], Benedikt Hofer[1,2,3], Benedikt Simbrunner[1,2,3], Ana Frias[5], Ricardo Silvestre[5], Joana Camões Neves[5], João Belmiro[5], Kerstin Zinober[1,4], Vlad Taru[1,4], Christian Sebesta[1,2,3], Paul Thöne[1,2,3], Marlene Hintersteininger[1,2,3], Lorenz Balcar[1,2,3], Lukas Hartl[1,2,3], Mathias Jachs[1,2,3], Georg Semmler[1,2,3], Michael Trauner[1,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3,4]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [3]Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [4]Christian-Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [5]Life and Health Sciences Research Institute (ICVS), University of Minho; Gastroenterology Department, Braga Hospital, Portugal, Braga, Portugal*
E-mail: georg.kramer@meduniwien.ac.at

Background and aims: Systemic inflammation (SI) and portal hypertension (PH) drive cirrhosis progression. We longitudinally analyzed stage-specific trajectories of Interleukin-6 (IL-6) – a surrogate for SI – and von Willebrand Factor Antigen (vWF) – a marker of PH – in patients with compensated (cACLD), decompensated (dACLD) and recompensated advanced chronic liver disease to determine their impact on clinical transitions.
Method: This prospective two-center study (Vienna/Braga, 2017–2024) included ACLD patients at first combined measurement of vWF and IL-6, with consecutively ≥2 measurements of IL-6, vWF and MELD ≥ 6 months between the first and last measurement. We applied a 5-state multi-state model (cACLD, first and further decompensation, clinical recompensation [CR], liver-related death

[LRD]) and a Bayesian joint modeling framework to link longitudinal biomarker trajectories (linear mixed-effects models) with state transition hazards (Cox regression), adjusted for MELD as a time-dependent covariate (last-observation-carried-forward).
Results: 472 patients (273 cACLD, 199 dACLD) were included (mean age 53.5 ± 12.8 years; 67.1% steatotic liver-disease; median MELD 11 [IQR: 8–15]), contributing 3954 vWF and 2918 IL-6 values. During a median follow-up of 35.5 (25.5–96.6) months, 138 transitions to first decompensation, 124 to further decompensation, 56 to CR and 35 to LRD occurred. Rising IL-6 trajectories predicted the transition to first decompensation (per 20% increase [+20%], adjusted hazard ratio [aHR]: 1.21, p < 0.001), further decompensation (per +20%, aHR: 1.17, p < 0.001) and LRD (per +20%, aHR: 1.15, p < 0.001), independent of MELD. Conversely, falling IL-6 was associated with CR (per 20% decrease, aHR: 1.17, p = 0.007 from first decompensation, aHR: 1.18, p < 0.001 from further decompensation). Rising vWF independently predicted first (per +20%, aHR: 1.39, p < 0.001) and further decompensation (per +20%, aHR: 1.19, p < 0.001), but not CR or death.
Conclusion: Longitudinal modeling reveals that rising trajectories of SI (IL-6) and PH (vWF) drive liver disease progression independently of hepatic dysfunction (MELD). While rising vWF predicts progression – particularly to first decompensation, IL-6 trajectories predict courses from first to further decompensation and mortality (rising levels), but also towards recompensation (falling levels). These data highlight the dynamic and stage-dependent prognostic relevance of PH and SI in ACLD, with cessation of SI being a key facilitator of cirrhosis recompensation.

TOP-471-YI
The modified hepatic encephalopathy staging tool has significantly greater diagnostic consistency, prognostic performance and clinical impact compared with the West Haven criteria

Annarein Kerbert[1], Caterina Chesta[2], Pooja Balachandran[2], Aaryan Panchal[2], Jing Xia[2], Darren Rubin[3], Rajeshwar Prosad Mookerjee[2], Tarek Hassanein[4], Rajiv Jalan[2]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]University College London, London, United Kingdom; [3]Yaqrit Discovery Limited, London, United Kingdom; [4]Southern California Liver Centers, San Diego, United States*
E-mail: j.c.kerbert@lumc.nl

Background and aims: Hepatic encephalopathy (HE) is a serious complication of advanced liver cirrhosis, necessitating accurate and consistent diagnosis and staging in clinical practice and research. The widely used West Haven criteria (WHC) suffer from significant inter-observer variability. This study aimed to develop the modified Hepatic Encephalopathy Staging Tool (mHEST) as a more objective and reproducible method for HE assessment in regulated clinical trials. Its diagnostic consistency, prognostic performance and clinical impact were compared with the WHC.
Method: The study comprised 2 parts. *Part 1* involved revising the original HEST score, based on feedback from an expert panel. Key changes included removing asterixis and adding standardized questions. A two-round online validation survey was conducted: 49 healthcare professionals from 6 countries evaluated 6 video vignettes of actors portraying various HE stages. After viewing an mHEST training video, participants assessed the vignettes twice (5–10 days apart) using mHEST. Inter- and intra-rater agreement were analyzed. In *Part 2*, a prospective, single-center study enrolled 128 hospitalized patients with acutely decompensated cirrhosis. Trained professionals independently assessed HE, using both WHC and mHEST. Ammonia levels were measured at baseline and clinical outcomes were assessed upto one year. Diagnostic consistency, prognostic performance, and impact on existing scoring systems were compared.
Results: In *Part 1*, inter-rater concordance across vignettes ranged from 83.3–100%, and intra-rater agreement from 81.0–100%. In *Part 2*, inter-rater reliability was profoundly higher with mHEST than with WHC (kappa = 0.934 vs. 0.367). mHEST improved the performance of scoring systems incorporating HE assessment, including Child-Pugh and CLIF-C Organ Failure scores. Plasma ammonia levels significantly increased stepwise with rising mHEST grades, but not with WHC grades. In particular, significantly higher ammonia levels were detected in patients with mHEST grade 2 compared to those with grade 0/1 (p < 0.0001), which was not seen with WHC. Unlike WHC, mHEST grade 0/1 was independently associated with a better 1-year survival (HR = 0.515, 95% CI = 0.270–0.982, p = 0.044) in multivariate Cox regression models.
Conclusion: mHEST is a user-friendly tool for HE-assessment outperforming the WHC in diagnostic accuracy, prognostic performance and clinical impact. It has been accepted by the U.S. Food and Drug Administration as an endpoint for HE clinical trials.

TOP-472
Real-world effectiveness of Tolvaptan for hyponatremia in cirrhosis across global regions: a target trial emulation

Kazuya Okushin[1], Ryosuke Tateishi[1], Mitsuhiro Fujishiro[1], Takeya Tsutsumi[1], Kazuhiko Koike[1], Tomohiro Tanaka[2]. *[1]The University of Tokyo, Tokyo, Japan; [2]University of Iowa, Iowa City, United States*
E-mail: tomohiro-tanaka@uiowa.edu

Background and aims: Tolvaptan, an oral vasopressin V2-receptor antagonist, promotes electrolyte-free water excretion, and is widely used in Asian countries, including Japan for the treatment of ascites. However, its role in Western countries is largely limited to the management of hyponatremia due to regulatory restrictions and concerns over hepatotoxicity.
Method: We conducted a retrospective cohort study using the TriNetX Research Network, which aggregates electronic health records from healthcare organizations across global regions, emulating a target trial of cirrhotic patients with hyponatremia. Eligible adults were assigned to tolvaptan plus sodium supplementation (tolvaptan group) or sodium supplementation alone (control). Patients with autosomal dominant polycystic kidney disease were excluded. The primary outcome was 30-day all-cause mortality; secondary outcomes included correction of hyponatremia, changes in liver and renal function parameters, and initiation of hemodialysis. Survival was analyzed using Kaplan-Meier curves with the log-rank test and Cox proportional hazards models. Propensity score matching was applied to balance baseline covariates.
Results: Among 188,707 eligible patients, 2130 received tolvaptan. After 1:1 matching, 1983 patients were analyzed in each group. Baseline demographics and comorbidities were well balanced, although serum sodium remained slightly lower in the tolvaptan group (standardized mean difference, 0.522). Thirty-day mortality was lower in the tolvaptan group compared with controls (14.4% vs. 16.1%; log-rank test p = 0.09, with hazard ratio [HR] 0.87, 95% confidence interval [CI] 0.74–1.02). By the end of the follow-up, serum sodium levels were significantly lower in the tolvaptan group compared with the control group (131.7 ± 133.1 mmol/L, p < 0.001). Hemodialysis initiation did not differ significantly (3.6% vs. 3.7%; log-rank p = 0.76, HR 0.95, 95% CI 0.68–1.33). Renal and liver function parameters were generally comparable, with no evidence of excess hepatotoxicity.
Conclusion: In this large real-world target trial emulation across global regions with ethnic diversity, tolvaptan use was not significantly associated with short-term mortality in cirrhotic patients with hyponatremia, although point estimates consistently favored the tolvaptan group. Further evaluation of the safety and effectiveness of tolvaptan in diverse clinical settings is warranted.

WED-415
Clostridioides difficile mortality in cirrhotic patients matches other bacterial infections in the antimicrobial resistance era

Dimitra Krystallaki[1], Florentia Athanasaki[1], Eleni Geladari[2], Krystalia Dimitriou[1], Nikolaos-Nektarios Karamanolis[1], Iliana Mani[1],

Vasileios Sevastianos[2], Anna Xanthaki[3], Alexandra Alexopoulou[1].
[1]*Second Department of Internal Medicine and Research Laboratory, Hippokration General Hospital, Medical School, National & Kapodistrian University of Athens, Greece, Athens, Greece;* [2]*Third Department of Internal Medicine and Liver Outpatient Clinic, Evangelismos General Hospital, Athens, Greece;* [3]*Microbiology Department, Hippokration General Hospital, Athens, Greece*
E-mail: dimikryst@gmail.com

Background and aims: Bacterial infections (BI) are common in advanced liver cirrhosis and the type of infection may affect prognosis. *Clostridioides difficile* infection (CDI) has been associated with increased short-term mortality but comparative data with other type of BI in the era of increasing antimicrobial resistance are limited. This study aimed to compare outcomes between cirrhotic patients with CDI and those with other BI, and to identify independent predictors of mortality.
Method: We retrospectively analyzed consecutively admitted patients with liver cirrhosis in two tertiary hospitals: with CDI (January 2022–June 2025) and other BI (June 2024–January 2025). CDI was diagnosed based on symptoms of colitis and positive stool antigen and toxin A/B by enzyme immunoassay. Other BI diagnosis was based on the World Health Organization criteria (Aware Antibiotic Book). For all cases, second BI (distinct site and pathogen) and multidrug-resistant organisms (MDRO) were recorded. Patients with advanced hepatocellular carcinoma, recurrent CDI, or fungal infections were excluded.
Results: A total of 101 patients were included (36 CDI, 65 non-CDI), most with decompensated cirrhosis (92.1%). Patients with CDI, compared to those with other BI, were older (median age 73 vs 63 years, p = 0.024), had more comorbidities (Charlson Comorbidity Index 7 vs 6, p = 0.004), more frequent prior exposure to antibiotics (80.6% vs 58.5%, p = 0.024), proton pump inhibitors (66.7% vs 41.5%, p = 0.016), rifaximin (58.3% vs 35.4%, p = 0.026), hospitalizations (80.6% vs 58.5%, p = 0.005), and previous CDI (27.8% vs 3.1%, p < 0.001). Second BI were more prevalent in the CDI group (44.4% vs 21.5%, p = 0.016), while MDRO prevalence was similar between groups (22.2% vs 33.8%, p = 0.261). Thirty- and 90-day mortality did not differ significantly between groups (log-rank p = 0.691 and p = 0.564, respectively). In the overall cohort, Cox regression multivariate model identified Child–Pugh score (HR 1.44, 95% CI 1.13–1.83, p = 0.003) and MDRO (HR 3.07, 95% CI 1.06–8.87, p = 0.039) as independent predictors of 30-day mortality. Among CDI patients, second BI by MDRO independently predicted 30-day mortality (HR 6.04, 95% CI 1.01–36.2, p = 0.049).
Conclusion: In hospitalized cirrhotic patients with infection, short-term mortality appears to be primarily determined by liver disease severity and MDRO, rather than the presence of CDI. In CDI, MDRO-related second infections are the main determinant of 30-day prognosis.

WED-416
Reevaluating hypercoagulability in the portal vein and the impact of TIPS on platelet activation in cirrhosis

Viktoria Moeller[1], Anselm Kunstein[1], Christian Weigel[1], Alexander Killer[1], Eric Tietz[1], Kai Jannusch[1], Mihael Vucur[1], Tom Luedde[1], Peter Minko[1], Johannes Bode[1], Carolin Angendohr[1].
[1]*Universitätsklinikum Düsseldorf, Düsseldorf, Germany*
E-mail: carolohr@gmx.de

Background and aims: In liver cirrhosis, dysregulated hemostasis predisposes patients to hemorrhage and thrombotic complications. The portal vein represents a frequent site of thrombosis, but the underlying mechanisms remain unclear. Previous studies suggested that the portal vein represents a hypercoagulable environment, promoting platelet activation and subsequent thrombogenesis.
Method: We enrolled 34 patients with liver cirrhosis undergoing transjugular intrahepatic portosystemic shunt (TIPS) implantation. Platelet count, activation, and reactivity were assessed by flow cytometry before and after TIPS, as well as across multiple vascular compartments including the portal vein, superior mesenteric vein, hepatic vein, and peripheral vein. In addition, we measured key coagulation factors involved in secondary hemostasis in the indicated vessels.
Results: Platelet counts declined with advancing liver disease, but no changes in platelet activity or reactivity were observed. Despite elevated platelet counts in the portal vein, we found no evidence of increased platelet activation or reactivity. Moreover, no differences in secondary hemostasis were detected across the different vascular compartments. TIPS implantation did not lead to a short-term increase in platelet activation.
Conclusion: Contrary to prior reports, the portal vein does not appear to constitute a hypercoagulable environment. TIPS implantation does not trigger acute platelet activation. These findings suggest that relief of portal hypertension, and the resulting reduction in venous stasis, may exert a greater influence on thrombosis risk than interventions targeting hemostasis.

WED-417
Is 100 the new 250? Ascites fluid PMN >100 has the highest predictive value and odds for 30-day mortality in a national cirrhosis cohort undergoing paracentesis

Scott Silvey[1], Nilang Patel[1], Jasmohan Bajaj[1]. [1]*Virginia Commonwealth University, Richmond, United States*
E-mail: jasmohan.bajaj@vcuhealth.org

Background and aims: An ascites PMN count ≥ 250/ml is considered a corollary for Spontaneous Bacterial Peritonitis (SBP) in the absence of cultures. With changing bacteriology & cirrhosisdemographics, this threshold may need re-evaluation. Aim: Determine impact of differing PMN thresholds on 30-day mortality in a national cirrhosis cohort.
Method: Using the Veterans Affairs Corporate Data Warehouse (VA-CDW), we collected data from Veterans admitted between 2009 and 2024 for cirrhosis & ascites and who received paracentesis ≤ 24 hours into admission. Only patients with valid PMN counts were included. The outcome was 30-day death post-paracentesis. Baseline admission data were compared between groups who died/did not at 30-days. We analyzed PMN thresholds ranging from 50 to 500 with the goal of identifying the cutoff value that optimized positive predictive value (PPV) & odds ratio (OR) of death. We tested this range of PMN values & used smooth splines to fit curves to this data, visually selecting the point where PPV/OR did not increase substantially. Other metrics (sensitivity, specificity, NPV) were also calculated.
Results: 4111 Veterans with cirrhosis & ascites + paracentesis ≤ 24hrs into admission were included (median age 66, 96.3% male, 31.1% alcohol), of which 16.9% died at 30-days. The median PMN count was 19 [IQR: 6–68], which was significantly higher between those who did/did not die (33 vs. 18, $p < 0.001$). Patients who died had higher comorbidities (6 vs 5, p < 0.001), WBC count (8.8 vs 6.8, p < 0.001) & cirrhosis severity (MELD-Na 22 vs 18, albumin 2.8 vs 2.7, both p < 0.001) and. PMN threshold analysis: PMN count ≥ 100 (prevalence: 20.3%) optimized both PPV & OR of death (PPV 25.3%, Sensitivity 30.4%, Specificity 81.8%, NPV 85.2%), and the OR of death vs. those below this threshold was 1.96 (95% CI: [1.63–2.35], $p < 0.001$). Specifically, these metrics increased rapidly until a value of 100 was reached, at which point diminishing returns became evident. Using the defined cutoff for SBP (PMN > 250), the PPV (26.4%) and ORs (1.97 [1.59–2.42]) increased only marginally. Between 100–250 PMNs, an increase in PMN count of 50 corresponded to 11% further increased odds of death, but this increase was not statistically significant ($p = 0.53$).
Conclusion: An ascites fluid PMN ≥ 100/ml is associated with the highest odds ratio for 30-day death in a national cohort of inpatients with cirrhosis. This was comparable to higher values including ≥250/ml used for SBP. A lower PMN count could be considered for optimal prognostication.

WED-418

Dynamic assessment of the AMMON model can guide preventative therapies of patients at risk of liver-related events

Paloma Poyatos-García[1], Jose Sanchez-Serrano[1], Anabel Fernández-Iglesias[2], Rocío Gallego-Durán[3], Carmen Vinaixa[4], Paloma Lluch-García[1], Juan Antonio Carbonell-Asins[5], Rajiv Jalan[6], María Pilar Ballester[1]. [1]*Hospital Clinico Universitario de Valencia, Valencia, Spain;* [2]*Fundació de Recerca Clinic Barcelona-IDIBAPS, Barcelona, Spain;* [3]*Instituto de Biomedicina de Sevilla, Sevilla, Spain;* [4]*Hospital Universitario y Politécnico La Fe, Valencia, Spain;* [5]*Instituto de Investigación Sanitaria INCLIVA, Valencia, Spain;* [6]*University College London, London, United Kingdom*
E-mail: mapibafe@gmail.com

Background and aims: Hyperammonaemia is an independent predictor of hospitalization with liver-related events (LRE) in patients with cirrhosis. The AMMON model, which integrates ammonia with other clinical variables through a machine learning approach, has demonstrated superior performance than traditional severity scores to predict all LRE and death. However, its dynamic role in guiding personalized preventative therapies for patients at risk is unclear. The primary aim of the study was evaluate the dynamic role of the AMMON-OHE model to predict LRE. Exploratory aims were to study the relationship between the model and pathophysiological factors associated with LRE.
Method: A prospective, longitudinal study of consecutive outpatients with cirrhosis followed at two liver units in Valencia between November 2022 and November 2024 was conducted. Clinical, laboratory, and inflammatory, vascular and fibrogenic markers data were collected at baseline, 3, and 6 months. Patients were followed until LRE, liver transplantation, death or study closure in November 2025. Patients were stratified into risk groups (high, medium and low), and dynamic AMMON-OHE categories (stable, progression, regression or remission -low risk-) were defined based on the model changes.
Results: A total of 177 patients were included (75% male; median age 63 years; 63% alcohol-related cirrhosis) exhibited median (IQR) Child-Pugh and MELD-Na of 5 (5–7), and 9 (7–11), respectively. Median plasma ammonia was 36 μg/dL (0.4 × ULN). The cumulative incidence of 1-year LRE differed significantly across dynamic AMMON categories ($p = 0.006$): 44% (remained high risk), 40% (progression), 29% (regression), 20% (remained medium risk), and 10% (remained low risk). Dynamic assessment of the model accurately stratified the risk of hospitalization with LRE both at 3 and 6-months, with the best cut-off to minimize the risk of OHE being remission. AMMON-OHE categories correlated with inflammatory markers (CRP, IL-6), vascular factors (angiopoietin 2, ICAM1, vWF) and PDGFRβ.
Conclusion: Repeated assessment of the AMMON model provides robust dynamic stratification for hospitalization with LRE in outpatients with cirrhosis. These findings support its potential utility in guiding personalized preventative therapeutic strategies in clinical practice and reveal associations with underlying vascular and fibrogenic pathophysiological mechanisms.

WED-419

Culture-independent nanopore metagenomics for pathogen detection in the ascitic fluid for spontaneous bacterial peritonitis in liver cirrhosis patients

Chhagan Bihari[1], Rosmy Babu[2], Vikas Khillan[1], Pratibha Kale[1], Ramesh Prasad[1], Rakhi Maiwall[1], Omkar Rudra[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences New Delhi, Delhi, India;* [2]*ILBS, DELHI, India*
E-mail: drcbsharma@gmail.com

Background and aims: Spontaneous bacterial peritonitis (SBP) is a life-threatening complication of decompensated cirrhosis with high short-term mortality. Conventional ascitic fluid culture has limited sensitivity, leading to frequent culture-negative SBP. We evaluated whole-genome nanopore metagenomics to characterize microbial profiles, mortality-associated taxa, and concordance with culture across SBP groups.
Method: Adults (18–65 years) with decompensated cirrhosis and suspected SBP were enrolled, and ascitic fluid was collected before antibiotics administration. Interim assessment of 48 culture-positive SBP samples and 72 each of culture-negative SBP and non-neutrocytic ascites were sequenced using Oxford Nanopore P2 Solo after low-biomass DNA extraction, followed by stringent filtering.
Results: 91.7% (44/48) of culture-positive SBP, 40.2% (29/72) of culture-negative SBP, and 16.7% (12/72) of non-neutrocytic ascites samples had high-confidence bacterial DNA ($p < 0.001$). Alpha diversity was lowest in culture-positive SBP ($p = 0.0005$) whereas Bray-Curtis dissimilarity varied significantly between groups ($p = 0.00016$). Pseudomonas aeruginosa, Escherichia coli, Klebsiella pneumoniae, Enterococcus faecium, and Stenotrophomonas maltophilia were the most common results of conventional culture in culture-positive SBP which matched metagenomic profiles that were dominated by E. coli, K. pneumoniae, Salmonella enterica, Acinetobacter baumannii, S. maltophilia, and P. aeruginosa, with a shorter turnaround time of 9 hours vs. 5 days. Salmonella enterica, P. aeruginosa, E. coli, and Staphylococcus aureus were found in all culture-negative SBP while Bacillus, Streptomyces, and Staphylococcus species predominated in non-neutrocytic ascites. However, species-specific read counts 4.8 times lesser than culture-positive SBP. Non-neutrocytic ascites demonstrated an even lower burden; 6.8 times lower than culture-positive SBP. Within 30 days 9.1% (4/44) of culture-positive SBP and 6.9% (2/29) of culture-negative SBP died from septic shock. fatal cases were enriched for S. maltophilia with an average of 53477 read counts per sample and S. aureus (4885 reads) and E. coli (1581 reads), respectively.
Conclusion: Metagenomics aligns with conventional culture in culture-positive SBP, however with a reduced turnaround time, while significantly enhancing pathogen detection in culture-negative cases.

WED-420

Extreme heat exposure is associated with an increased risk of all-cause hospitalization in patients with cirrhosis

Therese Bittermann[1,2], Douglas Schaubel[1], Qufei Wu[1], Charles Leonard[1], David Kaplan[1]. [1]*University of Pennsylvania, Philadelphia, United States;* [2]*Queensland Institute of Medical Research Berghofer, Brisbane, Australia*
E-mail: tess.bittermann@health.qld.gov.au

Background and aims: Extreme heat exposure is associated with increased morbidity and mortality in patients with chronic diseases, but the impact on patients with cirrhosis is unknown. This study evaluated the impact of extreme heat exposure on all-cause hospitalization in a validated retrospective cohort of U.S. veterans with incident cirrhosis.
Method: We combined data from the U.S. Veterans Health Administration and publicly available daily maximum temperature (Tmax) data at 3414 weather stations between 2008 and 2021. Extreme heat events were defined as any day (± 3 days) with Tmax >95th percentile for that calendar day/weather station during the study period. Multivariable proportional rates models evaluated the association of extreme heat events on all-cause hospitalization, adjusted for demographics, severity of liver disease, comorbidities, Socioeconomic Deprivation Index (SDI) and climate type. Subgroup analyses were pursued to investigate differences in the impact of heat on outcomes.
Results: The study cohort included 131,793 U.S. veterans with incident cirrhosis between 2008 and 2021. Median follow-up was 1178 days (IQR: 389–2275). The cohort was 96.9% male with median age 63 years (IQR: 58–69). Liver disease etiology included 36.4% with hepatitis C virus, 38.0% with metabolic dysfunction associated steatotic liver disease and 23.9% alcohol. Overall, 60.6% were Child-

Turcotte-Pugh (CTP) class A, 33.8% CTP B and 5.6% CTP C at baseline. High socioeconomic deprivation (SDI 80–100) was present in 24.7%. The most common climate types were mixed-humid (31.9%), cold (29.4%) and hot-humid (20.2%). Extreme heat was significantly associated with an increase in all-cause hospitalization: adjusted rate ratio (RR) 1.79 (95% CI: 1.77–1.80). The excess hospitalization risk was not altered by CTP class (RR 1.80 for class A, RR 1.77 for class B/C) or socioeconomic deprivation (RR 1.79 for SDI <80, HR 1.82 for SDI 80–100). Minimal differences were also observed by climate type, with the HR for hospitalization ranging from 1.76 in hot-humid to RR 1.88 in marine and mixed-dry climates.

Conclusion: Extreme heat is greatly associated with increased all-cause hospitalization in patients with cirrhosis. The magnitude of this risk is unaffected by baseline severity of liver disease, socioeconomic deprivation or climate type. Understanding the impact of climate-related stress, such as extreme heat, on patients with cirrhosis is critical to developing adaptations in care and public health interventions that improve outcomes.

WED-421

Food insecurity, frailty, and oral health are key drivers of impaired quality of life in a large US multicenter cohort of adults with compensated cirrhosis

Adam Buckholz[1], Ani Kardashian[2], David Goldberg[3], Neehar D. Parikh[4], Mandana Khalili[5], Manal F. Abdelmalek[6], Bilal Hameed[5], Matthew Robert Kappus[7], Monica Tincopa[8], Nicole Welch[9], Arun J. Sanyal[10], Patricia Jones[3], Vijay Shah[6], Russell Rosenblatt[1], Rohit Loomba[8], Amreen Dinani[7], Srinivasan Dasarathy[9], Norah Terrault[2], Ann Kan[11], Abigail Smith[11], Elliot Tapper[4], Jasmohan Bajaj[10]. *[1]NewYork-Presbyterian/Weill Cornell Medical Center, New York, United States; [2]University of Southern California, Los Angeles, United States; [3]University of Miami, Miami, United States; [4]University of Michigan, Ann Arbor, United States; [5]University of California San Francisco, San Francisco, United States; [6]Mayo Clinic Health System, Rochester, United States; [7]Duke University, Durham, United States; [8]University of California San Diego, La Jolla, United States; [9]Cleveland Clinic, Twinsburg, United States; [10]Virginia Commonwealth University, Richmond, United States; [11]Northwestern University, Chicago, United States*
E-mail: apb9012@med.cornell.edu

Background and aims: Cirrhosis is associated with impaired quality of life (QoL). Most studies have assessed QoL in decompensated cirrhosis, but data in compensated patients are limited. We examined factors associated with QoL in a large prospective, multicenter cohort of adults with compensated cirrhosis.

Method: The Liver Cirrhosis Network Cohort study prospectively enrolled adults from 10 representative sites across the US with compensated cirrhosis based on liver biopsy within 5 years or a combination of imaging, liver stiffness, and/or blood-based biomarkers and no decompensation within 1 year. Baseline data collection included sociodemographics, medical history, and surveys, including the Patient Reported Outcomes Measurement Information System (PROMIS)-29 Profile v2.1 to calculate an overall preference score (PROPr) ranging from 0 (worst) to 1 (ideal) and 7 domain-level T-scores. Multivariable linear and logistic regression models were fitted for PROPr and probability of T-scores >1 standard deviation (SD) away from the population mean for subdomains where >20% of participants demonstrated impairment. LASSO was used to guide variable selection among sociodemographic/clinical covariates.

Results: Of 1156 participants, median age was 62 years, 76% were white, 44% employed, 13% were food insecure, 34% had fair/poor oral health, and median MELD was 8. Median PROPr T-score was 0.44, and 27%, 23%, and 22% had impaired pain interference (PI), physical functioning (PF), and fatigue scores, respectively. Median PROPr did not vary by etiology of liver cirrhosis. In multivariable analysis, food insecurity (b = –0.14), frailty measured by the Liver Frailty Index (LFI; b = –0.07) and poor oral health (b = –0.05) were associated with worse PROPr (all $p < 0.001$). Food insecurity and higher LFI (more frailty) were also associated with higher odds of impaired T-scores for PF (odds ratio [OR] = 2.61 and 2.64, respectively), PI (OR = 3.07 and 1.77, respectively), and fatigue (OR = 2.54 and 1.49, respectively), all $p < 0.001$. Worse oral health was associated with higher odds of impaired PF and PI (OR = 1.30 and 1.25, $p = 0.002$ and 0.007, respectively), but not with impaired fatigue.

Conclusion: QoL impairment is substantial even in compensated cirrhosis and is associated with food insecurity, frailty, and poor oral health in cross-sectional analysis of a prospective multi-center cohort. Proactive screening for social determinants of health could lead to measures that improve QoL and outcomes in this population.

E-mail: vincenza.calvaruso@unipa.it

Background and aims: Understanding the aetiology, disease stage at diagnosis, and patterns of decompensation of cirrhosis is essential to define prognosis and optimize management. This study aimed to describe the contemporary clinical presentation of cirrhosis in Italy, characterize disease stages, and identify factors associated with hepatic decompensation.

Method: SORPRESA is a prospective, multicentre cohort study conducted in 11 tertiary hepatology centres in Italy during 2024. Consecutive patients with newly diagnosed cirrhosis or first clinical presentation were enrolled. Demographic, socioeconomic, etiological, clinical, and laboratory data were collected at baseline. Disease progression across three stages (compensated, first decompensation, multiple decompensations) was analysed using cumulative ordinal logistic regression. Covariates included aetiology (ALD,

MASLD, MetALD, HCV, HBV, autoimmune and other causes), age, sex, obesity (BMI ≥ 30 kg/m^2), diabetes, education, employment, family status, and housing conditions. A multinomial logistic regression model was applied to evaluate predictors of first decompensation, classified as acute (AD) or non-acute (NAD), versus compensated disease.

Results: A total of 1195 patients were included (mean age 64 ± 11.6 years; 73% male): 232 had ALD, 345 MASLD, 80 MetALD, 246 HCV, 159 HBV, 72 autoimmune, and 63 other aetiologies. Overall, 609 patients had compensated and 586 decompensated cirrhosis; among the latter, 416 experienced a first decompensation (232 AD, 184 NAD) and 170 multiple events. Aetiology emerged as the strongest predictor of progression: compared with ALD/MetALD, MASLD (OR = 0.67, 95% CI 0.48–0.96, p = 0.027) and viral/other causes (OR = 0.58, 95% CI 0.43–0.79, p < 0.001) were associated with lower risk of worsening. Obesity was protective only in the first transition (OR = 0.57, p < 0.001), suggesting an "obesity paradox." Living alone due to widowhood/divorce ("forced solitude") showed a borderline risk effect (OR = 1.39, p = 0.051). In the multinomial model, ALD significantly increased the relative risk ratio of both AD (RRR = 1.85, p = 0.001) and NAD (RRR = 2.08, p < 0.001) at first decompensation compared to compensated disease.

Conclusion: Alcohol-related and metabolic-associated liver diseases, together with social isolation, are associated with worse clinical outcomes in cirrhosis. These findings highlight the need for integrated medical and social interventions to improve prognosis.

WED-426

Glucagon-like peptide-1 receptor agonists reduce the risk of decompensation in patients with type 2 diabetes across different stages of liver disease

Montserrat Camps Fajol[1,2], Anna Brujats[1,2], Maria Poca[1,2], Càndid Villanueva[1,2], Ramon Bataller[3], Victor Gomariz[1], Andreu Ferrero[1], Edilmar Alvarado-Tapias[2,4,5]. *[1]Department of Gastroenterology and Hepatology, Hospital de la Santa Creu i Sant Pau, Institut de Recerca Sant Pau (IR Sant Pau), Barcelona, Spain; [2]Department of medicine, Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [4]Department of Gastroenterology and Hepatology, Hospital de la Santa Creu i Sant Pau, Institut de Recerca Sant Pau (IR Sant Pau), Department of Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Instituto de Salud Carlos III, Madrid, Spain*
E-mail: mcampsf@santpau.cat

Background and aims: Advanced chronic liver disease (ACLD) is associated with high morbidity and mortality, particularly after progression to decompensation. Obesity, type 2 diabetes mellitus and alcohol intake, accelerate disease progression. Glucagon-like peptide-1 receptor agonists (GLP-1 RA) improve metabolic and inflammatory parameters; however, their association with hepatic decompensation across different stages of liver disease remains unclear. This study aimed to evaluate the association between GLP-1 RA use and the risk of first and further hepatic decompensation in patients with type 2 diabetes and compensated ACLD (cACLD), decompensated ACLD (dACLD) and alcohol-related liver disease (ArLD).

Method: A systematic review of studies published between 2022 and 2025 was conducted using MEDLINE, Embase and CENTRAL. Observational studies comparing GLP-1 RA users with non-users or standard type 2 diabetes treatments were eligible. Included populations comprised adults with type 2 diabetes, with or without liver disease, including steatotic liver disease, cACLD, dACLD and ArLD. Two reviewers screened studies, extracted data and assessed risk of bias. A random-effects meta-analysis with restricted maximum likelihood estimation and meta-regression analyses was performed. Outcomes were reported as hazard ratios (HR) with 95% confidence intervals (CI).

Results: Thirteen observational studies comprising 2.121.028 patients were identified. Moderate heterogeneity was observed (I^2 = 39.2%), mainly driven by differences in study populations. Meta-regression showed no significant moderating effect of sex, treatment duration or follow-up (global p = 0.13). GLP-1 RA were associated with a reduced risk of hepatic decompensation in the pooled population (HR = 0.76, 95% CI 0.72–0.81; p < 0.001). In patients with cACLD (seven studies), GLP-1 RA were associated with a lower risk of first decompensation (HR = 0.73, 95% CI 0.65–0.83; p < 0.001). Among patients with dACLD (five studies), GLP-1 RA use was associated with a reduced risk of further decompensation (HR = 0.74, 95% CI 0.67–0.81; p < 0.001). Although based on limited evidence (two studies), GLP-1 RA were also associated with a reduced risk of decompensation in ArLD (HR = 0.63, 95% CI 0.50–0.79; p < 0.001).

Conclusion: GLP-1 RA use was associated with a reduced risk of hepatic decompensation across different stages of liver disease. Randomized controlled trials are needed to confirm these findings and identify patient subgroups most likely to benefit.

E-mail: lcanillas@psmar.cat

Background and aims: The current reference model for predicting postoperative mortality in cirrhosis is the VOCAL-Penn score. However, its predictive performance may decline in cohorts from our clinical setting. The aims of this study were: (1) to develop and validate a new model, and (2) to compare its performance with the VOCAL-Penn score.

Method: We conducted a multicenter, retrospective study in patients with cirrhosis undergoing major extrahepatic surgery. Two cohorts were included: non-transplant centers (A–training) and transplant centers (B–validation). Variables related to comorbidity, liver disease severity, and surgical urgency and complexity (minimal–low/moderate/high/extreme) were collected. Univariate analyses were performed using χ^2 and Mann–Whitney U tests. The predictive model was developed using binary logistic regression. Model discrimination (AUROC) was assessed in cohorts A and B and compared with the VOCAL-Penn score.

Results: A total of 2045 patients were included: cohort A (n = 1046) and cohort B (n = 999). Median age was 65 years, 68% were male, and

cirrhosis was alcohol-related in 49.6% and viral in 31.6%. Median platelet count was 127×10^9/L (IQR 86–178×10^9/L). Ascites was present in 36.5%, and esophageal varices in 69% of endoscopies (n = 1669). Surgery was urgent in 38.1% of cases. Surgical complexity was minimal–low (18.7%), moderate (54.8%), high (16.4%), and extreme (10.2%). Ninety-day postoperative mortality was 10.9% in cohort A (n = 114) and 10.1% in cohort B (n = 101). In cohort A, mortality was associated with age, ASA class, bilirubin, albumin, INR, creatinine, sodium, hemoglobin, platelet count, ascites, emergency surgery, and surgical complexity. Independent predictors of mortality [adjusted OR (IQR); p] were: age [1.08 (1.06–1.11); p < 0.001], bilirubin [1.38 (1.20–1.60); p < 0.001], INR [2.16 (1.30–3.58); p = 0.003], sodium [0.93 (0.89–0.98); p = 0.006], platelets [0.99 (0.99–0.99); p = 0.034], ascites [2.32 (1.27–4.24); p = 0.006], emergency surgery [2.01 (1.23–3.26); p = 0.005], and moderate [2.51 (1.11–5.70); p = 0.027], high [6.79 (2.74–16.81); p < 0.001], and extreme [11.96 (4.67–30.60); p < 0.001] surgical complexity. The AUROC for S-RISC versus VOCAL-Penn were 0.856 vs. 0.792 in cohort A (p = 0.002), and 0.872 vs. 0.826 in cohort B (p = 0.042).

Conclusion: The S-RISC model demonstrates excellent discrimination for predicting postoperative mortality in patients with cirrhosis in different hospital settings. In our clinical setting, S-RISC outperforms the VOCAL-Penn score.

WED-428

Transient hepatic elastography as a composite marker of advanced chronic liver disease severity

Aloma Campeche-Leão[1], Lais Garcez[2], Rosângela de Jesus[2], Helma Pinchemel Cotrim[3], Lourianne Cavalcante[2]. [1]*Hepatology and Gastroenterology, General Hospital Roberto Santos, Salvador, Brazil;* [2]*Federal University of Bahia, Hepatology and Gastroenterology, Salvador, Brazil;* [3]*School of Medicine, PPGMS, Federal University of Bahia, Salvador, Brazil*
E-mail: Lourianne@gmail.com

Background and aims: Advanced chronic liver disease (ACLD) with portal hypertension is associated with progressive hepatic dysfunction and adverse outcomes. Transient elastography (TE, FibroScan®) is widely used to assess liver stiffness, but its role as a composite marker integrating clinical severity, nutritional status, and muscle function remains unclear. We aimed to investigate whether TE reflects a multidimensional burden of disease in ACLD.

Method: We conducted a cross-sectional study (March 2024–July 2025) at a tertiary hepatology center in Brazil. Adults (>18 years) with ACLD and portal hypertension were included. Exclusion criteria: ascites, hepatocellular carcinoma, major decompensated comorbidities, inability to consent. Variables: liver stiffness (kPa, TE; categorized <15, 15–24.9, ≥25), age, sex, Child-Pugh, MELD-Na, nutritional status (GLIM), sarcopenia (EWGSOP), arm muscle circumference, and handgrip strength (HGS). Statistical analysis: linear regression and categorical comparisons (Jamovi v2.7.6).

Results: 132 patients were included. Higher TE values were associated with older age, higher MELD-Na, and worse Child-Pugh class (p < 0.05). Sarcopenia prevalence increased across TE strata (p < 0.001). Regression analysis showed each year of age (+0.15–0.20 kPa) and each MELD-Na point (+0.80–1.10 kPa) independently predicted higher stiffness. Malnutrition (GLIM) was more frequent in patients with ≥25 kPa (36.6%). HGS declined with increasing TE, particularly below EWGSOP cut-offs.

Conclusion: Liver stiffness by TE correlates not only with hepatic severity scores but also with nutritional and muscular impairment. TE may serve as a composite marker of systemic disease burden in ACLD, supporting integrated assessment strategies that combine elastography with functional and nutritional evaluation to improve risk stratification and patient care.

WED-429-YI

Artificial intelligence-based models enabling accurate diagnosis of spontaneous bacterial peritonitis using laboratory tests in China: a multicentre, retrospective cohort study

Zhiji Chen[1], Zhihang Zhou[1], Song He[1]. [1]*Second Affiliated Hospital of Chongqing Medical University, Chongqing, China*
E-mail: 894137655@qq.com

Background and aims: Spontaneous bacterial peritonitis (SBP) is the most common infection among patients with cirrhosis. Due to the widespread use of antibiotics and weakened immune systems, timely diagnosis of SBP is challenging. Laboratory tests are widely used in clinical practice, and some have demonstrated diagnostic and prognostic value for SBP. Our goal is to systematically evaluate the value of routine laboratory tests in predicting SBP and to develop a robust and generalizable integrated artificial intelligence (AI) model to assist in the identification of SBP patients.

Method: In this multicenter retrospective cohort study, we collected laboratory findings and clinical characteristics of patients with cirrhotic ascites (including those with confirmed and undiagnosed SBP) who visited 10 hospitals in China between January 1, 2014, and December 1, 2025. We employed a multi-criteria decision-based classification fusion (MCF) risk prediction framework to construct a comprehensive prediction tool integrating the prediction results of 10 artificial intelligence classification models for the diagnosis of SBP. This tool was evaluated on an internal validation set (5235 participants) and an external validation set (1879 participants). The primary endpoint was the predictive accuracy of the model in identifying SBP.

Results: We included 5235 participants in the internal validation set and 1879 participants in the external validation set. The MCF model achieved an area under the receiver operating characteristic (AUC) of 0.929 (95% CI 0.918–0.950) on the internal validation set and an AUC of 0.884 (0.882–0.887) on the external validation set. Compared to polymorphonuclear neutrophils (PMN) count, the model demonstrated higher AUC and sensitivity in identifying SBP. Even after excluding polymorphonuclear neutrophils (PMN) count, the MCF model still achieved acceptable predictive accuracy and outperformed state-of-the-art models in SBP prediction. MCF is packaged as an SBP prediction tool and made publicly available to provide estimated probabilities of SBP based on input laboratory test values.

Conclusion: When using laboratory test results from 10 hospitals, the MCF model consistently performed satisfactorily in the diagnosis of SBP. This model provides a low-cost, readily available, and accurate diagnostic tool for SBP.

WED-430

Computed tomography-defined sarcopenic obesity: an emerging risk factor for cardiovascular and cerebrovascular mortality in cirrhosis

Yanhua Chen[1], Cuncao Wu[2], Zixing Wang[3], Rui Huang[3]. [1]*Peking University Hepatology Institute, Peking University People's Hospital, School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China;* [2]*Department of Cardiology, Peking University People's Hospital, Beijing, China;* [3]*Peking University Hepatology Institute, Peking University People's Hospital, Beijing, China*
E-mail: cyaoh66@163.com

Background and aims: Sarcopenic obesity (Sa-O) and cardiovascular and cerebrovascular (CCV) disease share multiple overlapping risk factors and adversely affect prognosis in cirrhosis. But direct evidences linking Sa-O to CCV mortality in this population remain scarce. This study was thus designed to explore whether Sa-O can serve as an effective predictor of CCV mortality in cirrhosis.

Method: Body composition was obtained from L3 CT scans in this retrospective cirrhotic cohort. Sa-O (co-existence of sarcopenia and obesity) was assessed via three criteria: skeleton muscle index (SMI) < 38 cm^2/m^2 (female), <42 cm^2/m^2 (male) for sarcopenia; obesity was respectively defined by: (a) visceral adipose tissue area (VATA) ≥

80 cm^2; (b) visceral-to-subcutaneous adipose ratio > 1.47 for men and >1.29 for women; (c) body mass index ≥ 25 kg/m^2. The primary outcome was CCV mortality which was evaluated utilizing Fine-Gray models across three definitions in univariable, multivariable and subgroup analyses.

Results: Of 983 cirrhotic patients (male: 595 [60.5%]; age [standard deviation]: 58.4 [12.2] years; CCV deaths: 46 [4.7%]; follow-up duration [interquartile range]:4.56 [1.81–7.28] years), 181 (18.4%), 79 (8.0%), and 41 (4.2%) met criterion A, B and C for Sa-O, with 17 (9.4%), 7 (8.9%), and 5 (12.2%) CCV deaths occurring respectively. The three criteria delineated distinct phenotypes: criterion A (predominantly viral etiology) captured an intermediate profile; criterion B (predominantly alcohol-related with a male predominance) exhibited the greatest frailty and inflammation; and criterion C (predominantly non-viral, non-alcoholic, with a female predominance) had the most severe liver dysfunction. In competing risk analyses, only criteria A and C independently predicted CCV death. Notably, multivariable adjustment attenuated the hazard ratio (HR) for criterion A from 2.88 (95% Confidence Interval [CI]: 1.58–5.22, p = 0.0005) to 2.42 (95% CI: 1.22–4.79, p = 0.0115), whereas amplified that of criterion C from 2.92 (95% CI: 1.12–7.59, p = 0.0282) to 3.16 (95% CI: 1.26–7.92, p = 0.0143). Distinct adjustment effects may reflect underlying phenotypes heterogeneity, given that the intermediate profile of criterion A was less affected by extremes and severity of liver disease. Results were robust across the subgroup and sensitivity analyses.

Conclusion: The study confirms the use of VATA-defined Sa-O as an effective tool for CCV mortality risk stratification in cirrhotic patients.

WED-431-YI

Physical frailty is the most important predictor of early mortality in hospitalized patients with decompensated cirrhosis

Francesca D'Arcangelo[1], Laura Vivian[1], Alberto Ferrarese[1], Martina Gambato[1], Giacomo Germani[1], Marco Senzolo[1], Francesco Paolo Russo[1], Patrizia Burra[1], Alberto Zanetto[1].
[1]Gastroenterology/Multivisceral Transplant Unit, Padua University Hospital, Italy, Department of Surgery, Oncology and Gastroenterology, University of Padova, Padua, Italy, Padua, Italy
E-mail: francesca.darcangelo02@gmail.com

Background and aims: Patients with cirrhosis are at high risk of malnutrition, sarcopenia and frailty. However, most available evidence derives from North American outpatient cohorts. This study prospectively examined the impact of frailty and sarcopenia on short-term clinical outcomes in hospitalized individuals with cirrhosis.

Method: All consecutive patients with cirrhosis admitted to our unit between October 2021 and March 2023 were screened. Exclusion criteria were: age <18 or >70 years, pre-existing musculoskeletal disorders, and prior liver transplantation. At admission, the Liver Frailty Index (LFI) was assessed and patients were classified as robust (<3.2), pre-frail (3.2–4.5), or frail (>4.5). Skeletal muscle mass was measured through CT scan when performed during hospitalization; sarcopenia was defined as SMI <50 cm^2/m^2 in males and <39 cm^2/m^2 in females. Cox regression analysis was used to identify predictors of primary outcome.

Results: A total of 127 patients were included (median age 59 years; 68.5% male). Median MELD was 22 (IQR 17–27); 70% Child-Pugh class C cirrhosis. Alcohol was the leading aetiology (62%). Frailty was present in 48.8% of the cohort. CT-based muscle assessment was available for 94 patients, revealing sarcopenia in 60%. Patients with both frailty and sarcopenia showed an increased need for ICU care compared with robust and non-sarcopenic individuals. Frailty—but not sarcopenia—was associated with prolonged hospitalization (15 [9–27] vs. 6.5 [4–15] days in robust patients; p = 0.001). No significant differences in rehospitalization rates were observed based on frailty (p = 0.589) or sarcopenia (p = 0.065). Over a median follow-up of 96 days (37–384), 39.4% of patients died. Both frailty and sarcopenia were linked to higher mortality (60% vs. 20% and 58% vs. 38%, respectively; p < 0.001 and p = 0.009). In multivariate analysis, frailty (HR 3.377; 95% CI 1.729–6.597; p < 0.001) and ACLF (HR 2.354; 95% CI 1.124–4.929; p = 0.023) were the only independent predictors of mortality. The association between frailty and mortality persisted in post-hoc analyses stratified by ACLF status.

Conclusion: Frailty and sarcopenia are highly prevalent among hospitalized patients with cirrhosis and are associated with greater healthcare resource use. Frailty emerges as the strongest determinant of early mortality after hospitalization. Thus, the assessment of frailty should be considered in all patients with cirrhosis hospitalized due to acute decompensation.

WED-432

A clinical prediction model for severe hepatic encephalopathy and mortality post-transjugular intrahepatic portosystemic shunt in patients with cirrhosis

Stijn de Reus[1], Wenjing Wang[2], Michelle Spaan[1,3], Ellen Werner[1], Diederik Bijdevaate[4], Kay Pieterman[4], Harry L.A. Janssen[1,5], Adriaan J. van der Meer[1], Bettina E. Hansen[2,6], Raoel Maan[1].
[1]Department of Gastroenterology and Hepatology, Erasmus MC, Rotterdam, Netherlands; [2]Department of epidemiology, Erasmus MC, Rotterdam, Netherlands; [3]Department of Gastroenterology and Hepatology, Amsterdam UMC, Amsterdam, Netherlands; [4]Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, Netherlands; [5]Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, Toronto, Canada; [6]IHPME, University of Toronto & Toronto Centre for Liver Disease, University Health Network, Toronto, Canada
E-mail: s.dereus.1@erasmusmc.nl

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) indications are expanding in patients with portal hypertension. However, hepatic encephalopathy (HE) affects up to 50% of patients, which may present substantial clinical challenges, if severe. Prediction models identifying patients at high risk of severe HE or death can guide patient selection for TIPS.

Method: We retrospectively included consecutive cirrhotic patients receiving TIPS between January 2007 and December 2023 in a tertiary center. Patients with prior liver transplant (LT) were excluded. TIPS-indications were defined according to EASL guidelines and ascites as absent, controlled or refractory.

The primary composite endpoint was severe HE (leading to hospitalization) or all-cause mortality within three months, with LT as the competing event. Predictor selection was performed using Least Absolute Shrinkage and Selection Operator, and modeling was done using a Fine-Gray regression. Model validation was performed by 10-fold cross-validation and calibration.

Results: In total, 358 patients were included; 241 (67%) were male and the median age was 57 years (IQR 50–64). Alcohol-associated cirrhosis was the most common etiology in 191 patients (54%), followed by metabolic steatohepatitis in 44 (12%) and viral hepatitis in 39 (11%). TIPS indication was refractory ascites in 152 patients (42%). Of 175 patients receiving TIPS for variceal bleeding (49%), secondary prophylactic TIPS was the most frequent in 76 (43%). At three months, 124 patients had experienced composite endpoint (35%) and 10 had undergone LT (3%). Cumulative incidence of severe HE/death was 40.9% (95%CI 35.7–46.2). Age, diabetes, indication, etiology, ascites severity and MELD were included in the model. The model reached an AUC of 0.76 (95% CI 0.70–0.82) vs. an AUC of 0.69 for MELD and 0.66 for Child-Pugh score (CPS). Internal validation confirmed model performance (AUC 0.73). Calibration showed 124 observed vs. 127 predicted events at 90 days (36.4% vs 37.5%). Risk stratification into tertiles identified low-, intermediate-, and high-

risk groups, with three-month cumulative incidences of 15.0% (95% CI 8.2–21.8), 31.2% (22.5–40.0), and 62.7% (53.5–71.8).
Conclusion: We developed a competing-risk-based prediction model identifying patients at lower and higher risk for early adverse outcomes, which outperformed CPS/MELD. This model could support pre-procedural risk assessment using clinical parameters.

WED-433

Prevalence and associated factors of non-variceal upper gastrointestinal bleeding among cirrhosis patients on follow-up at a tertiary hospital in Ethiopia

Mahlet Desalegn[1], Henok Fisseha[1], Makida Girma[1], Kaleb Berhane[2], Wasihun Zewde[1]. [1]*St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia;* [2]*Adera Medical Centre, Addis Ababa, Ethiopia*
E-mail: malidmitik@yahoo.com

Background and aims: Liver cirrhosis is a major cause of morbidity and mortality worldwide. Upper gastrointestinal bleeding can be variceal or non-variceal. Non-variceal upper gastrointestinal bleeding accounts for 24–42% of bleeding episodes in cirrhotic patients with a mortality rate of 15–30%. Understanding its prevalence and associated factors is critical for prevention and improved outcomes. This study assessed the prevalence and predictors of NVUGIB among cirrhotic patients at a tertiary hospital in Addis Ababa, Ethiopia.
Method: A hospital-based cross-sectional study was conducted from December 2020 to December 2023 with a total of 234 patients in the study. The collected data were analyzed using Statistical Package for Social Sciences version 26.0. Bivariable and multivariable logistic regression were used to assess association between dependent and independent variables. Adjusted odds ratio with a 95% confidence interval was used to estimate the strength of association, and level of statistical significance was declared at p value <0.05.
Results: The prevalence of non-variceal upper gastrointestinal bleeding was 31.6% (95% CI: 26.0–37.8). with a mean (±SD) age of 39 ± 14 years. Independent predictors of non-variceal upper gastrointestinal bleeding included longer duration of cirrhosis (AOR = 1.01, 95% CI: 1.001–1.019, p = 0.03) and Human Immunodeficiency virus Infection (HIV) (AOR = 51.72, 95% CI: 5.65–471.8, p < 0.001). Lower odds of non-variceal upper gastrointestinal bleeding were observed in older patients (AOR = 0.96, 95% CI: 0.93–0.99, p = 0.007), those with hepatitis C virus (AOR = 0.12, 95% CI: 0.05–0.66, p = 0.009) or schistosomiasis (AOR = 0.03, 95% CI: 0.006–0.19, p < 0.001) as the cause of cirrhosis, prior beta-blocker use (AOR = 0.32, 95% CI: 0.14–0.70, p = 0.005), and higher international normalized ratio (AOR = 0.57, 95% CI: 0.36–0.89, p = 0.014). Non-variceal upper gastrointestinal bleeding patients also had lower systolic blood pressure at presentation (AOR = 0.97, 95% CI: 0.95–0.99, p = 0.010) but required fewer blood product transfusions (AOR = 0.25, 95% CI: 0.08–0.71, p = 0.009).
Conclusion: Non-variceal upper gastrointestinal bleeding (NVUGIB) accounted for nearly one-third of bleeding cases among patients with cirrhosis. It was significantly associated with longer duration of cirrhosis, younger age, and the presence of comorbidities. Implementing screening strategies to identify high-risk patients and adopting preventive measures are recommended to reduce the burden of NVUGIB.

WED-435

Sex-stratified prognostic associations of body fat composition and sarcopenia-related parameters in liver cirrhosis

Kei Endo[1], Hidekatsu Kuroda[1], Keisuke Kakisaka[1], Takayuki Matsumoto[1]. [1]*Iwate Medical University School of Medicine, Yahaba, Japan*
E-mail: keiendo@iwate-med.ac.jp

Background and aims: It remains unclear whether fat- and sarcopenia-related parameters show different prognostic associations between sexes. We aimed to evaluate sex-stratified associations of body fat composition and sarcopenia-related parameters with mortality in patients with liver cirrhosis.
Method: We retrospectively analyzed 535 patients with liver cirrhosis without hepatocellular carcinoma between January 2016 and October 202. Skeletal muscle index (SMI), subcutaneous adipose tissue index (SATI), and visceral adipose tissue index (VATI) were quantified using computed tomography at the third lumbar vertebra, and handgrip strength (HGS) was measured. Prognostic analyses were performed using Cox proportional hazards models adjusted for age, albumin–bilirubin score, and etiology (base model), separately for men and women. Associations with mortality were assessed using restricted cubic spline functions. Model discrimination was evaluated using Harrell's C-index with internal bootstrap validation (1000 resamples).
Results: During a median follow-up of 4.8 years, 134 patients died. Among 535 patients, 294 were men, the median age was 68 years, and 225 had virus-related cirrhosis. In men, restricted cubic spline analyses showed significant associations of SMI (P total < 0.01) and HGS (P total < 0.01) with mortality, with lower values conferring higher risk. SATI demonstrated a non-linear association with mortality (P total = 0.03, P non-linearity = 0.02), with increased risk at both low and high values, whereas VATI was not significantly associated (P total = 0.07). In women, SATI showed a significant linear association with mortality (P total = 0.03), while SMI (P total = 0.55), HGS (P total = 0.12), and VATI (P total = 0.09) were not significantly associated. In men, the optimism-corrected C-index of the base model was 0.698, which improved with the addition of HGS (0.746) and SMI (0.736), whereas SATI (0.699) and VATI (0.717) provided limited improvement. In women, the base model C-index was 0.790, and discrimination improved with fat-related parameters (SATI 0.800, VATI 0.805), while muscle-related parameters provided minimal improvement (SMI 0.795, HGS 0.796).
Conclusion: In sex-stratified analyses, muscle mass and strength were associated with prognosis in men, whereas subcutaneous adiposity showed a significant association in women. These findings suggest that the prognostic relevance of sarcopenia- and fat-related metrics may vary by sex, supporting the potential value of sex-stratified risk assessment in cirrhosis.

WED-436

The efficacy of Rifaximin in preventing liver cirrhosis complications, including spontaneous bacterial peritonitis, encephalopathy, variceal bleeding, and all-cause mortality in adult patients with liver cirrhosis : a meta-analysis

Camille Feliciano[1]. [1]*Skyline Hospital and Medical Center, San Jose Del Monte, Bulacan, Philippines*
E-mail: camillefelicianomd@gmail.com

Background and aims: Spontaneous bacterial peritonitis (SBP), hepatic encephalopathy, and variceal bleeding are serious complications of liver cirrhosis associated with a high recurrence rate and increased mortality. Norfloxacin, which is the most commonly used drug for the secondary prophylaxis of SBP, has been linked to the emergence of quinolone-resistant and Gram-positive SBP due to prolonged use. Rifaximin's broader antibacterial spectrum and non-absorbable nature make it a compelling alternative to Norfloxacin. This study aimed to evaluate the efficacy of Rifaximin in the prevention of liver cirrhosis complications including spontaneous bacterial peritonitis, encephalopathy, variceal bleeding, as well its effects on all-cause mortality.
Method: PubMed and Cochrane Library database were searched for articles published until August 24, 2023. Outcomes noted were occurrence of SBP, development of hepatic encephalopathy and variceal bleeding, adverse events, and mortality rate. Meta-analysis assessed the pooled Odds Ratios (ORs) with a 95% Confidence Interval by using Review Manager 5.3. A total of two hundred patients with liver cirrhosis Child-Pugh B and C were assigned to the Rifaximin group with dosages ranging from 800 mg to 1200 mg daily, while a

total of two hundred and seven patients with liver cirrhosis Child Pugh B and C were assigned to the Norfloxacin group with dosages of 400 mg to 800 mg daily, with a treatment duration of 6 months to 1 year. Study endpoints were: occurrence of SBP, hepatic encephalopathy, variceal bleeding, and all cause mortality.
Results: In this study, Rifaximin demonstrated significant efficacy in preventing SBP (Odds Ratio 0.19; $p < 0.0001$) and reducing all-cause mortality (Odds Ratio 0.55; $p = 0.02$), suggesting a strong clinical benefit over Norfloxacin. With an OR of 0.33 (95% CI: 0.17 to 0.64; $p = 0.001$), Rifaximin also shows significant efficacy in preventing hepatic encephalopathy. However, the effect on variceal bleeding was not statistically significant (Odds Ratio 0.76; $p = 0.74$).
Conclusion: Rifaximin demonstrates superior efficacy in preventing liver cirrhosis complications, including spontaneous bacterial peritonitis and hepatic encephalopathy, compared to the current standard of care, Norfloxacin. Additionally, Rifaximin exhibits a more favorable adverse effect profile and a reduced risk of antibiotic resistance.

WED-441
Uncontrolled ammonia is associated with increased healthcare resource utilization in hepatic encephalopathy
Jonathan Fischer[1], Christian Roy[1], Elliot Tapper[2]. [1]*Korro Bio, Cambridge, United States;* [2]*University of Michigan, Ann Arbor, United States*
E-mail: jfischer@korrobio.com

Background and aims: Ammonia is a key driver of hepatic encephalopathy (HE), and achieving ammonia control is essential for preventing morbidity and mortality. However, real-world ammonia control in HE remains poorly understood. We aimed to identify the proportion of patients with HE receiving standard therapies with uncontrolled ammonia and the impact of elevated ammonia on clinical outcomes.
Method: Patients with cirrhosis, HE treated with lactulose and/or rifaximin, ammonia ≥ 52.5 µM, and Model for End-Stage Liver Disease (MELD) ≤ 20 were identified in the All of Us database in 2022. Rifaximin-treated patients with uncontrolled ammonia and MELD ≤ 20 were chosen to identify a stable population with unmet needs that may be suitable for future outpatient clinical trials. Treatment patterns and inpatient healthcare utilization were analyzed, and ammonia findings compared to a urea cycle disorder (UCD) population with pathogenic or likely pathogenic single nucleotide polymorphisms in urea cycle genes.
Results: Of 3524 identified cirrhosis patients, 582 (16.5%) received HE pharmacotherapy, including 219 (38% of treated patients) treated with rifaximin. Among rifaximin-treated patients with ammonia measures, median ammonia was 69 µM, and 76% exhibited levels ≥ 1.5x upper limit of normal. Ammonia levels were higher in rifaximin-treated patients than in a UCD cohort (16 patients, median 56 µM). 75% of the rifaximin-treated patients with elevated ammonia had MELD ≤ 20. These patients with elevated ammonia and stable MELD demonstrated a significant increase in healthcare burden: mean HE-related hospitalizations were 2.33 versus 1.10 in all rifaximin-treated patients (incidence rate ratio (IRR) = 2.13, $p < 0.001$), and all-cause hospitalizations were 3.71 versus 1.96 (IRR = 1.89, $p < 0.01$).
Conclusion: Ammonia control remains a significant challenge that leads to a substantial healthcare burden in HE. Rifaximin-treated patients with uncontrolled ammonia and MELD ≤ 20 had significantly increased healthcare resource utilization compared to all rifaximin-treated HE patients, underscoring both the clinical severity and economic burden of inadequately controlled ammonia. Higher ammonia levels in HE patients compared to those in UCD highlight that current gut-targeted approaches may be insufficient for achieving adequate ammonia control in HE. These findings support the critical unmet need for novel therapies that directly target ammonia metabolism to reduce HE recurrence, improve patient outcomes, and decrease healthcare burden.

Hospital Universitario Ramón y Cajal. IRYCIS. CIBERehd. Universidad de Alcalá., Madrid, Spain*
E-mail: salvatore.piano@unipd.it

Background and aims: Further decompensation (FD) in cirrhosis, defined as the development of a second distinct portal hypertension-driven decompensating event, jaundice or recurrence of variceal bleeding, ascites or hepatic encephalopathy (HE), represents a critical prognostic stage associated with markedly increased mortality compared with first decompensation. However, the prognostic impact of different types of FD and the clinical trajectories after FD are not well characterized. The primary aim of this study was to characterize disease trajectories and mortality risk in patients with cirrhosis experiencing FD.
Method: We conducted a multicentre, retrospective, observational study including patients with cirrhosis followed at 10 centers in 6 countries who developed at least one episode of FD (according to Baveno VII criteria). Demographic, clinical, laboratory, endoscopic and treatment data were collected at first FD episode. All subsequent FD episodes were recorded until death, liver transplant or last follow-up (median time 371 days). Analysis of mortality was adjusted for age, sex, etiology, MELD-Na, ACLF and albumin at first FD.
Results: We enrolled 1523 patients (32% female, mean age 57.6 years, alcohol-related cirrhosis 59.2%). The most frequent first FD events were refractory ascites (23.1%), HE (14.5%), recurrent ascites (13.3%) and bleeding (10.7%), whereas recurrent bleeding (7.9%), SBP (6.9%), jaundice (6.8%), hepatorenal syndrome (HRS) (6.3%), ascites (6.2%) and recurrent HE (4.3%) were less common. Subsequent decompensation patterns differed significantly according to the type of first FD. The two-year cumulative incidence of mortality was 37.4%. In multivariable competing risk analysis (using recurrent bleeding as a reference group), ascites (sHR = 2.50; $p < 0.001$), refractory ascites (sHR = 2.01; $p = 0.002$), bleeding (sHR = 2.38; $p < 0.001$), HE (sHR = 1.77; $p = 0.018$) and HRS (sHR = 3.35; $p < 0.001$) as type of FD had a higher risk of mortality, whereas jaundice, SBP, recurrent ascites or recurrent HE did not. Age, MELD-Na, ACLF and albumin at FD were independently associated with mortality as well.
Conclusion: Distinct phenotypes of FD are associated with distinct clinical trajectories and prognosis. Patients developing a second distinct portal hypertension-driven decompensating event, as well as those with refractory ascites and hepatorenal syndrome have the worst prognosis. These findings have important implications for risk stratification and potential phenotype-driven therapeutic management.

Rectus femoris cross sectional area predicts further decompensation and mortality in patients surviving hospitalization for acute decompensation of cirrhosis

Roberta Gagliardi[1], Simone Incicco[1], Valeria Calvino[1], Marta Tonon[1], Carmine Gambino[1], Nicola Zeni[1], Sara Montagnese[1], Salvatore Piano[1]. [1]*Unit of Internal Medicine and Hepatology, Department of Medicine, University and Hospital of Padova, Padova, Italy*
E-mail: salvatore.piano@unipd.it

Background and aims: Sarcopenia is common in patients with cirrhosis and is associated with poor clinical outcomes. Further decompensation (FD) represents a critical prognostic stage with higher mortality than first decompensation, yet its association with sarcopenia remains poorly defined. Ultrasound measurement of rectus femoris cross-sectional area (RF-CSA) is a simple bedside tool to assess sarcopenia. This study evaluated the association between RF-CSA and the risk of FD and mortality in patients with cirrhosis surviving a hospitalization for acute decompensation (AD).
Method: Patients with cirrhosis discharged after a hospitalization for AD between 2019 and 2025 were prospectively enrolled. Clinical, demographic and laboratory data were collected during admission and on discharge. RF-CSA was measured at two-thirds of the distance from the anterior superior iliac spine to the superior patellar border. Previously identified RF-CSA thresholds (4.87 cm^2 in males; 2.42 cm^2 in females) were used to diagnose sarcopenia. Follow-up continued until death, liver transplantation or 180 days. Episodes of FD, defined as the development of a second portal hypertension–driven decompensating event and/or jaundice, recurrent variceal bleeding, recurrent/refractory ascites, recurrent hepatic encephalopathy (HE), spontaneous bacterial peritonitis and/or hepatorenal syndrome, were recorded.
Results: A total of 183 patients were included (mean age 65 ± 11 years; median MELD 16). Most had alcohol-related cirrhosis (61%) and ascites (70%). During the follow-up, 68 patients (37%) developed FD. These patients were older (66 ± 11 vs. 62 ± 10 years; p = 0.006), had a higher prevalence of HE (54% vs. 21%; p < 0.001), and showed lower RF-CSA values (2.87 [IQR 2.15–3.64] vs. 3.53 [IQR 2.65–4.82] cm^2; p = 0.003). Patients with sarcopenia according to RF-CSA thresholds had a higher risk of FD (42% vs. 22%; p = 0.012) and mortality (28% vs. 14.3%; p = 0.003). In multivariable analysis (adjusted for age, gender, MELD, and HE), RF-CSA was an independent predictor of both FD (sHR = 0.81; p = 0.035) and mortality (sHR = 0.67; p = 0.009).
Conclusion: In cirrhotic patients surviving a hospitalization for AD, sarcopenia assessed by RF-CSA is independently associated with FD and mortality at 180 days. Interventions aimed at preserving or increasing muscle mass may help reduce the risk of FD and improve patient outcomes.

WED-444

Comparative assessment and external validation of ultrasound-derived quadriceps indices against bioelectrical impedance analysis for sarcopenia screening in chronic liver disease

Paolo Gallo[1], Valentina Flagiello[1], Daniela Lemme[1], Antonio De Vincentis[2], Simone Di Cola[3], Andrea Falcomatà[1], Francesca Terracciani[1], Antonio Picardi[1], Umberto Vespasiani-Gentilucci[1]. E-mail: paolo.gallo@policlinicocampus.it

Background and aims: Sarcopenia is a common complication in chronic liver disease (CLD). Muscle ultrasound (US)-measurements are increasingly investigated as feasible bedside tools despite limited standardization. We aimed to evaluate whether US-derived quadriceps indices can serve as surrogates of appendicular skeletal muscle mass (ASMM) measured by bioelectrical impedance analysis (BIA) in patients with compensated cirrhosis.
Method: A prospective, two-phase study was conducted. In phase 1, we evaluated the correlation and agreement between US-based quadriceps measurements (average compression index-ACI- and average feather index -AFI-) and ASMM assessed by BIA in patients with compensated cirrhosis and a history (active disease or under surveillance) of hepatocellular carcinoma (HCC). Phase 2 externally validated these findings in an independent cohort of patients with compensated cirrhosis, regardless of HCC history.
Results: Phase 1 included 88 patients (mean age 73 years [SD7], 78% male). ACI and AFI showed significant correlations with ASMM/height^2 [r = 0.35 (95%CI 0.15–0.52), p = 0.001; r = 0.45 (95%CI 0.27–0.60), p < 0.001, respectively]. In sex-adjusted models, linear regression analysis confirmed AFI [β = 0.64 (95%CI 0.37–0.92)] and ACI [β = 0.50 (95%CI 0.21–0.78)] as significantly associated with ASMM/height^2 (p < 0.001 for both associations). In addition, Bland–Altman analysis showed a good level of agreement for these indices [bias and LoA of 0.007 (−0.239;0.253) and 0.021 (−0.205;0.247) for ACI and AFI, respectively]. Inter-rater reliability was high (ICC 0.94–0.96). Phase 2 included 47 patients (mean age 70 years [SD10], 66% male). In this external cohort, both indices confirmed good correlations [ACI r = 0.49 (95%CI 0.23–0.68), p < 0.001; AFI r = 0.50 [95%CI 0.25–0.69], p < 0.001]. In age- and sex-adjusted models, ACI [β = 0.89 (95%CI 0.44–1.33), p < 0.001] and AFI [β = 0.79 (95%CI 0.34–1.24), p < 0.001] remained independently associated. Finally Bland–Altman analysis confirmed excellent agreement in this population.
Conclusion: US-derived quadriceps measurements provide reproducible and non-invasive surrogates of skeletal muscle mass defined by BIA in patients with compensated cirrhosis, and retain good performance in external validation, supporting their use as a feasible and cost-effective tool for the assessment of sarcopenia in patients with CLD.

WED-445

Predictors of clinical course in patients surviving acute decompensation of cirrhosis

Carmine Gambino[1], Antonio Accetta[1], Enrico Pompili[2,3], Roberto Filomia[4], Chiara Passalacqua[5], Giulia Iannone[2], Concetta Pitrone[4], Gianluca Fusco[5], Clelia Asero[4], Giulia La Manna[5], Giacomo Zaccherini[2,6], Irene Cacciola[4], Giovanni Squadrito[5], Paolo Caraceni[2], Paolo Angeli[1], Salvatore Piano[1]. E-mail: carmine.gabriele.gambino@gmail.com

Background and aims: Three different clinical trajectories have been described in PREDICT study in patients surviving acute decompensation (AD) of cirrhosis, namely stable decompensated cirrhosis (SDC), unstable decompensated cirrhosis (UDC) and pre-ACLF, yet their prediction at the time of discharge remains challenging. The aim of this study is to investigate predictors of clinical courses at discharge after AD and 1-year mortality.
Method: We included 646 patients (age 63 [54–73] years; male 414 (64.1%); alcohol 297 [46%]; MELD 14 [11–18]) surviving AD of cirrhosis at the three tertiary care centers (University of Bologna, Messina and Padova), from 2011 to 2020. Patients were followed up until liver transplantation (LT), death or 1 year. Clinical and laboratory data at admission, during hospitalization and at discharge were collected.

Results: At 90-day after discharge, 369 (57.1%) patients were identified as SDC, 226 (35%) as UDC and 51 (7.9%) as pre-ACLF. Twenty-two (3.4%) patients underwent LT. At discharge, SDC patients showed, if compared to both UDC and pre-ACLF patients, lower WBC count (4.31 vs 4.83 vs 4.77 × 10^9/L; p = 0.039), creatinine (0.80 vs 0.87 vs 0.87 mg/dL; p = 0.011), bilirubin (1.70 vs 2.11 vs 3.08 mg/dL; p < 0.001), INR (1.32 vs 1.36 vs 1.57; p < 0.001) and MELD (12 vs 14 vs 17; p < 0.001); moreover, they showed higher haemoglobin (104 vs 103 vs 99 g/L; p = 0.01) and platelet count (97 vs 79 vs 73 × 10^9/L; p = 0.047). In a multivariable multinomial logistic regression model (adjusted for age, gender, aetiology, haemoglobin, CRP, albumin, and MELD – all at discharge) with SDC as reference, age (p < 0.01) and MELD (p < 0.001) were independently associated with clinical course, being each 1-point increase in MELD associated with 7.7% higher odds of UDC (OR 1.077, p < 0.001) and 24.6% higher odds of pre-ACLF (OR 1.246, p < 0.001). At 1-year after discharge, mortality rate was higher in pre-ACLF if compared to UDC and SDC (14.8% vs 35% vs 50.6%; p < 0.0001), and 66 (10.2%) patients underwent LT. In a multivariable model (adjusted for age, gender, aetiology, clinical trajectory, creatinine, bilirubin, INR and CRP at discharge), older age (sHR = 1.047; p < 0.001), higher CRP (sHR = 1.01; p < 0.0001), UDC (sHR = 3.10; p < 0.001) and pre-ACLF (sHR = 5.71; p < 0.001) were independent predictors of 1-year mortality.
Conclusion: We confirmed three distinct clinical trajectories after AD of cirrhosis with significantly different mortality. Older age and higher MELD at discharge independently predicted UDC and pre-ACLF trajectories.

WED-446

Neutrophil gelatinase-associated Lipocalin as an early biomarker of outcome after TIPS

E-mail: Geisselbrecht.Sophia@mh-hannover.de

Background and aims: Renal function is an important predictor in end-stage liver disease. However, serum Creatinine (sCr) is influenced by other cirrhosis-related factors such as sarcopenia and malnutrition. This study evaluated the potential of neutrophil gelatinase-associated lipocalin (NGAL) as a novel biomarker for predicting outcomes after transjugular intrahepatic portosystemic shunt (TIPS).
Method: Consecutive patients with decompensated cirrhosis undergoing TIPS insertion between 08/2019 and 04/2025 at centers in Hannover and Mainz were prospectively enrolled. SCr and plasma NGAL levels were measured before TIPS and at 1, 6, 12 and 24 months. Fine-Gray competing risk models were used to analyze survival (competing event: liver transplantation (LT)) and acute kidney injury (AKI) (competing events: death and LT) within three months and two years after TIPS, estimating subdistribution hazard ratios (sHRs) and absolute standardized hazard ratios (aSHRs). Multivariable models were adjusted for age, albumin, bilirubin, and sCr, while univariable models were conducted without adjustment.
Results: A total of 246 patients (median age 60 years, median MELD 3.0 score 15, 53% alcohol-related cirrhosis) were analyzed. Overall, patients showed improved sCr (p < 0.001) and NGAL (p = 0.048) over the course of 12 months, with the greatest benefit observed in patients with impaired renal function (sCr ≥ 1.5 mg/dL and high NGAL ≥ 187 ng/mL). At baseline, NGAL was significantly associated with IL-6 levels (β = 0.51, 95% CI 0.27–0.74; p < 0.001), corresponding to an ~42% increase in IL-6 per NGAL doubling. In univariate competing risk models, higher baseline NGAL was associated with increased two-year mortality (sHR: 1.001; p = 0.047) and AKI (sHR: 1.001; p = 0.04). Baseline NGAL was independently associated with three-month mortality in a multivariable competing risk model (asHR: 1.003; p < 0.001). In contrast, baseline NGAL was not associated with two-year mortality (asHR: 1.001; p = 0.34) or AKI (three-month asHR: 1.00; p = 0.8; two-year asHR: 1.00; p = 0.62) in multivariable competing risk models. However, NGAL levels at one month after TIPS insertion were associated with two-year mortality (asHR: 1.002; p = 0.04) and AKI (asHR: 1.003; p = 0.001).
Conclusion: Baseline NGAL levels were strong predictors of early mortality after TIPS, while NGAL levels at one month post-TIPS were associated with long-term mortality and the development of AKI, supporting NGAL as an early risk stratification biomarker after TIPS.

WED-447

Baseline characteristics of a prospective, multi-center study on the natural history of compensated cirrhosis: the liver cirrhosis network

Kara Wegermann[1], Abigail Smith[2], Srinivasan Dasarathy[3], Nicole Welch[3], Elizabeth Verna[4], Robert S. Brown, Jr.[5], Cynthia Moylan[1,6], Patrick S. Kamath[7], Vijay Shah[7], Patricia Jones[8], Elliot Tapper[9], Rohit Loomba[10], Claude Sirlin[10], Bilal Hameed[11], Andrew Stolz[12], Arun J. Sanyal[13], Jasmohan Bajaj[13], Daniela Ladner[2], Mandana Khalili[11], Norah Terrault[12], Neehar D. Parikh[9], David Goldberg[8].

E-mail: kara.wegermann@duke.edu

Background and aims: Factors driving decompensation among patients with compensated cirrhosis are incompletely understood. The multi-center NIH-sponsored Liver Cirrhosis Network (LCN) Cohort Study aims to elucidate natural history of compensated cirrhosis and develop risk stratification tools. The LCN also includes patients with recompensated cirrhosis, an emerging population with poorly described characteristics and natural history. Here, we describe baseline characteristics of the study population compared to other large US cohorts of patients with cirrhosis, and we compare characteristics of participants with always compensated versus recompensated cirrhosis.
Method: The LCN Cohort Study is a prospective, 3-year observational study at 10 US sites. Adults with compensated cirrhosis were enrolled based on: a) liver biopsy within 5 years or b) 2 of the following: liver biopsy >5 years ago, VCTE ≥ 12.5 kPa, MRE ≥ 5 kPa, imaging with

nodular liver and splenomegaly within 1 year, esophageal varices within 3 years, FIB-4 > 2.67 or platelets < 150,000 within 6 months. We performed a subgroup analysis of participants with recompensation, defined as prior ascites, variceal bleeding, or hepatic encephalopathy without treatment of decompensation ≥ 1 year. We compared demographic and clinical characteristics of our cohort to CDC death and OPTN transplant registry data.

Results: We enrolled 1221 participants from 2022 to 2025. Compared to the contemporary OPTN transplant waitlist registry, LCN participants were older (median age 62 vs 57 years), more often female (50% vs 39%), and more likely to have MASH (56% vs 19%), while a smaller proportion had alcohol-associated liver disease (ALD, 18% vs 44%). The age, race, ethnicity, and sex distribution mirrored the US population dying from cirrhosis in the CDC data from 2022 to 2023. Among 1221 LCN participants, 100 (8.0%) had a history of decompensation followed by recompensation. Recompensated participants had a lower BMI (median 28.7 vs 31.3 kg/m^2, p < 0.001), were less likely to have diabetes (30% vs 47%, p < 0.001) and were more likely to have ALD (55% vs 15%, p < 0.001).

Conclusion: LCN Cohort Study participants have similar demographics to the broader cirrhosis population in the US. The overall cohort had a lower prevalence of ALD compared to a liver transplant waitlist population, but those with recompensated cirrhosis were more likely to have ALD.

WED-448-YI

Development of a composite biomarker to predict risk of AKI and mortality following an acute decompensation of cirrhosis

Olivia Greenham[1], Kohilan Gananandan[1], Peter Holland-Fischer[2], Konstantin Kazankov[3], Rohit Sawhney[4], Naina Shah[1], Carolyn Hyde[5], Pragyan Acharya[6], Rajiv Jalan[1], Karen Louise Thomsen[1,3], Rajeshwar Prosad Mookerjee[1,3]. *[1]Liver Failure Group University College London, London, United Kingdom; [2]Aalborg University Hospital, Aalborg, Denmark; [3]Aarhus University Hospital, Aarhus, Denmark; [4]Eastern Health, Monash University, Melbourne, Australia; [5]Bio-Analysis Centre, London, United Kingdom; [6]All India Institute Of Medical Science, Delhi, India*
E-mail: olivia.greenham@nhs.net

Background and aims: Development of acute kidney injury (AKI) in cirrhosis patients is associated with worse outcomes. The current AKI diagnostic standard, serum creatinine, lacks sensitivity and specificity. Neutrophil gelatinase associated lipocalin (NGAL), reflecting renal tubular injury and dimethylarginines (ADMA and SDMA) related to endothelial dysfunction, are both processes involved in new AKI following acute decompensation (AD). The study aimed to assess the ability for plasma (p) pNGAL, pADMA, pSDMA and urine (u) uNGAL to predict outcomes in patients with AD.

Method: Stored plasma/urine samples were analysed from 122 patients at UCL recruited to DASIMAR, a prospective, observational study in AD patients. Simple plex assays for uNGAL and pNGAL, and mass spectrometry for pADMA and pSDMA were performed on paired urine and plasma samples taken at baseline (T1) and a second time point within 7 days (T2). Using a logistic regression model, increases in a composite of standardised variables (z scores), expressed as 1-standard-deviation (1SD), were used to predict outcomes.

Results: Of 122 patients (66% male, 51 years age, 71% ArLD), 21% had AKI with similar demographics to those with no AKI. 16% withh AKI and 9% with no AKI died within 3 months. Median uNGAL and pNGAL were significantly higher in the AKI group [uNGAL 106 vs 62 ng/ml p = 0.01, pNGAL 132 vs 71 ng/ml p < 0.001].

Univariate analysis showed higher pSDMA and uNGAL values at T1 and T2 were associated with an increased risk of new AKI. A 1SD increase in composite pSDMA and uNGAL at T1 and T2 was associated with a 1.7 and 1.9 fold respective increased risk for new AKI [OR 1.7 (CI1.3–2.6) p = 0.002] [OR 1.9 (CI1.3–3.2) p = 0.004]. Higher values of all 4 biomarkers at T2 were associated with increased 3 month mortality on univariate analysis. A 1SD increase in both composites pADMA and pNGAL, and pSDMA and uNGAL, at T2, resulted in a 1.9 fold and 1.5 fold respective increase in 3 month mortality risk [OR 1.9 (CI1.3–3.2) p = 0.009] [OR 1.5 (CI 1.1–3.1) p = 0.03].

Conclusion: Our data shows higher composite scores of uNGAL and pSDMA are associated with a greater risk of developing new AKI events during AD admissions, which may represent both renal tubular injury and endothelial dysfunction. Higher pSDMA, pADMA, and NGAL levels within 7 days of admission are also associated with an increased 3 month mortality, suggesting repeat measures of these novel markers may inform prognosis and guide early intervention, though this requires further validation.

WED-449

Real-world management of cirrhotic patients following the HALO program: a retrospective observational study

Tarek Hassanein[1], Fatma Barakat[2], Cristina Coll Ortega[3], Thomas Ardiles[4], Christopher Blanchette[5]. *[1]Southern California Liver Centers, Coronado, United States; [2]SCTI Research Foundation, Coronado, United States; [3]Grifols, Sant Cugat del Valles, Spain; [4]Grifols, Shared Services North America, Durham, United States; [5]Rutgers University, Center for Health Outcomes, Policy, and Economics, Ernest Mario School of Pharmacy, Piscataway, United States*
E-mail: thassanein@livercenters.com

Background and aims: Advanced stages of liver cirrhosis are associated with high rates of complications that pose a major burden to patients (pts) and healthcare systems. The Health and Liver Optimization (HALO) program was uniquely developed and implemented across 8 integrated clinics in Southern California for over a decade. This novel program includes tailored monitoring and close follow up and management of cirrhotic pts including monitoring of liver function, lifestyle modification, and supplemental use of human albumin. The aims of this analysis is to describe demographics, clinical characteristics and healthcare resource use of cirrhotic pts following the HALO program.

Method: This is a retrospective observational study of adult pts with seen at one of the clinics following the HALO program between January 2014 and December 2018 and had a confirmed diagnosis of cirrhosis (as documented by imaging or liver biopsy) during that time frame (index date). Pts previously transplanted, diagnosed with liver cancer, or those who did not have at least one follow-up visit before December 2019 were excluded. Follow-up was until December 2022, unless pt was transplanted, diagnosed with HCC, died, or was lost to follow-up.

Results: A total of 889 patients met the inclusion criteria. 52.4% were male. Mean age was 59.5 ± 10.2 years. 51.4% Hispanic or Latino and 91.1% were White or Caucasian. 37.9% had a history of HCV, 22.4% alcohol-related liver disease, 20.7% MASLD/MASH. The median follow-up duration was 34.4 months (1–119 months) with a median number of visits per pt during follow up of 14 (2–117). 24.5% received at least one albumin infusion. 16.6% underwent at least one paracentesis during follow-up. Only 10.9% had received TIPS. 52.3% were hospitalized at least once, largely not liver-related. 10.8% developed Hepatocellular Carcinoma. Most pts were alive at the end of follow-up (85.3%). 96.1% (854) of pts were not listed for transplant, primarily (in 772 pts) because their MELD score did not exceed 15 throughout their follow-up.

Conclusion: Implementing the Health and Liver Optimization (HALO) program in patients with Cirrhosis and End-Stage Liver Disease with the goal of pt stablization resulted in 1) low mortality, 2) lower hospitalization rate and duration, 3) decreased need for paracentesis or TIPS, and 4) significant improvement in early detection of liver cancer. These findings highlight the need for optimized and tailored strategies in advanced liver disease care.

WED-450

Predictive factors for explantation or mortality after tunneled peritoneal catheters in patients with cirrhosis and refractory ascites

Jérémy Hassoun[1], Natasha Ollier[2], Julien Vionnet[2], Montserrat Fraga Christinet[2], Joana Sofia Vieira Barbosa[2], Clemence Canivet[1], Giulia Magini[1], Laurent Spahr[1], Nicolas Goossens[1]. [1]*Hôpitaux Universitaires de Genève, Genève, Switzerland;* [2]*CHUV-Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*
E-mail: nicolas.goossens@hug.ch

Background and aims: Tunneled peritoneal catheters (PeCa) implantation represents a therapeutic option in patients with cirrhosis and refractory ascites who are not candidates for transjugular intrahepatic portosystemic shunt (TIPS). Early outcomes and complications remain poorly described. In patients undergoing PeCa implantation for refractory ascites, we aimed to study predictive factors for early catheter explantation or mortality.
Method: We retrospectively analysed 74 cirrhotic patients with contraindication to TIPS who underwent a PeCa implantation in two tertiary centers in Switzerland between 2014 and 2023. The primary outcome was catheter explantation or mortality within 90 days (90-d) after implantation. Predictive factors were evaluated using logistic regression analyses. Continuous values were described as median (IQR) and categorical as n (%).
Results: 74 patients (15% female) were included with a median age of 68 years (60–76); BMI of 23.2 kg/m^2 (21–27), MELD-score of 14 (11–18), and Child-Pugh score of 9 (8–10). Previous spontaneous bacterial peritonitis (SBP) was present in 31% (23/74) of patients prior to PeCa implantation. Within 90-d, the primary endpoint occurred in 52% (39/74) of the patients, including 28% (11/39) PeCa explantation and 72% (28/39) liver transplantation (LT) or death. Causes for explantation were SBP (73%), bleeding (9%), PeCa dysfunction (9%) or cellulitis (9%). Factors associated with the 90-d primary endpoint in univariable analyses included: MELD-score ($p = 0.04$), ECOG performance status (ECOG-PS) ≥ 2 ($p < 0.01$), female sex ($p = 0.01$), and previous hepatocellular carcinoma (HCC) history ($p = 0.01$). SBP prior to implantation was not associated with the outcome (odds ratio [OR] 0.6, $p = 0.32$). In multivariable analysis, ECOG-PS ≥ 2 (OR 1.9, $p < 0.01$), female sex (OR 2.7, $p = 0.02$) and history of HCC (OR 1.4, $p = 0.02$) were independently associated with 90-day outcome. After PeCa implantation, SBP was documented in 23% (17/74) within 90-d, occurring at a median of 20 days (11–56) after implantation and PeCa could be maintained in 47% (8/17) at 90-d follow-up.
Conclusion: PeCa placement is a feasible option for the management of refractory ascites in patients with cirrhosis who are not eligible for TIPS. Higher ECOG-PS, female sex and a history of HCC were associated with PeCa explantation or death during the study period. Previous SBP was not associated with 90-d primary outcome.

WED-451-YI

Post-TIPS decline in von Willebrand factor levels is independently associated with improved survival

Marlene Hintersteininger[1,2,3], Simon Johannes Gairing[4], Katrin Kirsch[4], Theresa Müllner-Bucsics[1], Susanna Riegler[1], Lukas Reider[5], Lorenz Balcar[1,2,3], Eva Maria Schleicher[4], Jasmin Soehngen[4], Lukas Müller[6], Michael Bernhard Pitton[6], Julia Weinmann-Menke[4], Peter R. Galle[4], Michael Trauner[1,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3,7], Christian Labenz[4], Lukas Hartl[1,2,3]. [1]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [2]*Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [3]*Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria;* [4]*Department of Internal Medicine 1, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany;* [5]*Division of Cardiovascular and Interventional Radiology, Department of Biomedical Imaging and Image-guided Therapy, Vienna, Austria;* [6]*Department of Radiology, University Medical Center of the Johannes Gutenberg-University, Mainz, Austria;* [7]*Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria*
E-mail: marli.hintersteininger@gmail.com

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) placement is an established option for patients with portal hypertension (PH)-related complications. Von Willebrand factor antigen (VWF) is a dynamic non-invasive marker for prognostication in patients with cirrhosis and PH. This study set out to investigate the prognostic relevance of VWF dynamics after TIPS in a bicentric cohort.
Method: All patients with liver cirrhosis who underwent TIPS placement at the University Medical Center Mainz between 2022 and 2025 (Mainz cohort) and the Medical University of Vienna between 2008 and 2025 (Vienna cohort) with available longitudinal VWF measurements at baseline (BL) and at 3 months (M3) of follow-up (FU) were included. Relative VWF change (ΔVWF) was calculated as the ratio of VWF at M3 to VWF at BL. Liver transplantation was considered as a competing event.
Results: A total of 142 patients (Mainz cohort: n = 49; Vienna cohort: n = 93) receiving TIPS (76.1% ascites; 43.9% bleeding) with a median age of 58 years, male predominance (69.7%) and a median MELD of 12 were included. Median BL VWF levels were 322.0% and significantly decreased to a median of 275.5% at M3 ($p < 0.001$) with 57.7% of patients displaying a decline of VWF at M3. Median relative ΔVWF was 0.97. A similar percentage of patients exhibited a VWF decline at M3 in the Vienna (60.2%) and in the Mainz cohort (53.1%; $p = 0.412$). Interestingly, patients with a decline at M3 had significantly higher BL VWF levels compared to those without (359.5% vs. 250.0%; $p < 0.001$), while MELD (12 vs. 12; $p = 0.841$) and liver disease etiology (ALD: 58.5% vs. 53.3%; $p = 0.753$) were comparable. The median FU duration was 14 months. Patients without VWF decline at M3 demonstrated a higher cumulative incidence of death at one year of FU compared to those with VWF decline (16.1% vs. 6.9%; $p = 0.030$). In multivariable competing risk regression analysis adjusted for age and MELD at M3, ΔVWF was an independent risk factor for death (adjusted subdistribution hazard ratio [asHR]: 3.10; 95%CI: 1.24–7.72; $p = 0.015$).
Conclusion: VWF levels decrease in more than half of the patients after TIPS placement. ΔVWF at M3 is an independent risk factor for death, underscoring the prognostic value of VWF dynamics after TIPS.

WED-452

Combined presence of cirrhosis-related hypogonadism and sarcopenia is common and independently linked to impaired survival

E-mail: marli.hintersteininger@gmail.com

Background and aims: Hypogonadism and sarcopenia are highly prevalent in male patients with liver cirrhosis (LC). Low testosterone levels have been linked to sarcopenia through disruption of the hypothalamic-pituitary-gonadal axis and impaired muscle protein synthesis, yet their overlap and combined prognostic impact in male patients with LC remains unknown.
Method: Male patients undergoing cross-sectional imaging (CT or MRI) within 180 days of the measurement of total testosterone (TT) and hepatic venous pressure gradient (HVPG) were included. Total psoas muscle thickness at the level of L3 (TPMT-L3) was independently measured by two radiologists, and the mean value was used for analysis. Hypogonadism was defined as TT levels <12 nmol/L. Sarcopenia was defined as a TPMT-L3 <12 mm/m (normalized to body height). Liver transplantation and death were considered as competing events.
Results: A total of 225 patients (median age: 59 years, alcohol-related etiology: 49.6%; decompensated LC: 68.4%, median MELD: 14) with median TT of 9.9 nmol/L (median bioavailable testosterone: 2.9 nmol/L) and median TPMT-L3 of 12.8 mm/m were included. Interreader agreement for TPMT-L3 measurements was good, with an intraclass correlation coefficient of 0.88 (95%CI: 0.84–0.91). Sarcopenia was present in 98 patients and hypogonadism in 129 patients, while combined sarcopenia-hypogonadism was found in 64 patients. Patients with sarcopenia had significantly lower TT levels compared to those without (7.7 vs. 11.9 nmol/L; $p = 0.006$). TT levels correlated positively with TPMT-L3 ($\rho = 0.26$) and albumin ($\rho = 0.42$) and inversely with MELD ($\rho = -0.53$; all $p < 0.001$). During a median follow-up of 24 months, patients with concomitant sarcopenia-hypogonadism had a significantly higher risk of all-cause mortality (asHR:1.82; 95%CI:1.04–3.19; $p = 0.036$) and liver-related death (asHR:2.57; 95%CI:1.39–4.75; $p = 0.003$) after adjustment for age, MELD, albumin and HVPG. Consistently, these patients exhibited a markedly higher 1-year cumulative incidence of death (41.3% vs. 13.6%; $p < 0.001$) and liver-related death (39.7% vs. 6.9%; $p < 0.001$) compared to patients without sarcopenia-hypogonadism.
Conclusion: About two third of male LC patients with sarcopenia show hypogonadism. The concomitant presence of sarcopenia-hypogonadism identifies a subgroup at particularly high risk of short-term mortality. The effectiveness of testosterone substitution to improve sarcopenia and outcomes in patients with LC needs further investigation.

E-mail: benedikt.s.hofer@meduniwien.ac.at

Background and aims: Growth differentiation factor 15 (GDF-15), a cytokine of the transforming growth factor-beta superfamily, modulates inflammation and cellular stress response. It has been implicated in the pathogenesis of various chronic diseases and may inhibit platelet function. We aimed to investigate the role of GDF-15 in cirrhosis by examining its link to disease-driving mechanisms, platelet activation, hepatic decompensation, and mortality.
Method: We prospectively recruited patients with cirrhosis undergoing hepatic venous pressure gradient (HVPG) and platelet activation measurements. Platelet activation was assessed by flow cytometry, including platelet surface P-selectin and glycoprotein IIb/IIIa (GPIIb/IIIa) expression after agonist stimulation. Serum GDF-15 levels were measured using an electrochemiluminescence immunoassay.
Results: A total of 106 patients (70.8% male, median age 55.1 years) were followed for a median of 51.5 (26.0–58.2) months. At baseline, 39.6% were compensated, median MELD was 11, median HVPG 18 mmHg, and median GDF-15 2880 (1850–4770) pg/mL. Higher GDF-15 levels were linked to more pronounced hepatic synthetic dysfunction (MELD Spearman's ρ: 0.50; albumin ρ: –0.57), portal hypertension (HVPG ρ: 0.47), systemic inflammation (C-reactive protein ρ: 0.45; interleukin 6 [IL-6] ρ: 0.55; procalcitonin ρ: 0.58) and fibrosis/fibrogenesis (liver stiffness ρ: 0.67; enhanced liver fibrosis test ρ: 0.64) (all $p < 0.001$). GDF-15 was higher in patients with detectable bacterial DNA in blood (3520 vs. 2250 pg/mL; $p < 0.001$) and correlated with lipopolysaccharide (ρ: 0.34; $p = 0.010$) and lipoteichoic acid (ρ: 0.37; $p = 0.004$). GDF-15 was not significantly linked to platelet activation after adjusting for liver disease severity, except for higher levels in patients with undetectable GPIIb/IIIa after stimulation. During follow-up, 38 patients decompensated and 21 died (61.9% liver-related). GDF-15 predicted decompensation in a multivariable model adjusted for HVPG, MELD, albumin and IL-6 (aHR per 100 pg/mL: 1.015; 95%CI: 1.004–1.026; $p = 0.007$). Similarly, there was a significant link between GDF-15 and a higher risk of liver-related (HR: 1.019; 95%CI: 1.007–1.032; $p = 0.002$) and all-cause mortality (HR: 1.019; 95%CI: 1.009–1.029; $p < 0.001$).
Conclusion: In patients with cirrhosis, GDF-15 reflects disease-driving mechanisms and facilitates risk stratification for hepatic decompensation, liver-related and all-cause mortality.

WED-457

MRI-derived splenic indices as novel predictors of liver decompensation

Kim Hogenberg[1], Jasper van Leengoed[1], Laura Boer[1], Job van der Palen[1], Donald Bouman[1], Maureen Guichelaar[1]. *[1]Medisch Spectrum Twente, Enschede, Netherlands*
E-mail: maureenguichelaar@yahoo.com

Background and aims: Liver decompensation places a major burden on healthcare systems. Early identification using MRI-derived markers, including sarcopenia and splenic characteristics, may enable preventive intervention. This study evaluated their prognostic value for predicting decompensation in cirrhosis.
Method: A retrospective analysis was performed on a large cohort of patients liver cirrhosis who underwent annual MRI scanning for HCC surveillance (2010–2024). Patients were excluded if they had <3 follow-up MRI scans or in case they had liver decompensation before

their first MRI scan. The MRI-derived variables included sarcopenic indices (transversal psoas muscle thickness (TPMT)/height, psoas muscle circumference (PMC) and splenic indices (splenic volume and splenic diffusion-weighted imaging derived parameters including, b-value ratios and apparent diffusion coefficient (ADC)). A mean of values at 4 regions of interest in the spleen was registered. Sarcopenia was diagnosed if TPMT of <17.3 mm/m for men and <10.4 mm/m for women.
Results: A total of 132 patients (62.9% men, mean age 68.1 ± 11.6 years) were included in the study of which 53 patients (40%) had sarcopenia. Mean follow-up was 29.8 ± 9.8 months during which 38 patients (29%) developed liver decompensation. A greater decrease in PMC and TPMT/height over time was observed in patients who developed liver decompensation (resp. $p = 0.07$; $p = 0.023$), indicating progressive muscle loss. Patients who developed liver decompensation had significantly larger splenic volumes and higher ADC and b-value ratios ($p < 0.001$), which increased over three years ($p < 0.01$). Logistic regression models of independent risk factors (splenic volume, b-value ratios and ADC at 1 and 3 years prior to liver decompensation) showed AUC's of resp. 0.79 and 0.75.
Conclusion: MRI-derived quantitative splenic indices demonstrated significant potential for predicting liver decompensation, outperforming sarcopenic indices. Validation in larger cohorts is warranted to confirm these findings and refine predictive models for clinical applicability.

WED-458
Machine learning prediction of covert hepatic encephalopathy in patients with liver cirrhosis based on clinical characteristics
Tiantian Hu[1,2,3], Baoyue Sheng[1], Qingqing Lei[1], Haoxiang Zhu[1,2], Yun-Hui Yang[1], Richeng Mao[1], Jie Tong[1], Xiaoting Zhao[1], Changrong Yuan[3], Zheng Zhu[3], Jinyu Wang[1,2], Jiming Zhang[1,2,4].

E-mail: 23111170004@m.fudan.edu.cn

Background and aims: Covert hepatic encephalopathy (CHE) is a common but frequently underdiagnosed complication of liver cirrhosis, associated with impaired quality of life and adverse clinical outcomes. Early identification of patients at high risk for CHE remains challenging in routine clinical practice. This study aimed to develop and externally validate machine learning–based predictive models for CHE in patients with liver cirrhosis using readily available clinical characteristics.
Method: A longitudinal cohort study was conducted among patients with liver cirrhosis at Huashan Hospital, Fudan University, from September 2023 to November 2025. Patients without overt hepatic encephalopathy at baseline were enrolled, and covert hepatic encephalopathy (CHE) was diagnosed using the Psychometric Hepatic Encephalopathy Score (PHES). The retrospective cohort (Study population 1, n = 309) was randomly divided into training and test sets (8:2), while an independent prospective cohort (Study population 2, n = 68) served as external validation. Missing data were addressed using multiple imputation. Feature selection was conducted in the training set using multicollinearity control, LASSO regression, and stability assessment. Six machine learning models were developed and optimized, with performance evaluated by discrimination, calibration, decision curve analysis, and SHAP-based interpretability.
Results: Among 377 included patients, 251 (66.6%) were diagnosed with CHE. Six predictors were selected for model development. The Random Forest model demonstrated the most stable performance across datasets, with AUCs of 0.9253 in the training set, 0.9118 in the test set, and 0.9189 in the external validation set. High sensitivity and favorable F1 scores were consistently observed. The model showed good calibration and superior clinical net benefit in decision curve analysis. SHAP analysis identified hepatitis B virus infection status, serum albumin level, and blood ammonia concentration as the most influential predictors. To support clinical application, a web-based risk prediction tool was developed and made publicly available.
Conclusion: A machine learning–based Random Forest model using routine clinical parameters demonstrated strong discrimination, calibration, and clinical utility for predicting covert hepatic encephalopathy in patients with liver cirrhosis. This model may facilitate early risk stratification and support clinical decision-making in real-world practice.

WED-459
The advanced liver disease MDT: a new model improving palliative care provision for patients with decompensated advanced chronic liver disease
Katharine Hutchison[1,2], Cristina Gatti[2], Amelia Stockley[2], Benjamin Hudson[2]. *[1]University of Exeter, Exeter, United Kingdom; [2]Exeter, United Kingdom*
E-mail: katharine.hutchison@nhs.net

Background and aims: Despite a high burden of physical and psychological symptoms, patients with decompensated advanced chronic liver disease (dACLD) seldom receive palliative care. Prognostic uncertainty, challenges with patient selection, and a lack of evidence-based frameworks are key barriers to timely referral. We describe outcomes from a novel model of care in which patients with dACLD are managed through an Advanced Liver Disease MDT (ALMDT) from onset of decompensation. Input from Allied Health Professionals (AHPs e.g. physiotherapy, dietetics) and palliative care (PC) specialists is obtained, and palliative interventions including advance care planning are considered, in parallel with disease modifying therapies (e.g. transplantation). Outcomes over a 3-year period are compared with patients managed without ALMDT input.
Method: All patients discussed at the ALMDT between July 2021-June 2024 were reviewed. Hospital records identified patients dying from dACLD without ALMDT discussion, including those with multiple decompensations or death on index admission. Data collected included demographics, PC and AHP input, ACP completion, transplant referral, mortality, and healthcare utilisation in the last year of life (LYOL).
Results: 248 patients were included in analysis. Of these, 171 were managed via the ALMDT, with a 12-month survival of 61.4%. 27 patients died after multiple decompensations without ALMDT input, and 50 died on index presentation. Non-ALMDT patients were more often female, from more deprived areas, and had higher rates of alcohol-related liver disease. PC referral occurred in 58.5% of ALMDT patients vs 7.4% of non-ALMDT patients. ALMDT patients had higher referral rates to physiotherapy/OT (56% vs 18.5%) and dietetics (57% vs 37%); ACP completion was 74% vs 0%. 28 patients died >12 months after ALMDT discussion (discussed early) and 66 died <12 months (discussed late). Early discussion was associated with higher day-case paracentesis rates (80.5% vs 52% late vs 16% never discussed), fewer Emergency Department attendances in LYOL (mean of 2.7 vs 3.7 if discussed late vs 4.4 if never discussed), and fewer inpatient days in LYOL (mean of 23.2 vs 35.4 if discussed late vs 32.3 if never discussed). 54% of patients discussed early died at home, vs 32% of those discussed late.
Conclusion: Managing dACLD through an ALMDT facilitates timely PC and AHP support without precluding curative options. Early discussion is associated with lower healthcare costs in the LYOL and improved end of life care.

Glucagon-like peptide- 1 receptor agonists improve survival and reduce healthcare utilization in decompensated hepatitis C cirrhosis

Jeeva Jaganathan[1], Marina Takawy[2], Hazem Abosheaishaa[1], Ghada Mohamed[3], Madhavi Reddy[1]. [1]*The Brooklyn Hospital Center, Brooklyn, United States;* [2]*Rochester Regional Health Unity Hospital, Rochester, United States;* [3]*Lahey Hospital and Medical Center, Burlington, United States*
E-mail: stanjeeva@gmail.com

Background and aims: Hepatitis C virus (HCV) infection remains a major cause of cirrhosis and liver-related mortality worldwide despite effective direct-acting antiviral (DAA) therapies. HCV causes hepatic steatosis by interfering with lipid metabolism and activating fatty acid synthesis pathways, accelerating disease progression. Glucagon-like peptide- 1 receptor agonists (GLP-1 RAs) have been shown to reduce lipogenesis and inflammation resulting in reduced hepatic decompensation risk in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) and cirrhosis patients with type 2 diabetes. However, the impact of GLP-1 RAs on outcomes in HCV cirrhosis patients remains unstudied. To assess the effect of GLP-1 receptor agonists on clinical outcomes in decompensated HCV cirrhosis.
Method: Patients with HCV-related cirrhosis and decompensation (ascites, hepatic encephalopathy or variceal bleeding) were identified using the TriNetX US Collaborative Network. The index event was GLP-1 RA initiation (GLP-1 RA users) who were compared with matched non-users in a 1:1 ratio. Outcomes were assessed over one year including all-cause mortality, liver-related decompensation events, critical care utilization, inpatient admissions and transplant-related outcomes. Propensity score matching balanced demographics and comorbidities including diabetes, obesity, hypertension, and malnutrition between cohorts. Kaplan-Meier survival analysis and Cox proportional hazards regression were used.
Results: Overall, 4798 patients (GLP-1 RA users) and equal matched non-users were identified. GLP-1 RA users had substantially lower all-cause mortality compared to non-users (3.1% vs 13.7%; hazard ratio [HR] 0.21, 95% CI 0.18–0.26; $p < 0.001$). GLP-1 RA users demonstrated reduced liver-related decompensation events (HR 0.38, 95% CI 0.31–0.46; $p < 0.001$). Inpatient hospitalization (8.8% vs 17.3%, relative risk [RR] 0.51, 95% CI 0.42–0.62) and critical care utilization (4% vs 9.7%, RR 0.41, 95% CI 0.34–0.50) were significantly lower in GLP-1 RA users. Additionally, trends towards reduced transplant waitlist placement (0.7% vs 2.0%) and liver transplantation (0.4% vs 1.5%) were observed.
Conclusion: In this nationwide propensity-matched cohort study of decompensated HCV-related cirrhosis patients, GLP-1 RA use was associated with significantly improved survival, reduced complications, and reduced healthcare utilization. Prospective studies are warranted to confirm beneficial effects and safety profile of GLP-1 RAs in this population.

WED-461-YI

Neurofilament light chain in serum predicts overt hepatic encephalopathy in liver cirrhosis

Elise Jonasson[1], Birgitte Jacobsen[1], Lea Ladegaard Grønkjær[1], Mette Lauridsen[1]. [1]*Esbjerg Hospital, University Hospital of Southern Denmark, Esbjerg, Denmark*
E-mail: elise.jonasson.nielsen@rsyd.dk

Background and aims: Overt hepatic encephalopathy (OHE) remains a frequent and severe complication in patients with cirrhosis, however there is a lack of predictive biomarkers. Neurofilament light chain (NfL) is a marker of early central nervous system injury and have been explored in serum as a diagnostic biomarker of minimal hepatic encephalopathy and OHE. We aimed to investigate the prognostic potential of NfL in serum for predicting OHE.
Method: This prospective cohort study included 112 patients. Serum NfL was measured at study inclusion and patients were divided into two groups based on NfL levels (low NfL < 47.6 pg/mL and high NfL ≥ 47.6 pg/mL). During follow up, OHE, liver transplantation and death was registered. Cumulative incidence functions were estimated, and Gray's test was used for unadjusted comparisons. Adjusted absolute risk differences at 6 months, 1 year, and 2 years were estimated using pseudo-observations and generalized linear models, adjusting for prior OHE.
Results: Median follow-up time was 371 days (IQR 291–520), 18 patients developed OHE and 16 patients died or underwent liver transplantation. Cumulative incidence functions showed a higher incidence of OHE in patients with high NfL ($p = 0.007$, Gray's test). At 6 months, 1 year, and 2 years, the cumulative incidence of OHE was consistently lower in patients with low NfL (3.5%, 7.8%, and 13%, respectively) compared with patients with high NfL (16%, 28% and 35%, respectively). In analyses adjusted for prior OHE, high NfL was associated with an increased absolute risk of OHE at all evaluated time points. Patients with high NfL had progressively higher absolute risk of OHE, with adjusted risk difference of 13 percentage points at 6 months ($p = 0.030$), 22 percentage points at 1 year ($p = 0.010$), and 25 percentage points at 2 years ($p = 0.035$), compared with patients with lower NfL. A history of OHE was independently associated with a markedly higher absolute risk of OHE at all time points (all $p < 0.01$).
Conclusion: High NfL ≥ 47.6 pg/mL identifies patients at increased risk of developing OHE. The consistently large absolute risk differences observed across all time points suggest that NfL captures underlying vulnerability to future OHE beyond prior OHE status alone. Serum NfL may therefore represent a useful biomarker for early risk stratification and identification of patients who could benefit from closer monitoring or preventive strategies, either alone or as add on to psychometric tests.

WED-462

Neurofilament light chain in cerebrospinal fluid and serum identifies minimal and overt hepatic encephalopathy

Elise Jonasson[1], Lea Ladegaard Grønkjær[1], Birgitte Jacobsen[1], Mette Lauridsen[1]. [1]*Esbjerg Hospital, University Hospital of Southern Denmark, Esbjerg, Denmark*
E-mail: elise.jonasson.nielsen@rsyd.dk

Background and aims: Minimal hepatic encephalopathy (MHE) is common in patients with liver cirrhosis but remains underdiagnosed due to limitations of psychometric testing. Neurofilament light chain (NfL) and glial fibrillary acidic protein (GFAP) have been proposed as markers of early central nervous system injury and have been explored in serum as biomarkers of hepatic encephalopathy (HE). Both remain unexplored in cerebrospinal fluid (CSF), even though CSF is pathophysiological closer to the site of end-organ damage. We aimed to investigate NfL and GFAP in CSF and serum across the spectrum of HE and to assess their diagnostic utility for HE.
Method: In this cross-sectional study, patients with liver cirrhosis and age- and sex-matched healthy controls (HC) underwent lumbar puncture, blood sampling, and psychometric testing. Patients were divided into three groups based on Psychometric Hepatic Encephalopathy Score: i) unimpaired, ii) MHE and iii) OHE (West Haven Criteria ≥ grade 1). NfL and GFAP were measured in CSF and serum by Simoa HD-X Analyzer (Quanterix, Billerica, MA, USA). Associations between CSF and serum concentrations were assessed using Spearman correlation, and receiver operating characteristic (ROC) analyses evaluated diagnostic performance for HE.
Results: Thirty-five patients (57% unimpaired, 26% MHE, 17% OHE) and 14 HC were included. CSF and serum NfL were higher in MHE and OHE compared to unimpaired patients and healthy controls. There was no difference between unimpaired patients and HC. CSF GFAP was modestly elevated in MHE and OHE versus healthy controls, whereas serum GFAP did not differ between groups. CSF and serum concentrations were strongly correlated for NfL (rho = 0.89, p <

0.0001) and moderately for GFAP (rho = 0.50, p = 0.0004). ROC analyses showed good diagnostic performance of NfL for identifying MHE and OHE, with AUCs of 0.88–0.90 in CSF and 0.93–0.95 in serum. A CSF NfL cut-off of 1144 pg/mL yielded 93% sensitivity and 75% specificity. GFAP showed lower and inconsistent discriminatory ability, particularly in serum.
Conclusion: NfL in CSF and serum reflect neuroaxonal injury in MHE and OHE and shows strong diagnostic performance, outperforming GFAP. Serum NfL therefore emerges as a promising biomarker for early detection of hepatic encephalopathy, either alone or to enhance the specificity of psychometric testing.

E-mail: pgines@clinic.cat

Background and aims: The ALBUCAT trial demonstrated that intravenous human albumin (HA) administration increases serum sodium levels and reduces 28-day mortality in patients with decompensated cirrhosis and hypervolemic hyponatremia. However, the pathogenic mechanisms underlying these beneficial effects remain incompletely understood. We therefore evaluated circulatory biomarkers involved in sodium and water homeostasis to elucidate the pathophysiological effects of albumin in these patients.
Method: Plasma samples from participants in the multicenter, open-label, randomized ALBUCAT trial were analyzed. Patients with serum sodium ≤ 133 mEq/L were randomized 1:1 to receive intravenous HA for up to 10 days (1 g/kg on day 1 followed by 40 g/day) plus standard of care (SoC; fluid restriction and diuretic withdrawal) or SoC alone. Renin, aldosterone, noradrenaline, copeptin and prostaglandin E2 (PGE2) were measured at baseline, day 5 and day 10 or end of treatment.
Results: Plasma samples were available in 48 of 52 patients (92%): 26 in the SoC group and 22 in the HA group. Baseline biomarker levels did not differ between groups. Under SoC, plasma renin showed no significant changes over time (1491 µUI/mL at baseline and 2000 µUI/mL at day 10; p = 0.052). In contrast, HA administration was associated with a marked and sustained reduction in renin concentrations, from 1763 µUI/mL at baseline to 785 µUI/mL at day 5 and 881 µUI/mL at day 10 (both p = 0.002), resulting in significantly lower levels compared with SoC at day 10 (p = 0.040). Aldosterone followed a similar pattern, remaining stable under SoC while decreasing significantly after HA administration (global treatment-by-time interaction p = 0.002). Copeptin showed a directionally concordant but non-significant trend toward lower levels after HA, with an early decrease at day 5, whereas noradrenaline and PGE2 were unaffected. Notably, reductions in renin and aldosterone concentrations were most pronounced in patients treated with HA who ultimately achieved hyponatremia resolution, whereas non-responders—particularly under SoC—showed no consistent changes over time.
Conclusion: HA administration was associated with a selective reduction in renin and aldosterone levels, predominantly among patients who achieved hyponatremia resolution. These findings suggest that effective improvement in circulatory function with suppression of the renin–angiotensin–aldosterone system underlies the clinical benefits of HA in hypervolemic hyponatremia.

WED-464

Comparative prognostic performance of MELD-based and GEMA scores: a real-world cohort study

Furkan Kabukcu[1], Burcu Gürbüz[2], Hakan Oral[3], İbrahim Nahit Şendur[2], Bengi Ozturk[2], Taylan Kav[2], Onur Keskin[2]. *[1]Hacettepe University Faculty of Medicine, Department of Internal Medicine, Ankara, Türkiye; [2]Hacettepe University Faculty of Medicine, Department of Gastroenterology and Hepatology, Ankara, Türkiye; [3]Hacettepe University Faculty of Medicine, Department of Haematology, Ankara, Türkiye*
E-mail: furkankabukcu@gmail.com

Background and aims: Accurate prognostic stratification in cirrhosis is essential for clinical decision-making and liver transplantation prioritization. We aimed to compare the prognostic performance of MELD, MELD-Na, MELD 3.0, GEMA, and GEMA-Na scores for predicting liver-related outcomes and transplant-free survival.
Method: We retrospectively included cirrhotic patients followed between January 2020 and December 2025. A total of 178 patients were analyzed. MELD, MELD-Na, MELD 3.0, GEMA, and GEMA-Na scores were calculated. The primary outcome was a composite endpoint of all-cause mortality or liver transplantation, with transplant-free survival evaluated in secondary analyses. Survival analyses were performed using Kaplan–Meier method. Discriminative performance was assessed using ROC curves, with pairwise comparisons performed using the DeLong test. Cox proportional hazards models and Harrell's C statistics were used to assess independent prognostic values.
Results: The median age was 57 years (range 18–89), and 90/178 patients (50.6%) were male. During follow-up, 68/178 (38.2%) patients died and 20/178 (11.2%) underwent liver transplantation. Median follow-up duration was 35.4 months (0.5–70.6). Median MELD was 10 (6–31), MELD-Na was 11 (6–32), MELD 3.0 was 12 (6–32), GEMA was 11 (6–28), GEMA-Na was 13 (8–35). Patients with scores above predefined cut-off values for all models had significantly shorter survival (all p < 0.001). MELD 3.0 demonstrated the highest discriminative ability for prediction of the primary outcome (AUC = 0.759), followed by GEMA-Na (AUC = 0.724) and MELD-Na (AUC = 0.715). Pairwise ROC comparisons showed significantly superior performance of MELD 3.0 compared with MELD and GEMA scores (all p < 0.05). Kaplan–Meier analyses using predefined cut-off values demonstrated significant separation of survival curves across all scoring systems (log-rank p < 0.001). In Cox regression analyses, MELD 3.0 and GEMA-Na were significant predictors, with MELD 3.0 showing the highest time-dependent discriminative performance

(Harrell's C = 0.747). For transplant-free survival, MELD 3.0 and GEMA-Na remained the strongest predictors. Harrell's C statistic for transplant-free mortality was highest for MELD 3.0 (C = 0.780).
Conclusion: MELD 3.0 and GEMA-Na demonstrated superior prognostic performance compared with traditional MELD and MELD-Na models for predicting liver-related outcomes and transplant-free survival. Overall, MELD 3.0 showed the strongest prognostic performance among the scoring systems.

WED-465
Low health literacy in patients with steatotic liver disease and depressive symptoms
Leonard Kaps[1], Christian Labenz[2], Alexander Barton[1], Jörn M. Schattenberg[1], Maurice Michel[1]. [1]*Department of Medicine II, University Medical Center, Homburg/Saar, Germany;* [2]*Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany*
E-mail: leonardkaps@googlemail.com

Background and aims: Health literacy (HL) describes patients' ability to access, understand, and use health information to manage their health and navigate the healthcare system. While HL is known to influence outcomes in chronic diseases, data in chronic liver disease - particularly steatotic liver disease (SLD) - are limited, and the potential impact of comorbid depression on HL remains largely unexplored. This study aimed to investigate whether depressive symptoms are associated with impaired health literacy in patients with SLD.
Method: In this bicentric study, 198 patients with SLD (173 in Homburg and 25 in Mainz, Germany) were enrolled from 2019 to 2025 at tertiary medical centers. Health literacy was assessed using the German validated Health Literacy Questionnaire (HLQ), comprising nine subscales. SLD and compensated advanced chronic liver disease (cACLD) were diagnosed using liver stiffness measurement (LSM; FibroScan). Steatosis was defined by a controlled attenuation parameter (CAP) ≥ 275 dB/m; cACLD was indicated by LSM ≥ 15 kPa, while values ≤ 10 kPa ruled out cACLD. Depressive symptoms were assessed using the Hamilton Depression Rating Scale (HDRS) and the Patient Health Questionnaire (PHQ-9).
Results: Forty-nine patients (33%) exhibited depressive symptoms. There were no differences between patients with and without depressive symptoms regarding gender, ≥10 years of schooling, LSM, or body mass index (BMI). Patients with depressive symptoms had significantly lower HLQ scores in subscale 3 ("Actively managing my health," $p < 0.05$), subscale 6 ("Ability to actively engage with healthcare providers," $p < 0.0001$), subscale 7 ("Navigating the healthcare system" $p < 0.001$), and subscale 9 ("Understanding health information well enough to know what to do", $p < 0.05$). Overall, subscale 3 showed the lowest scores, whereas subscales 6 and 9 showed the highest. Patients with cACLD scored lower only in subscale 9 compared with those without cACLD. In multivariable regression analyses, associations between depressive symptoms and lower HLQ scores remained significant for subscales 6 and 7 after adjustment for gender, age, BMI, years of schooling, and cACLD.
Conclusion: Depressive symptoms are common in patients with SLD and are associated with impaired health literacy, particularly regarding engagement with healthcare providers and navigation of the healthcare system.

WED-466
Burden and outcomes of multidrug-resistant spontaneous bacterial peritonitis: experience from a resource-constrained setting
Chitta Ranjan Khatua[1], Lelin Kumar Jena[1], Partha Sarathi Behera[1], Aniket Ranjan[1], Prajna Anirvan[2], Manas Kumar Panigrahi[3], Shivaram Prasad Singh[2]. [1]*MKCG Medical College, Brahmapur, India;* [2]*Kalinga Gastroenterology Foundation, Cuttack, India;* [3]*AIIMS Bhubaneswar, Bhubaneswar, India*
E-mail: gudduchhotu3@gmail.com

Background and aims: Spontaneous bacterial peritonitis (SBP) is a common and life-threatening condition, and multidrug-resistant (MDR) bacterial infections further adversely affect patient outcomes. We performed a prospective study to evaluate the impact of MDR infections on outcomes in SBP.
Method: From October 2016 to August 2025, all cirrhosis patients with SBP were included and on hospitalization, all relevant clinical parameters were recorded. Outcomes were compared between patients with and without MDR bacterial infections, with a three-month follow-up to assess both short- and long-term impacts of MDR infections.
Results: Out of 1667 cirrhosis patients, 10.9% (n = 182) had SBP. MDR infection was prevalent in 22.5% (n = 41). Enterococcus (46.4%) and E. coli (36.6%) were common isolated bacteria, followed by Klebsiella (7.3%), Staphylococcus aureus (4.9%), Pseudomonas aeruginosa (2.4%), and Acinetobacter (2.4%). Patients with MDR infections had higher Model for End-Stage Liver Disease (MELD) scores ($p < 0.001$), MELD-Na scores ($p < 0.001$), Child-Turcotte-Pugh (CTP) scores ($p < 0.001$), a higher incidence of acute-on-chronic liver failure (ACLF) (83.8% vs. 47.9%; $p < 0.001$), and acute kidney injury (AKI) (86.5% vs. 51.4%; $p < 0.001$). MDR infection was also associated with decreased ascitic protein levels (1.20 g/dL vs 1.60 g/dL; P = 0.015). Furthermore, patients with MDR infection demonstrated increased frequency of multiple site infections (61% vs. 19.1%; $p < 0.001$), and had decreased in-hospital survival (HR = 0.227; 95% CI = 0.132–0.391; $p < 0.001$), also at 28 days (HR = 0.325; 95% CI = 0.204–0.517; $p < 0.001$), and 90 days (HR = 0.336; 95% CI = 0.226–0.500; $p < 0.001$).
Conclusion: One tenth of decompensated cirrhosis patients had SBP, with more than one fifth having MDR infection. Enterococcus and E. coli were commonly isolated MDR bacteria. MDR infections were associated with lower ascitic fluid protein levels, a higher frequency of infections at multiple sites, and an increased prevalence of ACLF and AKI. SBP with MDR bacteria was associated with a lack of clinical response to antibiotic treatment and increased short-term and long-term mortality.

WED-467
Impact of long-term albumin administration on mortality and cirrhosis-related complications: are these data sufficient to change practice?
W. Ray Kim[1], Cristina Coll Ortega[2], Cristina Fuster[2], Thomas Ardiles[3], Shrikar Reddy Badikol[4], Rahul Rajkumar[4], Elisabet Viayna[2]. [1]*Mayo Clinic College of Medicine & Science-Arizona, Division of Gastroenterology and Hepatology, Phoenix, United States;* [2]*Grifols, Sant Cugat del Vallès, Spain;* [3]*Grifols, Research Triangle Park, United States;* [4]*Boston Strategic Partners, Inc., Boston, United States*
E-mail: cristina.coll@grifols.com

Background and aims: Long-term albumin (LTA) administration has been evaluated in several clinical trials as a disease-modifying therapy to reduce mortality and prevent cirrhosis-related complications in patients with decompensated cirrhosis and ascites, with conflicting results. In light of recently published clinical trial data, we conducted a systematic literature review (SLR) and meta-analysis (MA) of all available clinical trials to assess the impact of LTA on long-term mortality and cirrhosis-related complications.
Method: Included studies were clinical trials identified through PubMed (1995–present) and conference abstracts (2022–2025) in adults with cirrhosis and ascites comparing at least 4 weeks of LTA therapy with standard of care or placebo and reporting at least 12-month mortality. The primary endpoint was 12- to 36-month mortality; secondary endpoints included ascites, refractory ascites (RA), hepatic encephalopathy (HE), renal dysfunction, spontaneous bacterial peritonitis (SBP), hyponatremia, and gastrointestinal (GI) bleeding, each assessed at ≥12 months follow-up when available. A

random-effects model was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs). Heterogeneity was assessed using Chi-squared and I-squared statistics.
Results: Of 22 studies screened, 7 met the eligibility criteria, including 1431 subjects altogether. Fifteen studies were excluded: 13 lacked a comparator, 1 was not a clinical trial, and 1 did not involve adult patients. LTA was associated with a significant reduction in 12- to 36-month mortality (OR: 0.66 [95% CI: 0.47–0.93], p = 0.02). The odds of developing ascites (OR: 0.30 [95% CI: 0.16–0.54], p < 0.0001), RA (OR: 0.52 [95% CI: 0.33–0.81], p < 0.01), HE (OR: 0.62 [95% CI: 0.41–0.95], p = 0.03), renal dysfunction (OR: 0.45 [95% CI: 0.21–0.97], p = 0.04) and SBP (OR: 0.30 [95% CI: 0.16–0.54], p < 0.0001) were significantly lower in the LTA group. No significant differences were observed for hyponatremia (OR: 0.62 [95% CI: 0.36–1.06], p = 0.08) or GI bleeding (OR: 1.15 [95% CI: 0.60–2.23], p = 0.67).
Conclusion: These data indicate that LTA is associated with a significant reduction in mortality and key cirrhosis-related complications, supporting its potential role as a disease-modifying intervention in patients with decompensated cirrhosis and ascites. Future research is needed to define the patient population most likely to benefit and to optimize treatment protocols, including individualized therapeutic strategies.

WED-468
Lack of social network and support are predictors of mortality in cirrhosis. Results from an incidence cohort with long-term follow-up

Thit Mynster Kronborg[1], Malene Barfod O'Connell[1], Frederikke Agerbo[2], Søren Møller[3,4], Nina Kimer[1,3]. *[1]Gastro Unit, Medical Division, University Hospital Hvidovre, Denmark, Department of Clinical Medicine, Copenhagen University, Copenhagen, Denmark; [2]Biostatistics Sanos, Søborg, Denmark; [3]Department of clinical medicine, Copenhagen University, Diagnostic Unit, Department of clinical physiology and nuclear medicine, Hvidovre University Hospital, Copenhagen, Denmark; [4]Diagnostic Unit, Department of Clinical Physiology and Nuclear Medicine, Hvidovre University Hospital, Hvidovre, Denmark*
E-mail: nina.kimer@regionh.dk

Background and aims: Liver cirrhosis is a severe disease with high mortality and increased risk of admissions. Recently, frailty, as both a physical and social concept, has been suggested as a reliable predictor.
The study aimed to investigate different facets of frailty in cirrhosis and examine its potential to predict mortality and admissions.
Method: Data from a prospective cohort study of patients with newly diagnosed cirrhosis were analysed. Physical tests (Short Physical Performance Battery and Hand grip strength) were performed, along with questionnaires regarding quality of life, sociodemographic factors, loneliness, regarding both structural and functional social dimensions. Follow-up of admissions and mortality was registered for at least three years.
Results: A total of 208 patients were included. We found a significant reduction in mortality for patients with handgrip > 30 kg (Hazard ratio 0.50 [0.27, 0.94]), Short physical performance battery > 8 points (0.39 [0.23, 0.66]) and not receiving home care (0.48 [0.27;0.85]). We found a significantly increased risk of death in patients with no psychological support (2.02 [1.12, 3.62]) and when the closest contact was other than family (2.15 [1.42, 3.25]) Being married (0.68 [0.47, 0.97]), not receiving home care (0.58 [0.37, 0.92]), higher scores on physical performance (>8 (0.55 [0.36, 0.83]), and quality of life (>5 (0.50 [0.33, 0.76]) was associated with a reduced risk of admission to hospital.
Conclusion: Lack of close family contact and no psychological support from relatives predict mortality in patients with liver cirrhosis. Physical frailty has a major impact on survival.

WED-473
Beyond age and disease severity: the pivotal role of intestinal and systemic inflammation as drivers of physical frailty in advanced chronic liver disease

Tomáš Koller[1], Daniel Jan Havaj[2], Dana Knutova[1], Daniela Žilinčanová[2], Petra Vrbova[1], Svetlana Adamcova Selcanova[2], Lubomir Skladany[2]. *[1]Lekárska fakulta Univerzity Komenského a Univerzitná nemonica Bratislava, 5. interná klinika, Odd. gastroenterológie a hepatológie, Bratislava, Slovakia; [2]Fakultná nemocnica FD Roosevelta, Odd. hepatológie, gastroenterológie a transplantácie (HEGITO), 2. interná klinika Slovenskej zdravotníckej univerzity, Banská Bystrica, Slovakia*
E-mail: koller.tomas@gmail.com

Background and aims: In hospitalized patients with advanced chronic liver disease (ACLD), physical frailty is a potent, independent predictor of adverse outcomes. While driven by multifactorial causes—including age, protein catabolism, and inflammation—identifying reversible factors is essential for developing targeted therapeutic interventions.
Method: Data were analyzed from the two-center, prospective RH7 cirrhosis registry. We included patients with complete records for anthropometrics, etiology, and frailty status as measured by the Liver Frailty Index (LFI). Assessments included disease severity (MELD-Na, MELD3, CLIF-C AD), protein metabolism (serum albumin), systemic inflammation (WBC, lymphocyte %, CRP), intestinal inflammation (fecal calprotectin), and active alcohol use (phosphatidylethanol >0.3μmol/l or history of heavy drinking).
Results: The cohort included 697 patients (median age: 57; 62.4% male). Alcohol-related cirrhosis was the primary etiology (64.4%), with 18.6% active heavy drinkers. Median MELD-Na was 18.3; 23.8% had refractory ascites. The median LFI was 4.28 (IQR 3.7–5.0); frailty was defined as LFI ≥ 5.25 (80th percentile). Multivariate analysis identified six independent predictors of frailty (Model AUROC = 0.818; 95% CI: 0.786–0.846):
• Age (OR 1.07; 95% CI 1.05–1.09)
• Alcohol-related cirrhosis (OR 1.78; 1.05–2.92)
• Serum albumin (OR 0.94; 0.90–0.98)
• Serum CRP (OR 1.01; 1.0–1.02)
• MELD-Na (OR 1.11; 1.07–1.15)
• Fecal calprotectin (OR 1.07; 1.04–1.10)
Notably, refractory ascites, active heavy drinking, and WBC count were not independently associated with frailty status.
Conclusion: Physical frailty in hospitalized ACLD patients is driven by age, hepatic dysfunction, and a distinct inflammatory profile characterized by both systemic (CRP) and intestinal (fecal calprotectin) markers. These data suggest that intestinal inflammation and protein metabolism are more closely linked to frailty than heavy drinking or mechanical complications like ascites, highlighting new potential therapeutic targets for intervention.

WED-474
Circulating fibronectin reflects disease severity and predicts variceal bleeding in advanced chronic liver disease

Georg Kramer[1,2,3,4], Irina Andreea Lie-Undurean[1,2,3], Benedikt Simbrunner[1,2,3,4], Mathias Jachs[1,2,3], Lorenz Balcar[1,2,3], Benedikt Hofer[1,2,3,4], Lukas Hartl[1,2,3], Georg Semmler[1,2,3], Christian Sebesta[1,2,3], Paul Thöne[1,2,3], Marlene Hintersteininger[1,2,3], Philipp Schwabl[1,2,3,4], Michael Trauner[1,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3,4]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [3]Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [4]Christian-Doppler Laboratory for Portal*

Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria, Vienna, Austria
E-mail: georg.kramer@meduniwien.ac.at

Background and aims: Fibronectin is a multifunctional extracellular matrix glycoprotein involved in coagulation, tissue remodeling and immune regulation. We investigated the role of fibronectin in advanced chronic liver disease (ACLD), focusing on its association with key disease-related pathways and clinical outcomes.
Method: Patients with ACLD undergoing hepatic venous pressure gradient (HVPG) measurement and laboratory phenotyping were prospectively recruited. Baseline serum fibronectin was related to markers of liver function, fibrosis, inflammation and coagulation. First and further decompensating events were analyzed using Fine-Gray competing-risk regression, with hepatocellular carcinoma, non-liver-related death and liver transplantation as competing events.
Results: At baseline, 108 (36.2%) had compensated and 190 (63.8%) decompensated ACLD. Median MELD score was 12 (IQR 9–16), median HVPG 17 (IQR 12–21) mmHg and median fibronectin level were 32.95 (IQR 25.50–41.68) mg/dL. Fibronectin levels were significantly lower in decompensated than compensated ACLD (30.25 vs. 38.75 mg/dL; $p < 0.001$). Lower fibronectin levels were associated with impaired hepatic synthetic function (albumin $\rho = 0.43$; INR $\rho = -0.54$; MELD $\rho = -0.47$), more pronounced portal hypertension (HVPG $\rho = -0.22$), systemic inflammation (IL-6 $\rho = -0.38$; CRP $\rho = -0.17$) and extracelluar matrix remodeling assessed by the enhanced liver fibrosis (ELF) test ($\rho = -0.20$; all $p < 0.01$). Fibronectin correlated positively with key coagulation parameters, including fibrinogen ($\rho = 0.55$), antithrombin III activity ($\rho = 0.51$) and protein C activity ($\rho = 0.50$; all $p < 0.001$). During a median follow-up of 29.5 months, 20 patients (6.7%) experienced first decompensation and 75 (25.2%) further decompensation, of whom 15 patients (5.0%) developed first variceal bleeding. 47 (15.8%) patients died from liver-related causes. Interestingly, higher fibronectin levels were independently associated with an increased risk of first variceal bleeding (aSHR 6.41; $p = 0.020$) after adjustment for HVPG and MELD 3.0. In contrast, fibronectin was not significantly associated with non-bleeding decompensating events.
Conclusion: In patients with ACLD, fibronectin correlates to biomarkers representing distinct disease-related pathomechanisms. While lower levels generally reflect advanced liver dysfunction, higher fibronectin levels independently identify patients at increased risk for variceal bleeding.

WED-475

Hypoleptinemia in cirrhosis is associated with increased one-year-mortality in women undergoing transjugular intrahepatic portosystemic shunt

Frederike Krus[1], Shreeya Sharma[1], Paulina Bauer[1], Robert Schierwagen[1], Jannik Sonnenberg[1], Simone Anna Keimburg[1], Philipp Wöhler[1], Sabine Klein[1], Maximilian Joseph Brol[1], Frank Erhard Uschner[1], Kai-Henrik Peiffer[1], Sara Noemi Reinartz Groba[1], Martin Sebastian McCoy[1], Michael Praktiknjo[1], Jonel Trebicka[1,2], Julia Fischer[1]. [1]*University of Münster, Faculty of Medicine and University Hospital of Münster, Department of Internal Medicine B, Münster, Germany;* [2]*European Foundation for the Study of Chronic Liver Failure - EFClif, Barcelona, Spain*
E-mail: frederike.krus@ukmuenster.de

Background and aims: Leptin, a metabolic hormone predominantly secreted by white adipose tissue, regulates systemic metabolism and modulates immune responses to bacterial infection (BI). In chronic liver disease, leptin exerts pro-inflammatory and pro-fibrogenic effects, contributing to hepatic fibrosis. Circulating leptin levels are known to differ substantially between sexes, with higher levels observed in women. However, the clinical relevance of these sex-specific differences for leptin in patients with cirrhosis remains unclear. This study aimed to investigate the role of circulating leptin with a particular focus on sex-specific outcomes in cirrhosis.
Method: In this study, leptin levels were analyzed in a cohort of patients with liver cirrhosis ($n = 157$) who underwent Transjugular intrahepatic portosystemic shunt (TIPS) placement. Leptin levels were measured in plasma samples taken from the right atrium, hepatic vein, portal vein, and cubital vein at the time of TIPS implantation using enzyme-linked immunosorbent assay (ELISA).
Results: In our cohort, circulating leptin levels correlated positively with body mass index (BMI, $p < 0.0001$), which was identified as an independent determinant of leptin concentrations. Based on BMI-adjusted leptin levels, 24% of patients were classified as hypoleptinemic. Unexpectedly, hypoleptinemic patients were predominantly of female sex and obese. Hypoleptinemia was associated to a significantly increased one-year mortality ($p = 0.0462$), an effect predominantly observed in female patients ($p = 0.0145$) compared to those of male sex ($p = 0.8270$). Paired portal and hepatic vein measurements revealed significantly higher leptin concentrations in the portal vein compared to the hepatic vein ($p < 0.0001$), indicating hepatic leptin clearance. Notably, in advanced disease stages (CHILD C cirrhosis and MELD score > 15), this portal–hepatic venous gradient was no longer detectable ($p = 0.2413$ and $p = 0.2101$).
Conclusion: Women with liver cirrhosis may develop a relative leptin deficiency, despite higher physiological leptin levels identifying leptin as a sex-specific prognostic factor in advanced liver cirrhosis. Hepatic leptin clearance decreases with cirrhosis progression, potentially worsening outcome. These findings highlight leptin metabolism as a promising target for further mechanistic and therapeutic studies in liver cirrhosis.

WED-476

Prevalence, risk factors, and clinical outcomes of micronutrient deficiencies in patients with cirrhosis: a prospective cohort study

Narisorn Lakananurak[1], Warasinee Hathayamat[1], Phatcharaporn Chanwidoon[1]. [1]*Department of Medicine Faculty of Medicine Chulalongkorn University, Bangkok, Thailand*
E-mail: narisorn.l@chula.ac.th

Background and aims: Patients with cirrhosis are highly vulnerable to malnutrition and micronutrient deficiencies. Current guidelines recommend empiric supplementation, yet inappropriate use may cause toxicities and liver injury, particularly with fat-soluble vitamins and certain trace elements. Data on prevalence, risk factors, and clinical impact of micronutrient abnormalities in cirrhosis remain scarce. This study aimed to evaluate prevalence, risk determinants, and outcomes of micronutrient deficiencies in cirrhotic patients.
Method: This is a prospective cohort study. A total of 110 patients with cirrhosis were enrolled at outpatient clinics. Serum vitamin A, vitamin D, vitamin E, zinc, copper, and high-sensitivity C-reactive protein (hs-CRP) were measured. Demographics, cirrhosis severity, and complications were recorded. Patients were followed for 6 months to assess clinical outcomes including infection, mortality, hepatic encephalopathy, ascites, and readmission.
Results: Hepatitis B infection was the leading cause of cirrhosis (25.5%), followed by alcohol-related cirrhosis (18.2%) and cirrhosis related to metabolic dysfunction-associated steatohepatitis (MASH) (16.4%). Regarding disease severity, 61.8% of patients were classified as Child-Pugh A, 24.5% as Child-Pugh B, and 13.6% as Child-Pugh C. Micronutrient deficiencies were frequent: vitamin A (51.2%), vitamin D (34.9%), vitamin E (4.8%), zinc (60%), and copper (12.7%). Half of the patients (50%) had multi-micronutrient deficiencies (≥2 deficiencies). Mean ± standard deviation (SD) hs-CRP levels were 3.6 ± 4.7 mg/dL, which did not influence micronutrient status (<20 mg/dL). Independent risk factors for multi-micronutrient deficiencies were Child-Pugh class B/C (odds ratio (OR) 7.8; 95% confidence interval (CI) 1.9–31.5; $p = 0.004$) and Model for End-Stage Liver Disease (MELD) score > 11 (OR 5.2; 95% CI 1.5–18.4; $p = 0.010$). After adjustment for cirrhosis severity, multi-micronutrient deficiencies

were significantly associated with infectious complications (hazard ratio (HR) 4.7; 95% CI 1.2–18.8; p = 0.031).
Conclusion: Micronutrient deficiencies are highly prevalent in cirrhosis, with zinc, vitamin A, and vitamin D most commonly affected. Multi-micronutrient deficiencies are frequent and linked to adverse outcomes, particularly infection, independent of cirrhotic severity. Child-Pugh B/C and MELD >11 identify high-risk patients who may benefit from targeted micronutrient evaluation and supplementation.

WED-477
Prognosis after TIPS in patients aged ≥70 years: a multicentre french cohort study
Hélène Larrue[1], Julie Tainturier[2], Olivia Pietri[3], Laurent Milot[4], Charlotte Bouzbib[5], Baptiste Giguet[6], Sophie Metivier[1], Marie-Noëlle Hilleret[7], Jean Paul Cervoni[8], Fanny Lebosse[9], Louis Dalteroche[2], Lena Dube[6], Angelo Della Corte[9], Zakaria Maghlaoua[7], Dominique Thabut[5], Marc Bourliere[3], Florent Artru[6], Marika Rudler[5], Floriane Sellier[3], Laure Elkrief[2], Christophe Bureau[1], Jérôme Dumortier[4]. *[1]Toulouse University Hospital, Toulouse, France; [2]CHU de Tours, Tours, France; [3]Hôpital Saint-Joseph, Marseille, France; [4]Hôpital Edouard Herriot, Lyon, France; [5]AP-HP Sorbonne Université, Hôpital Universitaire Pitié-Salpêtrière, Paris, France; [6]University hospital centre Pontchaillou, Rennes, France; [7]CHU de Grenoble, Grenoble, France; [8]CHU de Besançon, Besançon, France; [9]Hôpital de la Croix Rousse, Lyon, France*
E-mail: larruehelene@gmail.com

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is an effective treatment for complications of clinically significant portal hypertension; however, its use in elderly patients remains controversial. Data regarding outcomes and prognostic stratification after TIPS in patients aged ≥70 years are limited. We aimed to assess survival, further decompensation, and prognostic determinants after TIPS in this population.
Method: We conducted a retrospective multicentre cohort study including consecutive patients aged ≥70 years who underwent TIPS between 2010 and 2024 in nine tertiary hepatology centres in France. Overall survival and further decompensation-free survival were evaluated up to 24 months. Prognostic factors were analysed using univariable and multivariable Cox models. In patients undergoing TIPS for refractory ascites (RA), a machine-learning model (XGBoost) was additionally developed to explore individualized prognostic stratification.
Results: A total of 402 patients were included (66.7% men; mean age 73.9 ± 3.5 years). TIPS was performed electively in 76.4% of cases, most frequently for RA (51.7%). During a median follow-up of 338 days, 210 patients died, corresponding to an estimated 2-year overall survival of 47.8%. Overall survival did not differ according to the period of TIPS placement (before vs after 2017). Survival varied according to indication, with lower 2-year survival in patients treated for RA (42.2%) and rescue TIPS (39.9%). Nearly half of the cohort (49.8%) experienced at least one episode of further decompensation, with decompensation-free survival rates of 49.0% at 1 year and 41.8% at 2 years; hepatic encephalopathy occurred in 43.8% of patients. No patient underwent liver transplantation. In the overall cohort, age, male sex, serum bilirubin, INR, and ascites were independently associated with mortality. An XGBoost model integrating multiple prognostic variables was created and improved individualized risk prediction.
Conclusion: Outcomes after TIPS in patients aged ≥70 years remain heterogeneous and strongly depend on indication. Patients treated for refractory ascites showed poor long-term survival, even in this large and contemporary multicentre cohort from expert centres, highlighting the need for careful patient selection in this setting. Advanced age and markers of liver failure identify patients at higher risk. Machine-learning approaches may help refine prognostic stratification beyond conventional scores in this growing population.

WED-478
Shear wave elastography combined with ALBI score enhances prediction of hepatic decompensation in advanced chronic liver disease
Jaejun Lee[1], Jung Hyun Kwon[1], Soon Kyu Lee[1]. *[1]Catholic University of Korea, Seoul, Korea, Rep. of South*
E-mail: pwln0516@gmail.com

Background and aims: Hepatic decompensation (HD) is a key determinant of prognosis in advanced chronic liver disease (ACLD). Shear wave elastography (SWE) is widely used to assess fibrosis, but its prognostic value for HD remains uncertain. We evaluated SWE alone and combined with ALBI for risk prediction.
Method: 2759 patients with ACLD who underwent SWE between 2019 and 2025 were analyzed. The endpoint was time to first HD event. Predictive performance of SWE, alone and with ALBI, was evaluated in training (n = 1839) and test (n = 920) sets.
Results: SWE alone showed good performance for predicting HD (C-index 0.760) and OS. A 10-kPa threshold effectively stratified risk, with high-risk patients having higher hazards of HD and death ($P < 0.001$). SWE and ALBI showed no statistical interaction, supporting their potential for complementary synergistic effects when combined. Integrating SWE with ALBI grade created a simple three-tier classification that further improved stratification, with high-risk patients (SWE >10 kPa and ALBI grade 2/3) having a 16.6-fold risk of HD and a 21.4-fold risk of death compared with low-risk patients ($P < 0.001$). A Cox model in the training set generated a weighted linear formula (SWE + 20 × ALBI), termed the SALBI score, achieving the highest accuracy (C-index: training 0.802, test 0.820), outperforming SWE, ALBI, FIB-4, and MELD. The SALBI score stratified high- versus low-risk groups with 13.0-fold and 15.0-fold risks in train and test sets ($P < 0.001$).
Conclusion: SWE is a robust prognostic marker for HD. A linear score combining SWE with ALBI further improves prediction and provides a practical tool for stratification.

WED-479
Prevalence of alcohol use among patients with cirrhosis in the United States: a prospective cohort study
Ria Loomba[1], Kaleb Tesfai[2], Ricki Bettencourt[2], Nikhil Kalita[2], Chinar Sheth[2], Egbert Madamba[2], Veeral Ajmera[2], Luis Antonio Diaz[2]. *[1]Georgetown University, Washington, United States; [2]University of California San Diego, MASLD Research Center, La Jolla, United States*
E-mail: luisdiazpiga@gmail.com

Background and aims: Alcohol use is a leading risk factor for hepatic decompensation and hepatocellular carcinoma among patients with cirrhosis. AASLD and EASL practice guidelines universally recommend complete abstinence from alcohol use in patients with cirrhosis. However, many patients with cirrhosis continue to consume alcohol despite these recommendations. Therefore, we aimed to determine the prevalence of alcohol use using validated questionnaire as well as phosphatidyl ethanol (PEth), a quantitative and objective biomarker of alcohol use, in a prospective cohort of patients with cirrhosis in the United States.
Method: This prospective study included adults with cirrhosis residing in Southern California. Cirrhosis was diagnosed based on AASLD criteria, either on liver biopsy, imaging, and/or laboratory and clinical evidence. We performed a standardized interview, physical exam, laboratory testing (including PEth), vibration-controlled transient elastography (VCTE) and magnetic resonance imaging (MRI). Alcohol consumption was quantified using the Lifetime Drinking History and Alcohol Use Disorders Identification Test (AUDIT). Current alcohol use was defined as either a positive test on PEth or confirmed alcohol use based upon self-report on AUDIT.
Results: The cohort comprised of 183 adults with cirrhosis. The mean (±SD) age in years and body mass index (BMI) was 59.1 ± 11.6 and 29.8 (±6.2) kg/m 2, respectively. 56% were female and 48% were of Hispanic ethnicity. The mean (±SD) LSM was 24.1 kPa (±17.1). 88

(48.1%) had MASLD cirrhosis, 52 (28.4%) had alcohol-associated cirrhosis, and 21 (11.5%) had viral hepatitis related cirrhosis. The prevalence of current alcohol use was 31%. Among those with continued alcohol use, 79% provided self-reports of alcohol consumption, but PEth testing revealed occult alcohol use in 21% (N = 12) who denied alcohol consumption on validated questionnaire. We then compared MELD, FIB-4, platelets, HDL, MCV, ANI, LSM by VCTE, LSM by MRE among those with alcohol use versus those without alcohol use. Alcohol use among cirrhosis patients was associated with higher MRI-PDFF (p-value < 0.01).
Conclusion: Alcohol use is present in 31% of patients with cirrhosis, and PEth testing in cirrhosis can uncover occult alcohol use. Future guidelines may consider PEth testing to detect occult alcohol in cirrhosis to improve the outcomes of patients with cirrhosis.

WED-480
Breaking the habit: evaluating the routine use of spontaneous bacterial peritonitis prophylaxis
Shauna Madigan[1,2], Eugene Phan[3], Keshani Alagiyage[4], Kathleen Davy[4], Kirsty Campbell[5], Jeyamani Ramachandran[4], Mohamed Asif Ali Chinnaratha Mohamedashrafali[3]. *[1]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [2]Lyell McEwin Hospital, Gastroenterology, Elizabeth Vale, Australia; [3]Lyell McEwin Hospital, Adelaide, Australia; [4]Flinders Medical Centre, Adelaide, Australia; [5]Royal Darwin Hospital, Darwin, Australia*
E-mail: shaunamadigan@gmail.com

Background and aims: Spontaneous bacterial peritonitis (SBP) is the most common bacterial infection in patients with decompensated cirrhosis and is associated with high mortality and morbidity. Despite advances in medical care, 1-year mortality after the first episode of SBP ranges from 31% to 93%. SBP prophylaxis is given to patients either as primary prophylaxis (PP) to prevent the initial episode or secondary prophylaxis (SP) to prevent recurrence. The evidence for this practice is based on outdated data published more than two decades ago. With the emergence of multidrug-resistant organisms (MDRO), routine SBP prophylaxis practices need to be re-evaluated. We aimed to investigate the impact of PP and SP on survival and the development of MDRO.
Method: Data was collected retrospectively for patients admitted with cirrhosis-related ascites from three tertiary centres in Australia between January 2022 and December 2023, with follow-up until death or December 2024.
Results: A total of 379 patients were included, 61% being male, a median (IQR) age of 62 (19) years, MELD-Na score of 21 (9) and follow-up of 1.2 (1.9) years. Alcohol was the predominant aetiology (59%) for cirrhosis, and 73 (19.2%) had MDRO at baseline. On index admission, 13 (3.4%) patients were already on SP, 21 (5.5%) were on PP, and 51 (13.5%) patients were diagnosed with SBP. Post index admission, 32 (8.4%) and 48 (21%) patients were commenced on PP and SP, respectively. During the follow-up, 52 (13.7%) patients had an episode of SBP. The mean SBP-free survival was similar between those on PP and those meeting criteria but not commenced on PP [2.9 v 2.7 years, c2 = 3.7, p = 0.2], and with or without SP [2.2 v 2.0 years, c2 = 1.1, p = 0.3]. Overall survival was similar between those not on SP [median (95%CI): 1.7 (1.2–2.1) years] and those on SP [median (95%CI):1.8 (1.5–2.2) years], c2 = 0.5, p = 0.5. Overall, the risk of developing MDRO culture-positive SBP during follow-up was significantly higher for those on either PP or SP [27.5% v 9.4%, c2 = 18.1, p < 0.001]. The risk was only higher for those who had MDRO positive status at baseline [64.7% v 5.4%, c2 = 29.6, p < 0.001] but not for those with MDRO –ve status at baseline [17.5% v 10.3%, c2 = 2.5, p = 0.1].
Conclusion: This study shows that in a real-world setting, the use of PP and SP for SBP does not have a survival benefit. In fact, those who have MDRO at baseline have worse survival outcomes if started on prophylaxis. Future randomised controlled trials are required to justify PP and SP for SBP.

WED-481
Dynamic network collapse in decompensated hepatic cirrhosis
Yanpei Mai[1], Suzhen Jiang[1], Shuo Yang[2], Zixing Wang[1]. *[1]Peking University Hepatology Institute, Beijing, China; [2]Peking University People's Hospital Radiology Department, Beijng, China*
E-mail: wangzixing@pkuph.edu.cn

Background and aims: Alterations in intrahepatic communication networks – driven by fibrotic bridging, vascular shunting, and metabolic dysfunction – serve as latent biomarkers for impending cirrhotic decompensation. However, the dynamic hepatic connectomes and its role in signaling decompensation remain unexplored.
Method: We enrolled hepatic cirrhotic patients (2022–2025) undergoing gadoxetic acid-enhanced upper abdominal MRI with ≥5 imaging phases (non-contrast, arterial early, arterial late, portal venous, equilibrium). Dynamic contrast-enhanced T1-weighted MRI using a GE Discovery 750 3.0 T or Siemens Prisma 3.0 T scanner with standardized axial acquisition. Liver partitioned into 8 segments (I-VIII). Representative slices. Circular ROIs placed centrally in Segments I–VIII, avoiding vessels and lesions. 837 radiomic features per segment were extracted via PyRadiomics. Sliding window (window size = 3 phases) was applied to build topological networks. Intersegmental connectivity quantified by Pearson correlation, with sparsity controlled at 0.2. Small-worldness, modularity, hub distribution, nodal centrality were analyzed.
Results: Significant network reorganization was observed in decompensated compared to compensated livers within the arterial-portal venous-equilibrium window. This included an increase in modularity (indicating functional fragmentation: 0.066 vs. 0.038), sigma (reflecting heightened randomness: 1.514 vs. 1.434), and a decrease in average path length (suggesting impaired information transfer efficiency: 0.786 vs. 0.818); all P < 0.05. Segment V dominated the liver network in compensation (20% hub prevalence, consistent with its anatomical centrality). Decompensation triggered hub redistribution: Peripheral Segments II–V & VII–VIII: 12–15%; Marginal Segments I & VI: 8–10%. This indicate collapse of compensatory network. The betweenness centrality of Segment I (measure of its information-bridging role) predicted decompensation risk: 18.2%, 54.2%, and 83.3% in low, medium and high risk stratus, respectively. High-risk groups showed significantly elevated HRs for onset of ascites, hepatic encephalopathy and variceal bleeding; all P < 0.05.
Conclusion: This study pioneers a network paradigm for cirrhosis prognostication, shifting from isolated segmental biomarkers to system-level monitoring. The arterial-portal-equilibrium phase offers a critical window for detecting connectome-driven decompensation signals, with Segment I centrality emerging as a clinically important predictor.

WED-482
Association between occupational exposure and hepatocellular carcinoma risk in Egypt: a preliminary case–control analysis
Mohamed Mahmoud Marey[1], Malak A. Hassan[1], Nada Mohamed Faragallah[1], Mariam H. Ghallab[1], Rana Saleh Sharaf[1], Mohamed Mohamed Belal[1], Ahmed Kamal Hussein. *[1]Faculty of Medicine-Alexandria University, Alexandria, Egypt*
E-mail: mohamed.mahmoud2101@alexmed.edu.eg

Background and aims: Occupational exposures have been explored for various cancers, but the association has not been as well-established in hepatocellular carcinoma (HCC). This case-control study aims to explore the role of occupational risk factors in the development of HCC among cirrhotic patients in Egypt.
Method: This case-control study was conducted at Alexandria Main University Hospital, Egypt. Data collection took place between February 2025 and December 2025 by trained personnel using predesigned questionnaires. The control group included cirrhotic patients who achieved negative viremia (HCV or HBV) after treatment for at least 2 years. The cases group included patients with HCC on top of cirrhosis who have achieved negative viremia (HCV or HBV) after

treatment for at least 2 years. Preliminary analysis was conducted using Jamovi software.
Results: The mean age of HCC cases was higher than cirrhotic controls (64.5 ± 10.0 vs 60.8 ± 10.9 years). Males predominated among HCC cases (61.3%), whereas controls showed a slight female predominance (53.5%). Hepatitis C was the predominant cause of cirrhosis among HCC cases (93.5%), while controls had more heterogeneous etiologies, including HCV (40.2%) and MASLD (33.3%). Agriculture was the most common occupation in both groups, accounting for 38.7% of HCC cases and 35.6% of controls.
In this preliminary case–control analysis, rural residence showed an increase in the odds of HCC compared with cirrhotic controls (OR: 1.12; 95% CI: 0.49–2.53). Farming as a primary occupation was associated with HCC risk (OR: 1.02; 95% CI: 0.45–2.35). Exposure to pesticides or fertilizers was not associated with an increase in HCC odds (OR: 0.62; 95% CI: 0.13–2.99), as was employment in an industrial setting (OR: 0.61; 95% CI: 0.21–1.77).
Conclusion: While limited by sample size and preliminary power, these findings suggest that traditional occupational and socio-economic risk factors may play a role in HCC development among cirrhotic patients after sustained viral clearance. Importantly, the study design using cirrhotic patients without HCC as controls rather than general population comparators intentionally minimized the dominant carcinogenic effects of active HCV or HBV infection and cirrhosis-related disease progression, allowing a more isolated evaluation of non-viral, occupational, and socioeconomic exposures. Larger studies are warranted to refine HCC risk stratification in the Egypt's post HCV elimination era.

WED-483
Viscoelastic haemostatic assessment in cirrhosis using ClotPro®: clinical interpretation of manufacturer-derived viscoelastic reference ranges

Buzias Maria[1], Cristiana Grapa[1], Marta Besleaga[1], George Cioclu[1], Mohammad Al Khalili[1], Cristian Tefas[2], Zeno Sparchez[2], Bogdan Procopet[2], Rares Craciun[2]. *[1]"Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]Gastroenterolgy Department, "Prof. Dr. O. Fodor" Regional Institute of Gastroenterology and Hepatology, Department of Internal Medicine, "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania, Cluj-Napoca, Romania*
E-mail: rarescraciun@ymail.com

Background and aims: Patients with cirrhosis frequently exhibit abnormal conventional coagulation tests (CCTs), including prolonged INR, thrombocytopenia and hypofibrinogenemia. Viscoelastic testing (VET) enables functional assessment of clot initiation and firmness. ClotPro® (enicor GmbH, Munich, Germany) is a cartridge-based VET device with limited validation in advanced liver disease. We aimed to evaluate haemostatic profiles in cirrhosis using ClotPro® and the clinical relevance of manufacturer-derived reference ranges and exploratory viscoelastic thresholds.
Method: We performed a cross-sectional analysis of consecutive adult patients with cirrhosis and abnormal CCTs undergoing ClotPro® testing. EX- and IN-tests were analyzed. Clot initiation was assessed by clotting time (CT), reflecting coagulation factor activity, and clot firmness by maximum clot firmness (MCF), reflecting platelet and fibrinogen contribution. Parameters were interpreted using manufacturer-provided adult reference ranges.
Results: 120 patients were included (Child A/B n = 59, Child C n = 61). Using manufacturer-derived reference ranges, clot firmness was frequently classified as reduced: EX-MCF was below range in 94/120 (78.3%) and IN-MCF in 88/120 (73.3%) patients, with no difference between Child classes ($p = 0.93$). Clot initiation deteriorated with disease severity. EX-CT was longer in Child C (69 [57–83] vs 55 [49–66] s, $p = 0.002$), and EX-CT above the upper reference limit was more frequent in Child C (35/61, 57.4% vs. 15/59, 25.4%; $p = 0.001$). Despite abnormal CCTs and frequent classification as hypocoagulable, only 24/120 (20.0%) patients reached an exploratory viscoelastic threshold commonly considered clinically actionable in ROTEM-guided bleeding algorithms (EX-CT >80 s), including 18/65 (27.7%) patients with INR >2. Among patients with fibrinogen <1.5 g/L, a composite viscoelastic abnormality was present in 29/36 (80.6%), while in patients with platelet count $<50 \times 10^3$/µL, it occurred in 49/52 (94.2%) patients.
Conclusion: In cirrhosis with abnormal standard coagulation tests, application of manufacturer-derived ClotPro® reference ranges classifies most patients as hypocoagulable. However, only a minority demonstrate viscoelastic abnormalities reaching exploratory thresholds that would support correction of coagulation factor, fibrinogen or platelet deficits. These findings highlight the importance of functional viscoelastic interpretation and the need for disease-specific ClotPro® thresholds in cirrhosis.

WED-484
The kidney-liver axis decoded: machine learning redefines mortality prediction in cirrhotic patients with acute kidney injury

Jeril Lasington[1], Lawin Steve Mathew Lasington[2]. *[1]New York Medical College, Valhalla, United States; [2]Rutgers University-Newark Arch, Newark, United States*
E-mail: jeril.lasington@gmail.com

Background and aims: Acute kidney injury (AKI) occurs in 20–50% of hospitalized cirrhotic patients and is a major mortality driver. Traditional scores including MELD and SOFA incorporate renal parameters but were not designed for the unique pathophysiology of AKI in cirrhosis, which includes hepatorenal syndrome (HRS), prerenal azotemia, and acute tubular necrosis. We developed machine learning (ML) models for predicting ICU mortality in cirrhotic patients with AKI and compared performance against established scores.
Method: This retrospective cohort study used MIMIC-IV (v3.1) to identify adults with cirrhosis and concurrent AKI or HRS requiring ICU admission (2008–2022). Predictors from the first 24 hours included renal parameters, liver function, metabolic markers, hemodynamics, AKI subtype, cirrhosis complications, and ICU interventions. Four ML algorithms (Logistic Regression, Random Forest, XGBoost, Gradient Boosting) were trained using 80/20 stratified splits with five-fold cross-validation. Performance was compared against MELD, MELD-Na, and SOFA using bootstrap DeLong testing (n = 2000).
Results: Among 2720 patients (mean age 59.8 years; 64.1% male; 22.1% HRS), hospital mortality was 34.3%. Logistic Regression achieved highest discrimination (AUC 0.841, 95% CI 0.805–0.872), significantly outperforming MELD (0.729, +15%, $p < 0.0001$), MELD-Na (0.726, $p < 0.0001$), and SOFA (0.728, $p < 0.0001$). Creatinine trajectory (both maximum and minimum values) emerged as the strongest predictor, followed by lactate, age, sepsis, and hepatic dysfunction markers. Subgroup analysis revealed superior performance in non-HRS AKI (AUC 0.855) compared to HRS (AUC 0.744), suggesting HRS may require distinct prognostic approaches.
Conclusion: ML significantly outperforms traditional scores for ICU mortality prediction in cirrhotic patients with AKI. The dominance of creatinine trajectory suggests dynamic AKI course impacts prognosis more than single-timepoint measurements. These findings support developing AKI-specific prognostic tools integrating renal trajectory, hepatic function, and systemic illness severity. External validation is warranted.

WED-485
Refining non-acute decompensation to improve risk stratification in advanced chronic liver disease

Martin Sebastian McCoy[1], Marta Tonon[2], Jan Hähner[1], Hannah Guembel[1], Stine Johansen[3], Frank Erhard Uschner[1], Maximilian Joseph Brol[1], Lena Wolters[1], Thies Wedemeyer[1], Ronja Hartmann[1], Mareike Schroeder[1], Marvin Petrikowski[1],

Julia Fischer[1], Florian Rennebaum[1], Jörn Arne Meier[1], Josune Cabello Calleja[1], Eduardo Cervantes-Alvarez[1], Philip Ferstl[4], Richard Moreau[5], Christoph Welsch[4], Stefan Zeuzem[4], Kai-Henrik Peiffer[1], Aleksander Krag[3], Salvatore Piano[2], Paolo Angeli[2], Michael Praktiknjo[1], Jonel Trebicka[1,3,4,5]. *[1]Department of Internal Medicine B, University of Münster, Münster, Germany, Münster, Germany; [2]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine (DIMED), Padova, Italy; [3]Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark, Odense, Denmark; [4]Department of Internal Medicine I, Goethe University, Frankfurt, Germany, Frankfurt, Germany; [5]European Foundation for Study of Chronic Liver Failure, EF-Clif, Barcelona, Spain, Barcelona, Spain*
E-mail: martinsebastian.mccoy@ukmuenster.de

Background and aims: Non-acute decompensation (NAD) has been proposed to bridge the gap between compensated cirrhosis (CC) and acute decompensation (AD). However, its application for risk stratification is limited by inconsistent definitions. We compared NAD definitions with different ascites severities to compare prognostic performance and risk stratification.
Method: In this multicenter observational study, an outpatient derivation cohort (n = 565) was validated in an independent outpatient cohort (n = 632) and contextualized using a hospitalized AD cohort (n = 1512). Ascites severity and sustained diuretic therapy were evaluated at the lower boundary between CC and NAD. Three NAD frameworks were compared: STRICT criteria (HE grade ½ or ascites grade 2), EXTENDED (incl. ascites grade 1) and INCLUSIVE (incl. diuretic-controlled ascites). Primary endpoints were mortality and progression to AD.
Results: Across outpatient cohorts, patients with ascites grade 1 or diuretic-controlled ascites showed worse outcomes than ascites/diuretic-free individuals. A stepwise risk gradient was observed across ascites phenotypes, with increasing mortality, disease progression, and systemic inflammation. In the derivation cohort, 3-year mortality remained low among ascites/diuretic-free patients (6.4%) but converged at 17% in patients with diuretic-controlled and grade 1 ascites ($p < 0.01$). In the validation cohort, this gradient was reproduced without convergence (3-year mortality: 2.7%, 10.1%, and 24.4%, respectively; $p < 0.001$). Applying these risk patterns to INCLUSIVE NAD criteria increased prevalence from 11% to 62%. While STRICT criteria identified patients at highest risk, they misclassified early decompensation: over 75% of patients progressing to AD within 1 year were classified as non-NAD/compensated, compared with 14% under the INCLUSIVE definition. Consequently, mortality among non-NAD/compensated patients declined stepwise with framework expansion, indicating improved risk separation. In a merged cohort of 2077 patients, INCLUSIVE NAD represented a distinct intermediate-risk phenotype between CC and AD.
Conclusion: Diuretic-controlled ascites is a functional marker of decompensation, aligning with the BAVENO-based concept of recompensation. STRICT NAD criteria identify high-risk patients but lack sensitivity for early decompensation. INCLUSIVE NAD definitions improve identification of at-risk individuals, strengthen long-term risk stratification and facilitate clinical adoption.

WED-489-YI
Frailty in patients with advanced chronic liver disease is reduced using BCAA supplementation (Amino L40) combined with community-based structured exercise programme

Matthew McKenna-Barry[1,2], Reza Saeidi[1,2], Ciara O'Connor[1,2], Noel McCaffrey[3], John Ryan[1,2], Karen Boland[1,2]. *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland; [3]ExWell Medical, Irish Wheelchair Association, Dublin, Ireland*
E-mail: matthewmckennab24@rcsi.com

Background and aims: Frailty, the reduced physiological reserve to health stressors, increases the risk of death, decompensation and hospitalisation for patients with advanced chronic liver disease (ACLD). Effective therapies are required to mitigate this syndrome.
Method: Patients with ACLD were recruited from a single centre. The intervention consisted of 12 weeks once daily 30 g Amino L40 (Ajinomoto Inc) (7 g protein, 23 g carbohydrate, 2.72 g leucine, 0.76 g isoleucine and 0.8 g valine) and a community based structured exercise programme combining aerobic and resistance exercises twice weekly. This pilot cohort were recruited sequentially and compared to patients in an ongoing randomised controlled trial of two wings; standard of care with dietician evaluation (control) or once daily 30 g Amino L40 alone. Liver Frailty Index (LFI) was measured at induction, 3 weeks and 12 weeks. Mann-Whitney U testing was performed to analyse continuous outcomes.
Results: 122 patients were recruited, 26 were assigned to combination, 48 to control and 48 to Amino L40 alone. There were no statistically significant differences of gender, age, aetiology or MELD between groups. Interim analysis was performed for 17 combination patients, 35 Amino L40 alone patients and 33 control patients at week 3 while recruitment is ongoing. Interim analysis was performed for 10 combination patients, 37 Amino L40 alone patients and 40 control patients at week 12 while recruitment is ongoing.
Combination patients completed median 15.5 (IQR 11–21.75) exercise classes at week 12. Adherance with Amino L40 was median 99% (IQR 90–100%) for combination and 85% (67–100%) for Amino L40 alone. Change in LFI from induction to week 3 for the combination group was median −0.42 (IQR −0.5–−0.28), −0.23 (−0.45–−0.10), $p = 0.036$ in comparison to combination, for Amino L40 alone and −0.17 (−0.32–0.11), $p = 0.002$ in comparison to combination, for control. Change in LFI from induction to week 12 for the combination group was median −0.59 (IQR −0.77–−0.36), −0.35 (−0.5–−0.11), $p = 0.029$ in comparison to combination, for Amino L40 alone, and −0.11 (−0.40–0.2), $p = 0.003$ in comparison to combination, for control. Statistically significant differences in thigh muscle thickness by ultrasound or phase angle were not seen between groups.
Conclusion: The provisional results of this study show that combination structured exercise and Amino l40 resulted in a significant reduction in LFI for patients with ACLD in comparison to Amino l40 alone or control treatment.

WED-490
A comparison of thromboelastometry-guided versus standard of care blood product transfusion strategies in patients with liver cirrhosis undergoing dental extractions

Irina Girleanu[1], Cristina-Maria Muzica[1], Laura Huiban[1], Sebastian Zenovia[1], Raluca Avram[1], Iulian Buzincu[1], Anca Trifan[1]. *[1]Universitatea de Medicină și Farmacie 'Grigore T. Popa' Iași, Iași, Romania*
E-mail: gilda_iri25@yahoo.com

Background and aims: Dental extractions are frequently needed in patients with liver cirrhosis, especially before liver transplantation. The aim of this study was to evaluate the efficacy and safety of a ROTEM-based algorithm in managing the administration of prophylactic blood components to cirrhotic patients undergoing dental extractions.
Method: All cirrhotic patients who were consecutively admitted to a tertiary university hospital from November 2024 to May 2025 and underwent dental extractions were included in the study. The patients were randomly assigned to two groups, with each subjected to a protocol to guide blood product transfusion [fresh frozen plasma (FFP), platelets and/or cryoprecipitate] prior to dental extraction: the standard-of-care (SOC) group -a transfusion protocol based on standard coagulation tests and thromboelastometry group-a transfusion protocol based on rotational thromboelastometry.
Results: Overall, 52 cirrhotic patients were included, with 26 in each group. There were no clinically significant differences regarding the baseline characteristics between the study groups. Postoperative bleeding occurred after two procedures in the SOC group. Patients

from the ROTEM group received less FFP transfusions than the SOC group (3.8% vs. 30.8%, p = 0.010). Blood products transfusion was needed less in patients evaluated using ROTEM compared to the SOC group (30.8% vs. 80.8%, p = 0.0001). There were no differences regarding the length of the hospital stay (p = 0.829) and 30-days survival (p = 0.298) between the two study groups.
Conclusion: Using ROTEM-guided blood product transfusion before dental extraction can prevent excessive blood products transfusion in patients with liver cirrhosis and should be used instead SOC tests.

WED-491
Physician perspectives on palliative care referral and integration in liver cirrhosis: a mixed-methods study
Chung Yau Nah[1], Raphael Lee[1], Xuan Yong Lee[1], Choon Pooh Heng[1], Wan Fen Yip[2]. [1]*Woodlands Health Campus, Singapore, Singapore;* [2]*National Healthcare Group, Singapore, Singapore*
E-mail: brandon.nah@gmail.com

Background and aims: Early integration of palliative care (PC) improves symptom control, advance care planning (ACP) and quality of life in patients with liver cirrhosis, yet referrals remain inconsistent and delayed. This study aimed to explore inter-specialty perspectives on PC integration and referral barriers.
Method: This preliminary analysis is part of a single-centre mixed-methods study surveying physicians from Internal Medicine (IM), Gastroenterology and Hepatology (GH) and Palliative Medicine (PM) at a tertiary hospital in Singapore. A cross-sectional questionnaire assessed perceptions of referral timing, ACP, symptom management, receptiveness and barriers using a 5-point Likert-scale (1 = strongly disagree; 5 = strongly agree), with non-parametric group comparisons and correlation analyses.
Results: 22 physicians participated, representing majority of physicians across departments (GH 9/10; IM 7/9; PM 6/9; 64% consultants; 50% female). While early PC was considered appropriate for decompensated cirrhosis (DC) (GH/IM mean 4.19; PM 4.00), referrals and goals-of-care (GOC) discussions were often delayed (GH/IM 4.25; PM 4.17). Primary physicians were viewed as mainly responsible for disease education, prognostic discussions and GOC conversations. PM physicians perceived lower patient (PM 2.50; GH/IM 3.31, p = 0.024) and family (PM 2.67; GH/IM 3.38, p = 0.027) receptiveness to PC than GH/IM physicians, with higher receptiveness associated with greater willingness to refer. Perceptions of psychosocial care responsibility differed, with each specialty attributing greater responsibility to the other (GH/IM 2.81 vs PM 4.00, p = 0.018; PM 2.33 vs GH/IM 3.50, p = 0.036). Key barriers differed; PM physicians reported greater concern about PC's perceived impact on primary physician–patient relationship (4.17 vs 2.38, p = 0.001), discomfort initiating PC discussions (4.59 vs 2.50, p = 0.001) and limited institutional support (3.83 vs 2.50, p = 0.003). All agreed that clear referral criteria, training primary physicians in prognostic discussions and increased awareness of PC among patients and medical colleagues facilitated referral.
Conclusion: Despite broad recognition of PC's role in DC, specialty-specific differences and barriers persist. Addressing clinician discomfort, clear referral criteria and clarifying the complementary roles of primary and specialist PC may facilitate earlier and more consistent integration. Findings will inform focus group discussions to develop context-specific strategies for timely PC referral.

WED-492
Phase angle as a predictor of mortality in patients with liver cirrhosis
Lenka Nosáková[1], Diana Vážanová[1], Jakub Hoferica[1], Eva Baranovičová[2], Katarína Dirnbachová[2], Peter Banovcin[1]. [1]*Department of Internal Medicine – Gastroenterology, University Hospital Martin, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia;* [2]*Martin Biomedical Centre – BioMed, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia*
E-mail: lenka.bubernakova@gmail.com

Background and aims: Conventional scoring systems used to assess survival in patients with liver cirrhosis are believed to have several limitations. The aim of our study was to assess the relationship between phase angle, the MELD-Na and CPT scoring systems, and mortality in patients with liver cirrhosis.
Method: From October 2022 to January 2024, we conducted a prospective observational study on patients with liver cirrhosis. The study's primary goal was to evaluate the relationship between body composition and patient survival. Body composition was measured using bioelectrical impedance analysis with the TANITA MC-780MA device, which provided us with phase angle (Pha) values. Patients were dichotomized into sarcopenic and non-sarcopenic groups based on Pha values. This cutoff point was determined using the "maximizing log-rank statistic" method. Patient survival was analyzed using the Cox regression model. Differences between variables were expressed as mean differences (MD). Correlations between variables were assessed using Spearman's correlation coefficient.
Results: We enrolled 41 patients with liver cirrhosis, 14 women (34.1%). The average age of patients with sarcopenia was 59.9 ± 8.38 years, while in the non-sarcopenic group it was 56.7 ± 10.5 years. Sarcopenic patients had an average phase angle that was 2.2 lower compared to non-sarcopenic patients (MD: 2.2; 95% CI: 0.679–3.37; p = 0.007). The average BMI was significantly lower in sarcopenic patients compared to non-sarcopenic patients (26.5 ± 4.36 vs. 29.8 ± 5.21 kg/m^2; p < 0.05). The average MELD-Na score was 14.88 ± 5.25 in the sarcopenic group and 14.75 ± 7.96 in the non-sarcopenic group, which was not a statistically significant difference. In our study, we observed a relationship between mortality and Pha value, where a 1-degree decrease in Pha was associated with a 10% increase in mortality during the follow-up period (HR 1.10; 95% CI: 0.95–1.26; p = 0.196). A significant difference in Pha values was observed between patients with CPT stage A and B cirrhosis. However, we did not observe a correlation between Pha and disease prognosis as expressed by MELD-Na score (rho = –0.054; p = 0.743).
Conclusion: Our results suggest a higher tendency toward mortality in liver cirrhosis patients with lower phase angle values. No association was observed between Pha and MELD-Na score. Further studies with larger patient samples are needed to confirm our findings.

WED-493
The safety of anticoagulant treatment in cirrhotic patients with portal vein thrombosis and severe thrombocytopenia
Irina Girleanu[1], Georgeta Oancea[1], Ioana Coruga[1], Cristina-Maria Muzîcă[1], Laura Huiban[1], Cojocariu Salloum[1], Ana-Maria Singeap[1], Sebastian Zenovia[1], Remus Stafie[1], Stefan Chiriac[1], Adrian Rotaru[1], Simona Juncu[1], Carol Stanciu[1], Anca Trifan[1]. [1]*Universitatea de Medicină și Farmacie 'Grigore T. Popa' Iași, Iași, Romania*
E-mail: gilda_iri25@yahoo.com

Background and aims: Portal vein thrombosis (PVT) is a frequent complication of liver cirrhosis. Although anticoagulation is recommended in selected patients, severe thrombocytopenia represents a relative contraindication. We aimed to assess the safety of anticoagulant treatment in cirrhotic patients with PVT and severe thrombocytopenia.
Method: We performed a prospective observational study including 121 cirrhotic patients treated with anticoagulation for non-malignant PVT. After the anticoagulant initiation, the patients were follow-up for 1 year. Severe thrombocytopenia was defined as a platelet count $<50 \times 10^9$/L.
Results: Severe thrombocytopenia was present in 25 patients (20.7%). Patients with severe thrombocytopenia had higher MELD-Na scores compared with those with platelet counts $\geq 50 \times 10^9$/L (median 19 vs.

15, p = 0.03). Most of the patients were diagnosed with partial PVT (70.3%). The majority of the patients received apixaban or rivaroxaban (81 patients, 66.9%), 33 patients (29.7%) were treated with enoxaparin, and only 4 patients (3.4%) received acenocoumarol. There were no differences regarding the type of anticoagulant treatment between the study groups. Hemorrhagic complications occurred in 28.0% of patients with severe thrombocytopenia and in 18.8% of those without (p = 0.40). Major bleeding events were uncommon and did not differ between groups (4.0% vs. 6.3%, p = 1.00). There was no difference in the mortality rates between the two study groups (8.0% vs. 18.8%, p = 0.24).
Conclusion: Anticoagulant therapy in cirrhotic patients with PVT appears safe even in the presence of severe thrombocytopenia, with low rates of major bleeding and no increase in mortality. These findings warrant confirmation in prospective studies.

E-mail: andrea.pasta@edu.unige.it

Background and aims: Socioeconomic determinants may influence the trajectory of cirrhosis beyond traditional clinical scores. This study aimed to evaluate the association between degrees of material deprivation (MD) and the demographic, etiological, and clinical characteristics of patients with newly diagnosed cirrhosis.
Method: In this prospective, multicenter study, patients with newly diagnosed cirrhosis were consecutively enrolled from 11 tertiary hepatology centers across Italy in 2024. MD was quantified across multiple domains and summarized as standardized z-scores. Demographic, etiological, and comorbidity profiles were compared between patients in the highest and lowest MD tertiles.
Results: A total of 1195 patients were included (mean age 64 ± 11.6 years; 73% male): 232 had ALD, 345 MASLD, 80 MetALD, 246 HCV infection, 159 HBV infection, 72 autoimmune liver disease, and 63 other etiologies. Patients with the highest MD were younger (60 ± 13 vs. 62 ± 10 years, p < 0.001) and more frequently female (25.4% vs. 17.9%, p < 0.001). Harmful alcohol consumption (40.8% vs. 20.6%, p < 0.001) and drug addiction (13.5% vs. 4.1%, p < 0.001) were more common among those with greater deprivation. Conversely, patients with the lowest MD exhibited more metabolic features, including higher BMI (28.4 vs. 26.5 kg/m^2, p = 0.033), arterial hypertension (51.8% vs. 41.5%, p = 0.009), and diabetes (44.1% vs. 33.1%, p = 0.162). ALD prevalence was higher among the most deprived (47.3% vs. 24.8%, p < 0.001), while MASLD was more frequent among the least deprived (53.8% vs. 33.1%, p < 0.001). No significant differences were observed for viral hepatitis (p = 0.590) or autoimmune liver disease (p = 0.762). Cluster analysis identified three distinct constellations: social disadvantage, metabolic dysfunction, and autoimmune/viral profiles.
Conclusion: This nationwide cohort delineates three phenotypic patterns of cirrhosis at diagnosis. Material deprivation is strongly linked to alcohol-related and behavioral risk factors, while metabolic and autoimmune/viral forms prevail in more advantaged contexts. Integrating social risk assessment into clinical stratification may improve targeted prevention and management strategies in cirrhosis.

WED-495-YI
Efficacy and safety of low-dose albumin infusion in patients of decompensated cirrhosis with acute kidney injury

Deep Patel[1], Aman Aggrawal[1], Ajay Kumar[1], Ashok Dalal[1], Siddharth Srivastava[1], Ujjwal Sonika[1], Sanjeev Sachdeva[1]. *[1]Govind Ballabh Pant Institute of Postgraduate Medical Education and Research, New Delhi, India*
E-mail: ajaykumar.aiims@gmail.com

Background and aims: Acute kidney injury (AKI) in patients with decompensated cirrhosis (DC), is managed with 20% Human Albumin infusion for initial 48 hours, however studies evaluating albumin infusion dose are limited. Also, human albumin infusion is associated with risk of volume overload, allergic reactions and is costly. This study evaluates the efficacy and safety of low-dose albumin (0.25–0.3 g/kg/d for 48 hours) in patients with DC and AKI stage IB or above.
Method: Patients with decompensated cirrhosis with AKI admitted in tertiary care centre from September 2022 to August 2025 screened and enrolled after excluding patients with Chronic kidney disease, Hepatocellular Carcinoma, respiratory or circulatory failure and on maintenance albumin therapy. The patients received intravenous 20% Human Albumin (100 ml) for 2 consecutive day, the response to albumin was defined as reduction of serum creatinine to within 0.3 mg/dl of the baseline value. The baseline demographic, clinical, biochemical data with response to albumin at 48 hours, adverse effects and mortality were noted.
Results: A total of 252 patients (n = 215 [83%] males, mean age 46.5 ± 11.3 years) were enrolled. Alcohol was the most common aetiology (62.6%), followed by hepatitis C (12.3%). The median MELD-Na was 28.46, and 182 patients (72.2%) were in Child–Pugh C. AKI resolution was noted in 116 (44.7%) patients, 59 patients (23.4%) after 24 hours and additional 57 patients (22.6%) after 48 hours of albumin infusion. Significant volume overload was seen in 2 patients (0.7%), mean duration of hospital stay was 7.98 ± 4.63 days. In hospital mortality was observed in 25.7% (n = 65).
Conclusion: The Low-dose albumin (0.25–0.3 g/kg/d for 48 hours) is safe and effective for volume repletion in decompensated cirrhosis patients with AKI.

WED-496

Myosteatosis is associated with a higher postoperative incidence of ACLF and mortality in patients with liver cirrhosis, independent of Child-Pugh and VOCAL-Penn scores

Felix Piecha[1], Mattis Kreutzer[2], Alexandra Linke[1], Nina Böhling[2], Alexander Isaak[2], Christoph Riedel[1], Maike Theis[2], Jörg C. Kalff[2], Torid Jacob[3], Juliana Goediker[3], Jonel Trebicka[3], Johannes Kluwe[1], Peter Huebener[1], Jürgen Rockstroh[2], Samuel Huber[1], Ansgar W. Lohse[1], Peter Bannas[1], Christian Strassburg[2], Alois Martin Sprinkart[2], Luetkens Julian[2], Michael Praktiknjo[3], Johannes Chang[2]. [1]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany;* [2]*University Hospital Bonn, Bonn, Germany;* [3]*University Hospital Münster, Münster, Germany*
E-mail: f.piecha@uke.de

Background and aims: Patients with liver cirrhosis are at an increased risk for postoperative morbidity and mortality. Surgical outcomes are determined by the severity of liver disease and the type of surgery. Sarcopenia, defined as the quantitative and qualitative loss of skeletal muscle mass, strength, and function, is common in cirrhosis patients and an independent risk factor for adverse outcomes. This study aimed to assess the impact of myosteatosis as a marker of qualitative muscle impairment on the development of postoperative acute-on-chronic liver failure (ACLF) and overall transplant-free survival in cirrhotic patients undergoing surgery.
Method: In this retrospective, bicentric analysis, consecutive patients undergoing elective procedures between 2010 and 2022 without ACLF at the time of surgery were included. A contrast-enhanced CT in the portal venous phase within three months prior was required. Myosteatosis was defined according to current guideline recommendations (<41 HU for BMI <25 kg/m^2; <33 HU for BMI ≥ 25 kg/m^2). Subpopulation analyses included stratification by Child-Pugh score and risk assessment according to the Veterans Outcomes and Costs Associated with Liver Disease (VOCAL) Penn score. The primary endpoint was ACLF development within 28 days after surgery, the secondary endpoint overall one-year transplant-free survival.
Results: A total of 223 patients were included. The majority was male (157/223, 70%) and had alcohol-related liver cirrhosis (103/223, 46%). At the time of surgery, most patients were classified as Child-Pugh B (106/223, 48%), with a median MELD score of 10 (IQR 8–13). The most common surgical procedures according to VOCAL-Penn categories were open abdominal procedures (122/223, 55%). Myosteatosis was present in 157/223 patients (70%). Postoperatively, 60/223 patients (27%) developed ACLF within 28 days, and 67/223 patients (30%) died within one year. Patients with myosteatosis had a higher incidence of postoperative ACLF (31% vs. 16%, p = 0.02) and one-year mortality (35% vs. 16%, p = 0.003). These associations remained significant across Child-Pugh stages and VOCAL-Penn risk strata.
Conclusion: Myosteatosis, as a marker of muscle impairment, is independently associated with an increased risk of postoperative ACLF development and increased one-year mortality — independently of the Child-Pugh stage and VOCAL-Penn risk assessment. These findings support the inclusion of myosteatosis in preoperative risk assessment for patients with liver cirrhosis.

WED-497

Periprocedural bleeding in patients with cirrhosis: a prospective study

Adonis Protopapas[1], Erofili Papathanasiou[1], Vaia Kyritsi[1], Alexandra Tsankof[1], Christos Savopoulos[1], Andreas Protopapas[1]. [1]*First Propaedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessalloniki, Greece*
E-mail: adoprot@hotmail.com

Background and aims: Patients with cirrhosis are often considered to have a high risk of periprocedural bleeding, even in low-risk procedures. The aim of this study was to prospectively assess bleeding episodes in patients with cirrhosis undergoing non-surgical procedures.
Method: All non-surgical procedures performed in patients with cirrhosis in our department between May and October 2025 were prospectively documented, along with patient characteristics. The procedures were categorized as low-, indeterminate-, or high-risk according to a recent international consensus.
Results: Seventy-four patients undergoing a total of 204 procedures were included. Of these procedures, 49.0% were performed in patients with hepatocellular carcinoma, and 83.8% in patients with decompensated cirrhosis. The patients had a median MELD-Na score of 17.5 [6–37.7] and a median Child-Pugh score of 8 [5–13]. Furthermore, median platelet and INR values were 122 [23–391] and 1.23 [0.89–4.4], respectively. The most frequently performed procedures were therapeutic paracentesis (36.3%), diagnostic paracentesis (20.6%), esophagogastroduodenoscopy (14.2%), endoscopic variceal ligation (6.9%), central venous catheter insertion (5.4%), and transjugular intrahepatic portosystemic shunt placement (4.4%). The majority of procedures were classified as low risk (79.8%), with only 2% being high risk. 20.3% of patients were under anticoagulation during the procedure. Minor bleeding occurred in 4.4% of procedures, with no cases of major bleeding. There was a correlation of minor bleeding cases with anticoagulation use (p = 0.018).
Conclusion: In this prospective cohort, periprocedural bleeding in patients with cirrhosis was infrequent and limited to minor events, supporting the safety of most non-surgical procedures in this population.

WED-498

Prevalence and prognostic impact of hyperferritinemia in advanced chronic liver disease

Clemens Renhardt[1,2,3], Georg Kramer[1,2,3], Christian Sebesta[1,2,3], Marlene Hintersteininger[1,2,3], Paul Thöne[1,2,3], Benedikt Hofer[1,2,3,4], Benedikt Simbrunner[1,2,3,4], Mathias Jachs[1,2,3], Lukas Hartl[1,2,3], Paula Hoefinger[1,2], Lorenz Balcar[1,2,3], Georg Semmler[1,2,3], Albert Friedrich Stättermayer[1,2], Michael Trauner[1,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3,4]. [1]*Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [2]*Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [3]*Clinical Research Group MOTION, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria;* [4]*Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria*
E-mail: n12028120@students.meduniwien.ac.at

Background and aims: Hyperferritinemia is commonly associated with Metabolic dysfunction–associated steatotic liver disease (MASLD) and linked to hepatic inflammation and fibrosis. We assessed serum ferritin levels in well-characterized patients with advanced chronic liver disease (ACLD) and investigated the prognostic value of hyperferritinemia.
Method: Our study included ACLD patients of the VICIS study (NCT03267615), undergoing hepatic venous pressure gradient (HVPG) measurement from 01/2017 to 08/2025. We assessed serum ferritin levels and laboratory values reflecting iron homeostasis, inflammation and metabolic dysfunction. Patients were followed until death or liver transplantation.
Results: 1181 ACLD patients were included: ALD: 53.1%; decompensated (dACLD): 64.5%; median values for age: 57 years; MELD-Na: 14 points; HVPG: 17 mmHg, and ferritin: 126 µg/L. Hyperferritinemia (≥400 µg/L) was present in n = 232 (19.6%) including n = 89 (38.4%) with extensively elevated Transferrin saturation (> 60%; p < 0.001) and n = 3 (0.3%) with genetic HFE variants. Ferritin levels did not significantly differ between compensated (cACLD) and dACLD (median 132 vs. 121 µg/L; p = 0.210). ALD patients (median: 171 µg/L; IQR: 345 µg/L) had higher Ferritin levels than MASLD patients (median: 71.2 µg/L; IQR 164 µg/L; p < 0.001) and other etiologies (median: 104 µg/L; IQR: 210 µg/L; p < 0.001).

Hyperferritinemia was associated with higher total (≥200 mg/dL; p = 0.005) and higher LDL (≥100 mg/dL; p < 0.001) cholesterol, and higher uric acid levels (≥7 mg/dL; p = 0.018). As expected for acute phase proteins, ferritin levels correlated with CRP (Spearman = 0.28; p < 0.001) and IL-6 (Spearman = 0.26; p < 0.001). Follow-up data was available in 841 patients (median follow-up: 26.7 months). Hyperferritinemia was associated with liver-related mortality (log-rank p = 0.002). In multivariate Cox proportionate hazard analysis, hyperferritinemia was not an independent predictor of liver-related death (aHR: 0.978, 95% CI: 0.656–1.456; p = 0.911) while age (aHR: 1.027, 95% CI: 1.012–1.041; p < 0.001), MELD-Na (aHR: 1.096, 95% CI: 1.061–1.133; p < 0.001), and HVPG (aHR: 1.043, 95% CI: 1.019–1.067; p < 0.001) remained as independent risk factors for mortality.
Conclusion: Hyperferritinemia is common in cirrhosis and mainly linked to dysmetabolism and inflammation. Hyperferritinemia was not an independent risk factor for liver-related mortality.

WED-499
Closing the coding gap: International classification of diseases (ICD)-10 code K76.82 for hepatic encephalopathy achieves rapid uptake in U.S. real-world practice

Dominique Thabut[1,2], Pierbruno Ricci[3], Berenice Alard[3], Maxime Anné[3], Athéna Crespin[3], Stephanie Ferreira[3], Yacine Hajji[3], Dean Hum[3], Jennifer Jara Vargas[3], Jeremy Magnanensi[3], Pejvack Motlagh[3], Katharina Staufer[3], Jasmohan Bajaj[4], Jennifer Lai[5], Florence Wong[6], Jacqueline O'Leary[7]. [1]*Department of Hepatogastroenterology, Hôpital Pitié Salpêtrière-Assistance Publique-Hôpitaux de Paris, Liver Intensive Care Unit, Paris, France;* [2]*Centre de recherche Saint-Antoine, Inserm, Sorbonne Université, Paris, France;* [3]*Genfit S.A., Loos, France;* [4]*Virginia Commonwealth University School of Medicine, Richmond, United States;* [5]*Department of Medicine, University of California, San Francisco, United States;* [6]*University of Toronto, Toronto, Canada;* [7]*University of Texas, Southwestern, Dallas, Dallas, United States*
E-mail: pierbruno.ricci@genfit.com

Background and aims: Hepatic encephalopathy (HE) is a frequent and major complication of cirrhosis. Its epidemiologic assessment in administrative databases has been limited by coding constraints. Before October 2022, ICD-10 lacked a specific HE code, requiring reliance on generic codes or medication proxies (lactulose, rifaximin). Evidence on the diagnostic performance and real-world uptake of the new HE-specific code K76.82 is scarce and limited to hospital cohorts. We aimed to evaluate K76.82 adoption in U.S. clinical practice using a large dataset and assess its impact on coding specificity, critical for reimbursement tracking, and evaluation of HE care pathways.
Method: We analyzed Komodo's Healthcare Map, a U.S. claims database, including adults with cirrhosis hospitalized for acute decompensation (ascites, variceal bleeding, HE) and/or bacterial infection between January 2021 and December 2024 (N = 2,121,419). Annual use of K76.82 ICD code was compared with K72.90, K72.91, R27.8, R40.2, and K72.90 plus lactulose or rifaximin. In total, 2,845,899 codes occurrences were considered and normalized to 100% per year. Yearly proportions reflect each strategy's share of HE-coded events among all combined strategies. A Cochran–Armitage trend test was applied to evaluate the statistical significance of changes in the proportion of HE-coded events across years.
Results: K76.82 adoption rose rapidly: 17.81% in 2022, 64.99% in 2023, and 66.49% in 2024. Conversely, K72.90 declined from 70.07% in 2022 to 28.59% in 2023, remaining stable in 2024 at 28.34%. Codes K72.91 and K72.90 with lactulose/rifaximin dropped sharply between 2022 and 2024 (from 4.62% to 0.75% and from 3.11% to 0.68%, respectively), while R27.8 and R40.2 remained stable at about 2% each. A Cochran–Armitage test confirmed a significant upward trend in K76.82 adoption (p < 0.0001).
Conclusion: Within two years of introduction, K76.82 achieved substantial adoption in HE coding-related U.S. practice, progressively replacing nonspecific codes used for HE in the past and medication-based proxies, thereby enhancing specificity for HE identification in administrative datasets. This improvement supports more accurate evaluation of care pathways and reimbursement monitoring. To our knowledge, this is the first large-scale analysis (> 2 million patients) demonstrating real-world utilization; similar assessments in European cohorts are warranted to confirm coding harmonization.

WED-500
Post trans-jugular intrahepatic portosystemic shunt development of hepatic encephalopathy is not changed by early prophylactic treatment and does not increase mortality

Anna Rozenfeld Hemed[1], Niv Zmora[1], Oren Shibolet[1], Liane Rabinowich[1]. [1]*Tel-Aviv Medical Center, Tel Aviv and Gray Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel*
E-mail: annaroz7@gmail.com

Background and aims: Background: Hepatic encephalopathy (HE) after transjugular intrahepatic portosystemic shunt (TIPS) affects 35–50% of patients. Use of prophylactic agents (Lactulose and Rifaximin) to prevent post-TIPS HE remains controversial and currently not recommended by professional guidelines. Aim: To assess real world practice and identify potential predictors for post-TIPS HE and benefit from post-TIPS prophylaxis.
Method: Retrospective cohort study of patients undergoing TIPS at the Tel-Aviv Medical Center (2016–2024). The primary outcome was HE, with secondary outcomes of liver transplantation (LT) and mortality.
Results: Seventy-one patients underwent TIPS, the median age was 64.5 years and 53% were male. Primary liver disease was metabolic-dysfunction-associated-steatohepatitis in 34%, viral (20%), and alcohol (22%). Indications for TIPS were variceal bleeding (53.5%) and refractory ascites (35%). Prior to the procedure 22% had has at least one episode of HE and 24% were treated with Lactulose and/or Rifaximin. At the time of the procedure, Child-Pugh class was A/B/C in 25%/62%/6%, with a median MELD-Na of 10. Following TIPS, 55% received prophylactic treatment (Lactulose, rifaximin, or both). HE developed in 62% (14% in-hospital, 55% within one year). Development of HE was not predicted by pre-or post-TIPS MELD-Na or Child-Pugh score, TIPS diameter and post-TIPS gradient, or post-procedure ammonia levels. Rates of HE also did not differ according to initial prophylaxis treatment (56% with treatment, 69% without, p = 0.28), however in both groups INR was related to risk for post-TIPS-HE (p = 0.01). Statin therapy was documented in 18% of patients. Post-TIPS HE occurred in 21% of statin-treated patients compared to 17% of those not receiving statins (p = 0.71), with no association between statin use and HE development. Overall mortality was 26% vrsus 19% among patients developing HE. Four patients underwent LT.
Conclusion: Early post-TIPS prophylactic was predominantly administered to patients previously treated for HE and did not reduce post-TIPS HE rates. Development of HE was not associated with increased mortality.

WED-501-YI
Comparison of the safety and efficacy of tailored versus fixed-dose albumin in cirrhosis with sepsis-associated acute kidney injury: a randomised controlled trial

Shreyas Sarvesh[1], Rakhi Maiwall[1], Ankit Bhardwaj[1], Satender Pal Singh[1], Rajan Vijayaraghavan[1], Chitranshu Vashitshtha[1], Ankur Jindal[1], Shalini Thapar[1], Dr. Prashant Mohan Agarwal[1], Mradul Daga[1], Deepak Tempe[1], Manoj Kumar[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
E-mail: rakhi_2011@yahoo.co.in

Background and aims: Sepsis-associated acute kidney injury (SA-AKI) in cirrhosis is marked by circulatory dysfunction and frequent cardiopulmonary complications. Fixed-dose albumin may cause more pulmonary complications. We compared a point-of-care

ultrasound (POCUS)–guided tailored albumin strategy with fixed-dose albumin in cirrhotic patients with SA-AKI.
Method: In this single-centre, open-label randomised controlled trial, adults with cirrhosis and SA-AKI with proven or suspected sepsis were randomised 1:1 to POCUS-guided tailored 25% albumin or fixed-dose albumin (1 g/kg/day). The primary outcome was AKI resolution at 48 hours without cardiopulmonary complications.
Results: A total of 100 patients were analysed (tailored, n = 50; fixed, n = 50). Baseline characteristics were comparable, including age, MELD-Na, SOFA score, lactate, and proven sepsis (86% vs 84%; p = 0.98). The majority had spontaneous bacterial peritonitis (58% vs 52%; p = 0.64), and nosocomial acquisition was seen in (30% vs 28%; p = 0.89). AKI resolution (complete/partial) at 48 hours without cardiopulmonary complications was significantly higher with tailored dosing (42% vs 14%; p = 0.03). By day 7, AKI recovery remained superior in the tailored group (78.0% vs 52%; p = 0.02). Cumulative albumin dose was significantly lower in the tailored arm at 48 hours (107.1 ± 35.5 g vs 147.0 ± 24.8 g; p < 0.001) and at day 7 (162.1 ± 77.5 g vs 228.4 ± 80.8 g; p < 0.001). Cardiopulmonary complications were markedly reduced with tailored dosing (22% vs 78%; p < 0.001). On multivariate analysis, POCUS-guided tailored strategy (OR = 4.81,0.94–24.62) lower SOFA score (OR = 0.53,0.30–0.95), andNT-proBNP (OR = 0.997,0.995–1.000, and lower urea (OR = 0.94,0.90–0.98), and Δchange in inferior vena cava diameter (OR = 0.34,0.16–0.73,) independently predicted AKI resolution. The patients who required oxygen support were lower in the tailored-dose group versus the fixed-dose group (22% vs 80%; p < 0.001). The time to initiation of vasopressor therapy was delayed in the tailored-dose group [80 h (78–86) vs 42 h (29–50); p < 0.001].
Conclusion: POCUS-guided tailored albumin therapy leads to early AKI resolution with a significantly lower incidence of cardiopulmonary complications, the need for dialysis, and a reduced cumulative albumin dose in cirrhosis with SA-AKI. Lower SOFA score and NT-proBNP, the delta change in vena cava diameter and lower urea independently predict AKI resolution in SA-AKI.

RAAS inhibitors reduces mortality in a real-world multicentre study of liver cirrhosis
N Apoorva Sasikumar[1], Margaret Teng[1,2], Cheng Han Ng[2,3,4], Vincent Chen[5], Jimmy Che-To Lai[6], Karn Wijarnpreecha[7], Rahul Kumar[8], Apichat Kaewdech[9], Masayuki Ueno[10], Anand Kulkarni[11], Ming-Hua Zheng[12], Akash Roy[13], Ken Liu[14,15], Chitchai Rattananukrom[16], Mazen Noureddin[17], Mohammad Shadab Siddiqui[18], Mark Muthiah[1,2,19], Hirokazu Takahashi[20]. *[1]Alexandra Hospital, Singapore, Singapore; [2]National University Hospital, Singapore, Singapore; [3]Kurume University School of Medicine, Kurume, Japan; [4]Graduate School of Medicine, Yokohama City University, Kanagawa, Japan; [5]University of Michigan Medical School, Michigan, United States; [6]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [7]University of Arizona College of Medicine Phoenix, Arizona, United States; [8]Changi General Hospital, Singapore, Singapore; [9]Prince of Songkla University, Songkhla, Thailand; [10]Kurashiki Central Hospital, Kurashiki, Japan; [11]Asian Institute of Gastroenterology, Hyderabad, India; [12]First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [13]Apollo Multispeciality Hospital, Kolkata, India; [14]Royal Prince Alfred Hospital, Sydney, Australia; [15]University of Sydney, Sydney, Australia; [16]Srinagarind Hospital, Khon Kaen University, Khon Kaen, Thailand; [17]Houston Methodist Hospital and Houston Research Institute, Texas, United States; [18]University of Virginia School of Medicine, Virginia, United States; [19]National University Centre for Organ Transplantation, National University Health System, Singapore, Singapore; [20]Saga University, Saga, Japan*
E-mail: tenglpm@gmail.com

Background and aims: Renin–angiotensin–aldosterone system inhibitors (RAASi), including angiotensin-converting enzyme inhibitors and angiotensin receptor blockers, are frequently prescribed in patients with cirrhosis for cardiometabolic comorbidities, yet their impact on liver-related outcomes remains uncertain. This study evaluated the association between RAASi use and risks of hepatic decompensation and all-cause mortality in a real-world multicentre cohort of patients with liver cirrhosis.
Method: We conducted an observational study of 1063 patients with cirrhosis, including 501 RAASi users and 562 non-users. RAASi users were older and had a higher burden of metabolic comorbidities and chronic kidney disease. Inverse probability of treatment weighting (IPTW) was applied to balance baseline characteristics. Subdistribution hazard ratios (SHRs) were estimated for hepatic decompensation and all-cause mortality, with stratified analyses by cirrhosis risk category and exploratory analyses by decompensation and mortality subtypes.
Results: After IPTW, covariate balance was achieved with minimal residual imbalance. RAASi use was not associated with a reduced risk of hepatic decompensation in the overall cohort (SHR 0.87, 95% CI 0.63–1.21) or across individual decompensation phenotypes, including ascites, variceal bleeding, hepatic encephalopathy, and spontaneous bacterial peritonitis. In contrast, RAASi use was associated with a significantly lower risk of all-cause mortality (SHR 0.54, 95% CI 0.34–0.88). This mortality benefit was most pronounced in patients with moderate-risk cirrhosis (SHR 0.43, 95% CI 0.21–0.90) and was not statistically significant in high-risk cirrhosis. No differential associations were observed for hepatic versus non-hepatic causes of death.
Conclusion: In this multicentre real-world cohort, RAAS inhibitor use was associated with reduced all-cause mortality without an increase in hepatic decompensation. These findings support the safety of RAASi in selected patients with cirrhosis and suggest a potential survival benefit, particularly at moderate disease severity.

WED-506
Influence of albumin treatment duration on outcome of terlipressin therapy in patients with hepatorenal syndrome – acute kidney injury
Eva Maria Schleicher[1], Christian Labenz[1], Frank Erhard Uschner[2], Julian Pohl[3], Moritz Passenberg[4], Michael Praktiknjo[2], Christoph Welsch[5], Henrik Karbannek[6], Nina Böhling[7], Karsten Große[8], Marlene Reincke[9], Benjamin Maasoumy[10], Paul Jamme[11], Julian Cardinal von Widdern[12], Marcus Mücke[5], Jonel Trebicka[2], Cornelius Engelmann[3], Jassin Rashidi-Alavijeh[4], Cristina Ripoll[6], Dominik Bettinger[9]. *[1]University Medical Center of the Johannes Gutenberg-University, Mainz, Germany; [2]Department of Internal Medicine B, University Hospital Münster, Münster, Germany; [3]Department of Hepatology and Gastroenterology, Charité-Universitätsmedizin Berlin, Berlin, Germany; [4]Department of Gastroenterology, Hepatology and Transplant Medicine, University of Duisburg-Essen, Essen, Germany; [5]Medical Clinic 1, University Hospital, Goethe-University Frankfurt, Frankfurt am Main, Germany; [6]Department of Internal Medicine IV, Jena University Hospital, Jena, Germany; [7]Department of Internal Medicine I, Bonn University Hospital, Bonn, Germany; [8]Department of Internal Medicine III, University Hospital RWTH Aachen, Aachen, Germany; [9]Department of Medicine II, Medical Center University of Freiburg, Freiburg, Germany; [10]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [11]Department of Internal Medicine II, LMU University Hospital Munich, München, Germany; [12]Department of Internal Medicine I, University Hospital Halle, Martin-Luther-University Halle-Wittenberg, Halle, Germany*
E-mail: eva.schleicher@unimedizin-mainz.de

Background and aims: Volume expansion with albumin is recommended to establish a diagnosis of hepatorenal syndrome–acute kidney injury (HRS-AKI). Determining the optimal duration of albumin administration involves a careful balance between

minimizing the risk of overtreatment and ensuring timely diagnosis and therapy, while acknowledging the potential, but uncertain, impact on prognosis. Therefore, this study aimed to compare the effects of different albumin treatment durations on terlipressin response and the prognosis of patients with HRS-AKI treated with terlipressin and albumin.

Method: This multicenter retrospective study recruited 490 patients with HRS-AKI treated with terlipressin at 12 German centers. 145 patients were available for further analysis. The cohort was dichotomized into patients treated with albumin before initiation of terlipressin for <24 hours and for 24–60 hours. Patients were followed for treatment response to terlipressin, death, hemodialysis (HD), or liver transplantation (LTX).

Results: Median MELD score of the cohort was 25 [IQR 21; 31]. Most patients were classified as Child-Pugh class C (55%) or B (45%). Chronic kidney disease (CKD) was reported in 32%. Acute-on-chronic liver failure (ACLF) was present in 67% of patients, and 26% had a history of HRS-AKI. At the time of AKI diagnosis, stage 1 AKI was observed in 41% of patients, stage 2 in 28%, and stage 3 in 31%. During follow-up, 59 patients (40.7%) reached a complete response to treatment with terlipressin, and 96 patients (66.2%) died or received a LTX. In a multivariable Fine and Gray analysis of predictors of any response to terlipressin therapy, albumin duration was not associated with a complete response to terlipressin (sHR 0.94; 95% CI 0.65–1.34; $p = 0.70$). In further multivariable models the influence of albumin treatment duration on the likelihood of achieving any response did not change (HR 1.01; 95% CI 0.69–1.47; $p = 0.95$). Of note, albumin treatment duration did not affect HD-/LTX-free survival, neither in univariable nor multivariable analyses.

Conclusion: This study provides real-world evidence to inform current clinical practice by demonstrating that albumin treatment duration (24 or 48 hours) had no significant impact on terlipressin treatment response. These results suggest that ensuring a sufficient duration of albumin therapy (48 hours) can prevent unnecessary terlipressin overtreatment and help optimize management protocols for HRS-AKI by aligning timely diagnosis with optimal treatment effectiveness.

WED-507

Dynamic spleen stiffness measurement as a prognostic tool in critically Ill patients with cirrhosis and ACLF

Elena von Maldeghem[1], Philipp Kalus[1], Sophia Rusch[1], Patricia Mester-Pavel[1], Vlad Pavel[1], Martina Müller-Schilling[1], Stephan Schmid[1]. [1]*Universitätsklinikum Regensburg, Regensburg, Germany*
E-mail: stephan.schmid@ukr.de

Background and aims: Non-invasive elastography techniques are well established for the assessment of liver fibrosis and portal hypertension. While liver stiffness measurement is routinely applied, spleen stiffness has emerged as a promising surrogate marker of portal hypertension. However, data on its feasibility and clinical relevance in the intensive care unit (ICU), particularly in patients with cirrhosis and acute-on-chronic liver failure (ACLF), remain scarce. This prospective study aimed to evaluate the feasibility of serial spleen stiffness measurements using acoustic radiation force impulse (ARFI) elastography in critically ill patients and to assess their association with clinical course and outcomes.

Method: A total of 44 ICU patients with chronic liver disease, with and without ACLF, were prospectively enrolled. Spleen stiffness was measured every 2–4 days using ARFI elastography. Clinical parameters including liver and renal function, ventilation settings, use of organ support therapies, and outcome data were recorded and analyzed.

Results: ARFI-based spleen stiffness measurement was feasible in all patients. Higher spleen stiffness values were significantly associated with the need for renal replacement therapy ($p < 0.001$) and invasive mechanical ventilation ($p < 0.001$). An inverse correlation was observed between ventilation pressures and spleen stiffness ($p = 0.017$), suggesting a potential mechanical influence on measurements. No significant associations were found with age, body mass index, or vasopressor requirement. Serial measurements revealed dynamic changes in spleen stiffness that paralleled the clinical course and evolution of organ dysfunction.

Conclusion: Serial ARFI-based spleen stiffness measurement is feasible and reliable in critically ill patients with cirrhosis in the ICU setting. Beyond reflecting portal hypertension, spleen stiffness values were associated with extrahepatic organ dysfunction and markers of organ failure. Spleen stiffness may therefore represent a non-invasive, bedside-available biomarker for dynamic risk stratification and clinical monitoring in patients with cirrhosis and ACLF.

WED-508

Systemic inflammation identifies patients with decompensated cirrhosis at high risk for further decompensating events

E-mail: christian.a.sebesta@meduniwien.ac.at

Background and aims: In decompensated cirrhosis (DC), hepatic dysfunction, portal hypertension (PH) and systemic inflammation (SI) may represent differential drivers of further decompensation (FD) and liver-related death (LRD). This study aimed to (i) validate our recently proposed SI biomarker C-reactive protein (CRP, ≥0.5 mg/dL) and interleukin-6 (IL-6, ≥14 pg/mL) cutoffs (Costa/Simbrunner et al; JHepatol 2021) in a temporal validation cohort and (ii) evaluate their prognostic significance beyond MELD and PH severity.

Method: Patients with DC had SI biomarkers, MELD and hepatic venous pressure gradient (HVPG) measured and were followed for FD events and LRD as key outcomes. Multivariable regression models were adjusted for MELD, HVPG and SI biomarkers. Stratifications for MELD ≥ 15 (liver transplant cut-off) and HVPG ≥ 16 mmHg (severe PH) were applied.

Results: 278 patients (median age: 56 years; 64% male, alcohol: 66%) with DC (ascites: 92%, encephalopathy: 29%; bleeding: 8%) and median MELD: 13 and median HVPG: 19 mmHg were included. The incidence of FD and LRD after 1 year (Y1) was 27.7% and 13.7%, while 6.5% underwent transplantation. In multivariable Cox models adjusted for MELD and HVPG, both CRP and IL-6 were independently associated with 90-day FD (aHR logCRP: 2.48, $p < 0.001$; aHR logIL-6: 1.48, $p = 0.004$) and Y1 FD (aHR logCRP: 2.30, $p < 0.001$; aHR logIL-6: 1.37, $p = 0.007$). In models for LRD additionally adjusted for age, CRP predicted 90-day LRD (aHR logCRP: 2.50, $p = 0.035$), whereas logIL-6 showed only a trend (aHR logIL-6: 1.63, $p = 0.054$). Neither biomarker was associated with Y1 LRD. In competing-risk analyses (competing events: transplantation and non–LRD), CRP ≥ 0.5 mg/dL and IL-6 ≥ 14 pg/mL were both associated with a higher cumulative incidence of FD ($p < 0.05$). DC patient stratification by CRP ≥ 0.5 mg/dL and IL-6 ≥ 14 pg/mL, consistently identified patients at particularly high risk of

FD across MELD (≥15 vs. <15) and HVPG (≥16 vs <16 mmHg) risk groups.
Conclusion: In patients with DC, the SI biomarkers CRP and IL-6 predict the risk of FD events independently of hepatic dysfunction (MELD) and PH severity (HVPG). SI biomarkers may therefore be valuable for clinical risk stratification and for enriching DC trials with patients at high short-term risk for decompensating events.

WED-509-YI
Impact of jaundice on outcomes in patients with cirrhosis and ascites and implications for the definition of further decompensation
Lorenz Balcar[1,2], Markus Maagaard[3,4], Enrico Pompili[5,6], Valeria Santori[7], Lucie Simonis[1,2], Roberta Gagliardi[7], Jan Embacher[1,2], Mads Israelsen[3,4], Adrian Wunderbaldinger[1,2], Antonio Accetta[7], Christian Sebesta[1,2], Mattias Mandorfer[1,2], Michael Trauner[1], Paolo Angeli[7], Aleksander Krag[3,4], Thomas Reiberger[1,2], Paolo Caraceni[5,6], Salvatore Piano[7], Georg Semmler[1,2,3,4], Marta Tonon[7], Nikolaj Torp[3,4]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; [3]Centre for Liver Research (FLASH), Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [4]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark; [5]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [6]Unit of Semeiotics, Liver and Alcohol-Related Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [7]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine (DIMED), University of Padova, Padova, Italy*
E-mail: georg.semmler@meduniwien.ac.at

Background and aims: The role of jaundice in the natural history of cirrhosis is controversially discussed. Hence, the aim of this study was to evaluate the prognostic information derived from jaundice in patients with cirrhosis and ascites as single first decompensation.
Method: Retrospective cohort study including 875 patients with cirrhosis and ascites from four European tertiary centres followed from first hepatic decompensation with ascites (baseline). Time-dependent analyses were performed to evaluate the role of jaundice according to different bilirubin cut-offs (≥3/6/12 mg/dL) for liver-related mortality next to further decompensation as defined by Baveno VII.
Results: The median age was 57 years, the primary aetiology was alcohol-related liver disease (55%), 51% had grade 3 ascites and median MELD score was 14 at first hepatic decompensation. Bilirubin ≥ 3 mg/dL was present in 35% and ≥6 mg/dL in 10%, respectively. Patients were followed for a median of 3.9 years. The cumulative incidence of jaundicedefined by bilirubin ≥ 3 mg/dL at 1 year was 47%, 20% of ≥6 mg/dL, and 6.1% of ≥12 mg/dL, with ≥3 mg/dL yielding the best discrimination regarding liver-related mortality and being further investigated. Jaundice was an independent predictor of liver-related mortality in univariable and multivariable Cox regression analyses adjusting for age, sex, ascites grade, MELD, albumin and aetiological cure, but its consideration as further decompensation event worsened discrimination as compared to further decompensation without jaundice alone (C-statistics: 0.814 vs. 0.767, $p < 0.001$). Specifically, Simon-Makuch estimates for liver-related mortality were 23% vs. 6.6% in those with and without jaundice at 1 year, 43% vs. 4.0% in those with and without further decompensation, and 23% vs. 2.7% in those with the combined endpoint further decompensation and/or jaundice.
Conclusion: Jaundice is frequently co-occurring with ascites as first hepatic decompensation, and is associated with liver-related mortality. However, implementation of jaundice into the definition of further decompensation did not improve prognostication. This suggests that these two events should rather be handled separately than lumped together.

WED-510
Differentiation of minimal and grade 1 hepatic encephalopathy using neurophysiological, neuropsychological, magnetic resonance spectroscopic, and systemic inflammatory parameters
Barjesh Sharma[1,2,2], Lalit Kummetha[1], Shrey Bhatt[1], Venkatesh Sudharsan[1], Siddharth Srivastava[1], Kalpana Bansal[1], Bhawna Mahajan[1], Neera Chaudhry[1], Monica Tandon[1], Sanjeev Sachdeva[1], Ajay Kumar[1], Ashok Dalal[1], Ujjwal Sonika[1]. *[1]Govind Ballabh Pant Institute of Postgraduate Medical Education and Research (G.I.P.M.E.R), Gastroenterology, New Delhi, India; [2]Govind Ballabh Pant Hospital, Gastroenterology, New Delhi, India*
E-mail: barjeshchandersharma@gmail.com

Background and aims: Hepatic encephalopathy (HE) is traditionally classified into overt and minimal HE (MHE). The International Society for Hepatic Encephalopathy and Nitrogen Metabolism clubbed MHE and grade 1 HE in "covert" HE. However, these appear as distinct entities. This study aimed to compare inflammatory markers, magnetic resonance spectroscopy (MRS), Bispectral Index (BIS), spectral electroencephalography (EEG) parameters, and the natural history of MHE and grade 1 HE.
Method: In this prospective study, 150 cirrhotics were categorised into three groups: no HE (n = 50), MHE (n = 50), and grade 1 HE (n = 50). Patients were assessed using West Haven criteria grading, the psychometric hepatic encephalopathy score (PHES), critical flicker frequency (CFF), MRS, analysis of inflammatory markers (cytokines, endotoxin), Bispectral index (BIS), and spectral EEG. All patients were followed for HE progression, complications, hospitalisations, and mortality over 12 months.
Results: Patients with grade 1 HE showed significantly higher levels of ammonia (164.08 ± 30.12 vs 123.42 ± 19.97), endotoxins (0.60 ± 0.05 vs 0.47 ± 0.04) and cytokines compared to MHE. MRS revealed reduced myoinositol/choline ratios and elevated glutamine in HE groups. BIS and EEG metrics effectively distinguished MHE from grade 1 HE with high diagnostic accuracy. Model for End-Stage Liver Disease (MELD), IL-12, BIS, and EEG changes were independent predictors of survival.
Conclusion: MHE and grade 1 HE exhibit distinct inflammatory, neuropsychological, and neurophysiological profiles, as well as differences in survival. Incorporating multimodal biomarkers (CFF, MRS, BIS, EEG, and cytokines) facilitates early differentiation and risk stratification between MHE and grade 1 HE. These findings show that MHE and grade 1 HE are distinct entities.

WED-511
Burden and predictors of fatigue among patients with chronic liver disease
Ankita Singh[1], Akash Shukla[1], Gaurav Lodha[1]. *[1]Seth G S Medical College, Mumbai, India*
E-mail: drakashshukla@yahoo.com

Background and aims: Fatigue impairs health-related quality of life in chronic liver disease and is driven by both central and peripheral components, which should be evaluated in combination to enable a more accurate assessment of its overall burden. In this study, we aim to study the prevalence of fatigue in different etiologies and their predictors.
Method: Single-centre, cross-sectional study of patients with compensated advanced chronic liver disease (CACLD) and decompensated cirrhosis. FACIT-F (functional assessment of chronic illness therapy – fatigue scale), CES-D (centre for epidemiologic studies depression scale) and LFI (Liver frailty index) were used for comprehensive assessment of fatigue in the study population. Fatigue severity based on FACIT-F scores was categorized as mild (30–39), moderate (20–29), and severe (<20). CES-D scores >16 was considered to be associated with depressive features.

Results: A total of 100 patients were included in the study. The median age was 48 years (IQR 39–55), and 73 were men. Alcohol-related liver disease was the most common etiology (31%), followed by metabolic dysfunction–associated steatotic liver disease (MASLD) (19%) and hepatitis B (13%). 17 patients had cACLD, 69 were CTP-B and 14 were CTP C cirrhosis. The median FACIT-F score was 36 (IQR 25–42). Mean handgrip strength was 21 ± 6 kg, and mean LFI score was 4.3 ± 0.43. Overall, 62 patients reported fatigue, categorized as mild, moderate, and severe in 27 (43.5%), 22 (35.5%), and 13 (21%) of patients, respectively. Median CES-D score was 11 (IQR 4–23) and depressive features were observed in 42% of patients. Prevalence of fatigue was comparable between patients with CACLD and decompensated cirrhosis (64.7% vs 61.4%, p = 0.801). The presence of fatigue correlated with higher CES-D (p = 0.009) & LFI scores (p < 0.001); and with etiology [MASLD (15/19, 78.9%) and HCV (4/5, 80%) vs alcohol (54.8%), HBV (38.46%) and other etiologies].
Conclusion: Fatigue affects approximately two-thirds of patients with advanced chronic liver disease, and correlates with depressive features and etiology (MASLD and HCV) rather than decompensation.

WED-512-YI
Safety and outcomes of glp-1 receptor agonists in patients with cirrhosis: a meld-matched real-world cohort study
Abdullah Sohail[1], Zhexiang He[1], Sara Naimimohasses[1], Antonio Sanchez[1]. [1]*The University of Iowa, Iowa City, United States*
E-mail: antonio-sanchez@uiowa.edu

Background and aims: The safety of glucagon-like peptide-1 receptor agonists (GLP-1 RA) in cirrhosis is uncertain because these agents may alter gastrointestinal motility, biliary physiology, and metabolic parameters relevant to hepatic function. Prior studies have been limited by small sample sizes and inadequate adjustment for liver disease severity. Using a large, multicenter, real-world dataset, we evaluated the safety of GLP-1 RAs in patients with cirrhosis.
Method: Adults with cirrhosis were identified in the TriNetX Research Network and stratified into GLP-1 RA users and non-users. Patients with a history of liver transplantation, hepatocellular carcinoma, or pregnancy were excluded. Propensity score matching (1:1) generated two balanced cohorts of 28,091 patients each, matched on demographics, comorbidities, and MELD-related laboratory parameters (bilirubin, INR, creatinine, and sodium), yielding equivalent baseline liver disease severity. Outcomes at 90, 180, and 365 days included all-cause mortality, ascites, hepatic encephalopathy, spontaneous bacterial peritonitis (SBP), esophageal variceal bleeding, sepsis, pancreatitis, gastroparesis, and gallbladder disease.
Results: At 90 days, mortality was significantly lower in GLP-1 RA users (4.0%) than in non-users (8.4%) (risk difference −4.4%, 95% CI −4.8 to −4.0; p < 0.001). At 180 days, SBP occurred in 0.7% of GLP-1 RA users versus 1.6% of non-users (risk difference −0.9%, 95% CI −1.1 to −0.8; p < 0.001), while variceal bleeding rates were similar (1.5% vs 1.6%; p = 0.515). At 1 year, mortality remained significantly lower among GLP-1 RA users (7.3%) than non-users (13.7%) (risk difference −6.4%, 95% CI −6.9 to −5.9; p < 0.001), with corresponding survival probabilities of 91.6% and 83.6%. Across all time points, GLP-1 RA use was not associated with increased risk of hepatic decompensation, infectious complications, pancreatitis, gastroparesis, or gallbladder disease; hazard ratios consistently favored GLP-1 RA users, including an HR of 0.39 for SBP at 180 days (95% CI 0.33–0.46).
Conclusion: In this large matched real-world cohort of patients with cirrhosis with MELD-aligned baseline liver disease severity, GLP-1 RA exposure was not associated with excess hepatic or gastrointestinal complications. It was associated with significantly lower short- and intermediate-term mortality and reduced SBP incidence. These data support the safety of GLP-1 RAs in appropriately selected patients with cirrhosis and highlight the need for prospective validation.

WED-513
Outpatient albumin infusions reduce paracentesis without increasing costs in cirrhosis: a national real-world cost-comparison study

E-mail: siddharth.sood1@nh.org.au

Background and aims: Refractory ascites reduces quality of life and drives high healthcare costs. Long-term human albumin therapy (HA) shows benefits in select groups, but real-world effectiveness remains unclear, limiting widespread adoption beyond a few countries. We evaluated healthcare utilisation and costs of HA compared to a historical cohort in Australia - the largest real-world analysis of HA outside Italy.
Method: A retrospective real-world healthcare cost-comparison study was conducted across 11 Australian centres through the Gastroenterology Society of Australia Liver Faculty Clinical Research Network comparing patients starting HA with a historical cohort. Exclusions: TIPPS, transplant, or PVT. Costs were based on predetermined estimates: A$357.55 for a medical day unit infusion, A $68.50 per 20 g albumin, A$1230 for outpatient abdominal or pleural paracentesis, and A$2195/night for inpatient admissions or ED presentation. Patients were censored at transplant, death, or 6 months follow-up. Appropriate statistical tests were applied to compare groups.
Results: We analysed 134 HA patients and 140 controls. Both groups were matched for age (p = 0.61), gender (p = 0.15), and MELD-Na (median 19.0 HA v 17.8 controls, p = 0.07). HA patients received 2298 infusions (avg 40 g/session). Ascites severity improved in more patients receiving HA (57.1%) than controls (26.7%) (RR 2.14, p < 0.0001) with a correlating reduction in paracentesis: 405 paracentesis in HA (median 0 per 100 patient days (100ptd) [IQR 0–1.7] vs 763 paracentesis in controls (2.7/100ptd [IQR 1.1–4.4]) p < 0.0001. Over 6 months there was no differences between groups with relation to admissions (188 vs 223, p = 0.27) nor length of stay (2.19 vs 2.72 days/100ptd, p = 0.15). Mortality did not differ (22/134 (16.4%) v 33/140 (23.6%)), although Kaplan-Meier curves appeared to diverge at 6 months (p = 0.67). More liver transplants occurred in the HA group (8, 5.97%) compared to controls (2, 1.43%), p = 0.045. Total healthcare costs for the HA group were A$4,643,788, compared to A $5,761,856 over 6 months. The median cost per patient/100ptd was A $12,627 (IQR 7459–28,369) for HA group and A$12,966 (IQR 5127–33,389) for controls, p = 0.72.
Conclusion: In a real-world Australian setting, HA did not increase healthcare costs. Importantly, patients receiving HA required significantly fewer paracentesis. Depending on local healthcare systems, HA

appears to offer a cost-neutral approach to improving care for patients with cirrhosis.

WED-514

Half-dose albumin for the prevention of post-paracentesis circulatory dysfunction (PPCD) in cirrhotic patients with acute decompensation undergoing paracentesis <5 liters: a randomized controlled trial

Pongnarin Nawalerspunya[1], Witchayaporn Praguylertluk[1], Suppana Chuensakul[2], Thanaput Kunlayawutipong[3], Suraphon Assawasuwannakit[4], Siwanon Nawalerspanya[5], Apichat Kaewdech[1], Naichaya Chamroonkul[1], Phunchai Charatcharoenwitthaya[6], Pimsiri Sripongpun[1]. *[1]Prince of Songkla University, Division of Internal Medicine, Faculty of Medicine, Hat Yai, Thailand; [2]Naresuan University Hospital, Amphoe Mueang Phitsanulok, Thailand; [3]Chiang Mai University, Amphoe Mueang Chiang Mai, Thailand; [4]Panyananthaphikkhu Chonprathan Medical Center Srinakharinwirot University, Amphoe Pak Kret, Thailand; [5]Paholpolpayuhasena Hospital, Amphoe Mueang Kanchanaburi, Thailand; [6]Siriraj Hospital Mahidol University, Bangkok, Thailand*
E-mail: pim072@hotmail.com

Background and aims: Albumin replacement (8 g/L) is suggested for large-volume paracentesis (>5 L) to prevent post-paracentesis circulatory dysfunction (PPCD), but not for modest-volume paracentesis (MVP; <5 L) in ambulatory settings, according to standard clinical guidelines. Nonetheless, patients with acute decompensation (AD) are more hemodynamically vulnerable. A prior study suggested that without albumin, patients with acute-on-chronic liver failure undergoing MVP experience PPCD rates of up to 70%, a risk significantly lowered by standard-dose albumin administration (8 g/L). Data regarding PPCD in AD settings are limited. Given the substantial cost of standard therapy and pilot data suggesting the non-inferiority of half-dose (4 g/L) in ambulatory settings, we aimed to determine whether half-dose albumin is effective in preventing PPCD in patients with AD undergoing MVP.
Method: This is a preliminery analysis of a multicenter, randomized, open-label, controlled trial. We included hospitalized patients with AD undergoing MVP. Patients with BCLC-D hepatocellular carcinoma, disseminated intravascular coagulation, and serum creatinine >1.5 mg/dL were key exclusion criteria. Eligible patients were randomized to receive either albumin replacement 4 g/L of ascites removed (ALB group) or no albumin replacement (Control group). The primary endpoint was PPCD, defined as a >50% increase in plasma renin activity on day 6 above baseline. Secondary outcomes included PPCD-related complications, in-hospital mortality, and 28-day mortality.
Results: Of 89 screened patients from 5 centers, 22 were eligible for analysis (ALB group: n = 9; Control group: n = 15). The cohort was 81.8% male with a mean age of 60.4 ± 11 years, baseline BMI of 25.2 ± 5.5 kg/m^2, and baseline serum albumin level of 2.7 ± 0.6 g/dL. The predominant etiology of cirrhosis was alcohol-related (50%). PPCD incidence was 44.4% in the ALB group vs 58.3% in the control group (p = 0.67). Acute kidney injury (AKI) within 6 days occurred in 11.1% vs 7.7% (p = 1.0), in-hospital mortality was 11.1% vs 15.4% (p = 1.0) in the ALB and control groups, respectively, and 28-day mortality was not significantly different between the two groups.
Conclusion: MVP increases the risk of PPCD in cirrhotic patients with AD. In this preliminary study, half-dose albumin replacement did not reduce the incidence of PPCD, AKI, in-hospital mortality, or 28-day mortality. The lower albumin dose may explain the difference in findings compared to earlier study.

WED-515

Early mortality prediction in cirrhotic patients presenting to the emergency department: the CIRR-SOS score

Leonardo Stella[1,2], Giuseppe Marrone[1], Luca Miele[1,3], Marco Biolato[1], Antonio Liguori[1,3], Antonio Gasbarrini[1,3], Francesco Franceschi[1,3], Francesca Romana Ponziani[1,3], Marcello Covino[1,3]. *[1]IRCCS Fondazione Policlinico A. Gemelli, Rome, Italy; [2]Link Campus University, Rome, Italy; [3]Università Cattolica del Sacro Cuore, Roma, Rome, Italy*
E-mail: leonardo.dr.stella@gmail.com

Background and aims: Patients with cirrhosis frequently present to the emergency department (ED) and are at high risk of early death. Existing prognostic scores are unreliable. We developed a pragmatic early-mortality score (the CIRRhotic patients Rapid Short-term Outcome Score, CIRR-SOS) for adults with cirrhosis presenting to the ED, and compared its performance with established prognostic systems.
Method: We performed a retrospective cohort study of consecutive adults with known cirrhosis presenting to the ED of a tertiary referral center between 2015 and 2024. 4.401 patients were included (28-day mortality 7.3%, 320 deaths). Candidate predictors were derived from vital signs, laboratory tests, and comorbidity burden (Charlson Comorbidity Index, CCI). Stepwise AUC-maximizing logistic regression with collinearity control was used to derive CIRR-SOS. Internal validation used five-fold stratified cross-validation under classic refit and fixed-score schemes, bootstrap resampling, and assessment of discrimination (AUC), calibration (Brier score, calibration plots), reclassification (continuous NRI), and clinical utility (decision curve analysis). CIRR-SOS was compared with other prognostic scores. Survival and risk trajectories were evaluated across CIRR-SOS tertiles using Kaplan–Meier and cumulative incidence analyses, and phenotypic clusters were explored via multidomain radar and chord plots.
Results: The ten independent predictors included in the CIRR-SOS were bilirubin, INR, creatinine, white blood cell count, hemoglobin, oxygen saturation, arterial pressure range, respiratory rate, and comorbidity burden. The apparent AUC for 28-day mortality was 0.701 (95% CI 0.676–0.723), with a Brier score of 0.072 and good calibration. Both probability-based and point-based CIRR-SOS models achieved AUC 0.701, outperforming MELD, MELD-Na, CLIF-C AD, mSOFA, qSOFA, and CCI (all DeLong p < 0.02), and showed uniformly positive continuous NRI (Net Reclassification Improvement) versus all comparators. Cross-validation and bootstrap analyses confirmed stable performance (mean AUC ~ 0.70) with consistent retention of core predictors. CIRR-SOS tertiles defined low-, intermediate-, and high-risk groups with 28-day mortalities of 9.1%, 18.8%, and 28.6%, respectively, with early separation of the high-risk group and later divergence between intermediate and low risk.
Conclusion: CIRR-SOS can be a simple, ED-focused, and clinically interpretable tool for early mortality risk stratification in adults with cirrhosis.

WED-516

A combination of normal inflammation parameters does not rule out infection in patients with acute decompensation

Marija Stojiljkovic[1], Stefanie Quickert[2], Vanessa Trentzsch[2], Philipp Reuken[2], Andreas Stallmach[2], Alexander Zipprich[2], Cristina Ripoll[2]. *[1]Jena University Hospital, Department of Internal Medicine IV (Gastroenterology, Hepatology, Infectious Diseases and Central Endoscopy), Jena, Germany; [2]Jena University Hospital, Jena, Germany*
E-mail: vanessa.trentzsch@med.uni-jena.de

Background and aims: Acute decompensation (AD) in cirrhosis is frequently precipitated by infections. Work-up to rule out infections may be resource and time consuming. C reactive protein alone is not useful to rule out infection, since this may be normal in cirrhosis despite infection. Nevertheless, in clinical practice decisions are based on a combination of parameters including both clinical signs and several lab tests. The aim of this study was to evaluate whether

the combination of biochemical inflammatory parameters can be used to rule out infection in patients with AD.
Method: Retrospective monocentric study including all patients with cirrhosis and AD and confirmed infections were included. Patients with increase in 1, 2 or 3 inflammatory parameters [CRP (c-reactive protein), leucocytes and PCT (procalcitonin)]. Variables are reported as n (percent), or median (IQR) according to distribution.
Results: A total of 123 patients (Child Pugh A 16 (13%), B 49 (39.8%), C 58 (47.2%), MELD 19 (14–25), median age 63 (52–71) years, male 77 (63%) with mainly alcohol related liver disease 74 (61%) were included. Infections included pneumonia in 23, UTI (urinary tract infections) in 42, bacteremia in 22, cholangitis in 1, SBP (spontaneous bacterial peritonitis) 12, combination in 23. Only 25/122 (21%) had fever (≥37.8°C). Median CRP, PCT and leucocytes was (41.8 (20.9–67.4) mg/dL, 0.58 (0.22–1.18) ng/ml, 8.8 (6.2–14) 10^3/mL, respectively. Notably, 8 patients (6,5%) had completely normal inflammatory parameters. None of these patients had fever, one patient had left shifting (84%) and one patient had leucopenia. From the other patients 29.3, 34.1 and 30.1% of patients had 1, 2 or 3 high serum inflammatory parameters. Isolated CRP was the only inflammatory parameter in all patients who had only one inflammatory parameter, albeit in 3 patients this increase was only mild (≤10 mg/dL). If slight abnormal levels CRP (<10 mg/dL) and leucocytes (<15.000) are disregarded, than up to 11% (n = 13) of infections would be overseen.
Conclusion: Bacterial infections occur in 6.5% of patients despite normal inflammatory markers, and must thoroughly excluded even when laboratory values are unremarkable.

WED-517
Prognostic value of morphological imaging features in liver cirrhosis: a cohort study
Signe Swerkersson[1,2,3], Wolf Bartholomä[1,2,4], Olof Dahlqvist Leinhard[1,2,5], Mikael Forsgren[1,2,5], Henrik Stjernman[6], Daniel Sjögren[1,7], Patrik Nasr[1,2,8], Markus Holmberg[1], Peter Lundberg[1,2,4], Martin Rejler[6,9], Nils Dahlström[1,2,4], Stergios Kechagias[1], Mattias Ekstedt[1,2]. *[1]Department of health, medicine and caring sciences, Linköping university, Linköping, Sweden; [2]Center for medical image science and visualization (CMIV), Linköping university, Linköping, Sweden; [3]Clinical department of radiology, Capio St Göran hospital, Stockholm, Sweden; [4]Clinical department of radiology in Linköping, Region Östergötland, Linköping, Sweden; [5]AMRA Medical AB, Linköping, Sweden; [6]Department of internal medicine, Ryhov hospital, Region Jönköping County Council, Jönköping, Sweden; [7]Department of medicine, Eksjö Hospital, Region Jönköping County Council, Eksjö, Sweden; [8]Wallenberg center for molecular medicine (WCMM), Linköping university, Linköping, Sweden; [9]The Jönköping academy for improvement of health and welfare, Hälsohögskolan, Jönköping university, Jönköping, Sweden*
E-mail: signe.swerkersson@liu.se

Background and aims: Current guidelines prioritize liver stiffness measurement for diagnosing and monitoring cirrhosis, while imaging is considered supportive. Nevertheless, Magnetic Resonance Imaging (MRI), Computed Tomography (CT), and ultrasound remain widely used. Certain MRI features—such as surface nodularity and portosystemic collaterals—may indicate disease progression and risk of decompensation, yet their prognostic value and reproducibility are poorly defined. We aimed to determine whether morphological MRI features predict decompensation and to measure interreader agreement of the assessments.
Method: In a prospective, multicenter cohort study 150 patients with liver cirrhosis underwent hepatocellular carcinoma surveillance with abbreviated MRI. Baseline T1-weighted dynamic contrast MRIs were independently scored by two radiologists using a 5-point cirrhosis impression score based on anatomical features of chronic liver disease and portal hypertension (1 = none, 2 = subtle, 3 = moderate, 4 = evident, and 5 = severe changes). Patients were categorized into two groups: none–moderate changes versus evident–severe changes. Interreader agreement was evaluated with Cohen's kappa. Decompensation events during 2-year follow-up were compared between groups using Fisher's exact test ($p < 0.05$ considered significant).
Results: Of 131 evaluated patients (mean age 64 ± 11 years; 43% women), 31% had prior decompensation, but 90% were Child-Pugh A at baseline. Steatotic liver disease was predominant (72%), with 43% alcohol-related liver disease. Imaging grades were none (7%), subtle (16%), moderate (27%), evident (36%), and severe (13%). Nine patients (7%) developed decompensation (ascites, encephalopathy, and/or variceal bleeding) within a median of 220 days. All events occurred in the evident–severe group (9/60; 15%), none in the none–moderate group (0/71; $p < 0.001$). Sensitivity and negative predictive value were 100%, whereas specificity was 58% and positive predictive value 15%. Interreader agreement was moderate-substantial (kappa = 0.59).
Conclusion: Morphological MRI features are strongly associated with the risk of decompensation in cirrhosis and demonstrate good reproducibility between readers. These findings validate the clinical relevance of imaging-based stratification and suggest that morphological assessment may complement current monitoring strategies.

WED-521
Oral anticoagulant use and clinical outcomes in patients with cirrhosis: a United States national cohort study
Tomohiro Tanaka[1], Andrea Holcombe[2], Gosia Clore[2], Mingyue Sun[3], Alexandra Bixby[4], Jennifer Lai[5], David Axelrod[4]. *[1]University of Iowa Carver College of Medicine, Iowa City, United States; [2]Center for Access & Delivery Research and Evaluation (CADRE), Iowa City VA Health Care System, Iowa City, United States; [3]University of Iowa Health Care, Iowa City, United States; [4]University Hospitals - Cleveland Medical Center, Cleveland, United States; [5]University of California San Francisco, San Francisco, United States*
E-mail: tomohiro-tanaka@uiowa.edu

Background and aims: While the long term oral anticoagulation (OAC) in patients with cirrhosis has shifted from coumadin to direct oral anticoagulants (DOACs) based on ease of use and patient preference, the impact of this shift on patient mortality and access to liver transplantation (LT) has not been well characterized in a contemporary data set.
Method: We used Epic Cosmos, a vendor-facilitated patient-level electronic health record aggregation that includes longitudinal diagnoses, procesures, laboratory results, and prescription-dispensation records across participating health systems in the United States. We assessed the rate of morality and gastrointestinal bleeding (GIB) in adults with cirrhosis who were initiated DOACs with with patients placed on warfarin between January 2019 to November 2024. Four distinct propensity score (PS) matched cohorts were developed based on indication for OAC: all-indications, Atrial fibrillation (AF), venous thromboembolism (DVT/PE), and portal vein thrombosis (PVT). Mortality risk was calculated using Fine-Gray models with LT as a competing risk, and gastrointestinal bleeding (GIB) risk was assessed with death and LT as competing risks.
Results: Among 93,663 OAC initiators in the cohort, DOAC use increased from 74% in 2019 to more than 95% in 2024 (P <0.001). Among all patients, DOACs use was associated with higher risk of mortality (Subdistribution hazard ratio [sHR] 1.14, 95% CI 1.06–1.20) and GIB (sHR 1.16, 95% CI 1.04–1.28). In contrast, among patients with AF, DOACs did not increase either mortality or GIB (sHR 0.99, 95% CI 0.87–1.11 and sHR 1.19, 0.93–1.52, respectively). In the DVT/PE and PVT cohorts, DOACs were associated with a higher risk of mortality (sHR 1.22, 95% CI 1.10–1.33 and sHR 1.45, 95% CI 1.25–1.67, respectively), but not with GIB; DOAC users were less likely to undergo liver transplantation than warfarin users (Gray's test, p <0.001). Findings were consistent between the primary Fine-Gray models and supplemental Cox proportional hazard models, as well as across per-protocol marginal structural models and sensitivity analyses.

Conclusion: Among patients with cirrhosis who require oral anticoagulants for PE/DVT or PVT, DOAC use was associated with higher mortality and a lower likelihood of LT than warfarin. No differences were noted in the cohort with AF. This mortality differential highlights the need to better understand underlying mechanisms and support individualized, indication- and context-specific OAC for patients with cirrhosis.

WED-522

Rifaximin improves myosteatosis in decompensated cirrhosis - randomized trial

Sunil Taneja[1], Abhik Halder[1], Madhurima Sharma[1], Harish Bhujade[1], Yaswant Kumar[1], Amol Patil[1], Arka De[1], Nipun Verma[1], Madhumita Premkumar[1], Ajay Kumar Duseja[1]. *[1]Postgraduate Institute Of Medical Education And Research, Chandigarh, India*
E-mail: drsuniltaneja@hotmail.com

Background and aims: Myosteatosis has emerged as a distinct phenotype associated with muscle dysfunction, poor transplant outcomes and overall mortality in patients with decompensated cirrhosis. This study aimed to evaluate the efficacy of rifaximin in ameliorating myosteatosis in patients with decompensated cirrhosis.
Method: Out of 137 screened patients with decompensated cirrhosis, 95 (69.3%) had CT-defined myosteatosis. Eighty eligible patients were randomly assigned 1:1 to receive rifaximin plus standard medical therapy (rSMT, n = 40) and standard medical therapy alone (SMT, n = 40). The primary outcome was improvement in myosteatosis at six months. Secondary outcome measures included impact on frailty, body fat composition, muscle mass, prognostic scores, hospitalisation and survival.
Results: The cohort had a male predominance (68.8%, n = 55), with a mean age of 54 ± 9.0 years. The leading cause of cirrhosis was MASLD (52.5%, n = 42), followed by MetALD (22.5%, n = 18) and alcohol related cirrhosis (17.5%, n = 14). The rSMT group showed significant improvement in mean muscle attenuation (HU) from 16.97 ± 12.24 to 23.25 ± 9.92 ($p < 0.00$), compared to the SMT group ($p = 0.01$) at 6 months. The delta change in HU was significantly greater with rSMT (6.28 ± 5.94 vs. 4.48 ± 13.83; $p < 0.00$), with 88.9% showing HU improvement. Logistic regression identified rSMT as an independent predictor of ≥5% HU gain (OR = 0.33, $p = 0.04$). LFI improved modestly in both groups with no between-group difference. In the rSMT group, fat mass decreased from 21.15 (16.62–25.02) at baseline to 20.60 (17.62–24.20) at 6 months ($p = 0.03$). In the SMT group, fat mass decreased from 21.60 (15.05–29.38) to 21.05 (15.25–29.68) ($p = 0.34$). rSMT led to a significant increase in muscle mass ($p < 0.00$), while SMT showed a decline ($p = 0.00$); delta change favoured rSMT ($p < 0.00$). The phase angle improved in both groups, although the difference was non-significant. Prognostic scores improved significantly in the rSMT group, with greater reductions in MELD Na (−3.39 ± 5.36 vs. −1.10 ± 5.00; $p < 0.05$). Ascites control was superior in rSMT (75% vs. 42.1%; $p = 0.01$). Hospitalisation rates were lower (2.8% vs. 23.7%) and survival was higher (97.5% vs. 92.5%) in rSMT, though not statistically significant.
Conclusion: Rifaximin therapy in decompensated cirrhosis has a significant impact on improving myosteatosis, muscle mass, and disease severity, with better ascites control, a reduction in hospitalisation rate, and a trend toward improved survival.

WED-523

A multicentre multistate modelling on the natural history of liver decompensation: longitudinal analysis of 1450 patients

E-mail: nicole.sytang@outlook.com

Background and aims: Cirrhosis often remains silent until decompensation, after which survival deteriorates sharply. Contemporary, transition-aware estimates are limited, especially in Asian-predominant cohorts. We analysed trajectories from compensated advanced chronic liver disease (cACLD) through sequential decompensations to death.
Method: In this multicentre study, we analyzed retrospective data from an adult cohort with liver stiffness ≥ 15 kPa from vibration-controlled transient elastography across 13 institutions internationally. Decompensation included ascites, hepatic encephalopathy, spontaneous bacterial peritonitis, or variceal bleeding. Multistate models were constructed to characterize patient trajectories across four main clinically meaningful states: baseline cACLD, first decompensation, a subsequent second decompensation, and death. Etiology-specific subgroup analyses were conducted, and effects of univariable predictors on transitions were also examined.
Results: Among 1450 patients, 162 (11.2%) developed a first decompensation over median follow-up of 4.27 years. From baseline cACLD, first decompensation occurred at 2.49 per 100 person-years with a median time of 1.57 years (IQR: 0.75–3.54), while death occurred at a rate of 1.01 per 100 person-years with a median time of 4.05 years (IQR: 2.55–6.30). The rate of a second decompensation was higher following the first decompensation, at 43.73 per 100 person-years at a median time of 0.44 (IQR: 0.19–1.07) years. Patients with alcohol-associated liver disease had the highest rate of progression

from baseline to first decompensation, whereas patients with metabolic dysfunction-associated steatotic liver disease had the highest progression rate into a second decompensation following a first decompensating event.
Conclusion: Most patients with cACLD remain compensated, but once decompensation occurs, trajectories accelerate and worsens survival. Transition-aware, etiology-stratified estimates enable individualized prognostication and earlier risk-guided intervention, including timely transplant referral.

WED-524
Active smoking is linked to persisting systemic inflammation and higher mortality after TIPS
Tammo Lambert Tergast[1], Marlene Hintersteininger[2], Ida Edler[1], Anja Tiede[1], Sarah Lisa Schütte[1], Jim Benjamin Mauz[1], Theresa Müllner-Bucsics[2], Paul Hemetsberger[2], Patrik Attalla[2], Lorenz Balcar[2], Benedikt Hofer[2], Michael Trauner[2], Mattias Mandorfer[2], Heiner Wedemeyer[1], Benjamin Maasoumy[1], Thomas Reiberger[2], Lukas Hartl[2]. *[1]Medizinische Hochschule Hannover, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover, Germany; [2]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria*
E-mail: tergast.tammo@mh-hannover.de

Background and aims: Insertion of a transjugular intrahepatic portosystemic shunt (TIPS) is an effective therapy for patients with cirrhosis and portal hypertension-related complications. Smoking is common in patients with cirrhosis, however data on its effect on clinical outcomes after TIPS implantation are scarce. This study investigates the impact of smoking or history of smoking on the clinical course after TIPS implantation.
Method: All consecutive patients with cirrhosis undergoing covered TIPS implantation at the Vienna General Hospital (2005–2022) or Hannover Medical School (2009–2021) with available information on smoking status were included in this study. Furthermore, information regarding systemic inflammation using C-reactive protein (CRP) as a surrogate were collected at baseline (BL), 3 (M3) and 6 months (M6) after TIPS placement. To determine the clinical impact of smoking on clinical outcomes, competing risk regression (CRR) was performed.
Results: Overall, 616 patients were included (66% male, median MELD: 12; alcohol-related liver disease was the main etiology: 65.6%). Regarding smoking status, 106 (17.2%) individuals were former and 230 (37.3%) were active smokers. The median number of packyears among former and active smokers was 30.0 and 11.6% were diagnosed with chronic obstructive pulmonary disease. Severity of systemic inflammation decreased significantly after TIPS placement in never smokers (CRP at BL: 0.93 mg/dL vs. M3: 0.73 mg/dL vs. M6: 0.70 mg/dL; $p = 0.026$) and former smokers (CRT at BL: 0.87 mg/dL vs. M3: 0.43 mg/dL vs. M6: 0.46 mg/dL; $p < 0.001$), but not in active smokers (CRP at BL: 0.75 mg/dL vs. M3: 0.49 mg/dL vs. M6: 0.77 mg/dL; $p = 0.859$). On adjusted CRR analysis, both never smokers (asHR: 0.60, 95%CI: 0.36–0.82; $p = 0.004$) and former smokers (asHR: 0.54, 95%CI: 0.37–0.97; $p = 0.037$) showed a significantly lower risk of death compared to active smokers.
Conclusion: Ongoing smoking is associated with persisting inflammation after TIPS implantation and is independently linked to higher mortality.

WED-525
Incidence and predictors of overt hepatic encephalopathy after elective TIPS in cirrhosis: data from a prospective multicenter randomized controlled trial

Background and aims: Elective transjugular intra hepatic portosystemic shunt (TIPS) placement increases liver-transplant free survival (LTFS) and reduces further decompensation in cirrhosis with recurrent/refractory ascites or recurrent variceal bleeding. Although post-TIPS overt hepatic encephalopathy (OHE) remains frequent, predictive factors are difficult to establish due to heterogeneous retrospective studies, and its impact on mortality is debated. This study aimed to identify predictors of OHE and severe OHE (SOHE) after TIPS and to assess their prognostic value in a homogeneous population issued from a randomized controlled trial.
Method: This is an ancillary study of a multicenter, randomized, double-blind, placebo-controlled trial assessing the efficacy of rifaximin versus placebo in preventing OHE (grade ≥ 2) after elective TIPS in patients with cirrhosis. The primary endpoint was the incidence of OHE and SOHE (grade ≥ 3) at 3 months. Secondary endpoints included the incidence of OHE and SOHE (grade ≥ 3) at one-year, predictive factors for OHE and SOHE and liver-transplant free survival (LTFS), analyzed using Fine and Gray competing risk models and Cox regression, including time-dependent and landmark analyses.
Results: Among 186 patients who underwent TIPS, OHE occurred in 36.0% at 3 months and 46.2% at one year, and SOHE in 11.8% and 18.2%, respectively. Older age (HR 1.05, 95% CI 1.01–1.08, $p = 0.004$) and diabetes (HR 2.24, 95% CI 1.38–3.63, $p = 0.001$) were independently associated with OHE occurrence at both timepoints, while rifaximin was protective. MELD score independently predicted early SOHE ($p = 0.046$). MELD score ($p < 0.001$) and baseline B-type Natriuretic Peptide (BNP) ($p = 0.005$) were independently associated with reduced one-year LTFS. OHE, whether early or late, did not impact LTFS, but SOHE occurrence was significantly associated with reduced one-year LTFS ($p < 0.001$).
Conclusion: In patients who underwent elective TIPS, age and diabetes are independent predictors of post-TIPS OHE. Only severe OHE occurrence significantly impacted liver-transplant free survival.

WED-526-YI
Intestinal abundance of Enterococcus is linked to a higher risk of infection post transjugular intrahepatic portosystemic shunt (TIPS-) insertion: first results from the TIPINF study
Anja Tiede[1,2], Jenny Fiebig[3], Laura Buttler[1], Annika Zietz[1], Jim Benjamin Mauz[1], Jennifer Witt[1], Lea Wagner[1], Liv Grete Ahl[1], Matti Peperhove[4], Tammo Lambert Tergast[1], Sabrina Woltemate[3], Heiner Wedemeyer[1,2], Marius Vital[2,3], Benjamin Maasoumy[1,2]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover, Germany; [2]German*

E-mail: tiede.anja@mh-hannover.de

Background and aims: Intestinal dysbiosis has been linked to portal hypertension and disease progression in patients with cirrhosis. Moreover, distinct clusters of intestinal dysbiosis correlated with specific clinical complications such as hepatic encephalopathy (HE) and infections in decompensated cirrhosis. Transjugular intrahepatic portosystemic shunt (TIPS-) insertion is a relevant treatment option for portal hypertension. However, the impact of gut dysbiosis on the clinical course post TIPS-insertion remains largely unexplored.
Method: A number of 106 consecutive patients with decompensated liver cirrhosis undergoing TIPS-insertion between 09/2022 and 03/2025 were prospectively included in the TIPINF study. Patients were followed-up for occurrence of infection, HE, and death for one year post-TIPS. Of 47 patients, baseline stool samples (prior to TIPS) were available for the current analysis. Microbiome composition was assessed by metagenomic shotgun sequencing. Microbial clustering was based on Bray-Curtis dissimilarity and relative bacterial abundances.
Results: Patients were predominantly male (57%) with a median age of 60 years and MELD of 10. Most TIPS were implanted for treatment of refractory ascites (70%), with alcohol-related liver disease (47%) being the most common cirrhosis etiology. We identified three distinct microbiota patterns in our cohort: An Enterococcus-dominated (C1), a Bifidobacteria-dominant (C2), and a diverse microbiome clustering most similar to those of healthy individuals (C3). Of note, Enterococcus-dominance was linked to an intestinal abundance of fungi species e.g. Candida. During follow-up, 15 patients (32%) developed a bacterial infection. Enterococcus-abundance was linked to a significantly higher risk of bacterial infection (C1 vs C2+C3: HR 2.75, p = 0.04) in a competing risk analysis, which remained significant in the multivariable model after adjusting for baseline-MELD (C1 vs C2+C3: HR 4.24, p = 0.002). Moreover, patients with Enterococcus-dominance had a numerically higher incidence of overt HE (50% vs 31%). However, neither competing risk analysis for HE-development during follow-up nor Cox regression analysis for 1-year-mortality were statistically significant (C1 vs C2+C3: HR 1.95, p = 0.19; HR 2.24, p = 0.17).
Conclusion: Intestinal dysbiosis is associated with adverse clinical outcomes after TIPS-implantation. An Enterococcus-dominated microbiome is independently associated with an increased risk of post-TIPS bacterial infections.

WED-527
Effect of PPI exposure and discontinuation on infection outcomes in cirrhosis

Arianna Toscano[1], Maria Stella Franzè[1], Clelia Asero[1], Gaia Caccamo[1], Roberto Filomia[1], Concetta Pitrone[1], Carlo Saitta[1], Irene Cacciola[1].
[1]Unit of Medicine and Hepatology, University Hospital of Messina, Unit of Medicine and Hepatology, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy
E-mail: arianna.toscano13@gmail.com

Background and aims: Proton pump inhibitors (PPIs) are frequently prescribed, often without appropriate indications. Concerns are rising about inappropriate PPI use, as increasing evidence suggests a potential association between PPI exposure and several complications, including bacterial infections (BIs). This study aimed to evaluate the impact of PPI use on infections features, antibiotic failure, and survival in cirrhotic patients hospitalized for BIs.
Method: We retrospectively analysed 232 cirrhotic patients [137 males, median age 67 years] accounting for 255 infectious episodes, consecutively hospitalized from January 2009 to December 2016. Clinical, laboratory and microbiological data were collected. Data on PPI use, indication, type, and treatment discontinuation at discharge in case of improper prescription were collected. Follow-up was continued until the last available contact.
Results: One-hundred seventy-seven out of 232 patients (76.3%) were PPI users. Compared with non-users, PPI users presented higher rates of decompensation at admission (p = 0.010), higher procalcitonin levels (p = 0.014), a greater prevalence of spontaneous bacterial peritonitis (p = 0.031), as well as significantly higher rate of second antibiotic failure (p = 0.015). No significant differences were observed in mortality at 1 and 3 months or in readmission rates. In the univariate regression analysis, PPI use was associated with increased risk of jaundice (HR 1.85, 95% CI 1.29–2.66; p < 0.001), ascites (HR 3.14, 95% CI 1.99–5.00; p <0.001), and hepatic encephalopathy (HR 1.83, 95% CI 1.27–2.62; p = 0.001). PPI discontinuation was associated with a significantly reduced risk of death at both univariate (HR 0.31, 95% CI 0.15–0.64; p = 0.001) and multivariable ((HR 0.41, 95% CI 0.20–0.85, p = 0.017) regression analyses. Kaplan–Meier analysis confirmed significantly improved survival in patients who discontinued PPIs after infection resolution (p < 0.001).
Conclusion: Our findings suggest that ongoing PPI exposure may contribute to the development of major liver-related complications, whereas withdrawal of unnecessary PPI therapy was associated with a significant survival benefit. These findings support the importance of critically reassessing PPI indications in cirrhotic patients.

WED-528
UCH-L1 and GFAP as novel biomarkers for early detection of hepatic encephalopathy

Pere Vaquer-Grimalt[1], Apol·lonia Moll[2], María del Carmen Gassent[2], Ana Belén Martínez[3], Maria Inés Barceló[3], Lucía Bonet-Vidal[1], Juana Maria Ferrer[4], Ana Escarda Gelabert[1], Margalida Vanrell Garau[1], Daniel Morell[5], Lydia Sastre[1]. *[1]Department of Hepatology, Hospital Universitario Son Espases, Palma, Spain; [2]Department of Radiology, Hospital Universitario Son Espases, Palma, Spain; [3]Department of Neurology, Hospital Universitario Son Espases, Palma, Spain; [4]Department of Immunology, Hospital Universitario Son Espases, Palma, Spain; [5]Department of Laboratory Medicine, Hospital Universitario Son Espases, Palma, Spain*
E-mail: perevaquergrimalt@hotmail.com

Background and aims: Hepatic encephalopathy (HE) is a major decompensation in cirrhosis and a leading cause of hospitalization, with substantial clinical, psychosocial, and economic consequences. Diagnostic strategies have remained inadequate, particularly for covert HE, which relies on the Psychometric Hepatic Encephalopathy Score (PHES), a tool infrequently used and insufficiently sensitive. As a result, many patients remain undiagnosed despite their increased risk of progression. We evaluated brain-injury biomarkers as objective and accessible tools for detecting minimal HE (MHE) and overt HE (OHE).
Method: Single-center, cross-sectional study including healthy controls, cirrhotic outpatients (non-HE and MHE), and hospitalized patients with OHE. Exclusion criteria were prior OHE, neurological or psychiatric disease, hepatocellular carcinoma, recent major surgery, chronic heart disease, long-standing type 2 diabetes, or HIV. All outpatients and controls underwent PHES, StroopApp®, EEG, and brain MRI; MHE was defined by ≥2 abnormal tests. UCH-L1, GFAP, ammonia, IL-6, S100β, and enolase were measured using commercial immunoassays. ROC analysis assessed diagnostic performance.
Results: Sixty-seven participants were included (controls, n = 15; non-HE, n = 14; MHE, n = 27; OHE, n = 11). Biomarker levels increased stepwise across HE stages. UCH-L1 was significantly higher in MHE vs non-HE (143.2 ± 37.7 vs 88.2 ± 15.1 pg/mL; p = 0.003), and GFAP showed a similar pattern (27.9 ± 12.2 vs 17.2 ± 5.2 pg/mL, p = 0.008). Ammonia, S100β, and IL-6 were markedly elevated only in OHE (p < 0.0001). Enolase showed no discriminatory value. UCH-L1 discriminated HE vs non-HE with an AUC of 0.89, while GFAP showed

moderate discrimination (AUC = 0.75). ROC 95% CI and optimal sensitivity/specificity values are being calculated.
Conclusion: UCH-L1 and GFAP emerge as promising biomarkers for the objective detection of MHE, a stage frequently missed by current diagnostic strategies. In contrast, ammonia, S100β, and IL-6 were associated exclusively with OHE, supporting distinct biological pathways across HE severity. These findings suggest that brain-injury biomarkers may improve early diagnosis and risk stratification in cirrhosis, warranting prospective validation.

WED-529
Severity at diagnosis and progression in chronic liver disease by aetiology: a nationwide cohort study of 146,654 individuals in Sweden, 2002–2022
Juan Vaz[1], Ulf Strömberg[1], Ying Shang[2], Axel Wester[2], Andrea Lindfors[2], Hannes Hagström[2]. [1]*School of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden;* [2]*Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden*
E-mail: juan.vaz@gu.se

Background and aims: Many individuals with chronic liver disease (CLD) are diagnosed at an advanced stage, but population-level evidence comparing severity at presentation and subsequent progression across CLD aetiologies remains limited. We aimed to assess the burden of major adverse liver outcomes (MALOs) at diagnosis across aetiologies, identify factors associated with MALOs at presentation, and estimate the cumulative incidence of MALOs among individuals presenting with non-cirrhotic CLD.
Method: Using nationwide Swedish register data, we identified all adults (≥18 years) diagnosed with CLD between 2002 and 2022. CLD was classified by single or combined aetiologies. MALOs at presentation were defined as decompensated cirrhosis, liver failure, hepatocellular carcinoma, liver transplantation, or liver-related death within prespecified time windows. Multinomial logistic regression was used to examine factors associated with MALOs at the first presentation. Among individuals presenting with non-cirrhotic CLD, cumulative incidence functions accounting for competing risks were used to estimate progression to MALOs.
Results: We identified 146,654 adults with CLD. The most common aetiologies were hepatitis C (20%), alcohol-related liver disease (ALD; 18%), metabolic dysfunction-associated steatotic liver disease (MASLD; 13%), and hepatitis B (12%). At diagnosis, 13.4% of individuals presented with MALOs, with ascites being the most common (8% of overall, accounting for 61% of all MALOs). MALOs were most common among individuals with ALD (41%) and cryptogenic cirrhosis (38%). ALD was associated with markedly increased odds of MALOs at presentation (adjusted odds ratio [aOR] 40.8, 95% confidence interval [CI] 37.3–44.7). Among 102,923 individuals presenting with non-cirrhotic CLD, ALD –alone or in combination with other aetiologies– was associated with the highest 10-year cumulative incidence of progression to MALOs.
Conclusion: More than one in eight individuals with CLD in Sweden were diagnosed only after a MALO has occurred. Severity at presentation and subsequent progression vary substantially by underlying disease patterns, with ALD conferring particularly high risk.

WED-530
Machine learning and generative artificial intelligence models outperform established prognostic scoring systems in predicting acute decompensation in patients with chronic liver disease
Mathew Vithayathil[1], James Bell[1], Alexander Cole[1], Claudia Moore-Gillon[1], David Kockerling[1], Rooshi Nathwani[1], Lucia Possamai[1], Heather Lewis[1], Nowlan Selvapatt[1], Maud Lemoine[1], Ameet Dhar[1]. [1]*Imperial College London, London, United Kingdom*
E-mail: mathew.vithayathil@doctors.org.uk

Background and aims: Patients with cirrhosis are at risk of acute decompensation but robust predictors are lacking. This study developed and validated a machine learning model to predict risk of liver decompensation necessitating admission in patients being managed in a dedicated cirrhosis service.
Method: Cirrhosis patients from a tertiary hepatology centre were retrospectively included. Patients were randomly divided into training and validation cohorts. Baseline clinical variables relating to demographics, disease aetiology, biochemistry, liver complications (ascites, encephalopathy, varices) and liver-related pharmacotherapy (beta-blockers, diuretics, rifaximin) were collected. Models using baseline variables to predict 6-month episodes of liver decompensation resulting in admission were developed using 8 supervised learning algorithms, including the TabPFN generative foundation model, and 13 feature selection techniques. The top 3 performing machine learning/feature selection combinations were combined using ensemble learning. Model performance was benchmarked against established liver prognostic scores. K-means clustering stratified patients for acute decompensation risk.
Results: 403 patients were included in training (n = 270) and validation (n = 133) cohorts. The ensemble model consisting of logistic regression, ridge regression and neural network algorithms was predictive of 6-month decompensation in training (AUC 0.75, 95% CI 0.68–0.82) and validation (AUC 0.84, 95% CI 0.72–0.94). Feature selection identified bilirubin, albumin, INR, ascites and diuretic use as the key predictor variables. The model significantly outperformed CP grade (AUC 0.78, $p < 0.001$), MELD (AUC 0.77, $p = 0.03$ and UKELD (AUC 0.72, $p < 0.001$) in predicting 6-month risk of decompensation admission during validation. Unsupervised machine learning identified 3 distinct risk groups, with significant differences in median time-to-decompensation in training and validation (high-risk: 3.0 months, 95% CI 0.5–6.0 vs. moderate-risk: 25.7 months, 95% CI 8.8–36.7 vs. low-risk: median not reached, 95% CI 47.2-upper limit not reached; $p < 0.001$) cohorts.
Conclusion: Machine learning based algorithms using routine clinical variables outperform established prognostic liver scores in predicting risk of admission due to decompensation in patients managed in a dedicated cirrhosis service. Ensemble models can stratify risk of admission, allowing for personalised care strategies including follow-up intervals and ambulatory monitoring in higher risk groups.

WED-531
Optimal glycaemic targets to prevent major adverse cardiovascular events and risk of hypoglycaemia in patients with type 2 diabetes and cirrhosis
Mary Yue Wang[1], Sherlot Juan Song[1], Nana Peng[1], Grace Lai-Hung Wong[1], Vincent Wai-Sun Wong[1], Jimmy Che-To Lai[1], Terry Cheuk-Fung Yip[1]. [1]*The Chinese University of Hong Kong, Sha Tin, Hong Kong*
E-mail: maryyo@link.cuhk.edu.hk

Background and aims: Glycaemic management in patients with T2DM and cirrhosis is challenging due to limited options of anti-diabetic agents and risk of hypoglycaemia. We aimed to determine the association between glycaemic control and clinical outcomes and compare optimal glycaemic targets in individuals with T2DM, with and without cirrhosis.
Method: This retrospective study included adult individuals with T2DM, with or without cirrhosis, after excluding individuals with missing demographic data, type 1 diabetes, missing haemoglobin A_{1c} (HbA_{1c}) records within 1 year, and major adverse cardiovascular events (MACE) before T2DM diagnosis or within 1 year. The primary outcome was MACE. All-cause mortality and hypoglycaemia were secondary outcomes. Restricted cubic spline analysis was used to assess potential non-linear relationship between time-weighted average (TWA) HbA_{1c} and the outcomes. Cause-specific hazard

ratios (CSHR) and 95% confidence interval (CI) were estimated, treating non-MACE-related death as competing risks.
Results: Of 695,549 patients with T2DM, 16,007 (2.3%) had compensated cirrhosis (mean age 68.8 years, 58.5% men) and 3331 (0.5%) had decompensated cirrhosis (mean age 67.9 years, 59.3% men). TWA HbA_{1c} level had a linear relationship with risk of MACE in compensated cirrhosis group (CSHR of per 1% HbA_{1c} increase [95% CI]: 1.09 [1.06–1.12], p <0.001), decompensated cirrhosis group (CSHR of HbA_{1c} [95% CI]: 1.11 [1.06–1.17], p <0.001) and non-cirrhosis group (CSHR of HbA_{1c} [95% CI]: 1.09 [1.08–1.09], p <0. A HbA_{1c} level of 6–7% had the lowest mortality incidence in all T2DM patients with or without cirrhosis. Patients with decompensated cirrhosis had the highest 10-year incidence of hypoglycaemia compared to the compensated cirrhosis and non-cirrhosis groups (15.91 vs 9.05 vs 3.92 per 100 person-years, respectively). Hypoglycaemia was associated with an increased risk of all-cause mortality in all groups (adjusted HR [95% CI]: non-cirrhosis group: 4.18 [4.08–4.28], compensated cirrhosis group: 2.80 [2.52–3.12], decompensated cirrhosis group: 2.70 [2.34–3.11], all p < 0.001).
Conclusion: HbA_{1c} <7% works equally well for T2DM patients with or without cirrhosis as it is associated with a lower risk of MACE and all-cause mortality. However, excessively low HbA_{1c} levels should be managed with caution in cirrhotic patients, given the potential impact of extrahepatic complications and higher risk of mortality and hypoglycaemia.

WED-532
Exploratory analysis of neurofilament light chain across steatotic liver disease suggests utility in hepatic encephalopathy but not in obesity-related cognitive dysfunction

Elise Jonasson[1], Lea Ladegaard Grønkjær[1], Birgitte Jacobsen[1], Mette Lauridsen[1], Charlotte Wernberg[1]. [1]*Liver Research Group, Department of Gastroenterology and Hepatology, University Hospital of South Denmark, Esbjerg, Denmark*
E-mail: elise.jonasson.nielsen@rsyd.dk

Background and aims: Overt hepatic encephalopathy (OHE) remains a severe complication of cirrhosis, while obesity is associated with cognitive dysfunction. There is an unmet need for markers of minimal hepatic encephalopathy (mHE), OHE, and cognitive dysfunction. Neurofilament light chain (NfL) is a marker of neuroaxonal injury and has been proposed as a biomarker of OHE. We aimed to explore NfL across the spectrum of steatotic liver disease (SLD) in patients undergoing cognitive testing.
Method: We analysed two prospective cohorts, with data on cognitive testing using the Continuous Reaction Time (CRT), Portosystemic Encephalopathy Syndrome (PSE), and Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). Patients with cirrhosis were classified as no mHE, mHE, or OHE (n = 38/31/16) based on PSE results or admission with OHE. The second cohort included patients with obesity undergoing liver biopsy, classified as no-MASLD + normal cognition, MASLD + normal cognition, or MASLD + cognitive impairment (n = 17/42/20), defined as ≥2 abnormal tests or RBANS sum score <79. NfL was measured in biobank samples collected at the time of testing, including in 19 healthy controls.
Results: We included 187 patients. The cirrhosis and obesity cohorts differed markedly in sex (69% vs. 32% men), age (63 ± 15 vs. 49 ± 23 years), BMI (28 [6] vs. 42 [8] kg/m^2), and median Nfl levels (23.1 [20] vs. 8.6 [4] pg/ml). The biopsy-confirmed MASLD in the obesity cohort was predominantly mild–moderate, with steatohepatitis in 23/42 vs. 6/20 patients, and fibrosis stages F1/F2/F3 in 10/23/9 and 12/7/1, respectively. In the cirrhosis cohort, NfL increased stepwise across severity: no mHE 14.6 (13), mHE 27.7 (24), and OHE 36.9 (51) pg/ml (p < 0.001). NfL was significantly higher in mHE and OHE compared with healthy controls and cirrhosis without mHE (p < 0.001), with no difference between mHE and OHE (p = 0.3). In contrast, NfL levels were low, had a slight trend, but overlapped across cognitive subgroups in the obesity cohort (p = 0.1). Healthy controls had a median NfL of 12.1 (6.8) pg/ml.
Conclusion: Nfl levels increase with worsening HE in cirrhosis, supporting its role as a biomarker of neuroaxonal injury in HE. In obesity-related MASLD, NfL levels were lower and not associated with cognitive impairment, potentially reflecting BMI-related suppression and limited statistical power. Larger, adequately powered studies are needed to clarify the utility of NfL across the SLD spectrum.

WED-533
Rifaximin improves hyperammonemia through alteration in duodenal microbiota in patients with liver cirrhosis

Shunhei Yamashina[1], Akira Uchiyama[1], Masahiro Tada[1], Kei Ishizuka[1], Maki Morinaga[1], Hiroo Fukada[1], Reiko Yaginuma[1], Kyoko Fukuhara[1], Kazuyoshi Kon[1], Kenichi Ikejima[1]. [1]*Department of Gastroenterology, Juntendo University School of Medicine, Tokyo, Japan*
E-mail: syamashi@juntendo.ac.jp

Background and aims: Hepatic encephalopathy in cirrhosis is associated with gut dysbiosis; however, the small-intestinal microbiota remains incompletely understood compared with stool-based assessments. Proton pump inhibitor treatment has been reported to be associated with a higher risk of small intestinal bacterial overgrowth. Small intestinal bacterial overgrowth has also been linked to hepatic encephalopathy in cirrhosis. Here, we investigated the effects of rifaximin on duodenal microbiota and hyperammonemia in patients with cirrhosis and examined whether these effects differed according to concomitant acid-suppressive therapy.
Method: Twelve adults with cirrhosis and esophageal varices received rifaximin (1200 mg/day) for 12 weeks. Duodenal aspirates were obtained by upper endoscopy before and after treatment with rifaximin, and serum ammonia was measured at both time points. Acid-suppressive therapy was defined as proton pump inhibitor or potassium-competitive acid blocker use. 16S rRNA sequencing was processed with QIIME 2/DADA2. Alpha diversity and weighted UniFrac-based beta diversity (principal coordinate analysis; PERMANOVA) were assessed, and Differentially abundant taxa were identified using LEfSe.
Results: Serum ammonia and aspartate aminotransferase (AST) decreased significantly after rifaximin, whereas platelets, alanine aminotransferase, albumin, bilirubin and gamma-glutamyl transpeptidase were unchanged. The reductions in ammonia and AST were significant mainly in the acid-suppressive group. In the duodenal microbiota, rifaximin decreased Faith phylogenetic diversity, the Shannon index, and observed amplicon sequence variants, while Pielou evenness was preserved. Weighted UniFrac distances showed separation of microbial communities between before and after treatment. LEfSe identified reduced relative abundance of *Peptostreptococcales Tissierellales* and *Parvimonas micra* after rifaximin; in the acid-suppressive subgroup, *Selenomonas* was also reduced.
Conclusion: Rifaximin improved hyperammonemia accompanied by changes in the duodenal microbiota in patients with cirrhosis. These effects appeared more pronounced in patients receiving acid-suppressive therapy, suggesting that small-intestinal dysbiosis may influence treatment response.

E-mail: wantingyang1999@163.com

Background and aims: China bears a high burden of hepatitis B, and effective management of hepatitis B–related cirrhosis remains a major clinical challenge. Although "cirrhosis recompensation" has recently been recognized as a distinct disease stage and carries substantial theoretical and societal value, practical treatment guidelines are lacking. We established a prospective cohort study with the proportion of patients achieving recompensation at week 72 as the primary endpoint to evaluate an optimized human albumin–based treatment strategy.
Method: Patients with decompensated HBV-related cirrhosis were recruited from 17 centers across China and centrally randomized to an intensive or standard treatment group. Based on validated Baveno VII recompensation criteria in entecavir-treated patients, an albumin target of 34 g/L was set for the intensive group. Albumin was infused at baseline, with levels rechecked after 3–5 days and discontinued once ≥34 g/L was achieved. Albumin levels were reassessed at weeks 8, 16, and 24, and additional infusions were given if targets were not met. In the standard group, the albumin target was 30 g/L, with other interventions identical to the intensive group.
Results: From December 2023 to July 2025, 148 patients with decompensated HBV-related cirrhosis were enrolled and randomized into the standard (n = 74) and intensive (n = 74) treatment groups. The total albumin infusion volume (intensive group, 100 g (IQR: 70 g–150 g) vs. standard group, 70 g (IQR: 50 g-100 g), p = 0.0005) and post-infusion albumin concentrations (intensive group, 35.4 g/L (IQR: 34.0 g/L–37.4 g/L) vs. standard group, 33.2 g/L (IQR: 30.9 g/L–36.2 g/L), p = 0.0029) differed significantly, confirming differences in treatment intensity. Baseline characteristics were well-matched between groups, including age (p = 0.3851), sex (p = 0.4869), Child-Pugh score (p = 0.3913), mean serum albumin levels (p = 0.5022), and diuretic use at enrollment (p = 0.1725). All patients continue active follow-up for the primary endpoint (rate of recompensation), with final analyses planned upon trial completion.
Conclusion: The baseline characteristics in our study were evenly distributed, and the protocol successfully achieved a significant difference in albumin infusion volume between the standard and intensive treatment groups. Upon completion of this trial, the assessment of recompensation rates in both groups is expected to provide key evidence to optimize albumin therapy regimens for patients with decompensated hepatitis B-related cirrhosis.

WED-538
Prefrailty and frailty predict hospitalisation in patients with cirrhosis

Ismael de Jesus Yepes Barreto[1], Dagoberto Duarte[1], Luis Molina[1], Jorge Yepes[1], Maria Valera[1], Fernando Garcia[1]. *[1]Universidad de Cartagena, Asociacion Colombiana de Hepatologia, Cartagena de Indias, Colombia*
E-mail: ismayep@yahoo.com

Background and aims: The Liver Frailty Index (LFI) has emerged as a clinically relevant predictor of hospitalisation and adverse outcomes in cirrhosis, reflecting reduced functional reserve and impaired response to stressors. However, the LFI was primarily developed and validated in North American and European populations, with limited representation of Latin American patients. Given regional differences in muscle mass and strength, its prognostic performance may vary across populations. We aimed to evaluate the prognostic value of the LFI for hospitalisation in patients with cirrhosis in Colombia.
Method: We conducted a prospective observational cohort study including consecutive adult patients with cirrhosis attending an outpatient hepatology centre in Cartagena, Colombia, between November 2024 and June 2025. Cirrhosis was diagnosed using clinical, biochemical, imaging, elastographic, and/or histological criteria. Frailty was assessed at baseline using the LFI, based on handgrip strength, chair stands, and balance tests, and categorised as robust (<3.2), prefrail (3.2–4.5), or frail (>4.5). Patients were followed every 60 days to assess hospitalisation. Associations between frailty status and hospitalisation were analysed using chi-square tests.
Results: A total of 121 patients were included; 61.2% were female, and most had compensated disease (80.8% Child–Pugh A, 19.2% Child–Pugh B). According to the LFI, 23.1% were robust, 57.0% prefrail, and 19.8% frail. During a median follow-up of 11.1 months, 26.4% experienced at least one hospitalisation. Hospitalisation rates increased progressively across frailty categories: prefrail vs robust (29.0% vs 10.7%, p = 0.05) and frail vs robust (37.5% vs 10.7%, p = 0.02). Patients classified as Child–Pugh B had higher hospitalisation rates than those with Child–Pugh A (65.2% vs 16.5%, p < 0.001). Additional factors associated with hospitalisation included prior hospitalisation, first episode of hepatic decompensation, older age, lower body mass index, and lower serum albumin levels.
Conclusion: Liver Frailty Index was strongly associated with hospitalisation risk not only among frail patients but also in those classified as prefrail. These findings indicate that prefragility represents an early and clinically relevant stage of vulnerability rather than a benign condition.

WED-539
Health literacy is independently associated with frailty in cirrhosis

Ismael de Jesus Yepes Barreto[1], Nicole Chamorro[1], Guillermo Donado[1]. *[1]Universidad de Cartagena, Asociacion Colombiana de Hepatologia, Cartagena de Indias, Colombia*
E-mail: ismayep@yahoo.com

Background and aims: Health literacy (HL) is the ability to obtain, process, and understand health information to make appropriate health decisions. In cirrhosis, limited HL and frailty are independently associated with adverse outcomes, higher healthcare utilisation, and mortality. Frailty can be assessed using the Hepatic Frailty Index (HFI). The association between HL and frailty in cirrhosis has not been previously evaluated The aim of this study was to assess the association between health literacy and frailty in patients with cirrhosis.
Method: We conducted a cross-sectional, observational, and analytical study including patients with a confirmed diagnosis of cirrhosis

who attended outpatient care between September and December 2025. All participants completed the Spanish version of the Short Assessment of Health Literacy (SAHL-S), a validated instrument to assess health literacy. Frailty was evaluated using the Hepatic Frailty Index. Frailty was defined as an HFI score ≥ 4.5. Continuous and categorical variables were described as means (standard deviation) and percentages, respectively. Univariate and multivariable logistic regression analyses were performed to identify factors associated with frailty.

Results: A total of 98 patients with cirrhosis were included. According to the hepatic frailty classification, 16.5% were classified as robust, 63.7% as prefrail, and 19.8% as frail. The majority of patients were female (56.1%), and most had compensated disease; 87.4% were classified as Child–Pugh A, 11.6% as Child–Pugh B, and 1.1% as Child–Pugh C. Mean age was 64.6 ± 12.8 years. Adequate health literacy was observed in 82.1% of patients. In univariate analysis, adequate health literacy was associated with a lower risk of frailty, while increasing age was associated with a higher risk. No significant association was observed between Child–Pugh class and frailty. In multivariable logistic regression analysis, adequate health literacy remained independently associated with a lower likelihood of frailty (OR 0.26, 95% CI 0.07–0.89, p = 0.032), after adjustment for age. Older age was also independently associated with frailty (OR 1.07 per year, 95% CI 1.01–1.13, p = 0.025).

Conclusion: In patients with cirrhosis, health literacy was independently associated with frailty, beyond age and liver disease severity. These findings suggest that health literacy is a modifiable determinant of frailty and support incorporating health literacy assessment into routine cirrhosis care.

WED-540-YI

Ammonia is an inconsistent marker of clinical outcomes in people with cirrhosis and hepatic encephalopathy: evidence from ten pooled systematic reviews and meta-analyses

Harry Zacharias[1], Lise Lotte Gluud[2], Marsha Morgan[1]. [1]*UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, Rowland Hill Street, London, United Kingdom;* [2]*Gastrounit, Medical Division, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark*
E-mail: h.zacharias@ucl.ac.uk

Background and aims: Ammonia plays a central role in the pathophysiology of hepatic encephalopathy (HE). However, the clinical utility of blood ammonia measurements in patients with cirrhosis is debated. Cochrane systematic reviews are conducted using rigorous standards for data identification, extraction, analysis, and interpretation. The treatment of HE has been subject to a series of Cochrane reviews in which data on blood ammonia were collected as a secondary outcome. This study aimed to further explore the clinical utility of ammonia in patients with cirrhosis, using data from these Cochrane reviews.

Method: Ten Cochrane systematic reviews evaluating, in turn, L-acetyl-carnitine, non-absorbable disaccharides, branched-chain amino acids, flumazenil, L-ornithine-L-aspartate, ammonia-lowering agents, probiotics, rifaximin, other antibiotics, and dopaminergic agents were included. Data were extracted from studies comparing these active agents with placebo/no treatment on timing of ammonia sampling, HE classification, mortality, and HE outcomes. Associations between ammonia (as standardised mean differences) and outcomes (as log risk ratios) were examined using random-effects meta-regressions.

Results: Data were available from 125 randomised clinical trials, involving 8342 people (4376 cases, 3966 controls). Information on ammonia was available in 68 (54%) trials, HE outcome data in 90 (72%); and mortality data in 96 (77%) trials. There were no significant correlations between ammonia and HE or mortality outcomes when all trial data were pooled, nor when stratified by treatment type or by type of HE (minimal, acute episodic, persistent/recurrent). However, when stratified by timing of sampling (baseline, end of treatment, change from baseline), baseline ammonia showed a significant inverse association with HE outcomes (slope = –0.50 [95% CI –0.86 to –0.14], p = 0.007, 41 RCTs, n = 2735).

Conclusion: Associations between ammonia and clinical outcomes were inconsistent across all trials, which likely represents between-study methodological heterogeneity. A higher ammonia at baseline was associated with a larger relative treatment effect on HE outcomes, but this likely reflects baseline risk and trial context rather than a useful biomarker of responsiveness to treatment. Hence, the clinical utility of blood ammonia measurement remains unclear. Its role in specifically defined contexts must be identified and tested with rigorous, concordant methodologies in order to define its utility as a clinical biomarker.

WED-541-YI

Clinical application of extensively drug-resistant organism (XDRO) colonization screening in patients with acute decompensation of cirrhosis (AD) in low and high prevalence countries

Nicola Zeni[1], Juan Bañares[2], Parminder Kaur[3], Marzia La Franca[4], Archana Angrup[5], Simone Incicco[4], Roberta Gagliardi[4], Valeria Calvino[4], Marta Tonon[4], Sunil Taneja[6], Ajay Kumar Duseja[3], Paolo Angeli[4], Nipun Verma[3], Salvatore Piano[4]. [1]*University of Padua, Padua, Italy;* [2]*Liver Unit, Digestive Diseases Division, Hospital Universitari Vall d'Hebron, Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain;* [3]*Department of Hepatology, PGIMER, Chandigarh, India;* [4]*Unit of Internal Medicine and Hepatology, Department of Medicine, University and Hospital of Padua, Padua, Italy;* [5]*Department of Medical Microbiology, PGIMER, Chandigarh, India;* [6]*Department of Hepatology, PGIMER, Chandigarh, Italy*
E-mail: nicola.zeni.1@gmail.com

Background and aims: Bacterial infection often precipitates AD and the increasing prevalence of XDRO infection complicates empirical antibiotic therapy and worsens clinical outcomes. Data on XDRO colonization in cirrhotic patients admitted to regular wards are scarce. Our study aimed to evaluate the prevalence of rectal XDRO colonization and its clinical impact in hospitalized patients with AD.

Method: A retrospective observational study was conducted with 232 patients in Padua Hospital, Italy and a validation cohort of 176 patients from PGIMER Chandigarh, India, all admitted for AD, undergoing XDRO surveillance with rectal swab within 48 hours of admission. Patients were followed-up until death, liver transplant or 90-days, to assess the development of XDRO-related infections as well as acute-on-chronic liver failure (ACLF), ICU transfer and 28-day and 90-day mortality according to rectal swab results.

Results: In Italian study cohort (61 ± 12 years old; 64% male, median MELD score 18), 39 (16.8%) tested positive for colonization by XDRO (CR *enterobacteriaceae* accounted for 60% of cases). Patients colonized by XDRO had higher incidence of XDRO infections (33% vs 4.4%; p = 0.017) and rectal swab guided antibiotic treatment would have covered 90% of pathogens. In multivariable analysis (adjusted by age, sex and MELD score), XDRO colonization was associated with higher risk of developing XDRO infections [HR = 3.93; p = 0.006]; moreover it was associated with an increased risk of developing ACLF (OR = 3.18, p = 0.002), being transferred to the ICU (OR = 3.40; p = 0.004), and mortality at 28-days (sHR = 4.39; p < 0.001) and 90-days (sHR = 4.50; p < 0.001). In Indian cohort a higher proportion of patients tested positive for XDRO colonization than Italian cohort (54.4% vs. 16.8%, p < 0.001). A higher prevalence of XDRO infection development in XDRO colonized patients (45% vs 19% p < 0.001) was confirmed and in multivariate analysis colonization was associated to XDRO infection development (sHR = 3.01, p < 0.001). The same XDRO was found in 77% of patients with culture-proven infections. XDRO colonization was not associated to an increased mortality risk, ACLF development or ICU transfer.

Conclusion: Irrespective of XDRO prevalence, colonization by XDRO is associated with an increased risk of developing XDRO infections, but not mortality, ACLF development and ICU transfer risk. Rectal swab could be a valuable screening tool for guiding empirical antibiotic treatment strategy in these patients.

WED-542

Portosystemic ammonia gradient (PAG) predicts risk of overt hepatic encephalopathy occurrence in patients after TIPS

Chuanfu Ding[1], Feng Zhang[1], YuZheng Zhuge[1]. [1]*Department of Gastroenterology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China, Nanjing, China*
E-mail: fzdndx@126.com

Background and aims: Overt hepatic encephalopathy (OHE) is a major complication after transjugular intrahepatic portosystemic shunt (TIPS) placement. However, reliable prediction of post-TIPS OHE remains challenging. We propose a novel index - the portosystemic ammonia gradient (PAG). This study aims to evaluate the effect of PAG in predicting OHE after TIPS.
Method: In this prospective pilot study, 38 cirrhotic patients undergoing elective TIPS were enrolled. PAG was defined as the difference between portal vein ammonia (PVA) and inferior vena cava ammonia (IVCA), measured simultaneously with portosystemic pressure gradient (PPG) before and after TIPS. Clinical outcomes, including OHE, were recorded, and the predictive performance of pre- and post-TIPS PAG and PPG was compared using ROC analysis.
Results: The mean PAG decreased from 42.9 ± 24.2 μmol/L pre-TIPS to 17.5 ± 8.9 μmol/L post-TIPS ($P < 0.001$). During 6-month follow-up, 13 patients (34.2%) developed OHE. Pre-TIPS PAG was lower in patients with OHE than in those without (29.3 ± 19.7 vs. 49.9 ± 23.6 μmol/L, $P < 0.001$). Logistic regression showed post-TIPS PPG (OR = 0.76, 95% CI: 0.57–0.97, $P = 0.04$) and pre-TIPS PAG (OR = 0.96, 95% CI: 0.92–0.99, $P = 0.02$) as independent OHE predictors. Pre-TIPS PAG had the highest predictive accuracy (AUC = 0.748), outperforming post-TIPS PPG, CTP, and MELD (AUC = 0.649, 0.605, 0.560). Patients with lower pre-TIPS PAG (<25.95 μmol/L) had higher cumulative OHE incidence (HR = 0.19, 95% CI: 0.06–0.60; $P = 0.004$).
Conclusion: PAG reflects residual hepatic ammonia metabolism and is a promising prognostic index for post-TIPS OHE, guiding individualized risk stratification and preventive strategies.

E-mail: chenhanng@gmail.com

Background and aims: Liver cirrhosis remains a major global health burden, yet accurate prognostication of hepatic decompensation remains a clinical challenge. Conventional biochemical indices: albumin, bilirubin, and INR form the cornerstone of clinical assessment but primarily reflect static hepatic function. This study characterised the relationship between these biochemical parameters and outcomes of decompensation and mortality.
Method: We conducted a retrospective multicentre cohort study using the Cirrhosis Outcomes and Research Endeavour (CORE) consortium, comprising 4090 adults with compensated advanced chronic liver disease across 12 centres in North America, Asia, and Australia. Associations between albumin, bilirubin, and INR levels and outcomes were evaluated using Cox proportional hazards and Fine-Gray competing risk models. Optimal thresholds were identified using maximally selected log-rank statistics and examined across subgroups stratified by liver stiffness measurement (LSM).
Results: Derangements in albumin, bilirubin, and INR were independently associated with higher risks of mortality and hepatic decompensation (all $p < 0.05$). However, differences between groups, though statistically significant, were of limited clinical significance, with biomarker values concentrated within narrow physiological ranges. Optimal prognostic thresholds were ≤39.7 g/L for albumin, ≥1.0 for INR, and ≥16.1 μmol/L for bilirubin in predicting mortality, with similar cut-offs for decompensation (38.0 g/L, 1.1, 22.2 μmol/L).
Conclusion: Standard biochemical indices remain essential for baseline assessment and provides foundational information on disease status. However, they exhibit limited dynamic predictive value for identifying individuals at risk of decompensation. Further refinement of existing prognostic models, particularly through the integration of dynamic clinical trajectories or molecular biomarkers, may offer substantially improved risk stratification and prognostication in compensated cirrhosis.

WED-544

Metabolic dysfunction exacerbates residual liver risks in virologically suppressed HBV cirrhosis

Ling Zhou[1], Jiankang Song[1], Mingchen Wang[1], Qiaoping Wu[1], Peishuang Xu, Jinjun Chen[2], HaiYu Wang[1]. [1]*Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, State Key Laboratory of Multi-organ Injury Prevention and Treatment, Key Laboratory of Infectious Diseases Research in South China (Southern Medical University), Ministry of Education, Guangzhou, China;* [2]*Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University,*

Chongqing, China, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, Chongqing, China
E-mail: 375612668@qq.com

Background and aims: The independent prognostic role of metabolic dysfunction (MD) in virologically suppressed HBV-related cirrhosis remains unclear. This study aimed to evaluate the prognostic value of MD and its components, by combining them with the Baveno VI-SSM model for risk stratification of LREs (hepatic decompensation and hepatocellular carcinoma).
Method: We enrolled 855 patients with HBV-related compensated cirrhosis who had achieved sustained virological suppression (undetectable HBV DNA for ≥6 months) on antiviral therapy. Patients were recruited from April 2019 to April 2022 at Nanfang Hospital, China. Participants were categorized by MD status (present [≥1 cardiometabolic risk factor] vs. absent) and glycemic status (normal, prediabetes, diabetes). Cumulative incidence of LREs was analyzed using Kaplan–Meier curves and multivariable Cox regression. Risk stratification further combined MD with the Baveno VI-SSM criteria (liver stiffness measurement [LSM] <20 kPa and platelet count >150 × 10^9/L, or spleen stiffness measurement [SSM] ≤ 40 kPa).
Results: MD was present in 75.8% (648/855) of patients (mean age 48.6 [SD 9.46] years; 83.3% male; 13.9% diabetes; median LSM 10.4 [IQR 7.4–17.0] kPa; median SSM 42.0 [27.3–65.2] kPa). During median follow-up of 31.0 months (IQR 26.5–43.5), MD patients had higher cumulative LRE incidence than non-MD (7.1% vs. 1.4%; log-rank P = 0.0026). Decompensation occurred exclusively in MD (P = 0.035), with higher HCC incidence (P = 0.023). Multivariable analysis showed MD independently raised LRE risk (aHR 3.48, 95% CI 1.07–11.33), adjusted for age, sex, BMI, baseline LSM, ALT, and FIB-4. Risk escalated dose-dependently by glycemic status (normal < prediabetes < diabetes; [HR for prediabetes: 2.46, 95% CI 2.17–5.17; p = 0.007]; [HR for diabetes: 4.01, 95% CI 1.63–9.89; p < 0.001]). By 48 months, cumulative LRE incidence diverged markedly within the MD subgroup: 13.9% in the unfavorable Baveno VI-SSM category versus 2.4% in the favorable (log-rank P < 0.001; HR 6.24, 95% CI 3.46–11.26). Decompensation rates were 4.5% versus 0% and HCC rates 9.4% versus 2.4% (HR 4.13, 95% CI 2.08–8.20; P < 0.001).
Conclusion: Metabolic dysfunction, especially dysglycemia, independently predicts liver disease progression in virologically suppressed hepatitis B virus-related compensated cirrhosis. Integrating metabolic assessment with the Baveno VI-SSM model enhances risk stratification, facilitating targeted surveillance and intervention for high-risk subgroups.

WED-545
Perioperative mortality, morbidity and sex-specific outcomes in cirrhotic patients undergoing non-hepatic surgeries: a multi-centered cohort study propensity score analysis
Julie Zhu[1], Victoria Straub[2], Patrick Gallagher[1], Ian Epstein[1], Magnus McLeod[3], Kara Matheson[4], Boris Gala-Lopez[5]. [1]*Digestive Care and Endoscopy, Dalhousie University, Halifax, Canada;* [2]*Faculty of Medicine, Dalhousie University, Halifax, Canada;* [3]*PEI Health, Charlottetown, Canada;* [4]*Research Methods Unit, NSHA, Halifax, Canada;* [5]*Department of Surgery, Dalhousie University, Halifax, Canada*
Email: julie.zhu@nshealth.ca

Background and aims: Patients living with cirrhosis may experience higher mortality and morbidity after non-liver related surgeries. We aim to evaluate the impact of cirrhosis and sex on 90-day outcomes after five non-hepatic surgeries.
Method: This is a population cohort study using provincial administrative health data. Data pull and dataset linkage were performed on those underwent partial/total colectomies, abdominal hernia repairs, hip/knee arthroplasties, bariatric surgeries or cholecystectomies in 10 centers from 2010 to 2022. Three primary outcomes were all cause-mortality, LOS, and readmission within 90 days of discharge (if survived). Propensity score analysis was based on inverse probability of treatment weighting, adjusting for baseline characteristics. Conditional logistic regression models were used to estimate odds ratio (OR) for all-cause mortality and marginal Cox frailty models to estimate hazard ratio (HR) for LOS and readmission. Multivariable analyses and sensitivity analysis were performed.
Results: Among a total of 158749 de-identified pts, 42228 with hospital admissions formed the analysis cohort. Outcomes of 1630 with cirrhosis were compared with 40,598 without cirrhosis. 51.7% (21845) were female. In adjusted analysis, the odds of 90-day all-cause mortality was higher for cirrhosis (OR 3.52 (95% CI 2.86, 4.34) p < 0.0001) compared to those without. Surgery type (global p < 0.0001) was also an independent risk factor in mortality. The association between surgery type and mortality varied by cirrhosis (interaction p-value < 0.0001). There was no statistically significant difference in mortality between sexes (OR 0.94 (95% CI 0.83, 1.05) p 0.2709). Cirrhosis (HR 0.43 (95% CI 0.40, 0.45) p < 0.0001), female sex (HR 0.93, 95% CI (0.91, 0.95) p < 0.0001) and surgery type (global p <0.001) were strong predictors of prolonged LOS in adjusted analysis. Readmission post discharge was independently associated with cirrhosis (HR 1.93 95% (CI 1.73, 2.15) p < 00001) and surgery type (p < 0.0001). Major orthopedic surgeries had the highest readmissions after index surgery (HR 1.91 95% CI (1.76, 2.07) p < 0.0001) compared to cholecystectomy.
Conclusion: Cirrhotic patients had higher post-op mortality, and various complications. The study also highlighted sex in determining post-op LOS, surgical type such as major orthopedic, non-elective surgeries in determining post-op outcomes. The results have major implications on resource allocation and perioperative care in patients with cirrhosis.

Fibrosis – Stellate cell biology

TOP-342-YI
Hepatic B cells interact with invariant natural killer T cells via CD40 to stimulate hepatic stellate cells
Jihyo Byun[1], Kyurae Kim[1], Kwangwoo Lee[1], Won-il Jeong[1]. [1]*Korea Advanced Institute of Science and Technology (KAIST), Daejeon 34051, Korea, Rep. of South*
Email: wijeong@kaist.ac.kr

Background and aims: Hepatic B cells contribute to liver fibrosis by secreting cytokines that activate hepatic stellate cells (HSCs), yet the mechanisms remain unclear. In the fibrotic microenvironment, damaged hepatocytes release damage-associated molecular patterns (DAMPs), including lipid-related molecules. In addition, B cells can present lipid antigens to invariant natural killer T (iNKT) cells via CD1d–T cell receptor (TCR) engagement, together with CD40–CD40L co-stimulatory signaling. Thus, this study examined the potential role of B-iNKT cell interactions in liver fibrosis.
Method: Wild-type (WT) and B cell-specific CD40-deficient mice were treated with carbon tetrachloride (CCl_4). Then, blood chemistry, histological staining, immunofluorescence, and qRT-PCR were performed. Primary hepatic cells were analyzed by bulk RNA sequencing, single-cell RNA sequencing (scRNA-seq), and flow cytometry. *In vitro* migration assays and co-culture experiments were conducted using hepatocytes, B cells, iNKT cells, and HSCs.
Results: Bulk RNA-seq revealed significant upregulation of B cell activation markers, including *Cd40, Cd86*, and *Cxcr4* in the fibrotic livers of WT mice compared to controls. Consistently, flow cytometry and immunostaining demonstrated marked accumulation of B cells and their interaction with activated HSCs (aHSCs) within fibrotic septa. Moreover, scRNA-seq and qRT-PCR analyses revealed aHSCs as the principal source of the B cell-recruiting chemokine ligand, CXCL12. In line with this, *in vitro* chemotaxis assays showed enhanced

B cell migration toward aHSCs, confirming their interaction, whereas aHSCs expressed neither TCR nor CD40L to stimulate B cells. Instead, we observed upregulated CD1d and CD40 in B cells isolated from CCl_4-treated mice or co-cultured with conditioned media from damaged hepatocytes, suggesting that B-iNKT cell interactions in fibrotic areas contribute to HSC stimulation. Both *in vivo* and *in vitro*, CD40 deficiency in B cells reduced CD1d and B-iNKT interactions, thereby attenuating HSC activation and liver fibrosis through decreased expression of *Tnfa* and *Tgfb*1.

Conclusion: Our findings indicate that aHSCs recruit B cells to the fibrotic niche through the CXCL12-CXCR4 axis, where hepatocyte-derived lipid-related DAMPs may initiate B-iNKT cell interactions. These interactions promote the production of fibrotic mediators by B cells via CD1d/TCR and CD40/CD40L signaling. Collectively, this mechanism highlights a potential therapeutic strategy for treating liver fibrosis.

Email: rfrances@umh.es

Background and aims: We have described a loss of expression of LSECtin in hepatic antigen-presenting cells in human cirrhotic liver biopsies that correlates with an expansion of a proinflammatory hepatic Th17 immune response.

Method: This project aims at delivering genetic cargo into the hepatic antigen presenting cells to restore the LSECtin expression for reducing the T-cell mediated inflammation. We used immortalized Kuppfer cells (imKCs) and liver sinusoidal endothelial cells (imLSECs), primary hepatic cells, and organs obtained from control and cirrhotic mice treated or untreated with functionalized nanoparticles. 10w-old male mice were subjected to a chronic liver injury protocol with 2 weekly oral doses of weight-controlled CCl_4 for 3 months. Control mice received vehicle (olive oil). A subgroup of mice received functionalized nanoparticles intraperitoneally twice per week in the last two weeks of liver injury protocol.

Results: Functionalized nanoparticles reached mainly the liver and its content was expressed by the endothelial cells found in the hepatic sinusoids. Administration of functionalized nanoparticles retrieved the gene and protein expression of LSECtin in the liver of mice with cirrhosis; and this effect is observed mainly in isolated hepatic LSECs, but not in isolated hepatic macrophages. The recovery of LSECtin expression in the cirrhotic liver is associated with lower infiltration of T lymphocytes (CD3) which suffer an immune reprogramming towards an antiinflammatory Treg phenotype. As consequence of reduced liver inflammation, we observe lower deposition of extracellular matrix proteins in the liver of mice with cirrhosis treated with functionalized nanoparticles, and improved liver function due to reduced circulating levels of ALT/AST and restored levels of albumin when compared to untreated cirrhosis mice. Mice with cirrhosis treated with functionalized nanoparticles showed reduced neuroinflammation due to reduced infiltration of myeloid cells in the brain and reduced protein expression of granzyme B in brain tissue homogenates.

Conclusion: LSECtin delivery by funcionalized nanoparticles increased the hepatic expression of LSECtin in experimental cirrhosis, leading to a reduction of T-cell mediated inflammation and fibrosis progression.

SIRT4 enhances NK cell cytotoxicity against hepatic stellate cells and reverses liver fibrosis via the AMPKα/p53/NKG2DL axis

Huan Chen[1], Feng Zhang[1], Yuzheng Zhuge[1]. *[1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China*
Email: ch960361753@163.com

Background and aims: Natural killer (NK) cells possess potent antifibrotic activity in liver fibrosis (LF) by directly targeting and suppressing activated hepatic stellate cells (HSCs). SIRT4, a key mitochondrial regulatory protein, is known to bridge cellular energy metabolism and viability. Nevertheless, its specific role in regulating NK cell-mediated cytotoxicity against HSCs has remained undefined.

Method: Liver fibrosis models were established in SPF C57BL/6 mice via CCl_4 injection or DDC diet. Human liver tissues were from fibrotic patients and healthy donors. Mouse HSCs were isolated by collagenase perfusion and density gradient centrifugation, activated by culture; human HSCs (LX-2) were cultured routinely. Splenic NK cells were isolated and cultured with IL-2. SIRT4 overexpression (pcDNA3.1-SIRT4) and knockdown (si-SIRT4) were performed in HSCs. Therapeutically, AAV8-pGAFP-SIRT4 mediated HSC-specific SIRT4 overexpression, with NK cell depletion to verify effect dependency. Functional and molecular assays detected NK cell cytotoxicity, AMPKα-p53 signaling, and ULBP1/2 expression.

Results: We observed a significant downregulation of SIRT4 in activated HSCs, in mouse models of LF (induced by CCl_4 or DDC), and in liver tissues from patients with fibrosis. Functional studies revealed that SIRT4 overexpression in HSCs enhanced their susceptibility to NK cell-mediated killing, whereas SIRT4 knockdown impaired it. Mechanistically, SIRT4 activates AMPKα, leading to enhanced phosphorylation and nuclear translocation of p53. Activated p53 directly binds to the promoters of ULBP1 and ULBP2, key ligands for the NKG2D receptor, and transactivates their expression. This SIRT4-AMPKα-p53 signaling axis thereby upregulates NKG2D ligands on HSCs, promoting NK cell recognition and cytotoxicity. Therapeutically, HSC-specific overexpression of SIRT4 via an adeno-associated virus vector (AAV8-pGAFP-SIRT4) activated hepatic NK cells, enhanced the clearance of activated HSCs, and effectively attenuated liver injury and fibrosis in mice. This antifibrotic effect was abolished upon NK cell depletion.

Conclusion: Our findings establish SIRT4 as a critical regulator of NK cell cytotoxicity against HSCs, operating through the novel AMPKα-p53-ULBP1/2 pathway. HSC-targeted SIRT4 gene therapy represents a promising and novel therapeutic strategy for the treatment of liver fibrosis.

FRI-304

Evaluation of clinically approved drugs in a Sprague-Dawley rat model of liver fibrosis induced by choline-deficient, L-amino acid defined (CDAA) diet

Jianing Zhou[1], Yanhao Qiu[1], Laia Vilà[1,2], Emma Barroso[1,2], Juan Carlos Laguna[1,2,3], Marta Alegret[1,2,3], Núria Roglans[1,2,3]. [1]*School of pharmacy and food sciences, Universitat de Barcelona, Barcelona, Spain;* [2]*IBUB, Barcelona, Spain;* [3]*CIBERObn, Barcelona, Spain*
Email: roglans@ub.edu

Background and aims: We have previously demostrated that pemafibrate, telmisartan and bempedoic acid administration prevents hepatic steatosis development in an experimental model of simple metabolic-associated steatotic liver disease (MASL) in Sprague-Dawley (SD) rats. In the current study, we aim to evaluate the effectiveness of these drugs for the treatment of liver fibrosis in a male rat model supplemented with a high-sucrose, high-fat, choline-deficient, L-amino acid-defined (CDAA) diet during three months.
Method: 42 Male (M) SD rats were randomly distributed into 5 groups: (1) control (CT; n = 6), which were fed standard chow, (2) CDAA (n = 8), (3) Pemafibrate (PEM; n = 8), (4) Telmisartan (TEL; n = 10) and (5) Bempedoic acid (BEMA; n = 10), which were fed the CDAA diet. All groups were maintained on their respective diet for three months. In the treatment groups, their respective compound was incorporated in the CDAA chow during the last month of feeding. At the end of the treatment period, blood samples were collected for serum isolation and liver tissue for RNA and protein extraction. Inflammatory and fibrotic processes were determined throw gene expression and serum analytes.
Results: After 3 months, CDAA diet increased significantly serum levels of hepatic injury markers, including alanine aminotransferase (ALT) (2.6X) and aspartate aminotransferase (AST) (1.75X). Among the tested compounds, bempedoic acid was the only one to significantly reduce transaminase levels, whereas telmisartan and pemafibrate each lowered one of them. Furthermore, all drug treatments reverted mRNA expression of several genes associated with MASH development compared with the CDAA group including genes related to fibrogenesis (*Acta2, Col1a1, Col1a2*), profibrotic mediators (*Tgf-ß, Pai-1*), extracellular matrix remodelling regulators (*Timp-1*), pro-inflammatory cytokines (*Tnf-α, Il1b*) and macrophage marker (*F4.80*). These findings are consistent with the ACTA2 and Col1A1 protein expression results, obtained by western blot analysis.
Conclusion: Our preliminary results suggest that the MASH induced by high-sucrose, high-fat, choline-deficient, L-amino acid defined diet (CDAA) in rats can be reversed through treatment with pemafibrate, telmisartan, and bempedoic acid. Nonetheless, these conclusions remain preliminary and additional experiments are needed to validate these results.
Grants: PID2023-146140OB-I00, funded by funded by MICIU/AEI/10.13039/501100011033 and FEDER-UE and 2021SGR-00345.

Email: amira.abdelhamid@ngu.edu.eg

Background and aims: Hippo pathway effectors, yes-associated protein (YAP) and transcriptional coactivator with PDZ-binding motif (TAZ), are key regulators of hepatic stellate cell (HSC) activation in liver fibrosis. Long non-coding RNAs (lncRNAs) are recognized as upstream modulators of YAP/TAZ and central contributors to HSC activation. However, their roles as downstream targets of YAP/TAZ in liver fibrosis remain unclear. Building on our prior identification of a YAP/TAZ-regulated lncRNA signature in hepatocellular carcinoma (HCC), this study aimed to characterize lncRNAs downstream of YAP/TAZ in HSCs and determine their contribution to HSC activation.
Method: To identify YAP/TAZ-regulated lncRNAs, YAP/TAZ knockdown (KD) was performed in LX-2 cells followed by RNA sequencing. Differentially expressed (DE) lncRNAs were shortlisted, and SNHG16 was selected for validation. SNHG16 levels were quantified by qRT-PCR after YAP/TAZ overexpression to evaluate its YAP/TAZ-mediated regulation, and after TGF-beta stimulation to assess its response to fibrogenic signaling. The functional impact of SNHG16 KD was assessed by quantifying HSC activation markers (alpha-SMA, COL1A1, TIMP2, TGF-beta, and MMP2) via qRT-PCR, with alpha-SMA protein levels validated by western blot (WB) and immunofluorescence (IF). Whole-proteome analysis was carried out in LX-2 cells after SNHG16 KD. DE proteins were identified, and enrichment analyses were used to characterize the biological processes and pathways impacted.
Results: YAP/TAZ KD resulted in 145 DE lncRNAs. Among these, SNHG16 was downregulated and selected for validation. Overexpression of YAP or TAZ elevated SNHG16 expression ($p < 0.0001$ and $p = 0.0266$, respectively). TGF-beta stimulation also induced SNHG16 ($p = 0.004$), implicating its role in fibrogenesis. Functionally, SNHG16 KD reduced mRNA levels of alpha-SMA ($p < 0.0001$), COL1A1 ($p < 0.0001$), TGFB1 ($p = 0.002$), and TIMP2 ($p = 0.0015$), and increased MMP2 ($p = 0.039$). alpha-SMA protein levels were decreased as indicated by WB ($p = 0.0161$) and IF ($p = 0.0435$). SNHG16 KD suppressed HSC proliferation ($p < 0.0001$), transwell migration ($p < 0.0001$), and colony formation ($p = 0.0005$). Whole proteome analysis showed SNHG16 KD dysregulated 328 proteins, enriched in cell cycle control, metabolic processes, and stress-response reprogramming in HSCs.
Conclusion: SNHG16 may act as a YAP/TAZ-dependent lncRNA that regulates various aspects of HSC biology. Its silencing could therefore be a potential therapeutic target in liver fibrosis.

FRI-306-YI

Anticoagulation attenuates liver fibrosis via targeting neutrophil extracellular traps and proteasome

Yingjie Ai[1,2], Detlef Schuppan[2], Shiyao Chen[1]. [1]*Zhongshan Hospital, Fudan University, Shanghai, China;* [2]*University Medical Center, Johannes Gutenberg University, Institute of Translational Immunology and Research Center for Immunotherapy, Mainz, Germany*
Email: 23111210016@m.fudan.edu.cn

Background and aims: Neutrophil extracellular traps (NETs) contribute to liver fibrosis by sustaining inflammation and activating hepatic stellate cells. Given that anticoagulants demonstrate antifibrotic potential in preclinical models and they modulate neutrophil activation and NETs formation, anticoagulation may suppress NETs release and thereby attenuate fibrogenesis. The 20S proteasome, the catalytic core of the ubiquitin–proteasome system, regulates immune responses and oxidative stress. This study aimed to investigate whether anticoagulation mitigates liver fibrosis through modulation of NETs and 20S proteasome activity.
Method: Advanced liver fibrosis was induced in mice via intraperitoneal injection of thioacetamide (TAA, 150 mg/kg), three times per week for 12 weeks. Mice were randomly divided into a treatment group (the factor X antagonist Edoxaban, Edo) and a control group

(Ctr) (each n = 6). Edo was given as a suspension by gavage (30 mg/kg in 0.2 ml) daily for 3 weeks, while controls received the same volume of saline, from week 10. Liver fibrosis, NETs formation and 20S proteasome subunit genes were assessed via RNA sequencing, WB and IHC.
Results: Masson's trichrome and Sirius Red staining revealed significantly reduced hepatic collagen deposition in the Edo group. RT-qPCR and WB demonstrated marked downregulation of fibrosis-related genes, including Col1a1, Fn, and Acta2 in the Edo group. Differential gene expression analysis also revealed enrichment in the NETs formation pathway. HE staining of the Edo group showed a significantly reduced neutrophil infiltration while IHC revealed reduced expression of NETs markers, including Myeloperoxidase and Neutrophil elastase. WB confirmed lower levels of citrullinated histone H3, another hallmark of NETs. Further correlation analysis across 68 NETs-associated genes identified multiple 20S proteasome subunit genes (Psmb7, Psma5, Psma6, Psmb1, Psmd8, Psmc2, Psmc5, Psmd6 etc.) as positively correlated with NETs markers and significantly downregulated in the Edo group. These transcriptomic alteration was validated by reduced protein expression detected via WB and IHC. Moreover, 20S proteasome activity assay demonstrated a significant decline in enzymatic activity upon anticoagulation.
Conclusion: Our findings suggest that anticoagulant therapy alleviates liver fibrosis by suppressing NETs formation and modulating proteasome activity. These results reveal a potential interplay between coagulation, innate immunity, and proteostasis in fibrogenesis.

FRI-307
ALR deficiency promotes HSCs activation and deteriorates liver fibrosis by perturbation of MCU-mediated calcium homeostasis
Ye Li[1], Yan-bo Wei[1], Ming-qiang Liu[1], Ling-Yue Dong[1], Wei An[1].
[1]*Capital medical university, Beijing, China*
Email: anwei@ccmu.edu.cn

Background and aims: Hepatic stellate cells (HSCs) activation is a pivotal pathogenesis for liver fibrosis (LF). Mitochondrial calcium (mCa^{2+}) dyshomeostasis is reportedly to contribute HSCs activation. We previously demonstrated that ALR overexpression could inhibit HSCs activation potentially through regulating mitochondrial calcium uniporter (MCU). However, the precious mechanisms dealt with ALR interaction with MCU remains unexplored. This study is aiming to unveil whether ALR inhibition on LF progression is associated to maintenance of mCa^{2+} homeostasis through interplay with MUC.
Method: *Alr* liver-knockout (ALR^{-CKO}) mice were established and LF were prepared either by fed choline-deficient high-fat diet (CD-HFD) or bile-duct ligation (BDL).
Results: We demonstrated that ALR expression was continuously downregulated in fibrotic livers of patients (F0-F4). Similarly, HSCs activation and LF lesion were deteriorated following CD-HFD or BDL treatment. The in-vitro study showed that *Alr*-deletion promoted mCa^{2+} influx by disrupting the dimerization of mitochondrial calcium uptake 1/2 (MICU1/2), the core regulatory components of MCU complex, which was coincided with HSCs activation. We confirmed that MICU1/2 dimerization was remarkably reduced both in human and mouse fibrotic liver tissues, which was positively correlated with decreasing ALR expression. Intriguingly, as confirmed by Co-IP assay, ALR appeared to interact mildly with MICU1 or MICU2, implying that ALR-offering modulation on MICU1/2 dimerization might probably be mediated by an alternative molecule. It is known that CHCHD4 is central to the functions of the mitochondrial disulfide relay system (DRS). To identify if ALR, as a member of DRS, could putatively modulate MICU1/2 dimerization via affecting CHCHD4 redox capacity, we then unveil on interaction between ALR and CHCHD4. Molecular analysis demonstrated that ALR could strengthen CHCHD4 activity via redox modification, enhance MICU1/2 dimerization, restrain mCa^{2+} overflow and ultimately HSCs activation. Further bioinformatic analysis and experiment results showed three cysteine residues at C4, C53, and C55 in CHCHD4 were apparently crucial to assist in MICU1/2 dimerzation since mutations of these cysteines resulted in significant loss of ALR interacting with CHCHD4, impairing ALR ability to restrict HSCs activation.
Conclusion: In all, current study elucidates novel mechanism for ALR alleviation of LF by promoting MICU1/2 topology and inhibiting mCa^{2+} dyshomeostasis in HSCs.

FRI-308
Lysyl oxidase inhibition disrupts angiogenin directed hepatic stellate cell activation influence by hepatoma cells
Basundhara Das[1], Bornika Roy[1], Prachi Sharma[1], Maryam Shaikh[2], Sampa Ghose[3], Subhrajit Biswas[1]. [1]*Amity Centre for Liver Research (ACLR), Amity Institute of Molecular Medicine & Stem Cell Research (AIMMSCR), Amity University Uttar Pradesh, Sector 125, Noida, India;* [2]*Heersink School of Medicine, University of Alabama at Birmingham, Birmingham, United States;* [3]*Department of Medical Oncology, All India Institute of Medical Sciences, New Delhi, India*
Email: dhara4713@outlook.com

Background and aims: Liver cancer progression relies on hepatoma cells fostering a supportive tumour microenvironment, often by activating hepatic stellate cells (HSCs). Lysyl oxidase, a matrix-modulating enzyme secreted abundantly by activated HSCs, plays a crucial role as collagen crosslinker in creating this microenvironment. Angiogenin (ANG) is known to play a key role in Hepatocellular Carcinoma (HCC)-mediated HSC activation. In previous studies, although individual inhibition of ANG and LOX has shown in reducing HCC influenced HSC activation and HCC progression respectively, their mechanistic interaction is unexplored. This study investigates targeting the enzymatic activity of LOX to abrogate HCC-mediated HSC activation via angiogenin and thereby reduce ECM remodeling during HCC progression.
Method: HCC stimulated LX2 (HSCs) cells were treated with a pan-LOX inhibitor (βAPN) or a specific LOXL2 inhibitor (LOXL2IN) *in vitro*. Angiogenin expression and nuclear localization were assessed via western blotting and immunofluorescence. CCl_4 was used to generate fibrotic/ cirrhotic background in orthotopic tumours by directly injecting Hepa1-6 cells in BL/6 mice to study the effect of βAPN (100 mg/kg) or LOXL2IN (10 mg/kg) *in vivo*. Liver sections were analyzed for fibrosis/cirrhosis, tumor size, histological staining as well as immunohistochemistry of Angiogenin, αSMA and ECM components (collagen, elastin).
Results: HepG2 secretes angiogenin as an inducer of LX2 cells' activation by altering various ECM proteins. We have stimulated LX2 cells by HepG2-conditioned media, where the expressions of LOX, LOXL2, αSMA were upregulated along with both angiogenin expression and its nuclear translocation. LOX inhibition significantly reduced αSMA and angiogenin expression in protein lysates and prevented nuclear translocation of angiogenin, rather retaining it peripherally/cytoplasmically or secreted, thereby mitigating HCC-mediated LX2 activation. *In vivo*, LOX inhibition reduced tumor size with less Ki67 expression and altered angiogenin localization in αSMA^{+} cells, aborogated ECM components.
Conclusion: Targeting LOX enzymatic activity effectively disrupts the self-sustaining cycle of hepatoma cells via HSCs by indirectly hindering the angiogenin axis, specifically its nuclear translocation and further transcriptional stimulation of lysyl oxidase gene family, suggesting a promising therapeutic strategy in HCC.

FRI-313
Resmetirom ameliorates fibrogenesis in hepatic stellate cells via thyroid hormone receptor alpha-fatty-acid-amide hydrolase 1 signalling pathway
Alba Cabaleiro[1], Eva Novoa[1], Borja López-Picallo[1], Natalia Lima[1], Cristina Roibello[1], Carmen Pena[2], Jose Iglesias-Moure[1], Ana Senra[1], María Luz Martínez-Chantar[3], Anabel Fernández-Iglesias[4],

Lille, Inserm, CHU Lille, Laboratory of Development and Plasticity of the Neuroendocrine Brain, Lille, France;* [6]*Universität Zu Lübeck, Lübeck, Germany*
Email: albalopez.cabaleiro@usc.es

Background and aims: Resmetirom is a liver-directed, thyroid hormone receptor beta (THRb)- selective agonist approved for treating metabolic-associated steatohepatitis (MASH) with moderate to advanced fibrosis. While Resmetirom hepatocyte-specific effects are well-established, its impact on other hepatic cells, particularly hepatic stellate cells (HSCs), the main fibrogenic cells, remains unknown. Accordingly, the aim of this study is to elucidate a potential direct role of Resmetirom in HSCs activation and fibrogenesis onset.
Method: Animal models, immortalized cell lines, and primary murine and human HSCs were used in combination with pharmacological treatments and genetic manipulation of thyroid hormone receptor-α (THRa) and fatty acid amide hydrolase (FAAH) to evaluate the effects of Resmetirom on the fibrogenic process.
Results: Resmetirom ameliorates MASH in mice through actions in both hepatocytes and HSCs. Resmetirom attenuates transforming growth factor beta-1(TGF-B1)-induced HSC activation via THRa and increased FAAH expression and activity. In contrast, their inhibition prevents Resmetirom from reducing fibrotic marker expression and the elevated glycolytic activity typical of activated HSCs.
Conclusion: These results uncover an unrecognized mechanism of action for Resmetirom, demonstrating that its antifibrotic efficacy extends beyond hepatocytes to include direct effects on HSCs via THRa and FAAH. Furthermore, these results may support future patient stratification, as individuals harboring THRa mutations could exhibit reduced responsiveness to treatment.

FRI-314

Targeting TRIM54: a potential protective strategy against liver injury in cirrhosis

Fan-E Cheng[1], Yaxi Zhang[1], Shihao Zheng[1], Wenying Qi[1], Size Li[1], Qiuyue Wang[1], Xinyu Zhao[1], Chunfeng Mei[1], Xiaobin Zao[2], Yong'an Ye[3]. [1]*Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China;* [2]*Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China;* [3]*Institute of Liver Diseases, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China*
Email: 18801020531@163.com

Background and aims: Cirrhosis represents the terminal stage of various chronic liver diseases, hallmarked by progressive fibrosis, architectural distortion, and eventual functional failure. TRIM54, a key member of the TRIM family, has been implicated as a central regulator in multiple hepatic pathological processes. However, its precise function and underlying mechanisms in the initiation and progression of cirrhosis remain elusive. This study aims to systematically elucidate the biological role of TRIM54 and delineate its molecular regulatory network during cirrhotic progression, thereby providing novel theoretical insights and identifying potential therapeutic targets for this disease.
Method: To investigate the role of TRIM54 in cirrhosis, we established two complementary rodent models: a DEN-induced rat model and a CCl_4-induced mouse model of liver cirrhosis. Phenotypic and mechanistic validation was performed using an AAV8-mediated liver-specific knockdown of TRIM54. This intervention was assessed through a combination of serum biochemical analysis, histopathological staining, Western blotting, and quantitative real-time PCR (qRT-PCR). Furthermore, an integrated multi-omics analysis was conducted by combining transcriptomic and proteomic sequencing data.
Results: TRIM54 expression was significantly upregulated in cirrhotic tissues, and its expression level was positively correlated with fibrosis markers (α-SMA and Col1a1). Concurrently, knockdown of TRIM54 led to marked improvements in liver function, accompanied by a reduction in fibrosis and inflammation, as well as suppression of Wnt/β-catenin signaling pathway activation. Integrated multi-omics analysis revealed significant co-enrichment of the Wnt signaling pathway, ubiquitin-mediated proteolysis, and PPAR signaling pathway at both the gene and protein levels, further validating that TRIM54 knockdown exerts its regulatory effects through these pathways. Mechanistically, TRIM54 was shown to promote the ubiquitination and subsequent degradation of AXIN1, thereby modulating the activation status of the Wnt/β-catenin signaling pathway.
Conclusion: The mechanism by which TRIM54 drives cirrhosis involves the ubiquitination-mediated degradation of AXIN1, leading to constitutive activation of the Wnt/β-catenin pathway. Notably, knockdown of TRIM54 reverses this activation and ameliorates disease progression, supporting its therapeutic potential.

Effects of combined Atorvastatin and Ambrisentan treatment on hemodynamic alterations and liver fibrosis in a translational rat model of advanced MASLD

M Serra Cusidó[1,2], Imma Raurell[1,2,3,4], María Martínez-Gómez[1,2,4], Eduard Mas[1,3], Juan M. Pericàs[1,2,3,4], Joan Genesca[1,2,3,4]. Email: maria.cusido@vhir.org

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by hepatic steatosis, which can progress to inflammation, fibrosis, and portal hypertension (PH). Despite its increasing clinical burden, therapeutic options remain limited due to the lack of translational animal models. Previous work from our group developed a non-fibrotic NASH model, which, when treated with Atorvastatin (Ato) and Ambrisentan (Amb) reduced steatohepatitis and PH. Considering those results, in this study we evaluate the combined effect of Ato and Amb on liver fibrosis, endothelial dysfunction, and hemodynamic alterations in a recently developed translational model of MASLD with advanced fibrosis.
Method: Male Sprague-Dawley rats were fed for 20 weeks with control diet (CD) or high-fat high-cholesterol diet supplemented with cholic acid and a glucose/fructose beverage (HFD). During the last 4 weeks, HFD rats received 10 mg/kg Ato, 2 mg/kg Amb, or both. At endpoint, liver hemodynamic was assessed, hepatic stellate cells (HSC) were isolated and liver samples were collected.
Results: MASLD rats exhibited increased AST/ALT, PH, insulin resistance, steatohepatitis and advanced fibrosis, corresponding to our known model features. Neither Ato nor Amb alone or combined reduced body weight or insulin resistance. Endothelial dysfunction was reversed by AtoAmb as P-Enos and KLF2 were restored. Markedly, AtoAmb led to fibrosis regression, evidenced by (1) decreased histological fibrosis stage, (2) reduced collagen deposition, (3) downregulation of Col1a1 and alpha-SMA to near-control levels, and (4) lower levels of metalloprotease inhibitor TIMP1. Moreover, AtoAmb HSC prevented collagen gel from contracting, indicating reduced cellular contractility. However, severe steatosis and PH remained unaffected. Linear modelling of portal pressure showed a poor association with fibrosis but a stronger correlation with steatosis

severity, both assessed histologically and quantitative, suggesting steatosis as the main driver to sinusoidal compression and so PH.
Conclusion: The combination of AtoAmb demonstrated a synergistic antifibrotic effect in a translational rat model of MASLD but failed to reduce PH, likely due to persistent severe steatosis and sinusoidal compression. These findings highlight the dissociation between fibrosis and portal pressure in advanced MASLD and emphasize the need for multi-targeted strategies addressing both lipid accumulation and fibrosis for effective PH management.

FRI-316
MicroRNA-based predictive staging of liver fibrosis severity in chronic liver disease
Alejandro del Castillo-Cruz[1,2,3], Victoria Cairoli[4,5,6], Júlia Cacho-Pujol[1,2,3], Lucía Calderón-Robles[1], Núria Benítez-Paredes[1], María Victoria Preciado[4,5,6], Pamela Valva[4,5,6], Anna Moles[1,2,7]. *[1]Instituto de Investigaciones Biomédicas de Barcelona (IIBB-CSIC), Barcelona, Spain; [2]IDIBAPS, Barcelona, Spain; [3]Universitat de Barcelona, Barcelona, Spain; [4]Instituto Multidisciplinario de Investigaciones en Patologías Pediátricas (IMIPP), Buenos Aires, Argentina; [5]CONICET-GCBA, Buenos Aires, Argentina; [6]Hospital de Niños Ricardo Gutiérrez, Buenos Aires, Argentina; [7]CiberEHD, Madrid, Spain*
Email: alejandro.cc.lab@gmail.com

Background and aims: Chronic liver diseases (CLD) are an increasingly common cause of global morbidity and mortality, characterized by persistent inflammation, activation of hepatic stellate cells, and extracellular matrix accumulation. In the absence of specific antifibrotic therapies and validated biomarkers, microRNAs (miRNAs) have emerged as key epigenetic regulators of fibrogenesis and liver regeneration. This study aims to characterize their expression profile in murine models and human CLD samples to evaluate their diagnostic, functional, and therapeutic potential.
Method: Levels of miR-92a-3p, miR-122-5p, miR-194-5p, miR-320a-3p, and miR-423-3p were quantified by RT-qPCR in livers of C57BL6/J mice subjected to different progressive experimental liver fibrosis models: CCl_4 (4 and 8 weeks, and reversal), BDL (7 and 14 days), MASH (6 months WD+CCl_4 and 2 months CDAHFD). The degree of fibrosis was confirmed by Sirius Red staining, RT-qPCR for Col1A1, TGFβ and hydroxyproline (HP) levels in liver tissue. Results from experimental models were validated in liver tissue and serum extracellular vesicles from patients with chronic hepatitis C (CHC), stratified according to fibrosis stage (METAVIR) $F < 2$ ($n = 16$) vs $F \geq 2$ ($n = 13$).
Results: Murine models showed a progression of liver fibrosis associated with classical markers (SR, Col1A1, TGFβ and HP), allowing differentiation between early and advanced stages. miRNA analysis revealed differential expression according to fibrosis severity: miR-92a-3p, miR-122-5p, miR-194-5p, miR-320a-3p, and miR-423-3p decreased in early stages in the CCl_4 and MASH models, whereas in BDL only miR-122-5p, miR-194-5p, and miR-423-3p decreased. While miR-122-5p, miR-194-5p and miR-423-3p showed a positive correlation with the degree of fibrosis in CCl_4 and MASH, in BDL only miR-122-5p did. These findings were validated in liver tissue and serum extracellular vesicles from CHC patients, where a similar modulation of miRNAs was observed according to fibrosis severity.
Conclusion: Hepatic expression of miR-122-5p, miR-194-5p and miR-423-3p is associated with the degree of fibrosis across different murine models of progressive liver disease and in patients, indicating their potential as biomarkers and therapeutic targets to stage fibrosis progression in chronic liver disease.

FRI-317
Modulation of collagen-binding integrins as a therapeutic strategy to inhibit liver fibrosis
Fatemeh Derakhshandeh[1], Stefan Hamelmann[1], Inaam Nakchbandi[1]. *[1]Heidelberg University Hospital, Heidelberg, Germany*
Email: fatemeh.derakhshandeh@uni-heidelberg.de

Background and aims: Aberrant tissue repair results in extracellular matrix (ECM) accumulation and fibrosis in almost all organs. Integrins are heterodimeric receptors that integrate signals from the matrix. Activation and downstream signaling of integrins leads to changes in the composition of ECM components like collagen. Previous studies highlighted the effects of integrins in various signaling pathways that regulate the onset and progression of fibrosis. Our aim was to study how integrins affect fibrosis and try to pharmacologically modulate these integrins.
Method: In vitro and in vivo studies, fluorescence polarization, proteomic analysis.
Results: siRNA-mediated depletion and genetic deletion of alpha11 and beta1 integrin subunits increased TGF-beta mRNA expression in hepatocytes. Subsequently, several polypeptides were tested for their ability to reduce TGF-beta, and the most effective was the pentapeptide Glycine-Leucine-Glutamine-Glycine-Glutamic (GLQGE) (International patent, PCT/EP2020/071319). GLQGE reduced TGF-beta expression by more than half ($p < 0.001$) in hepatocytes and lowered alpha-smooth muscle actin (alpha-SMA) expression (as a measure of activation) and collagen type I production in primary hepatic stellate cells and in NIH3T3 cells (by 30-50 percent, $p < 0.05$). Fluorescence polarization and in vitro assays, including integrin-specific knockdown controls (in NIH3T3 cells), confirmed that GLQGE binds to both alpha10beta1 and alpha11beta1 integrins. Daily administration of GLQGE in mice for 10 days at the end of a 6-week CCl_4 fibrosis model reduced TGF-beta protein to a third, and decreased alpha-SMA by 40 percent and collagen I by 20 percent ($p < 0.05$ for all). The reduction in alpha-SMA protein suggested that GLQGE directly suppressed the activation of hepatic fibroblasts. Proteomic analysis confirmed modulation of integrin signalling.
Conclusion: By acting on integrins, GLQGE inhibits hepatic stellate cell activation directly through integrin alpha10beta1 and alpha11-beta1, and indirectly via TGF-beta suppression in hepatocytes. This dual mechanism significantly reduces collagen production and alpha-SMA expression in vitro and in a liver fibrosis mouse model, providing clear experimental evidence that GLQGE effectively mitigates liver fibrosis.

FRI-318
Potential protective cooperation of interleukin-6-induced miRNA-9 during acute liver injury may underlie reparative and anti-fibrotic responses
Dana Eidelshtein[1], S. Nahum Goldberg[2], Eithan Galun[1], Jonathan Axelrod[1]. *[1]Hadassah University Hospital-Ein Karem, Goldyne Savad Institute of Gene Therapy, Jerusalem, Israel; [2]Hadassah University Hospital-Ein Karem, Department of Radiology, Goldyne Savad Institute of Gene Therapy, Jerusalem, Israel*
Email: dana.eidelshtein@mail.huji.ac.il

Background and aims: The role of interleukin-6 (IL-6) as a central cytokine involved in suppressing liver injury and fibrosis while promoting regeneration, has been known for several decades, yet its downstream mechanisms remain incompletely defined. MicroRNA-9 has been reported to exert anti-fibrotic effects in chronic liver disease, but its regulation during acute inflammatory liver injury is poorly understood. We aimed to define the relationship between interleukin-6 signaling and miR-9 and to assess whether this axis represents an endogenous mechanism that limits injury and fibrotic progression following acute liver injury.
Method: Single-cell RNA sequencing (scRNA-seq) analysis was used to identify cytokine-driven transcriptional programs following radiofrequency ablation (RFA) induced injury in mice- a clinically relevant

model of acute liver injury. In vitro, hepatocyte-derived cell lines were stimulated with IL-6 followed by quantitative PCR to analyze miR-9 host gene expression and intracellular and secreted mature miR-9 levels.
Results: ScRNA-seq and bioinformatics analysis of mouse liver on days 1 and 7 post-RFA indicated that early activation of interleukin-6 and STAT3 signaling was accompanied by increased miR-9-3HG expression in hepatocytes. Elevated IL-6 mRNA and miR-9 levels post-RFA were confirmed by qPCR analysis of total liver RNA. Incubation of hepatocyte-derived cell lines, HUH-7 and Hepa 1-6, with IL-6 or an IL-6/sIL-6 receptor fusion protein (HIL-6) induced MIR9 gene and mature miR-9 expression in a dose-dependent manner, but not in either HepG2 cells or human stellate cell-derived LX-2 cells.
Conclusion: These findings identify a novel IL-6–miR-9 axis linking inflammatory signaling and the regulation of protective regenerative and anti-fibrogenic responses following acute liver injury. Understanding how IL-6–driven miR-9 induction shapes hepatic cell interactions in the liver parenchyma may provide valuable insight into the mechanisms modulating fibrosis and repair post-injury.

FRI-319
Naringenin attenuates thioacetamide-induced liver fibrosis though epigenomic and transcriptomic reprogramming
Roberto Flores Peña[1], Fernando Caloca Camarena[1], Scarlet Arceo-Orozco[2], Jorge Alejandro Salto-Sevilla[2], Rebeca Rosas-Campos[3], Marina Galicia Moreno[2], Hugo Christian Monroy-Ramirez[2], Juan Armendariz-Borunda[4].

Email: floresp_roberto@hotmail.com

Background and aims: Hepatic fibrosis (HF) arises from the trans differentiation of quiescent hepatic stellate cells (HSC) into a myofibroblast-like phenotype, leading to an imbalance in extracellular matrix (ECM), collagen accumulation, and progressive liver injury. Epigenetic mechanisms may contribute to the persistence of HSC activation and disease progression. Naringenin (NAR), a flavonoid with anti-inflammatory and antifibrotic properties, may counteract these processes. We aimed to evaluate the antifibrotic and epigenetic effects of NAR in a thioacetamide (TAA)-induced HF model.
Method: Male Wistar rats (~200 g) were randomly allocated to five groups (n = 5): untreated (UT); NAR control (100 mg/kg/day, oral) for 4 weeks (NAR 4W); TAA (200 mg/kg, i.p., three times/week) for 4 weeks (TAA 4W); TAA for 8 weeks (TAA 8W); and TAA for 4 weeks followed by NAR for 4 weeks (TAA 4W + NAR 4W). Liver injury and fibrosis were assessed by histology (hematoxylin and eosin, Masson's trichrome, picrosirius red) and Smooth muscle alpha actin (alpha-SMA) immunohistochemistry. Transcriptomic changes were analyzed by ribonucleic acid (RNA) sequencing. Global deoxyribonucleic acid (DNA) methylation (5-methylcytosine, 5mC) was evaluated by dot blot, while DNMT isoforms and histone H3 acetylation were analyzed by western blot. Statistical analysis was performed using one-way ANOVA with Tukey's post hoc test ($p \leq 0.05$).
Results: TAA induced a different fibrosis-associated transcriptomic profile compared with UT. NAR attenuated these alterations, shifting gene expression towards a non-fibrogenic state. Consistently, NAR reduced histopathological injury, collagen I/III deposition, and alpha-SMA immunoreactivity. Fibrosis was associated with increased nuclear DNMT1 and DNMT3A expression and elevated global 5mC levels, whereas NAR reversed these epigenetic changes and restored histone H3 acetylation marks (H3K9ac and H3K14ac).
Conclusion: NAR mitigates HF and reverses epigenetic alterations associated with fibrosis, thus expanding its mechanisms of action as an epigenetic modulator and making it a potential candidate for the treatment of this disease. Further studies are required to clarify additional mechanisms and establish long-term safety before clinical application.

FRI-320
Identification of Sfrp1 in portal fibroblast and biliary fibrosis development
Wenrui Gao[1], Siham Benyahia[1], Haquima El Mourabit[1], Thierry Jaffredo[2], Sara Lemoinne[1], Chantal Housset[1], Nicolas Chignard[1], Axelle Cadoret[1]. *[1]Sorbonne Université, Inserm, Centre de Recherche Saint-Antoine (CRSA), Team Metabolic and biliary diseases of the liver, Paris, France; [2]Sorbonne Université, CNRS, INSERM, Institut de Biologie Paris Seine (IBPS), Laboratoire de Biologie du Développement, Paris, France*
Email: wenrui.gao@inserm.fr

Background and aims: Liver fibrosis results from the accumulation of extracellular matrix produced by myofibroblasts (MFs). In biliary disease, fibrosis arises in the portal area from MFs originating either from portal fibroblasts (PFs) or hepatic stellate cells (HSCs). The aim of our work is to identify the specific role of MFs derived from PFs or HSCs in biliary fibrosis.
Method: Mesenchymal cells were obtained from the bilio-vascular tree of the Abcb4 KO mouse model of biliary fibrosis and the CCl4 model of non-biliary fibrosis after enrichment by FACS by depleting cells expressing EpCAM, CD31, CD45 and CD11b. Mesenchymal cells underwent scRNAseq and resulting data were analyzed with Seurat v5. Fibrogenic cells (HSCs and PFs) were annotated as quiescent or myofibroblastic based on known markers in homeostatic and fibrotic settings. A differential gene expression analysis was performed to identify genes that could discriminate PFs from HSCs.
Results: Portal mesenchymal cells were isolated from Abcb4 KO mice and of CCl4-injected mice with an equivalent amount of liver fibrosis, as ascertained by Sirius red staining and Col1a1 gene expression. Within the scRNAseq data, we first identified fibrogenic cell populations from biliary and non-biliary fibrosis, respectively, and then merged and further annotated them as 8 clusters of MFs and 12 clusters of qPFs and/or qHSCs. Uniform Manifold Approximation and Projection (UMAP) visualization showed distinct projections between fibrogenic cell populations from biliary and non-biliary fibrosis, indicating specific cellular processes involvement. Gene expression analysis identified 12,294 differentially expressed genes (DEGs) between the PF and HSC lineages. Among DEGs, four genes were evidenced that were expressed in PF cells (pct.PF > 50%) and which expression was significantly higher ($p < 0.01$, logFC > 1.8) than in HSCs. Among these four genes, Sfrp1 showed an increased gene expression proportional to fibrotic tissue accumulation in Abcb4 KO and DDC-fed mice, as ascertained on whole liver by RT-qPCR.
Conclusion: By combining cell isolation and scRNAseq analysis, we show a specific involvement of PFs in the portal space during biliary fibrosis, while HSCs are solicited in non-biliary fibrosis. Furthermore, we identified Sfrp1 as a specific marker of the PF lineage that will allow us to better understand the specific involvement of these cells in liver fibrosis.

FRI-321
UBC13 prevents hepatic stellate cell activation by K63 ubiquitination of HMGB1
Sui Guoyan[1], Yoon-Seok Roh[1]. *[1]Department of Pharmacy, Chungbuk National University College of Pharmacy, Cheong-Ju, Korea, Rep. of South*
Email: ysroh@cbnu.ac.kr

Background and aims: Ubiquitination is a critical post-translational modification that regulates hepatic stellate cell (HSC) activation, a key event in the progression of liver fibrosis. Although K48-linked ubiquitination has been extensively characterized, the biological functions of global K63-linked ubiquitination in HSCs remain poorly understood. UBC13, an E2 ubiquitin-conjugating enzyme, specifically catalyzes K63-linked ubiquitination. In current study, we investigated the mechanisms underlying Ubc13-mediated global K63-linked ubiquitination in HSCs and its role in fibrotic progression.
Method: HSC-specific *Ubc13*-deletion mice were generated by crossing *Ubc13*$^{fl/fl}$ mice with Lrat^{Cre} or Pdgfrb^{CreERT2} mice. Liver fibrosis was induced by intraperitoneal injection of 20% carbon tetrachloride or by feeding 3,5-diethoxycarbonyl-1,4-dihydrocollidine diet. Ubiquitin-proteomics analyses were conducted using EV-LX2 and UBC13-overexpressing LX2 cells. Immunoprecipitation–mass spectrometry analyses (IP-MS) were performed in HEK293 T cells transfected with UBC13+K63 or HMGB1+K63 plasmids. RNA-sequencing was performed using EV-LX2 and HMGB1-overexpressing LX2 cells under TGF-β stimulation. UBC13 and α-SMA expression were also analyzed in cirrhotic patient liver samples to evaluate clinical relevance.
Results: During HSC activation, global K63-linked ubiquitination was markedly reduced, while K48-linked ubiquitination remained unchanged. UBC13 expression was significantly downregulated in activated HSCs from both human and murine fibrotic livers. In mice, HSC-specific deletion of *Ubc13* enhanced glycolysis-driven HSC activation and exacerbated liver fibrosis. Mechanistic analyses using ubiquitin proteomics and IP–MS revealed that UBC13 promotes the interaction between TRIM28 and HMGB1, thereby facilitating K63-linked ubiquitination of HMGB1 at Lys147 and its subsequent lysosomal degradation. This degradation restrains glycolysis-driven HSC activation, an effect recapitulated by UBC13 overexpression. Notably, UBC13 expression inversely correlated with α-SMA levels in livers of cirrhosis patients, supporting the translational relevance of the findings.
Conclusion: Hepatic stellate cell UBC13 restrains liver fibrosis through regulation of K63-linked ubiquitination-mediated HMGB1.

FRI-322
IGFBPs, MMPs, and cytokines as predictors of liver fibrosis: comparative analysis of biomarkers

Gabriela Gutierrez Reyes[1], Abigail Hernandez-Barragan[1], Marisela Hernandez-Santillan[1], Moises Martinez-Castillo[1], Ángel Daniel Santana Vargas[2], Paula Cordero-Pérez[3], José Luis Pérez-Hernández[2]. *[1]Universidad Nacional Autónoma de México, UNAM, School of Medicine, UIME, HIPAM Lab, Hospital General de México Dr. Eduardo Liceaga, Mexico City, Mexico; [2]Hospital General de México Dr. Eduardo Liceaga, Gastroenterology and Hepatology Department, Clinic of dream, Mexico City, Mexico; [3]Universidad Autónoma de Nuevo León, University Hospital Dr. José Eleuterio González, School of Medicine, Liver Unit, Monterrey, Mexico*
Email: gabgurey@yahoo.com.mx

Background and aims: Backgroung: Identifying serum biomarkers capable of effectively distinguishing fibrosis stages is critical for early diagnosis and therapeutic monitoring in chronic liver disease. AIM: To evaluate the diagnostic performance of insuline growth factor binding proteins (IGFBPs), cytokines, and matrix metalloproteinases (MMPs) across different fibrosis stages.
Method: A prospective, cross-sectional, multicenter study was conducted. Untreated patients with chronic hepatitis C (cHC) were recruited and classified using FibroScan® and/or FibroTest®. Receiver operating characteristic (ROC) curves were analyzed to compare serum levels of IGFBP 1-7 (ng/ml), cytokines in pg/ml (IL-1a, IL-2, IL-10. IL-12p70), and MMPs (2, 7 and 9; ng/ml) between F0, F1F2, and F3F4 fibrosis groups. Statistical significance was set at $p < 0.05$, and area under the curve (AUC), sensitivity (Se), and specificity (Sp) were reported.
Results: A total of 461 cHC patients met inclusion criteria and were classified into F0 (n = 130), F1–F2 (n = 55), and F3–F4 (n = 216). The IGFBPs: **4** (AUC = 0.754, $p < 0.001$; cut-off: 8.43 ng/mL; sensitivity = 70.9%, specificity = 88.6%); **5** (AUC = 0.722, $p = 0.002$; cut-off: 7.52 ng/mL); **2** (AUC = 0.711, $p = 0.003$; cut-off: 47.56 ng/mL); **7** (AUC = 0.714, $p = 0.002$; cut-off: 3.66 ng/mL); **3**(AUC = 0.660, $p = 0.023$; cut-off: 25.89 ng/mL): IL-10 (AUC = 0.679, $p = 0.009$; cut-off: 5.55 pg/mL; sensitivity = 61.9%, specificity = 84.6%) For advanced fibrosis (F3F4 vs F2), IGFBP-4 had the highest performance, followed by IGFBP-5, IGFBP-2, and IGFBP-7, the latter with the highest specificity (91.4%). IGFBP-3 also reached significance. Among cytokines and MMPs, IL-10 and MMP-7 discriminated F1F2 vs F3F4.
Conclusion: IGFBP-4, IGFBP-5, IGFBP-7, and IL-10 showed significant accuracy in distinguishing fibrosis stages, particularly in identifying mild fibrosis. Their high specificity and robust AUC values support their role as non-invasive biomarkers that may complement diagnostic of fibrosis and also can be used in other liver diseases that MASLD or MetALD.

Matricellular serum biomarkers predict fibrosis severity and clinical outcomes in autoimmune hepatitis and primary biliary cholangitis

Ludwig Horst[1], Rambabu Surabattula[2], Alexander Fierenz[1], Füssel Katja[1], Ansgar W. Lohse[1], Marcial Sebode[1], Sudha Rani Myneni[2], Detlef Schuppan[2,3,4], Christoph Schramm[1,5,6]. *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany; [3]Beth Israel Deaconess Medical Center, Boston, United States; [4]European Union Innovative Medicines Initiative 2 (IMI2) Joint Undertaking under grant agreement 777377: LITMUS (Liver Investigation: Testing Biomarker Utility in Steatohepatitis), Mainz, Germany; [5]Martin-Zeitz Center for Rare Diseases, Hamburg, Germany; [6]Hamburg Center for Translational Immunology (HCTI), Hamburg, Germany*
Email: l.horst@uke.de

Background and aims: Autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC) are major autoimmune liver diseases for which reliable biomarkers of fibrosis progression and prognosis remain limited. Thrombospondin-2 and -4 (TSP2/-4), insulin-like growth factor-binding protein 7 (IGFBP7), and cluster of differentiation 163 (CD163) have recently demonstrated predictive potential as biomarkers in people with metabolic dysfunction-associated steatohepatitis. We therefore hypothesised that these markers may serve as predictors of fibrosis and outcome in AIH and PBC.
Method: Serum levels of TSP2, TSP4, IGFBP7, and CD163 were quantified by validated ELISA in 166 individuals with AIH and 117 with PBC treated at the University Medical Center Hamburg-Eppendorf. Biomarkers were evaluated in relation to liver stiffness measured by transient elastography, disease activity, and patient outcomes, including liver-related endpoint-free survival.
Results: In multivariable regression analyses, TSP2, IGFBP7, CD163, and TSP4 were independently and positively associated with liver stiffness in both AIH and PBC ($p < 0.001$–0.007). ROC analyses showed that TSP2 and IGFBP7 effectively discriminated between patients with and without advanced fibrosis (≥F3; AUC 0.83–0.88). In AIH, elevated baseline serum levels of TSP2 and IGFBP7, indicative of advanced fibrosis, were significantly associated with reduced liver-related endpoint-free survival (liver-related death, liver transplantation, and complications of cirrhosis; Log-Rank $p < 0.001$–0.032).
Conclusion: Circulating TSP2, IGFBP7, CD163, and TSP4 were strongly associated with advanced fibrosis in individuals with AIH and PBC. Moreover, especially TSP2 was linked to liver-related endpoint-free survival in AIH, highlighting its promise as a prognostic biomarker.

Email: henriette.horstmeier@meduniwien.ac.at

Background and aims: Lipid immunometabolism is a key regulator of immune function and hepatic necroinflammation, thereby potentially impacting liver fibrosis. Controlled by the activity of adipose triglyceride lipase (ATGL), the lipolytic cleavage of triacyl glycerides to free fatty acids and glycerol shapes energy homeostasis, tissue biosynthesis and cell signaling. Given the lack of antifibrotic treatment options, we investigated the therapeutic potential of ATGL-inhibition in fibrosis in a time-resolved manner *in vivo*.
Method: Fibrosis was induced in C57BL/6 mice by carbon tetrachloride (CCl_4; 3x/week, 2 ml/kg, oral gavage) for 1, 2, 4 and 8 weeks in parallel to treatment with the ATGL-inhibitor Atglistatin (ATGLi) (2x/day; 200µmol/kg, oral gavage and via diet 2 mmol/kg chow), while the control groups received olive oil as vehicle control. Liver injury was assessed biochemically, while hepatic collagen proportionate area (CPA) and lipid accumulation were assessed by histology and portal pressure was measured invasively. Further analysis was conducted using multi-organ flow cytometry, bulkRNA sequencing and untargeted metabolomics.
Results: ATGL-Inhibition was confirmed by elevated liver-to-body-weight ratio [5.73 ± 0.11 vs. 4.6 ± 0.14%, $p < 0.0001$] and histologic hepatocellular lipid accumulation. Starting from week 2, ATGLi strongly reduced liver injury [AST: 1163 ± 872 vs. 4532 ± 2427 U/L, $p = 0.0001$], fibrosis [CPA: 5.72 ± 1.00 vs. 2.71 ± 1.20%, $p < 0.0001$] and portal hypertension [PP: 5.57 ± 0.55 vs. 7.76 ± 1.09 mmHg, $p < 0.0001$]. Flow cytometry revealed the expansion of hepatic, lymph nodal and splenic $CD8^+$T cells upon ATGL-inhibition, further identified as effector $CD44^{hi}CD62^{Lo}$ T-cells (T_{eff}) [49.96 ± 5.70 vs. 23.44 ± 10.06%, $p < 0.0001$, rel. to $CD8^+$] and $CD69^+$ tissue-resident memory T cells ($CD8^+$TRM) [34.67 ± 4.69 vs. 14.52 ± 5.96%, $p < 0.0001$, rel. to $CD8^+$]. Metabolomic profiling uncovered the increased biosynthesis of nucleotides, amino acids and redox equivalents.
Conclusion: Our data suggests improved liver fibrosis and portal hypertension upon ATGLi treatment in fibrosis. Mechanistically, ATGL inhibition promoted anti-oxidative and proliferative tissue metabolic activity. In kinetic synchrony, we observed the expansion of hepatic $CD8^+T_{eff}$ and $CD8^+$TRM, potentially maintaining their activation state and target profibrotic agents due to the optimized metabolic niche. Collectively, this points towards a novel antifibrotic mechanism via immunometabolic reprogramming.

Constitutive MAS1 G protein-coupled receptor participates in the pathogenesis of liver fibrosis

Philipp Althaus[1], Fernando Magdaleno[2,2], Robert Schierwagen[1], Frank Erhard Uschner[1], Maximilian Joseph Brol[1], Thomas Walther[3], Jonel Trebicka[1], Sabine Klein[1]. [1]*Münster University Hospital, Münster, Germany;* [2]*Epistem Limited, Manchester, United Kingdom;* [3]*University College Cork, Department of Pharmacology and Therapeutics, Cork, Ireland*
Email: sabine.klein@ukmuenster.de

Background and aims: The activation of the renin-angiotensin system (RAS) in experimental and human liver cirrhosis, leads to increased levels of angiotensin-II (Ang-II) and angiotensin type 1 receptor (AT1R) stimulation, thus contributing to liver fibrosis and portal hypertension (PTH) by activating HSCs. Mas-related G protein-coupled receptor (MAS1) is increased in the cirrhotic liver, representing an alternate mechanism that opposes the effects of the Ang-II/AT1R axis. Thus, we investigated the protective role of MAS1 as a potential antifibrotic receptor constitutively activated in liver fibrosis.
Method: Human blood samples were measured for Angiotensin levels. Gene and protein expressions were investigated in human donors and recipients. Wildtype (wt) and Mas-receptor knock out mice ($Mas1^{-/-}$) received CCl_4, MCD, WD or a bile-duct ligation (BDL) to induce liver fibrosis. BDL mice were treated with Ang(1-7) or AVE0991. To assess PHT, the portal pressure (PP) was measured. Murine livers were histologically analyzed and gene and protein expressions were measured. Hepatic stellate cells (HSC) were isolated from mice and cell lines were transfected with Mas1 plasmid.
Results: MAS1 deficiency stimulates Ang-II/AT1R signaling and thereby aggravates fibrosis and PTH in BDL and CCl_4-mice. *In vivo* studies showed that Ang-(1-7) and AVE0991 lowered portal pressure (PP) in MAS1 deficient mice after BDL, suggesting another receptor different than MAS1 involved in vasoconstriction. *In vitro*, Ang-(1-7) did not attenuate expression of fibrotic markers and contraction in MAS1 transfected HSC cells, suggesting that constitute activation of MAS1 is sufficient to relax HSC.
Conclusion: Constitutive activation of MAS1 in HSC reduces liver fibrosis and PTH.

Email: s.d.klomp@amsterdamumc.nl

Background and aims: Hepatic fibrosis is a dynamic process characterized by excessive extracellular matrix deposition following chronic liver injury. Regardless of type or etiology, liver fibrosis is driven by activated, collagen-producing myofibroblasts. Activated myofibroblasts overexpress platelet-derived growth factor receptor (PDGFR)-beta. This surface receptor may therefore be useful for diagnosis and disease monitoring, as well as for fibrosis-selective drug delivery. SP02SP26-ABD (Fibrobody®), a high-affinity, species-cross-reactive PDGFR-beta–binding construct, was developed as a pan-fibrosis vector for non-invasive imaging of, and selective intracellular targeted drug delivery to, activated myofibroblasts. This study aimed to evaluate the potential of the Fibrobody in targeting fibrotic tissue and its ability to discriminate fibrosis stages across different disease etiologies, using metabolic dysfunction–

associated steatotic liver disease (MASLD) and primary sclerosing cholangitis (PSC) as two distinctly different types of liver fibrosis.
Method: Mouse models of MASLD (choline-deficient, L-amino acid-defined high-fat diet) and PSC (chronic 3,5-diethoxycarbonyl-1,4-dihydrocollidine feeding) were utilized. Liver fibrogenesis was assessed by (immuno)histochemistry. Biodistribution and (intra-) hepatic uptake of ^{89}Zr-labelled Fibrobody were evaluated by PET-CT, *ex vivo* tissue distribution and autoradiography. Human liver specimens from patients with MASLD (n = 37) and PSC (n = 18) were analyzed using Sirius Red and alpha-smooth muscle actin (SMA) staining for fibrosis staging. PDGFR-beta expression was correlated with these fibrosis markers.
Results: In the mouse models, PDGFR-beta overexpression was selectively localized to the fibrotic liver tissue and corresponded with specific and high hepatic accumulation of ^{89}Zr-Fibrobody. In human MASLD and PSC liver samples, PDGFR-beta expression co-localized with collagen (in Sirius Red) and alpha-SMA. PDGFR-beta expression increased with fibrosis severity, enabling discrimination between stages in both MASLD and PSC.
Conclusion: Preclinical data confirm that PDGFR-beta is a robust marker of fibrotic remodeling in liver fibrosis. Furthermore, the data confirm that the Fibrobody is a selective and efficient PDGFR-beta-targeting vector. These results warrant further exploration into the diagnostic and therapeutic potential of the Fibrobody which will be further elucidated in planned and ongoing (pre-) clinical studies.

FRI-331
Targeting DNA stress response as a synthetic lethal strategy for activated hepatic stellate cells
Eui Jin Lee[1], Ja Hyun Koo[1]. [1]*Seoul National University, Seoul, Korea, Rep. of South*
Email: euijin1204@snu.ac.kr

Background and aims: Hepatic stellate cells (HSCs) drive liver fibrosis through myofibroblastic transdifferentiation, a process closely linked to rapid cell proliferation and YAP/TAZ activation. This hyper-proliferative state inherently leads to the accumulation of constitutive DNA damage. To maintain genomic instability, rapidly diving cells, such as cancer cells or stem cells, express high levels of DNA damage response proteins. However, the key element that let the activated HSCs survive in rapidly proliferating state remains unexplored. Therefore, the aim of this study is to identify critical survival regulator that enable activated HSCs to undergo hyper-proliferative state.
Method: To investigate synthetic lethality as a strategy to selectively target activated HSCs, we performed a kinase inhibitor library screening for seeking target kinase that inhibits YAP/TAZ activation. We validated the hit candidates using primary mouse HSCs and the human HSC line LX-2 and evaluated DNA damage accumulation to verify the specificity and mechanism of action. We utilized CCl_4-induced mouse liver fibrosis model to assess the therapeutic efficacy of the compound.
Results: Our screening identified Checkpoint kinase 1 (CHK1) as a critical survivor regulator for activated HSCs to maintain genomic instability. We showed that activated HSCs and fibrotic livers have elevated levels of constitutive DNA damage markers. Pharmacological inhibition of CHK1 effectively suppressed the activation and proliferation of HSCs, and it amplified DNA damage in activated HSCs, while quiescent HSCs remained unaffected. The administration of CHK1 inhibitors in CCl_4-induced mouse liver fibrosis model showed markedly attenuated liver fibrosis and improved liver function.
Conclusion: Our data showed that activated HSCs heavily rely on CHK1 to maintain their genomic instability in rapidly proliferating state. Therefore, targeting CHK1 represents a promising and selective therapeutic strategy for liver fibrosis.

FRI-332
Pathological role of argininosuccinate synthase 1 in metabolic dysfunction-associated steatotic liver disease-related liver fibrosis
Yen-Tung Chen[1], Lawrence Wirawan[2], Ming-Lung Yu[3], Ji-Min Li[4]. [1]*Institute of Precision Medicine, College of Medicine, National Sun Yat-sen University, Center of Excellence for Metabolic Associated Fatty Liver Disease (CEMAFLD), National Sun Yat-sen University, Kaohsiung, Taiwan;* [2]*School of Life Sciences, Indonesia International Institute for Life Sciences, Jakarta Timur, Indonesia;* [3]*Center of Excellence for Metabolic Associated Fatty Liver Disease (CEMAFLD), National Sun Yat-sen University, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan;* [4]*National Sun Yat-sen University, Kaohsiung, Taiwan*
Email: jmili@g-mail.nsysu.edu.tw

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide, with liver fibrosis representing a critical stage in disease progression and limited therapeutic options. Emerging evidence indicates that metabolic reprogramming plays a key role in fibrotic diseases. Argininosuccinate synthase 1 (ASS1), a key enzyme in arginine biosynthesis, has been shown by our group to be down-regulated in pulmonary fibrosis, where its loss leads to disease progression. However, the role of ASS1 in MASLD-associated liver fibrosis remains largely unexplored. This study aimed to investigate the contribution of the metabolic enzyme ASS1 to liver fibrosis in MASLD.
Method: Normal and MASLD mouse models were established by feeding a normal diet (ND) or a Western diet (WD) with 5% fructose in drinking water for 48 weeks. ASS1 expression in liver tissues was assessed by immunohistochemistry (IHC) and immunofluorescence (IF) staining. The role of ASS1 in hepatic stellate cell (HSC) activation was evaluated using wound-healing and Transwell invasion assays, while downstream signaling pathways were analyzed by RNA sequencing (RNA-seq) and confirmed by immunoblotting.
Results: Analysis of published RNA-seq datasets revealed significantly reduced *ASS1* expression in liver tissues from patients with NAFL and NASH, which was inversely correlated with *FAP* expression. A decline in *ASS1* mRNA levels was also observed in activated HSCs. In WD-fed mice, IHC staining of liver tissues with strong alpha-SMA expression revealed markedly diminished ASS1 levels, particularly in HSCs, which was further confirmed by IF staining showing reduced ASS1 expression in alpha-SMA-positive cells. Consistently, whole-liver homogenates from WD mice exhibited decreased ASS1 expression accompanied by increased alpha-SMA levels. *In vitro*, TGF-beta1 treatment of LX-2 cells significantly suppressed ASS1 expression. Moreover, ASS1 silencing enhanced LX-2 cell migration and invasion and notably increased fibrotic markers, including alpha-SMA, fibronectin, and COL1A1. Mechanistically, RNA-seq analysis identified enrichment of PI3K-Akt and mTOR signaling pathways in ASS1-deficient LX-2 cells.
Conclusion: Taken together, these findings suggest that down-regulated ASS1 expression is a hallmark of activated HSCs and drives the progression of liver fibrosis, supporting ASS1 as a potential therapeutic target for MASLD-related liver fibrosis.

FRI-333-YI
Decellularized liver matrix hydrogels suppress hepatic stellate cell activation via ROS-independent NRF2 activation
Jia Li[1], Qi Zhou[1], Junyu Wang[1], Yakun Li[1], Manon Buist-Homan[1], Vincent E. de Meijer[1], Martin Harmsen[1], Klaas Nico Faber[1], Han Moshage[1]. [1]*Umcg, Groningen, Netherlands*
Email: j.li03@umcg.nl

Background and aims: Hepatic stellate cells (HSCs) are the primary source of extracellular matrix (ECM) in liver fibrosis. Decellularized ECM (dECM)-derived hydrogels show therapeutic potential due to superior biocompatibility, yet the molecular mechanisms underlying their anti-fibrotic effects remain unclear. This study investigates

cellular pathways mediating dECM hydrogel-induced HSC deactivation.
Method: Soft (healthy liver stiffness) and stiff (fibrotic liver stiffness) hydrogels were fabricated from porcine liver dECM (LdECM), with stiffness modulated by ruthenium (Ru) crosslinking. Primary rat activated HSCs (aHSCs) cultured on tissue culture polystyrene (TCPS), soft or stiff hydrogels for 48 hours produced conditioned medium (CM). Fresh aHSCs on TCPS were treated with CM for 72 hours. A transwell co-culture system was then used to distinguish the effects of matrix-derived soluble factors from cellular paracrine signaling. Proteomic analysis, qPCR, and western blotting were used to assess HSC activation markers and identify key regulatory pathways. The role of reactive oxygen species (ROS) was investigated using the antioxidant N-acetylcysteine (NAC).
Results: Both CM treatment and co-culture with acellular LdECM hydrogels, regardless of stiffness, significantly suppressed proliferation and activation markers including collagen type 1 and alpha-smooth muscle actin in aHSCs. This demonstrated that soluble factors released from the hydrogel matrix are the dominant drivers of HSC deactivation, independent of direct cellular crosstalk. Proteomic profiling of treated aHSCs revealed a significant upregulation of the antioxidant defense system. This was validated by increased expression of key antioxidant enzymes. Mechanistically, LdECM hydrogels induced the nuclear translocation of nuclear factor erythroid 2-related factor 2 (NRF2). Crucially, this NRF2 activation was ROS-independent, as co-treatment with NAC failed to block NRF2 nuclear entry despite further reducing intracellular ROS levels.
Conclusion: LdECM hydrogels attenuate HSC activation by promoting a potent antioxidant program driven by the ROS-independent activation of NRF2. This finding reveals a novel mechanism where biomaterials can directly reprogram the cellular redox state to regulate HSC fate, offering a new therapeutic rationale for liver fibrosis.

FRI-334
Geniposidic acid suppresses hepatic stellate cell activation by regulating protein kinase B and glycogen synthase kinase 3-beta signaling

Yakun Li[1], Jia Li[1], Manon Buist-Homan[1], Han Moshage[1]. [1]*Umcg, Groningen, Netherlands*
Email: yakunli96@gmail.com

Background and aims: Activation of hepatic stellate cells (HSCs) is a central event in the progression of liver fibrosis and is characterized by excessive deposition of extracellular matrix. Geniposidic acid (GPA), a natural iridoid glycoside derived from *Gardenia jasminoides*, has been reported to exert hepatoprotective effects in conditions such as Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD). However, its direct role in regulating HSC activation remains unclear. This study aimed to investigate the effects of GPA on activated HSCs *in vitro* and to elucidate the underlying molecular mechanisms.
Method: Primary HSCs were isolated from male Wistar rats and fully activated by culturing on uncoated plastic for 7 days. Activated HSCs were treated with GPA (100 or 200 μM) for 72 h. Gene expression was analyzed by quantitative PCR, while protein levels were assessed by Western blotting and immunofluorescence. Real-time cell proliferation was monitored using the xCELLigence system. The Glycogen Synthase Kinase 3-beta (GSK-3 beta) inhibitor SB216763 was employed to verify pathway involvement.
Results: GPA significantly inhibited the proliferation of activated HSCs, reduced transcription of *Acta2* (alpha-smooth muscle actin), and decreased both mRNA and protein expression of collagen type I. In addition, GPA downregulated arginase 1 expression, indicating suppression of the arginine metabolic program associated with HSC activation. Mechanistically, the antifibrotic effects of GPA were associated with reduced protein kinase B (AKT) phosphorylation and concomitant activation of GSK-3-beta. Pharmacological inhibition of GSK-3 beta by SB216763 abolished the antifibrotic effects of GPA.
Conclusion: GPA attenuates HSC activation by modulating the AKT/GSK-3 beta signaling pathway. As a naturally occurring dietary and medicinal compound, GPA represents a promising candidate for antifibrotic intervention.

FRI-335
Anti-hepatic fibrosis effects and mechanistic investigation of small-molecule inhibitors targeting collagen β(1-O) galactosyltransferase

Jing Luo[1], Hongshan Wei[1]. [1]*Beijing ditan hospital, Beijing, China*
Email: 2211110783@pku.edu.cn

Background and aims: To screen small-molecule inhibitors targeting GLT25D1 to block collagen fibril synthesis/secretion with anti-fibrotic potential and elucidate their mechanism.
Method: The human GLT25D1 structure (AlphaFold2-predicted) was used with MOE software to screen >220,000 compounds. Anti-fibrotic efficacy of the lead compound (Tub B) was validated in three hepatic fibrosis mouse models. Effects on collagen synthesis, secretion, ER stress, and apoptosis in TGF-β1-activated LX-2 cells were assessed via WB, qRT-PCR, immunofluorescence, flow cytometry, and TEM.
Results: GLT25D1 deficiency (in mice and LX-2 cells) reduced fibrosis and collagen synthesis. Screening identified 23 GLT25D1 inhibitors. Tub B significantly inhibited collagen secretion in LX-2 cells in vitro and demonstrated hepatoprotection in vivo, reducing ALT/AST and fibrosis pathology in all three models. SPR confirmed Tub B binding to GLT25D1. Tub B treatment caused ER accumulation of COL1A1, induced ER ultrastructural damage, increased apoptosis markers, and activated the PERK-eIF2α-ATF4 UPR pathway.
Conclusion: Tub B, an inhibitor of collagen β(1-O) galactosylation, promotes collagen ER retention in HSCs, triggering PERK-eIF2α-ATF4-mediated ER stress and apoptosis, thereby attenuating hepatic fibrosis progression.

Email: wjimenez@clinic.cat

Background and aims: Liver fibrosis is driven by activation of hepatic stellate cells (HSCs) and overexpression of profibrogenic genes such as *COL1alpha1* and *alpha-SMA*. Pituitary tumor-transforming gene 1 (*PTTG1*) has emerged as a key regulator of cell proliferation and extracellular matrix remodeling, making its inhibition a promising antifibrotic target. This study aimed to evaluate the impact of *PTTG1* silencing via siRNA on the expression of profibrogenic genes in human liver tissue *in vitro* and *ex vivo*.

Method: Two complementary human experimental models were used: LX2 cells (a human hepatic stellate cell line) and Human Precision Cut Liver Slices (hPCLS). LX2 cells were treated with retinol-functionalized poly(β-amino ester) nanoparticles (ret-pBAE NPs) delivering *PTTG1*-targeted siRNA. In the *ex vivo* model, we obteined hPCLS from liver explants of cirrotic patients undergoing liver transplantation with Alcoholic liver disease (ALD) or Metabolic dysfunction–Associated Alcohol-related Liver Disease (MetALD) etiologies. hPCLS were incubated with Vivofectamine® Liver lipoplexes loaded with the same *PTTG1* siRNA. We tested the viabilitry of hPCLS after incubation through ATP assay. Gene expression of *PTTG1, COL1alpha1*, and *alpha-SMA* was quantified by RT-qPCR.
Results: In LX2 cells, *PTTG1* siRNA induced a significant reduction in *PTTG1* (−62%), *COL1alpha1* (−63%), and *alpha-SMA* (−72%) compared to controls. In hPCLS, the ATP assay indicates that the metabolic activity of hPCLS was within the normal limits at 72 hours in culture under both experimental conditions. *PTTG1* silencing decreased *PTTG1* (−21%), *COL1alpha1* (−88%), and *alpha-SMA* (−75%) in comparison to non treatrd hPCLS. These findings demonstrate the antifibrotic effect of *PTTG1* inhibition in a human derived cell line and in a multicellular, three-dimensional human liver model that closely mimics *in vivo* conditions.
Conclusion: *PTTG1* silencing via siRNA markedly downregulates key profibrogenic genes in both human hepatic stellate cells and hPCLs. These results highlight the potential of *PTTG1* interference as an innovative therapeutic strategy to mitigate the progression of human liver fibrosis.

FRI-337-YI

Transforming growth factor-β1 disrupts hepatic zonation and induces fibrotic endothelial remodeling in vivo

Lukas Neckermann[1], Pia Erdösi[1], Alaa Hammad[1], Eleusa Karavasili[1], Juri Paulischkis[1], Matthias Ebert[2], Steven Dooley[1], Anne Dropmann[1], Seddik Hammad[1]. *[1]Molecular Hepatology Section, Department of Medicine II, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; [2]II. Medical Clinic, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany*
Email: lukas.neckermann@medma.uni-heidelberg.de

Background and aims: Transforming growth factor-β1 (TGF-β1) is a key driver of hepatic fibrosis; however, its role in disrupting hepatic metabolic zonation and the liver sinusoidal endothelial cell (LSEC) niche remains incompletely understood. We sought to define the molecular and spatial consequences of chronic TGF-β1 signaling using a novel AAV8-based in vivo model integrated with spatial transcriptomic profiling.
Method: C57BL/6 mice received AAV8-TGF-β1 (low/high dose) or AAV8-YFP (control). Following expression, biochemical profiling and histological analyses were performed. GeoMX Digital Spatial Profiling (DSP) was employed to resolve zonal transcriptomic alterations. Complementary in vitro experiments were performed in hepatocytes and hepatic endothelial cells.
Results: AAV8-mediated TGF-β1 overexpression resulted in dose-dependent hepatocellular injury with elevated ALT, AST, and GLDH. Mechanistically, TGF-β1 induced SMAD2/3 phosphorylation and nuclear translocation, assembling transcriptional complexes with SMAD4 that repressed HNF4α, a master regulator of hepatocyte identity and metabolic zonation. Immunohistochemical analysis demonstrated loss of pericentral glutamine synthetase expression and periportal expansion of LYVE1- and E-cadherin-positive zones, reflecting disruption of metabolic zonation. TGF-β1 triggered LSEC capillarization evidenced by diminished LYVE1 and elevated CD34 expression with laminin deposition, accompanied by perisinusoidal α-SMA accumulation and basement membrane formation, confirming stellate cell activation. Spatial transcriptomic analysis via GeoMX revealed downregulation of WNT2/RSPO3 signaling pathways, consistent with erosion of pericentral WNT-driven hepatocyte identity and a shift toward periportal transcriptional programs.
Conclusion: Sustained hepatic TGF-β1 expression drives hepatocellular injury, loss of zonation, endothelial capillarization, and stellate cell activation, collectively establishing a profibrogenic hepatic microenvironment. This AAV8-TGF-β1 model provides a platform for mechanistic dissection of spatially defined TGF-β1-driven liver injury and remodeling.

Email: auog@novonordisk.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) lacks reliable circulating biomarkers reflecting progressive liver pathology, and which are translatable between preclinical models and patients. We aimed to correlate plasma biomarkers in a rat diet-induced MASH model (choline-deficient high-fat diet; CDHFD) to hepatic disease progression markers detectable in human MASH patients. We focused on C7 (complement component 7), ADAMTSL2 (ADAMTS-like protein 2), IGFBP7 (Insulin-like growth factor binding protein 7) and TIMP1 (tissue inhibitor of metalloproteinases 1) based on their link to fibrosis stage in human MASH patients.
Method: Rats were fed CDHFD to induce MASH. The 12-week study included biweekly blood sampling and staggered termination at 4, 8, and 12 weeks for liver histology and proteomics. Intervention initiation after 4 weeks: continued CDHFD plus oral ALK5 inhibitor (3 mg/kg q.d.) for 8 weeks or return to chow. Rat plasma and liver were analyzed by LC-MS/MS-based proteomics on an Evosep One LC with Astral MS (100SPD, DIA). To correlate, human plasma from the Fatty Liver Disease in Nordic Countries (FLINC) study was used (NCT04340817), depleted of abundant proteins and analyzed by DIA LC-MS (Q-Exactive HF-X).
Results: After 12 weeks, spleen weight and fibrosis (10-fold rise in Picrosirius Red staining) were increased as expected, consistent with late-stage MASH. At 8 weeks, fibrosis fell 54% with ALK5 inhibitor and 73% with chow reversal. In rat plasma and liver, C7, ADAMTSL2 and IGFBP7 rose progressively and correlated with fibrosis severity. After 8 weeks, ALK5 inhibition and chow reversal reduced C7 in plasma and liver; hepatic IGFBP7 declined with both interventions; ADAMTSL2 decreased in plasma and liver after ALK5 inhibition. These biomarker changes mirror histological antifibrotic effects. The circulating biomarker signatures seen in rats translated to humans with MASH and correlated with disease status in a patient cohort.
Conclusion: In a rat CDHFD model, longitudinal biomarker analysis correlated with fibrosis severity and showed consistent hepatic and plasma changes. Plasma elevations of the same biomarkers were observed in a human MASH cohort and correlated with fibrosis severity, supporting their translational relevance. Pharmacological intervention with ALK5 inhibitor modulated these biomarkers in the rat, but additional analysis with multiple compounds is needed to

understand the complete translational relevance of these biomarkers.

FRI-339

Acetyl-CoA carboxylase 2 inhibition in hepatic stellate cells drives their activation and enhances liver fibrosis

Email: tamara.parracho.martinez@usc.es

Background and aims: Acetyl-CoA carboxylase 2 (ACC2) is an enzyme localized to the outer mitochondrial membrane that inhibits fatty acid β-oxidation. Although its role in hepatocytes is well established, its function in hepatic stellate cells (HSCs) remains undefined.
Method: ACC2 expression was assessed in HSCs isolated from patients and mice with liver fibrosis. Genetic modulation of ACC2 was performed in cultured HSCs, and mice with HSC-specific deletion of ACC2 were subjected to different fibrosis-inducing diets.
Results: ACC2 expression was markedly reduced in activated human HSCs, displaying a negative correlation with fibrosis severity. Similar reductions were observed in rodent models of liver fibrosis, as well as in primary human HSCs and LX-2 cells activated by transforming growth factor-β1 (TGFβ1), fetal bovine serum (FBS), or saturated fatty acids. Ectopic ACC2 expression attenuated TGFβ1-, FBS-, and fatty acid–induced HSC activation by decreasing carnitine palmitoyltransferase-1 levels and mitochondrial respiration. Conversely, genetic silencing of ACC2 was sufficient to activate HSCs. Consistently, mice with HSC-specific ACC2 deficiency exhibited accelerated liver fibrosis when fed fibrosis-inducing diets, including a choline-deficient high-fat diet and a Western diet.
Conclusion: These findings demonstrate that loss or inhibition of ACC2 in HSCs promotes their activation and accelerates liver fibrosis, likely through enhanced fatty acid oxidation.

Impact of PNPLA3 p.I148M variant on qFibrosis-based collagen morphology in MASLD: analysis from Milan biobank cohort

Giulia Periti[1], Kutbuddin Akbary[2], Francesco Malvestiti[1,3], Serena Pelusi[1], Marco Maggioni[1], Luisa Ronzoni[1], Sara Margarita[1], Alessandro Cherubini[1], Jessica Rondena[3], Roberta D'Ambrosio[1], Daniele Dondossola[1], Daniele Prati[1], Dean Tai[2], Luca Valenti[1,3]. *[1]Fondazione Irccs Ca Granda Ospedale Maggiore Policlinico, Milano, Italy; [2]HistoIndex pte Ltd, Singapore, Singapore; [3]Università Degli Studi Di Milano, Milano, Italy*
Email: giulia.periti@gmail.com

Background and aims: PNPLA3 p.I148M variant is a major genetic determinant of metabolic dysfunction-associated steatotic liver disease (MASLD) evolution, promoting hepatic fat accumulation and fibrosis through altered hepatocyte lipid metabolism and hepatic stellate cell activation. Its effects on fibrosis morphology and spatial collagen organization are not adequately captured by conventional semi-quantitative histological staging. We aimed to evaluate associations between PNPLA3 p.I148M variant and collagen morphometric features in MASLD using artificial intelligence (AI)-based digital pathology analysis of liver biopsies.
Method: Fifty liver biopsies from MASLD patients in the Milan Biobank were analyzed using qFibrosis (qF), a stain-free Second Harmonic Generation/Two-Photon Excitation (SHG/TPE) microscopy platform with quantitative AI-based collagen morphometry. Associations between PNPLA3 genotype and collagen features were assessed using generalized linear models under an allelic genetic model, normalized for %SHG collagen and tissue area.
Results: Mean age was 55.8 ± 11.1 years, BMI 29.8 ± 4.4 kg/m^2; 90% were male and 40% had advanced fibrosis. PNPLA3 genotypes were I/I (28%), I/M (44%), and M/M (28%). Pathologist-based fibrosis staging correlated strongly with qF staging ($R^2 = 0.84$, $p < 0.0001$). PNPLA3 variant was associated with higher qF stage ($\beta = 0.66 \pm 0.20$, $p = 0.0014$), mortality risk score ($p = 0.016$), and multiple periportal collagen morphometric features, including increased thin and elongated collagen strings ($p < 0.05$). In advanced fibrosis, additional associations were observed in zone 2 and centrivenular regions ($p < 0.05$). Unsupervised analyses identified integrated periportal-perivascular steatosis-fibrosis patterns linked to PNPLA3, enabling development of a collagen-based score predicting PNPLA3 homozygosity (qPNPLA3).
Conclusion: PNPLA3 p.I148M variant is associated with distinct, region-specific collagen architectural patterns not captured by conventional histology. qFibrosis-based collagen morphometry reveals genotype-specific fibrosis patterns correlated with staging and allows development of prognostic indices. These findings support use of quantitative digital pathology to improve patient stratification, risk assessment, evaluation of antifibrotic response in genetically driven MASLD, warranting validation in larger, independent cohorts.

Male rats exhibit exacerbated hepatic and metabolic alterations than females in response to a high fat high fructose high cholesterol diet

Yanhao Qiu[1], Jianing Zhou[1], Núria Roglans[1,2,3], Emma Barroso[1,2], Marta Alegret[1,2,3], Juan Carlos Laguna[1,2,3], Laia Vilà[1,2]. *[1]School of pharmacy and food sciences, Universitat de Barcelona, Barcelona, Spain; [2]Barcelona, Spain; [3]CIBERObn, Barcelona, Spain*
Email: yqiuqiux231@alumnes.ub.edu

Background and aims: Currently, there are no approved pharmacological treatments for metabolic dysfunction-associated steatohepatitis (MASH). The aim of this study is to establish and characterize a

physiological model of MASH to enable the subsequent evaluation of candidate drugs.
Method: Male and female Sprague-Dawley rats were randomly distributed into 2 groups and fed a control (CT) or HFHFrHc diet for 6 months. At the end of the study, the animals were sacrificed and serum, liver and adipose tissues were obtained. Zoometric, liver histology, serum and liver triglyceride (TG) and cholesterol (C) concentrations, serum analytes and liver hydroxyproline (LHP) content were determined. Liver tissue was properly stored for RNA and protein extraction.
Results: After 6 months on a HFHFrHc diet, both male and female rats exhibited a comparable increase in body weight to that observed in CT rats. However, in both sexes, the HFHFrHc diet induced an increase in the liver weight relative to body weight compared with CT rats. Accordingly, HFHFrHc diet induced hepatic steatosis, characterized by elevated TG and C content in liver tissue. Serum TG levels were also significantly augmented in both sexes. Glucose and insulin levels only raised in HFHFrHc-fed male rats, leading to a reduced ISI index indicative of impaired insulin sensitivity in this group. LHP content was increased in both male and female rats fed the HFHFrHc diet, although the magnitude of this increase was greater in males (65% vs. 25% in females). Furthermore, serum ALT and AST levels were elevated exclusively in HFHFrHc male rats. Col1a1 protein levels also increased in both male and female rats fed the HFHFrHc diet; however, the extent of the increase was greater in males (3.2-fold) than in females (1.9-fold). Notably, females exhibited sex-specific differences in baseline antioxidant defenses, as evidenced by higher expression levels of Sod2 and Gpx1 regardless of dietary condition.
Conclusion: These preliminary findings demonstrate a sexual dimorphism in the response of SD rats to a HFHFrHc diet, with males developing a more severe phenotype characterized by impaired glucose metabolism and signs of hepatic injury and suggests a potential role for antioxidant activity in protecting females from fibrosis development. Grants: PID2023-146140OB-I00, funded by funded by MICIU/AEI/10.13039/501100011033 and FEDER-UE and 2021SGR-00345.

FRI-345-YI
Fibrosis stage-specific human hepatic stellate cell cultures exhibit distinct metabolic and matrix remodelling phenotypes in response to fibrogenic factors
Lai Wei[1], Una Rastovic[1], Sara Campinoti[1], Kavitha Kirubendran[1], Maya Medic[1], Bruna Almeida[1], Fabio Grundland Freile[1], Albert Hughes[1], Yunxi (Daisy) Gao[1], Tanya Shaw[2], Elena Palma[1], Shilpa Chokshi[1,3], Luca Urbani[1]. *[1]Roger Williams Institute of Liver Studies, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, Foundation for Liver Research and King's College Hospital, London, United Kingdom; [2]Centre for Inflammation Biology and Cancer Immunology, School of Immunology and Microbial Sciences, King's College London, London, United Kingdom; [3]Centre of Environmental Hepatology, Faulty of Health, University of Plymouth, University of Plymouth, Plymouth, United Kingdom*
Email: luca.urbani@researchinliver.org.uk

Background and aims: Liver fibrosis involves dysfunctional extracellular matrix (ECM) remodelling by activated hepatic stellate cells (HSCs), resulting in excess matrix deposition, disrupted tissue architecture, and impaired liver function. Recent omics studies identified distinct HSC populations and showed ECM dynamics vary by fibrosis stage and aetiology, but current models lack stage-specific ECM complexity and HSC functional profiling. We investigated ECM remodelling and metabolic and functional patterns *in vitro* using primary human HSCs from livers across different fibrosis stages.
Method: Primary human HSCs (n = 12) were isolated from livers with early to advanced fibrosis, classified as fibrosis grade (FG) 0 (no fibrosis), 1 (mild-moderate) and 2 (established-advanced). Cells were stimulated with TGF-β and assessed for phenotype and metabolism using RNAseq, immunofluorescence and Seahorse analysis. Cell-derived matrices (CDMs) were generated, decellularised, and characterised by proteomics, immunofluorescence, and computational analysis of matrisome composition and fibre architecture. Inhibitors of identified ECM-remodelling enzymes were tested for model validation.
Results: Human HSCs exhibited fibrosis stage-dependent phenotypic, metabolic, and transcriptomic profiles. FG1 HSCs showed the highest activation and collagen expression in response to TGF-β, while FG2 HSCs displayed increased senescence markers. FG1 cells were also more metabolically active. Transcriptomics revealed ECM deposition and remodelling genes consistently modulated by TGF-β, with higher expression in FG1 and FG2 cells for core and matrix-associated proteins and inflammatory markers. CDM analysis showed FG1 HSCs produced more ECM with greater fibre alignment, features linked to fibrosis progression and stiffening. FG1 cells were also most responsive to inhibition of ECM regulator TGM2 with ZDON, showing reduced collagen deposition and altered high-density fibre alignment.
Conclusion: Patient-derived HSCs and CDM models revealed fibrosis stage-specific metabolic and ECM remodelling patterns and differential antifibrotic responses, highlighting the need for stage-tailored therapeutic strategies.

FRI-346
Transcriptomic profiling and label-free collagen imaging of hepatic stellate cells cultured as 3D magnetic levitation spheroids
Nataliya Rohr-Udilova[1], Sandra Tüchler[1], Maximillian Lahsnig[2], Katharina Regnat[1], Karin Pfisterer[1], Matthias Pinter[1], Michael Trauner[1]. *[1]Medical University of Vienna, Vienna, Austria; [2]University of Vienna, Vienna, Austria*
Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and aims: Hepatic stellate cells (HSCs) produce extracellular matrix (ECM) in the liver. Increased activation of these cells represents a hallmark of liver fibrosis. Conventional adherent growth on plastic flasks induces HSC activation, which can be mitigated by magnetic levitation–based culture systems.
We aim to characterize pathways and processes in HSCs cultured as 3D magnetic levitation spheroids compared to standard 2D flask cultures.
Method: We used LX-2 immortalized human hepatic stellate cells as the model system. Cultures were performed in two formats: traditional 2D adherent culture and 3D magnetic levitation culture. Bulk mRNA sequencing was conducted in four independent biological replicates to analyze differential gene expression and perform gene ontology (GO) pathway enrichment analysis. Standard normalization and multiple-testing correction were applied. Additionally, 3D visualization of the extracellular matrix collagen was carried out using Second Harmonic Generation (SHG) microscopy which enables label-free 3D visualization.
Results: HSCs were cultured for two weeks using an optimized magnetic levitation protocol, followed by bulk mRNA sequencing. Bulk RNA-seq comparing 2D adherent and 3D magnetic levitation cultures revealed more than 6% differentially expressed genes (FDR-controlled). Representative changes include upregulation of HGF, LUM, PDGFRA, MMP1, COL7A1 and downregulation of COL1A1, LOX, SMAD3, SOX9, COL5A. Gene enrichment analysis performed with ClusterProfiler identified three major clusters with pronounced enrichment in 3D versus 2D cultures: (1) receptor signalling activation and regulation, (2) collagen extracellular matrix and cell-cell junctions, and (3) immune cell migration. SHG imaging revealed radial collagen structures within the 3D magnetic levitation spheroids.
Conclusion: Compared to traditional 2D culture, 3D magnetic levitation suggests a transcriptional shift toward reduced HSC activation markers, with altered immune and extracellular matrix pathways. Functional validation of activation status will be addressed

in future work including primary human HSC. Magnetic levitation culture may provide a valuable approach to study HSC biology and fibrosis.

The non-transcriptional activity of IRF3 induces profibrotic cytoplasmic stress granules

Jared Travers[1], Yingting Zhang[1], Emily Huang[1], Megan McMullen[1], Laura Nagy[1]. [1]*Cleveland Clinic Research, Cleveland, United States*
Email: nagyl3@ccf.org

Background and aims: Nucleic acid-induced activation of the antiviral transcription factor interferon regulatory factor 3 (IRF3) mediates hepatic fibrogenesis in murine models of fibrosis. IRF3 executes multiple transcriptional and non-transcriptional functions which contribute to the development of metabolic liver diseases. In this study, we aimed to delineate the relative contributions of the transcriptional and non-transcriptional activities of IRF3 to hepatic fibrosis.
Method: Wild-type (WT), *Irf3*-deficient ($Irf3^{-/-}$), and mice only expressing non-transcriptional IRF3 activity ($Irf3^{S1/S1}$) were subjected to the chronic carbon tetrachloride (CCl_4) model of liver fibrosis. Molecular mechanisms were investigated using primary murine HSCs and LX2 immortalized human HSCs.
Results: Expression of fibrogenic genes and hepatic fibrosis were decreased in primary HSC cultures and CCl_4-exposed liver tissue, respectively, obtained from $Irf3^{-/-}$ mice as compared to WT and $Irf3^{S1/S1}$ mice. Differentiation of primary murine HSCs in culture or stimulation of LX2 cells with transforming growth factor-beta (TGFβ) induced accumulation of endogenous double-stranded RNA (dsRNA), which triggered the assembly of pro-fibrotic IRF3-containing cytoplasmic stress granules. Finally, TGFβ-induced stress granule assembly was reduced upon short interfering RNA (siRNA)-mediated *IRF3* gene silencing in LX2 cells or in primary HSCs cultured from $Irf3^{-/-}$, but not $Irf3^{S1/S1}$, mice.
Conclusion: The non-transcriptional activity of IRF3 in HSCs mediates a novel profibrotic TGFβ-dsRNA-stress granule axis. These results suggest that cytoplasmic stress granules are important regulators of fibrosis and underscore the importance of antiviral pathways to sterile fibrotic responses.

Interleukin-33 and Serotonin drive hepatic fibrosis in alveolar echinococcosis via the gut-liver axis

Aliya Tulading[1], Guzinayi Abudukadi[1], Hai-Zhang Ma[2], Jing Wu[1], Yilizhati Azhati[1], Alimujiang Mamuti[1], Maiwulanjiang Maimaiti[1], Chun-Hui Lv[1], Rong-Dong He[1], Ming-Juan Wang[1], Repikaiti Yasheng[1], Mirizhati Nuermaimaiti[1], Guliziran Keranmu[1], Hui-cheng Zeng[1], Tao Li[1], Tuerganaili Aji[1], Yingmei Shao[1], Hao Wen[1], Tuerhongjiang Tuxun[1]. [1]*First Affiliated Hospital of Xinjiang Medical University, Urumqi, China;* [2]*Qilu Hospital, Shandong University, Jinan, China*
Email: 13276605069@163.com

Background and aims: Hepatic alveolar echinococcosis is characterized by progressive periparasitic fibrosis. Although both interleukin-33 and serotonin (5-hydroxytryptamine, 5-HT) are elevated in HAE patients, their functional interaction and underlying mechanisms in fibrosis remain unclear. This study aimed to elucidate the role and mechanism of the IL-33/5-HT axis in HAE-induced liver fibrosis.
Method: Clinical samples from patients with HAE, hepatic hemangioma, and hepatocellular carcinoma were analyzed using ELISA, quantitative PCR, western blotting, and immunohistochemistry. *Echinococcus multilocularis*-inoculated wild-type and IL-33 knockout mice were used to assess the fibrotic response. *In vitro* functional experiments were performed on hepatic stellate cells (HSCs) using agonist/antagonist treatments targeting the 5-HT receptor 2B (5-HTR2B).
Results: Serum levels of IL-33 and 5-HT were significantly elevated and correlated in HAE patients. Spatial localization of IL-33 and 5-HTR2B was observed within the fibrotic area. Infected IL-33 knockout mice exhibited attenuated fibrosis and disrupted 5-HTR2B signaling. Mechanistically, 5-HT promoted the activation, proliferation, migration, and extracellular matrix production of HSCs in a 5-HTR2B-dependent manner via ERK and AKT phosphorylation—all of which were effectively inhibited by the antagonist sarpogrelate.
Conclusion: Our findings reveal a pathogenic gut-liver axis pathway: IL-33 stimulates the gut to release 5-HT, which subsequently activates HSCs via the 5-HTR2B and downstream ERK/AKT signaling, thereby driving the fibrotic process in HAE. Targeting 5-HTR2B represents a potential therapeutic strategy for HAE-induced fibrosis.

FRI-349

The dual integrin inhibitor Bexotegrast, indicated for idiopathic pulmonary fibrosis, shows a anti-fibrotic phenotype in human MASH liver spheroids

Francisco Verdeguer[1], Radina Kostadinova[1], Philip Vonschallen[1], Jesus Glaus[1], Joel Zvick[1], Natacha Levy[1], Mathieu Petitjean[2], Adi Lightstone[2], Li Chen[2]. [1]*Insphero, Schlieren, Switzerland;* [2]*PharmaNest, Princeton, United States*
Email: francisco.verdeguer@insphero.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive, severe disease characterized by hepatic lipid accumulation, inflammation, and fibrosis. Despite some recent drug approvals, challenges remain in identifying novel anti-fibrotic compounds. Human preclinical models, including organoids/spheroids, provide powerful and translational approaches for drug discovery. This study tested anti-fibrotic compounds targeting TGF-beta signalling, indicated for idiopathic pulmonary fibrosis (IPF), in human liver spheroids.
Method: A human-derived 3D spheroid model containing primary human hepatocytes, Kupffer cells, liver endothelial cells, and stellate cells from healthy donors was used to induce a MASH phenotype for 10 days. Bexotegrast (PLN-74809) and PLN-1474, were first tested in an initial screening setup (screening A) across a 6-concentration range in triplicates, measuring Pro-Collagen 1(PC-1) at day 10 post-treatment. Bexotegrast was then selected for additional phenotypic characterization of the fibrotic biomarkers PC-1, Pro-collagen III (PIIINP), and Tissue Inhibitor of Metalloproteinases 1 (TIMP1) at days 5, 7, and 10 after MASH induction and drug treatment. Spheroids collected on day 10 underwent histology and Sirius Red staining, quantified with FibroNest digital pathology.
Results: Both PLN-1474 and Bexotegrast produced dose-dependent reductions in PC-1 in the initial screening A. Follow-up experiments with Bexotegrast showed statistically significant reductions in PC-1 and PIIINP at days 5, 7, and 10, and in TIMP1 at days 5 and 7. Bexotegrast also demonstrated a strong reduction in Sirius Red staining.
Conclusion: Human-derived 3D spheroid models serve as cost-effective and predictive tools for identifying successful anti-fibrotic drug candidates. Bexotegrast (PLN-74809) and PLN-1474, repurposed from ongoing idiopathic pulmonary fibrosis (IPF) trials, demonstrated promising anti-fibrotic effects in human MASH liver spheroids.

FRI-350

ESOR1 links liver fibrosis to hepatocellular carcinoma progression via endothelial EGFR signaling

Jin Wang[1,2]. [1]*Capital Medical University, Beijing, China;* [2]*Beijing Ditan Hospital, Beijing, China*
Email: 591073988@qq.com

Background and aims: Progressive liver fibrosis and hepatocellular carcinoma are pathologically interconnected, yet the molecular mechanisms linking fibrotic remodeling to tumor-promoting microenvironments remain incompletely understood. Liver sinusoidal

endothelial cells are central regulators of hepatic homeostasis and extracellular matrix (ECM) dynamics. C6orf120 is a previously uncharacterized ECM-associated protein with no defined role in chronic liver disease. Here, we report the first functional characterization of C6orf120 and propose its designation as EGFR Spatial Organizer 1 (ESOR1), based on its role in endothelial EGFR regulation across distinct fibrotic contexts.

Method: Wild-type and ESOR1-deficient mice were subjected to bile duct ligation (BDL) or carbon tetrachloride (CCl_4) administration to induce cholestatic and toxic liver fibrosis. Liver fibrosis and tissue mechanics were assessed by histology, second harmonic generation imaging, and ultrasound-based elastography. Single-cell RNA sequencing of pooled liver samples was performed to characterize endothelial cell states, followed by subclustering and gene program analyses. Endothelial EGFR signaling was examined using biochemical and imaging-based approaches. The impact of ESOR1 on tumor progression was evaluated in subcutaneous hepatocellular carcinoma models.

Results: Genetic ablation of ESOR1 consistently attenuated liver fibrosis induced by both BDL and CCl_4, accompanied by reduced collagen deposition and tissue stiffness. Single-cell transcriptomic analyses revealed that fibrotic injury induced profound LSEC dysfunction, characterized by loss of canonical LSEC identity and acquisition of capillarized endothelial features, whereas ESOR1 deficiency partially restored LSEC differentiation programs. Mechanistically, ESOR1 promoted endothelial EGFR activation and downstream transcriptional responses associated with receptor organization and ECM remodeling, which were blunted in ESOR1-deficient mice. Consistent with its role in shaping the fibrotic microenvironment, loss of ESOR1 significantly suppressed hepatocellular carcinoma growth and ECM accumulation in vivo.

Conclusion: We identify ESOR1 (formerly C6orf120) as a previously unrecognized extracellular matrix protein that regulates endothelial EGFR signaling to coordinate LSEC dysfunction, fibrotic remodeling, and hepatocellular carcinoma progression across distinct fibrotic etiologies, highlighting ESOR1 as a potential therapeutic target in chronic liver disease and HCC.

FRI-351
Hepatocyte ATF4 drives liver fibrosis via the YAP-SOX9-Osteopontin axis

Hao Wang[1], Wang Yiming[1], Ming Ni[1]. [1]*The First Affiliated Hospital, Nanjing Medical University, Nanjing, China*
Email: wyknyd@163.com

Background and aims: Liver fibrosis represents a pathological response to chronic injury, characterized by extracellular matrix accumulation and architectural disruption. While damaged hepatocytes are known to initiate fibrogenic signaling, the intracellular transcriptional machinery orchestrating their cross-talk with the hepatic microenvironment remains obscure. This study investigates the role of hepatocyte Activating Transcription Factor 4 (ATF4) in driving fibrosis progression via the regulation of the YAP/SOX9/Osteopontin (OPN) axis.

Method: We employed hepatocyte-specific ATF4 knockout mice $ATF4^{HKO}$ and subjected them to bile duct ligation (BDL) or methionine-choline deficient (MCD) diets to simulate cholestatic and metabolic fibrosis, respectively. Mechanistic investigations, including chromatin immunoprecipitation (ChIP), luciferase reporter assays, and RNA sequencing, were performed on primary hepatocytes. Furthermore, primary hepatocyte organoids were established and treated with ISRIB, a specific inhibitor of the integrated stress response, to evaluate the therapeutic potential of pharmacologically targeting ATF4 translation.

Results: Our results identify ATF4 as a critical driver of liver fibrosis across different etiologies. Hepatocytes with elevated ATF4 expression displayed a pro-fibrotic phenotype mediated by the upregulation of Yes-associated protein (YAP). Mechanistically, ATF4 promotes YAP expression, which subsequently functions as a transcriptional co-activator to directly induce SOX9 transcription. This upregulation of SOX9 triggers the secretion of OPN, a potent paracrine factor that activates hepatic stellate cells. Genetic ablation of ATF4 significantly attenuated fibrosis in vivo. Consistently, pharmacological blockade of ATF4 synthesis using ISRIB in hepatocyte organoids effectively suppressed the YAP-SOX9-OPN cascade and mitigated the fibrotic phenotype.

Conclusion: This study establishes hepatocyte ATF4 as a master regulator of fibrogenesis by orchestrating the YAP-SOX9-OPN signaling cascade. These findings suggest that disrupting this transcriptional axis—either genetically or pharmacologically—offers a promising therapeutic strategy to interrupt hepatocyte-stellate cell communication and halt the progression of liver fibrosis.

Umbilical cord mesenchymal stem cell-derived extracellular vesicles attenuate hepatic stellate cell activation via mitochondrial modulation

Junyu Wang[1,2], Qi Zhou[2], Jia Li[2], Manon Buist-Homan[2], Peter Olinga[1,2], Klaas Nico Faber[2], Martin Harmsen[2], Han Moshage[2]. [1]*University of Groningen, Groningen, Netherlands;* [2]*University Medical Center Groningen, Groningen, Netherlands*
Email: j.wang03@umcg.nl

Background and aims: Liver fibrosis is a major driver of chronic liver disease progression and remains without effective antifibrotic therapy. Mesenchymal stem cell (MSC)-derived secretome has shown promise in alleviating liver fibrosis; however, the molecular mediators and mechanisms underlying these effects remain incompletely defined. This study aimed to elucidate the antifibrotic mechanism of umbilical cord-derived MSC (UC-MSC) secretome, focusing on the contribution of extracellular vesicles (EVs) and their modulation of mitochondrial function in activated hepatic stellate cells (aHSCs).

Method: Human UC-MSCs were isolated and characterized by morphology and expression of specific surface markers. Serum-free conditioned medium from UC-MSCs (CM^{UC-MSC}) was collected after 48 hours of culture. EVs were isolated from CM^{UC-MSC} using ultracentrifugation and characterized by nanoparticle tracking analysis, cryogenic electron microscopy, and surface marker expression. Primary hepatic stellate cells (HSCs) were treated with complete CM^{UC-MSC}, the soluble factor fraction (SF^{UC-MSC}), or the EV fraction (EV^{UC-MSC}) of the UC-MSC secretome. Fibrosis-related gene and protein expression were determined using qPCR, immunofluorescence, and Western blotting.

Results: Both CM^{UC-MSC} and EV^{UC-MSC} reduced the *Acta2*/αSMA and cell proliferation, with EV^{UC-MSC} also reduced *Col1a1*/collagen type I expression in aHSCs. Depletion of EVs (SF^{UC-MSC}) attenuated these effects in aHSCs. The UC-MSC-derived secretome did not induce apoptosis or senescence and did not alter mitochondrial fusion or fission. Notably, it enhanced mitochondrial respiration without affecting glycolytic flux in aHSCs.

Conclusion: UC-MSC-derived secretome, particularly its EV fraction, attenuates HSC activation by enhancing mitochondrial respiration, thereby offering a promising therapeutic approach for liver fibrosis. These findings underscore the potential of MSC-derived EVs as effective and safer alternatives for fibrotic liver disease treatment and highlight the need for further studies to delineate their molecular interactions with key fibrotic signaling pathways.

FRI-353
The stiffness of liver-derived extracellular matrix hydrogels regulates hepatic stellate cell activation

Qi Zhou[1], Junyu Wang[1], Jia Li[1], Janette Heegsma[1], Vincent E. de Meijer[1], Pingnan Sun[2], Han Moshage[1], Klaas Nico Faber[1], Martin Harmsen[1]. [1]*University Medical Center Groningen, Groningen, Netherlands;* [2]*Shantou University Medical College, Shantou, China*
Email: j.wang03@umcg.nl

Background and aims: Hepatic stellate cell (HSC) activation is a central driver of liver fibrosis and is associated with excessive extracellular matrix (ECM) deposition, remodeling, and increased tissue stiffness. However, the specific contribution of ECM mechanical properties to HSC activation remains incompletely understood. This study aimed to develop a three-dimensional (3D) liver-derived ECM (L-ECM) hydrogel model with tunable stiffness to investigate the role of ECM mechanics in regulating HSC activation.
Method: Porcine L-ECM hydrogels with stiffnesses ranging from healthy to cirrhotic liver were generated using ruthenium-based photocrosslinking. Primary rat HSCs and the human HSC cell line LX-2 were embedded in the hydrogels and cultured for 2 or 4 days. HSC viability, morphology, collagen fibril organization, and expression of fibrosis-related genes and proteins were assessed. Additionally, L-ECM hydrogels derived from healthy and cirrhotic human liver tissues were compared to evaluate the relative contributions of ECM composition and mechanics to HSC activation.
Results: Porcine L-ECM hydrogels suppressed activation of primary HSCs and LX-2 cells in a stiffness-dependent manner, with lower stiffness strongly inhibiting activation and higher stiffness partially attenuating this effect. Human L-ECM hydrogels similarly suppressed HSC activation. Notably, when stiffness was comparable, no differences in HSC activation were observed between healthy and cirrhotic human L-ECM hydrogels.
Conclusion: ECM mechanical properties exert a dominant influence on HSC activation compared with ECM composition alone. These findings highlight mechanosignaling in HSCs as a critical therapeutic target, complementing biochemical strategies to prevent or reverse liver fibrosis.

FRI-354

Dynamic changes in type III collagen formation and degradation are associated with fibrotic activity following hepatic injury in rats

Thomas Wiggers[1], Mark Kuipers-Skarsfeldt[1], Ydalina Maria Moreno[1], Guillermo Fernández-Varo[2], Wladimiro Jiménez Povedano[2,3], Morten Karsdal[1], Diana Julie Leeming[1]. *[1]Nordic Bioscience A/S, Herlev, Denmark; [2]Biochemistry and Molecular Genetics Service, Hospital Clínic of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, CIBEREHD, ISCIII, Madrid, Spain, Barcelona, Spain; [3]Department of Biomedicine, University of Barcelona, Barcelona, Spain, Barcelona, Spain*
Email: twm@nordicbio.com

Background and aims: Non-invasive markers of collagen turnover enable assessment of drug effects on the extracellular matrix. Type III collagen formation (fibrogenesis) and degradation (fibrolysis) can be assessed with nordicPRO-C3™ and nordicCTX-III™, respectively. A shift toward fibrolysis has recently been associated with hepatic fibrosis improvement in patients with metabolic dysfunction-associated steatohepatitis (MASH), making PRO-C3 and CTX-III relevant targets for translational studies of hepatic fibrosis. We developed rodent versions of CTX-III (rCTX-III) and PRO-C3 (rPRO-C3) and applied them in two preclinical models of hepatic fibrosis.
Method: A chemiluminescent sandwich immunoassay for nordic rCTX-III and a competitive enzyme-linked immunosorbent assay for nordic rPRO-C3 were developed for rodent blood samples using monoclonal antibodies. rCTX-III detects a protease-generated neo-epitope in a cross-linked dimeric analyte, while rPRO-C3 targets a pro-peptide neo-epitope. rCTX-III and rPRO-C3 were measured in serum of two rat models: 83 rats with CCl_4-induced fibrosis by inhalation (1 L/min) twice weekly for 8, 12, 16, or 20 weeks (wks) and given water containing phenobarbital (0.3 g/L), including regression groups with 15 or 20 wks of CCl_4 followed by 6 wks of washout compared with healthy controls (n = 7 per group); and a bile-duct ligation model for 1 (n = 7), 2 (n = 7), or 3 wks (n = 8), plus 3-week sham surgery (n = 8) and baseline (n = 13).
Results: Within the CCl_4 model, control rats showed stable nnserum rPRO-C3 and rCTX-III levels. rPRO-C3 was increased at 12 wks ($p = 0.067$) and 20 wks ($p < 0.05$) of CCl_4 treatment, and at 15 wks of CCl_4 treatment followed by 6 wks of CCl_4 washout ($p < 0.05$) compared to controls. rCTX-III increased at 8 wks ($p < 0.05$), 12 wks ($p = 0.066$), 16 wks ($p < 0.01$) and 20 wks ($p = 0.062$) of CCl_4 treatment, but showed no difference compared to controls after 15 or 20 wks of CCl_4 followed by 6 wks of washout. In the bile-duct ligation model, rPRO-C3 levels were increased by 3 wks post-surgery ($p < 0.001$), while rCTX-III levels were increased at 1 week ($p < 0.001$), 2 wks ($p < 0.01$) and 3 wks ($p < 0.01$) compared to baseline.
Conclusion: We developed robust assays for the rodent fibrolysis marker rCTX-III and fibrogenesis marker rPRO-C3 and applied them in two hepatic fibrosis models, showing increased type III collagen turnover after injury. rCTX-III and rPRO-C3 may serve as translational biomarkers in antifibrotic drug development.

FRI-355

SOX9 drives hepatic stellate cell activation via a PFKFB3-mediated glycolysis-histone lactylation positive feedback loop

Guanglin Xiao[1], Zhiling Deng[1], Ke Qiu[1], Hong Ren[1]. *[1]Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases, Ministry of Education, Institute for Viral Hepatitis, The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China*
Email: renhong0531@cqmu.edu.cn

Background and aims: The molecular drivers initiating and sustaining aerobic glycolysis reprogramming in activated hepatic stellate cells (HSCs) are unclear. This study aimed to identify HSC-specific targets that facilitate this metabolic shift and elucidated their molecular mechanisms.
Method: We identified the core gene that drives hepatic fibrosis by promoting glycolysis, using six machine learning algorithms applied to a candidate gene set derived from the intersection of glycolysis-related genes, differentially expressed genes (GEO datasets), and key WGCNA modules. The expression of the core gene in HSCs was confirmed by immunofluorescence (IF) staining. The mechanism by which the core gene regulates glycolysis in HSCs was determined using chromatin immunoprecipitation (ChIP) assays.
Results: Integrated transcriptomic and single-cell RNA sequencing analysis of human liver fibrosis identified the glycolytic regulator SOX9 as a key pro-fibrotic molecule. SOX9 was upregulated in human fibrotic livers and mouse fibrosis models (induced by CCl_4 or TAA). Co-localization studies using markers for HSCs (alpha-SMA) demonstrated that SOX9 expression was predominantly enriched in activated HSCs during fibrogenesis. To establish a causal role, we constructed an AAV6 vector (AAV6-postn-shSox9) for HSC-specific knockdown of Sox9 in mice. Central carbon-targeted metabolomics of liver tissues revealed that Sox9 knockdown reduced glycolytic flux while enhancing TCA cycle activity compared to the control vector group. Similarly, modulating SOX9 in LX-2 cells regulated glycolysis and activation. Mechanistically, SOX9 directly transactivated the glycolytic enzyme gene PFKFB3, whose inhibition reversed SOX9-driven phenotypes. Elevated lactate from increased glycolysis triggered histone lactylation, which we identified as an upstream regulator of SOX9. Screening of eight histone lactylation sites in LX-2 cells under multiple conditions pinpointed H4K5la as the specific modification linked to SOX9 upregulation.
Conclusion: This study identifies SOX9 as an upstream regulator of glycolysis in HSCs and demonstrates the existence of a "glycolysis-lactate-histone lactylation" positive feedback loop centered on SOX9 during HSC activation.

Proinsulin connecting peptide attenuates transforming growth factor β1-induced profibrogenic responses in immortalized human hepatic stellate cells

Reiko Yaginuma[1], Kazuyoshi Kon[1], Kyoko Fukuhara[1], Shunsuke Ikejima[1], Masahiro Tada[1], Kei Ishizuka[1], Maki Morinaga[1], Hiroo Fukada[1], Akira Uchiyama[1], Shunhei Yamashina[1], Kenichi Ikejima[1]. [1]*Department of Gastroenterology, Juntendo University Graduate School of Meicine, Tokyo, Japan*
Email: yagirei@juntendo.ac.jp

Background and aims: Insulin resistance is one of the hallmarks of metabolic dysfunction in steatotic liver disease including MASLD and MetALD. Besides hyperinsulinemia, serum proinsulin connecting peptide (C-peptide) levels are elevated simultaneously; however, the biological roles of C-peptide in the pathogenesis of steatohepatitis have not been elucidated yet. Therefore, here we investigated the direct effect of C-peptide on profibrogenic responses in hepatic stellate cells (HSCs) utilizing immortal human HSC line LX-2.
Method: LX-2 cells were incubated with C-peptide (10 nM) in the presence of TGFβ1 (2.5 ng/mL) for 20 hr, and mRNA expression levels of type I collagen (COL1A1), α-smooth muscle actin (ACTA2), TGFβ1/3, SMAD4, MMP-1/-13, and TIMP-1 were quantified by RT-qPCR. Hydroxyproline contents in culture were determined colorimetrically.
Results: In LX-2 cells, incubation with TGFβ1 for 20 hr increased COL1A1 mRNA nearly 4.8-fold over basal levels; however, co-incubation with 10 nM C-peptide blunted this induction almost 26% ($p < 0.0001$). Indeed, TGFβ1-induced increases in cellular hydroxyproline contents were drastically prevented by simultaneous incubation with C-peptide for 72 hr. Further, TGFβ1-induction in ACTA2 mRNA, a hallmark of HSC transactivation, were also prevented nearly 26% by co-incubation with C-peptide ($p < 0.05$). Furthermore, TGFβ1-inductions in MMP-13 and TIMP-1 mRNA levels in LX-2 cells were also blunted by co-incubation with C-peptide significantly. Moreover, mRNA levels of SMAD4 were significantly decreased when LX-2 cells were incubated with C-peptide both in the absence or presence of TGFβ1, the levels being 17% and 22% lower than basal levels, respectively. Interestingly, C-peptide significantly decreased expression levels of TGFβ3 mRNA, but not TGFβ1 mRNA, in LX-2 cells both in the absence and presence of TGFβ1, the levels being 22% and 26% lower than controls, respectively. In addition, C-peptide decreased MMP-1 mRNA levels in LX-2 cells about 12% in the absence of TGFβ1 ($p < 0.05$).
Conclusion: These findings clearly demonstrated that C-peptide attenuates TGFβ1-induced collagen production and matrix-related gene expressions in LX-2 cells, indicating that C-peptide exerts proper biological effects in HSCs rather than a remnant peptide during insulin production. It is therefore hypothesized that C-peptide most likely plays a modulatory role in the progression of hepatic fibrosis in MASLD/MetALD.

Coagulopathy and lactate dehydrogenase predict fetal loss in liver dysfunction during pregnancy

Reshma Reshma[1], Premashis Kar[2], Jagdeep Kaur[3], Ayush Jasrotia[2]. [1]*Government Medical College, Amritsar, Max Superspeciality Hospital, Vaishali, Ghaziabad, India;* [2]*Max Superspeciality Hospital Vaishali, Ghaziabad, India;* [3]*Government Medical College, Amritsar, India*
Email: reshma.mallick92@gmail.com

Background and aims: Liver dysfunction during pregnancy is a major contributor to maternal and perinatal morbidity. We aimed to describe the clinical spectrum and identify laboratory predictors of adverse fetal outcomes in a tertiary cohort of pregnancy-related liver dysfunction.
Method: In this prospective observational cohort, pregnant women with liver dysfunction were enrolled and followed from admission until 6 weeks postpartum. Primary fetal outcomes were stillbirth and intrauterine growth restriction. Routine laboratory parameters, including international normalised ratio and lactate dehydrogenase, were assessed. Multivariable logistic regression was performed to identify independent predictors of intrauterine fetal death and growth restriction.
