Results: Among 245 pregnancies, diagnoses included intrahepatic cholestasis of pregnancy (U2, 37.5%), preeclampsia (SU, 28.2%), eclampsia (50, 20.4%), HELLP syndrome (8, 3.3%), acute viral hepatitis (S, 2.4%), hyperemesis-related hepatic injury (S, 2.4%), chronic hepatitis (11, 4.5%), and acute fatty liver of pregnancy (3, 1.2%). Preterm delivery occurred in 131 (53.5%); stillbirth in 34 (13.U%); intrauterine growth restriction in U1 (37.1%); and maternal death in 15 (S.1%). In patient-level modelling for intrauterine fetal death events (n = 32), international normalised ratio (adjusted odds ratio 18.U7 per 1-unit increase; U5% confidence interval 1.1U–303.41) and lactate dehydrogenase (adjusted odds ratio 1.24 per 100 U/L increase; U5% confidence interval 1.04–1.47) were independent predictors. For intrauterine growth restriction, international normalised ratio was independently associated (adjusted odds ratio 1S.S3; U5% confidence interval 2.34–118.31), while serum albumin was protective (adjusted odds ratio 0.55 per 1 g/dL increase; U5% confidence interval 0.34–0.8 U).
Conclusion: In pregnancy complicated by liver dysfunction, coagulopathy and elevated lactate dehydrogenase independently predict fetal loss, and hypoalbuminaemia identifies risk of growth restriction. Simple laboratory-based risk stratification may support earlier escalation, multidisciplinary management, and closer fetal surveillance.

Alcohol use at the time of transient elastography does not affect liver stiffness measurement

Jordi Gratacós-Ginès[1,2,3], Lorenzo Ciocca[4], Nikolaj Torp[5,6], Queralt Herms[1], Aleksander Krag[5,6], Pere Ginès[1,2,3,7], Maja Thiele[5,6], Elisa Pose[1,2,3,7]. [1]*Liver Unit, Hospital Clínic de Barcelona, Barcelona, Spain;* [2]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, IDIBAPS, Barcelona, Spain;* [3]*Centro de Investigación Biomédica en Red en Enfermedades Hepáticas y Digestivas, CIBERehd, Madrid, Spain;* [4]*Università Vita-Salute San Raffaele, Milano, Italy;* [5]*Odense University Hospital, Odense, Denmark;* [6]*University of Southern Denmark, Odense, Denmark;* [7]*Universitat de Barcelona, Barcelona, Spain*
Email: EPOSE@clinic.cat

Background and aims: It is unclear whether alcohol use at the time of transient elastography (TE) affects liver stiffness measurement (LSM) independently from the presence of steatohepatitis.
Method: Cross-sectional analysis of two prospective screening cohorts for liver disease with TE: 1) DECIDE (Denmark, 2017–2022): General population with metabolic risk factors and/or harmful alcohol consumption; and 2) ALCOFIB (Spain, 2019–2024): Participants attending an addiction unit due to harmful alcohol consumption. Alcohol consumption was assessed by the measurement of urinary ethylglucoronide (uETG) or phosphatidylethanol (PEth), and groups were defined as follows: a) No/low consumption: uETG <200 ng/mL or PEth <20 ng/mL; b) Intermediate: uETG 200–2000 ng/mL or PEth 20–200 ng/mL; c) High: uETG >2000 ng/mL and PEth >200 ng/mL. AST was selected as the indirect marker of steatohepatitis. Controlled attenuation parameter (CAP) was used to assess steatosis. Steatotic liver disease (SLD) subtypes were defined based on the latest international consensus nomenclature.

Results: A total of 3519 participants were included in the study. Both sexes were represented in similar proportions (52% males) and the median age was 57 years. Intermediate and high alcohol consumption were observed in 991 (30%) and 826 (25%) individuals, respectively. Four hundred fifty-four (13%) individuals had elevated AST levels. Median LSM was 4.8 kPa, and 345 (10%) participants had LSM ≥8 kPa. In multivariable linear regression analysis adjusted for covariables, alcohol use was not associated with LSM (B coefficients for intermediate and high consumption: −0.330 [−1.107–0.448] and −0.359 [−1.891–1.172], respectively). Conversely, AST (B = 0.065 [0.050–0.080]) and CAP (B = 0.007 [0.004–0.010]) were independently associated with LSM. Moreover, distribution of LSM was similar among alcohol consumption groups. In a secondary analysis using logistic regression, only AST and CAP, but not ongoing alcohol, were associated with LSM ≥8 kPa. Other notable factors associated with LSM were body mass index, blood glucose, GGT and platelet levels. Overall, similar results were observed in the different SLD subtypes.
Conclusion: Ongoing alcohol use at the time of TE does not affect LSM. Repeated LSM after alcohol abstinence should only be considered in patients with elevated liver enzymes.

SAT-512

Potential of reflex testing with the CORE model triggered by liver enzyme abnormalities to improve risk prediction in the general population

Fredrik Åberg[1], Lotta Hallamaa[1], Rickard Strandberg[2,3], Hannes Hagström[2,4]. [1]*Helsinki University Hospital and University of Helsinki, Helsingfors, Finland;* [2]*Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden;* [3]*Red Door Analytics, Stockholm, Sweden;* [4]*Division of Hepatology, Department of Upper GI Diseases, Karolinska University Hospital, Stockholm, Sweden*
Email: fredrik.aberg@helsinki.fi

Background and aims: The Cirrhosis Outcome Risk Estimator (CORE) risk-prediction model combines routine liver blood tests (ALT, AST, GGT) to estimate individual risk of liver-related events in the general population. We hypothesized that a reflex strategy—calculating CORE whenever any enzyme exceeds the upper limit of normal—would efficiently capture individuals at elevated CORE-predicted risk.
Method: In four Finnish health examination studies (FINRISK 2002, 2007, and 2012, and Health 2000) representative of the general population, we analyzed 24,000 participants (mean age 50 years, 46% men) with ALT, AST, and GGT measurements. To evaluate the suitability of a reflex-testing strategy, we calculated the proportion of individuals with CORE-predicted 10-year risk >1%, >3%, >5%, >7%, and >10% who would be identified by elevated liver enzymes, defined using IFCC-recommended sex-specific upper limits of normal (men/women: ALT 42/30 U/L; AST 35/33 U/L; GGT 68/40 U/L).
Results: Elevated GGT was the most sensitive marker, identifying 87% of those with CORE ≥1%, 99% with CORE ≥3%, and 100% with CORE ≥5%. Elevated AST detected 83%, 100%, and 100%, respectively, while elevated ALT detected 71%, 92%, and 95%. A dual-enzyme reflex strategy, where CORE was calculated if either ALT or GGT was elevated, detected 98% of individuals with CORE >1% and 100% of those with CORE >3%. A similar increase in detection was achieved by lowering the abnormality thresholds for ALT, AST, or GGT by only 5 U/L. Using elevated GGT alone as the reflex trigger, 87% of CORE tests could be avoided compared to testing the entire population.
Conclusion: A laboratory-integrated reflex-testing strategy, where CORE is automatically calculated whenever ALT, AST, or GGT is elevated, could provide an efficient and low-cost approach to identify individuals at high risk of future major adverse liver outcomes in clinical practice. As GGT was the most sensitive trigger, the reflex strategy could even be restricted to GGT alone.

SAT-513

High fibrosis-4 index is linked to hepatic decompensation and liver cancer in a nationwide matched cohort

Fadi Abu Baker[1], Rawi Hazzan[2], Tarek Saadi[3], Ariel Israel[4]. [1]*Hillel Yaffe Medical Center, Hadera, Israel;* [2]*Clalit Healthcare North District, Afula, Israel;* [3]*Rambam Healthcare Campus, Haifa, Israel;* [4]*Leumit Healthcare Services, Tel Aviv, Israel*
Email: Fa_fd@hotmail.com

Background and aims: The Fibrosis-4 (FIB-4) index is widely used to estimate hepatic fibrosis non-invasively, yet its real-world performance for identifying patients at risk for clinically relevant hepatic outcomes remains incompletely defined. We evaluated liver disease etiologies, advanced hepatic complications, and longitudinal hepatic outcomes in adults with high versus low FIB-4.
Method: In a nationwide real-world matched cohort study, adults aged 40 to 80 years with available laboratory values were included. Individuals with FIB-4 >= 2.67 (n = 21,540) were matched 1 to 1 to controls with FIB-4 <1.45 (n = 21,540) by age, sex, ethnicity, and socioeconomic status. Cross-sectional analyses assessed liver disease etiologies and complications, and longitudinal analyses evaluated incident cirrhosis and hepatic decompensation over a median follow-up of 6.2 years.
Results: At baseline, high FIB-4 was associated with higher prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) (10.5% vs 6.0%). Viral hepatitis was more common, including hepatitis B virus (HBV) infection (2.1% vs 0.6%; odds ratio (OR) 3.55, 95% confidence interval (CI) 2.91 to 4.34) and hepatitis C virus (HCV) infection (3.5% vs 0.3%; OR 11.98, 95% CI 9.29 to 15.44). Baseline cirrhosis was present in 7.10% versus 0.12% (OR 62.32, 95% CI 39.23 to 87.99). Advanced complications were markedly more frequent, including ascites (4.51% vs 0.35%; OR 13.53, 95% CI 10.69 to 17.12), encephalopathy (0.85% vs 0.06%; OR 15.46, 95% CI 8.62 to 27.73), and esophageal varices (1.81% vs 0.005%). Hepatobiliary malignancies were more prevalent, including hepatocellular carcinoma (0.55% vs 0.04%; OR 14.83, 95% CI 7.28 to 35.18) and cholangiocarcinoma (0.30% vs 0.03%; OR 9.31, 95% CI 4.27 to 24.07). During follow-up, incident cirrhosis occurred in 2.82% versus 0.03% (OR 104.06, 95% CI 47.53 to 284.29), and new-onset hepatic decompensation occurred in 4.39% versus 0.07% (OR 29.28, 95% CI 13.88 to 44.53).
Conclusion: In a large nationwide matched cohort, FIB-4 >= 2.67 identified individuals with substantially higher prevalence of MASLD and viral hepatitis, a markedly greater baseline burden of cirrhosis and advanced complications, and a pronounced long-term risk of incident cirrhosis and hepatic decompensation, alongside increased hepatobiliary malignancy. These findings support FIB-4 as a pragmatic tool to prioritize hepatology evaluation and risk-stratified surveillance pathways.

SAT-514

Diagnostic utility of the splenic-to-liver stiffness ratio in porto-sinusoidal vascular disease (PSVD): a multicentric study

Ayush Agarwal[1], Arun Valsan[2], Shubham Jain[1], Arathi Venu[2], Shiv Verma[1], Dhruv Advani[1], Sinchana Lakshmi[1], Pavit Singh[1], Arnav Aggarwal[1], Vishal Chauhan[1], Sarthak Saxena[1], Sagnik Biswas[1], Prasenjit Das[1], Shalimar Shalimar[1]. [1]*All India Institute of Medical Sciences, New Delhi, New Delhi, India;* [2]*Amrita Institute of Medical Sciences, Kochi, Kochi, India*
Email: ayushgrm@gmail.com

Background and aims: Differentiating porto-sinusoidal vascular disease (PSVD) from cirrhosis remains a significant clinical challenge due to overlapping features of portal hypertension. Liver stiffness measurement (LSM) has limited accuracy, particularly in the intermediate grey-zone range. As PSVD is characterized by elevated portal pressure without advanced hepatic fibrosis, splenic stiffness measurement (SSM) and the splenic-to-liver stiffness ratio (SSM/LSM) may better identify these patients. This study aimed to evaluate

the diagnostic performance of LSM and the SSM/LSM ratio in differentiating PSVD from cirrhosis.
Method: In this multicentric case–control study, biopsy-proven PSVD and cirrhosis patients with valid transient elastography were included. LSM and SSM were assessed with dedicated probes using the FibroScan Expert 630. Centre 1 (AIIMS, New Delhi) served as the derivation cohort, while Centre 2 (Amrita Institute, Kochi) was used for external validation. Diagnostic performance of LSM and SSM/LSM ratio was assessed using area under the receiver operating characteristic curve (AUROC). Optimal cutoffs derived in Centre 1 were applied unchanged to Centre 2, and sensitivity and specificity were compared. Subgroup analysis was performed in the LSM grey zone (10–20 kPa). Histological features associated with high LSM in PSVD were identified.
Results: A total of 183 patients were included (93 PSVD, 90 cirrhosis). Median LSM was significantly lower and SSM/LSM ratio significantly higher in PSVD across both centres ($p < 0.001$). In Centre 1 ($n = 109$), SSM/LSM ratio demonstrated excellent diagnostic accuracy comparable to LSM (AUROC 0.90 vs 0.87, $p = 0.39$), with an optimal cutoff of >2.8. On external validation (Centre 2, $n = 74$), the SSM/LSM ratio demonstrated superior specificity (61.5% vs 25.6%, $p < 0.001$) with comparable sensitivity (97.1% vs 100%) compared to LSM. In the grey-zone LSM subgroup, SSM/LSM ratio showed significantly higher diagnostic accuracy than LSM (AUROC 0.83 vs 0.65, $p = 0.02$). Among PSVD patients, elevated LSM was significantly associated with histological sinusoidal dilatation ($p = 0.001$), perisinusoidal fibrosis ($p = 0.008$), and portal tract vascular abnormalities ($p = 0.02$).
Conclusion: The splenic-to-liver stiffness ratio outperforms LSM alone in differentiating PSVD from cirrhosis in the LSM grey zone, and maintains diagnostic robustness on external validation.

SAT-515
Mortality prediction using non-invasive fibrosis scores independent of chronic liver disease in patients with COVID-19
Maximilian Joseph Brol[1], Elena Rosenquist[1], Julia Fischer[1], Richard Vollenberg[1], Frank Erhard Uschner[1], Frank Tacke[2], Münevver Demir[2], Jonel Trebicka[1,3], Phil Robin Tepasse[1]. *[1]Münster University Hospital, Department of Internal Medicine B, Münster, Germany; [2]Charité - Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Campus Virchow-Klinikum (CVK) and Campus Charité Mitte (CCM), Berlin, Germany; [3]European Foundation for the Study of Chronic Liver Failure-EF Clif, Barcelona, Spain*
Email: maximilian.brol@ukmuenster.de

Background and aims: Liver is an important organ in immunological responses. Chronic liver disease may influence outcomes in coronavirus disease 2019 (COVID-19), although this association may be driven by comorbidities rather than liver disease itself. Non-invasive scores based on routine lab tests (NIT) are commonly used to estimate liver fibrosis, despite being potentially confounded by non-hepatic systemic illness. This study aimed to evaluate the impact of chronic liver disease and the prognostic value of non-invasive fibrosis scores in COVID-19.
Method: This retrospective cohort study of prospectively collected data analyzed two cohorts of the German National Pandemic Cohort Network: (i) a university-hospital based high-resolution cohort (HRC) included hospitalized patients with detailed data ($n = 373$) and (ii) a cross-sectoral cohort (CSC) including patients with routine clinical data ($n = 2033$) across all levels of care. Outcomes were compared between patients with and without chronic liver disease. NITs, including FIB-4, APRI and NFS, were analyzed in all patients regardless of known liver disease at diagnosis. Survival analyses, multivariable Cox proportional hazards models, and ROC analyses were performed.
Results: Chronic liver disease was more frequently diagnosed in the HRC than in the CSC (11.2% vs. 6.0%). In the CSC, patients with chronic liver disease had higher unadjusted mortality than those without liver disease (17.4% vs 9.8%, $p = 0.028$), but this association was not significant after adjustment for comorbidities (HR 1.544, $p = 0.061$). In contrast, all NITs were significantly higher in non survivors across both cohorts at diagnosis of COVID, independent of pre-existing liver disease. High risk categories of FIB-4 (>2.67), APRI (>1.5), and NFS (>0.675) were independently associated with increased mortality. In multivariable Cox regression analysis, high risk categories of FIB-4 and APRI (HRC HR 7.057, $p < 0.001$; CSC HR 2.584, $p < 0.001$) were independently associated with increased mortality. Prognostic discrimination for mortality was above 0.7 for each NIT in both cohorts, with best performance for NFS in the HRC (AUROC: 0.832).
Conclusion: NITs, applied irrespective of known liver disease, were strong and independent predictors of mortality, indicating that these scores may capture systemic disease severity beyond liver specific pathology. These findings support the use of NITs for risk stratification in COVID-19 patients regardless of underlying liver disease status.

SAT-516
The impact of CFTR genotype on liver impairment in patients with cystic fibrosis
Valentina Cossiga[1], Mario Capasso[1], Emanuela Pellegrino[1], Paola Iacotucci[2], Simona Albano[1], Lorenza Ferrillo[3], Filippo Vetrone[1], Jolanda Somma[3], Luisa Ranieri[1], Maria Guarino[1], Vincenzo Carnovale[3], Filomena Morisco[1]. *[1]Department of Clinical Medicine and Surgery, Departmental Program "Diseases of the liver and biliary system", University of Naples Federico II, Naples, Italy; [2]Departement of Advanced Biomedical Sciences - University of Naples "Federico II", Naples, Italy; [3]Departement of Translational Medical Sciences - University of Naples "Federico II", Naples, Italy*
Email: valentina.cossiga@gmail.com

Background and aims: Cystic fibrosis-associated liver disease (CFLD) is a significant cause of morbidity and the third cause of death in this genetic disease. However, evidence of CFLD is usually subclinical until the disease is advanced, so CFLD is underdiagnosed. The aim of this study is to evaluate the impact of CFTR (Cystic Fibrosis Transmembrane conductance Regulator) genotype (F508del allele mutation) on liver impairment in patients with cystic fibrosis.
Method: A retrospective monocentric study was conducted at University of Naples Federico II enrolling all consecutive patients with cystic fibrosis with liver involvement (clinical, biochemical or instrumental abnormalities) referred to hepatological evaluation. Non-invasive evaluation of liver fibrosis with transient elastography was performed in all patients, together with the collection of clinical and biochemical data.
Results: Thirty-eight patients (65.7% male, mean age 35.1 ± 10.7 yrs) were enrolled. The cohort was divided into 3 groups according to CFTR genotype: group A homozygotes patients with F508del mutation (7 patients, 18.4%), group B heterozygous F508del mutation patients (13 patients, 34.2%) and group C including other mutations (18 patients, 47.3%). Group A showed a significant more severe CFLD compared to groups B and C as demonstrated by higher liver stiffness (27.8 ± 21.9kPa vs 8.7 ± 5.3 kPa vs 7.2 ± 4.0kPa; group A vs group B $p = 0.006$ and group A vs group C $p = 0.001$), higher FIB-4 score (2.7 ± 2.5 vs 0.9 ± 0.4 vs 0.8 ± 0.5; group A vs groups B and C $p = 0.01$), higher spleen diameter (171 ± 37 mm vs 126 ± 17 mm vs 117 ± 27.8 mm; group A vs group B $p = 0.0007$ and group A vs group C $p = 0.001$) and lower platelets count (155714 ± 135294/mm^3 vs 218692 ± 155628/mm^3 vs 287166 ± 131486/mm^3; group A vs groups B and C $p < 0.05$).
Conclusion: Homozygotes F508del allele mutation patients have severe CFLD with advanced liver fibrosis and significant portal hypertension. Our findings suggest that these patients should be promptly evaluated by hepatologists since diagnosis. Further studies with larger sample size are required to confirm this data.

SAT-517

Impact of adult population screening for liver cirrhosis using routine blood tests on rate of transient elastography referrals from primary care: a prospective intervention study

Joan Flores[1], Christina Trambas[2], Natasha Jovanovic[2], Bree James[2], Alexander Thompson[3], Jessica Howell[3]. *[1]Canberra Hospital, University of Melbourne, St Vincent's Hospital Melbourne, Canberra, Australia; [2]St Vincent's Pathology, Fitzroy, Australia; [3]St Vincent's Hospital Melbourne, University of Melbourne, Fitzroy, Australia*
Email: ericka@flores.com.au

Background and aims: Cirrhosis is often diagnosed late due to a lack of population screening programs. This study evaluated the effect of reflex reporting of Aspartate to Platelet Index (APRI) for routine blood test events on referral rate for vibration controlled transient elastography (VCTE).
Method: This prospective intervention study was conducted between 19 May 2024 to 18 May 2025 at a single tertiary hospital and statewide pathology service. Reflex calculation and reporting of APRI on routine blood test events in adults >18 years who had elevated ALT (laboratory upper limit 30 IU/mL females, 35 IU/mL males) commenced on November 19, 2024. Reports included APRI explanation, recommendation that VCTE be ordered for APRI >1.0 with link to VCTE referral. Pathology, demographic, appointment and VCTE data were collected from pathology service and hospital records. Monthly rate of VCTE referrals and proportion from primary care in the 6 months post intervention were compared to 6 months pre-intervention via regression modelling and Chi square test respectively.
Results: 23,764 blood test events in 12,031 individuals with elevated ALT had APRI reported. Of these, 8,339 were individuals with blood tests ordered in the community. 686 (8%) had APRI>1 and 175 (2%) had APRI>2. Median age of those with APRI>1 was 58 years (IQR 43, 71 years) and most were male (62% vs 38%, $p < 0.001$). Mean rate of individuals with APRI>1 who would require VCTE referral was 114 per month. There were 1192 VCTE referrals during the study period, of which 73 (6.1%) were from non-hepatology specialists including general practitioners (GPs). Mean weekly number of VCTE referrals increased from 0.09 per week pre-intervention to 0.53 per week post-intervention (post-estimation linear trend $p = 0.014$). The proportion of referrals from non-hepatology specialists and GPs increased from 3.0% (20/ 664) pre-intervention to 10.0% (53/ 528) post intervention (X^2 $p < 0.001$); referrals from GPs increased from 2.1% (14/664) pre-intervention to 4.2% (22/528, X^2 $p = 0.04$) post intervention. Post intervention, 17% (9/ 53) of people referred by non-hepatology specialists had F3 or 4 stage fibrosis on VCTE, compared to 5% (1/20) of those referred pre-intervention.
Conclusion: Reflex reporting of APRI on routine blood tests increased the proportion of VCTE referrals from non-liver specialists, without overwhelming VCTE service capacity. Reflex reporting of APRI by pathology services may be an effective, low-cost intervention to increase early diagnosis of cirrhosis.

SAT-521

Feasibility of adult population screening for liver cirrhosis using routine blood tests in Australia: a prospective cohort study

Joan Flores[1,2,3], Christina Trambas[1,4], Natasha Jovanovic[4], Bree James[4], Thai Hong[1], Zina Valaydon[5], Alexander Thompson[1,3], Jessica Howell[1,3]. *[1]Saint Vincent's Hospital Melbourne, Fitzroy, Australia; [2]Canberra Hospital, Garran, Australia; [3]University of Melbourne, Parkville, Australia; [4]Saint Vincent's Pathology, Fitzroy, Australia; [5]Western Health, Footscray, Australia*
Email: ericka@flores.com.au

Background and aims: Blood biomarker algorithms APRI and FIB-4 are recommended in guidelines for cirrhosis screening in people with liver disease. However, awareness and use in primary care are low. We evaluated the feasibility of reflex reporting of APRI and FIB-4 scores by a pathology service on routine blood tests to identify people at risk of cirrhosis.
Method: In this prospective cohort study, anonymised blood test results and demographic data were extracted for all St Vincent's Pathology statewide blood test events ordered in primary care between 8 August 2022 and 31 January 2023. APRI and FIB-4 were calculated for blood test events where FBE and LFTs were ordered together, restricted to adults aged 18 to 80 years with elevated ALT above the laboratory upper limit of normal (30 IU/mL females, 35 IU/mL males).
Results: 15,637 of 38,190 (41%) of individuals tested had elevated ALT. Of these, 6% (N = 478) had APRI >1.0 and 1% (N = 119) had APRI >2.0. Elevated APRI was more common in males (4% vs 3%, $p < 0.001$) but did not vary with age. 27% (N = 4694) had FIB-4 >1.3 and 3% (N = 519) had FIB-4 >2.67. FIB-4 >2.67 was more common in males (4 vs 2%, $p < 0.001$). Odds of FIB-4 >1.3 increased exponentially with age >45 years ($p < 0.001$). Kappa agreement between APRI >1 and FIB-4 >2.67 was 98% (SE 0.005). Median monthly rate of test events which would trigger transient elastography referral was 93 per month for APRI >1.0 and 87 per month for FIB-4 >2.67.
Conclusion: Reflex calculation and reporting of APRI >1.0 and FIB-4 >2.67 by pathology services on routine blood tests in primary care is a potentially feasible approach for population-level cirrhosis screening. Further studies are needed to determine the impact on cirrhosis case identification and referral to specialist care.

SAT-522

Diagnostic performance of the ELF score for liver fibrosis staging in chronic liver disease: a comparative study with FibroScan, serum markers, and liver biopsy

Tatsuya Fujino[1], Shingo Namino[1], Kazumi Yamasaki[1], Tomoyuki Suehiro[1], Yuki Kugiyama[1], Tomohito Kojima[1], Yasuhide Motoyoshi[1], Akira Saeki[1], Shinya Nagaoka[1], Atsumasa Komori[1], Hiroshi Yatsuhashi[1,2]. *[1]NHO Nagasaki Medical Center, Omura, Japan; [2]Clinical Research Center, National Hospital Organization Nagasaki Medical Center, Nagasaki, Japan*
Email: Yatsuhashihiroshi@gmail.com

Background and aims: This study aimed to validate the correlation between the Enhaned Liver Fibrosis(ELF) score and fibrosis stages based on FibroScan (liver stiffness measurement; LSM), and to compare its diagnostic performance with the FIB-4 index, APRI, and M2BPGi. Furthermore, we evaluated the association between the ELF score and histological fibrosis stages in patients who underwent liver biopsy.
Method: Two cohorts were analyzed: Cohort A: 373 patients with chronic liver disease (HBV, n = 105; HCV, n = 250; MASLD, n = 18) who underwent FibroScan and blood tests on the same day. Based on LSM values, they were classified into F1 (≤7.0 kPa, n = 213), F2 (7.1–9.9 kPa, n = 50), F3 (10.0–12.9 kPa, n = 34), and F4 (≥13.0 kPa, n = 76). Cohort B: 277 patients (126 males, 151 females; mean age 59.5 ± 14.4 years) with liver biopsy and ELF measurements. Etiologies included HBV (n = 71), HCV (n = 148), and MASLD (n = 58). Histological stages were F1 (n = 134), F2 (n = 68), F3 (n = 38), and F4 (n = 37). Statistical analyses included correlation analysis, group comparisons, and receiver operating characteristic (ROC) analysis.
Results: In Cohort A, the ELF score showed significant positive correlations with M2BPGi (r = 0.757), FIB-4 (r = 0.699), and APRI (r = 0.654) (all $p < 0.001$). Median ELF scores increased progressively with LSM-based stages (F1: 9.25, F2: 10.14, F3: 10.50, F4: 11.92; $p < 0.001$). For the diagnosis of stage ≥ F2, the ROC for ELF was 0.837, outperforming FIB-4 (0.806) and APRI (0.824). For ≥ F3, ELF demonstrated the highest specificity (0.928). For ≥ F4, ELF achieved the highest AUROC (0.874) among the three markers. In Cohort B (biopsy-proven), median ELF scores also rose significantly across all histological stages (F1: 9.81, F2: 10.53, F3: 11.39, F4: 12.07). The AUROCs for the diagnosis ≥ F2, ≥ F3, ≥ F4 were 0.778, 0.811, and 0.836, respectively, showing improved diagnostic performance with advancing fibrosis.

Conclusion: The ELF score effectively reflects fibrosis progression in chronic liver diseases (HBV, HCV, and MASLD) and demonstrates superior or comparable diagnostic performance to FIB-4, APRI, and M2BPGi. The strong correlation with M2BPGi suggests these markers may serve as complementary non-invasive tools. Furthermore, the clear stepwise increase in ELF scores according to histological stages underscores its clinical utility for identifying advanced fibrosis. Further studies focusing on etiology-specific analysis and longitudinal changes are warranted.

SAT-523

Genetic determinants of clinical phenotypes in pediatric liver transplant recipients with inherited liver diseases

Eyad Gadour[1], Ibrahim Hassan[1], Razan Bader[1], Hadi Kuriry[1], Ahmed Zidan[1], Mohammed Alqahtani[1]. *[1]King Fahad Specialist Hospital, Multiorgan Transplant Centre of Excellence, Pediatric Liver Transplantation, Dammam, Saudi Arabia*
Email: eyadgadour@doctors.org.uk

Background and aims: Inherited liver diseases (ILDs) in children present significant clinical heterogeneity, complicating diagnosis, prognosis, and management. Although genetic diagnosis is now routine, detailed genotype-phenotype correlations remain underexplored, particularly in familial cohorts. This study aimed to elucidate precise genotype-phenotype relationships in pediatric ILDs by analyzing clinical, histopathological, and genetic data from sibling pairs undergoing liver transplantation.
Method: We performed a retrospective cohort study at a tertiary liver transplant center in France, including 26 pediatric patients (13 sibling pairs) with genetically confirmed ILDs who underwent liver transplantation.Statistical analyses using Fisher's exact test and one-way ANOVA (IBM SPSS v28) assessed associations between genotypes and clinical/histological features. Significance was set at $p < 0.05$.
Results: The cohort predominantly comprised infants diagnosed before 1 year of age (76.9%, n = 20). Seven genes were implicated: ABCB11, ABCB4, AGXT, UGT1A1, GBE1, BCKDHA, and DCDC2. PFIC II (ABCB11 mutations) was the most prevalent diagnosis (30.8%, n = 8). Ascites was present in 23.1% (6/26) of patients and showed a trend toward association with genotype, although this did not reach statistical significance ($p = 0.053$). Histopathological analysis revealed cirrhosis as the predominant biopsy finding, occurring in 57.7% (15/26) of cases, and was uniformly associated with ABCB4, specific ABCB11 variants (c.2453A>T, homozygous c.2944G>A), GBE1, and DCDC2 mutations. Eight patients (30.8%) exhibited normal liver histology, which was restricted to carriers of AGXT, UGT1A1, and the ABCB11 c.2296G>A mutation. Mean PELD scores varied by genotype, ranging from 16.5 in patients homozygous for ABCB4 c.3838T>C to 38.5 in another homozygous ABCB4 c.3838T>C pair; however, these differences did not reach statistical significance ($p = 0$).
Conclusion: This study delineates robust genotype-phenotype correlations in pediatric ILDs within a familial cohort. The AGXT mutation defines a unique non-icteric renal phenotype, while specific ABCB11 and DCDC2 variants confer high risk for early coagulopathy and severe hepatocellular dysfunction. The lack of significant correlation between genotype and PELD scores highlights the multifactorial nature of disease severity. These findings emphasize the importance of comprehensive genetic testing for prognostic stratification and personalized clinical management in pediatric ILDs.

SAT-524

Percutaneous liver biopsy in Spain: current clinical practice and safety in the era of non-invasive tests

Mariano Gómez-Rubio[1], Rodrigo Nájera-Muñoz[1], Miguel Fernández-Bermejo[2], Valle Cadahía-Rodrigo[3], Rocio Calvo Hernandez[4], Diego Rojo[5], Luis Cortés García[6], Laura Paola Barreto-Anchury[7], Pablo Flores-Diez[3], Sergio Perez-Rodriguez[4], Laura Pages[8], María Galochino[6], Gemma Carrion Alonso[9], Cristina Martínez Cuevas[10], Sara María Monsalve Alonso[11], María Ojeda Remizova[12], Luis Eduardo Durán Durán[13], Esther Badia-Aranda[14], Ana Guiberteau[15], Leticia González-Moreno[16], María Rodríguez-Peláez[3], Benjamin Polo Lorduy[4], María Teresa Salcedo[17], Adela Navarro[6], Isabel Serra[7], Sonia Martín-Chavarri[9], Alicia SanJosé Crespo[10], Pablo Cavanagh Pérez-Nievas[11], Manuel Crespo Sánchez[12], Antonio Diaz[18], Maria Luisa Gutiérrez[19], Gadea Hontoria-Bautista[14], Cristina Corchado-Berjano[15], María Caldas-Álvarez[16], Carla Lucio-Fernández[20], Silvia Montoliu[21]. *[1]Department of Digestive Diseases. Email: mgomezrubio@salud.madrid.org

Background and aims: In the era of non-invasive tests, the role of percutaneous liver biopsy (PLB) in routine clinical practice is evolving. However, contemporary real-world data on its use, safety and clinical impact in Spain are lacking. This study aimed to describe current PLB practice and outcomes in a nationwide setting.
Method: We conducted a multicentre, retrospective observational study including 18 Digestive and Hepatology units in Spain. PLBs performed in 2012 and 2022 were analysed, covering a reference population of 10,227,640 inhabitants. Data were collected through the national PBHPE REDCap® registry (AEED, Spanish Association of Digestive Ultrasound). Utilisation rates, clinical indications, procedural characteristics, diagnostic yield and complications were assessed.
Results: A total of 1,126 PLBs were included, with an annual rate of 11.0 biopsies per 100,000 inhabitants. Mean age was 53.8 years and 51.2% were women; 64.5% of procedures were performed in outpatients. The main indications were abnormal liver tests (45.3%), autoimmune hepatitis (15.5%), hepatitis C (14.2%) and steatotic liver disease (12.0%). Pre-procedural coagulation assessment was performed in 83.3% of cases. Most biopsies (63.7%) were performed by experienced physicians (>100 procedures), predominantly gastroenterologists/hepatologists (87.9%). Ultrasound guidance was used in 95.4% of cases, either with pre-procedural skin marking (51%) or real-time guidance (49%). Automatic needles were employed in 69.6% of procedures, most commonly 16G (66.9%). Adequate liver tissue for

diagnosis was obtained in 91.0%, with a mean specimen length of 19.6 mm. Fibrosis stages were F0 (46.1%), F1 (23.1%), F2 (13.6%), F3 (9.8%) and F4 (7.4%). Pain was absent or mild in 95.8% of patients. No complications occurred in 93.9%. Severe complications were uncommon (1.1%), including liver haematoma (0.8%) and hemoperitoneum (0.3%). One procedure-related death (0.09%) was reported.
Conclusion: Despite the widespread use of non-invasive techniques, PLB remains an important diagnostic tool in clinical practice, particularly in cases of diagnostic uncertainty and immune-mediated liver diseases. When performed by experienced specialists with ultrasound guidance, PLB is safe, well tolerated and provides a high diagnostic yield. Optimising patient selection is essential to maximise clinical impact while maintaining a low risk profile.

SAT-525
Do large language models think like hepatologists? A multi-dimensional real-world study
Nada Abedin[1], Amaryllis Görz[1], Maximilian Freiherr von Beust[2], Anita Pathil-Warth[1], Ulrike Mihm[1], Stefan Zeuzem[1], Georg Dultz[1]. *[1]Medical Clinic 1, University Hospital Frankfurt, Frankfurt am Main, Germany; [2]Independent Researcher, Frankfurt, Germany*
Email: abedin@med.uni-frankfurt.de

Background and aims: Large language models (LLMs) are increasingly evaluated for clinical diagnosis, yet most studies focus exclusively on accuracy. Few studies have examined LLM performance across multiple dimensions in specialized domains such as hepatology and with real-life cases. We aimed to evaluate LLM performance using a multi-dimensional framework encompassing accuracy, guideline adherence, treatment quality, safety, and comparison to actual practice in a real-life cohort.
Method: We performed a retrospective study of 304 hepatology cases from a single-center outpatient clinic at University Hospital Frankfurt with a 1-year follow-up. Each case was evaluated using a LLM (Claude Sonnet 4.5) augmented with retrieval-augmented generation with access to hepatology guidelines (DGVS, EASL). The LLM received first-appointment data only, while ground truth diagnoses were established by specialists with longitudinal follow-up (mean 3.4 visits). Five dimensions were assessed: (1) diagnostic accuracy (exact and category-level), (2) guideline adherence, (3) treatment quality, (4) critical misses, and (5) comparison to actual management. Performance was stratified by disease category, complexity, and confidence level using Wilson confidence intervals and chi-square analysis.
Results: Diagnostic accuracy was 68.5% (95% CI 62.6%–73.8%) for exact diagnosis and 76% (95% CI 70.9%–80.4%) for category, achieved with first-appointment data only. The LLM demonstrated excellent guideline adherence (96.7%, 294/304) with correct guideline selection (92.4%, 281/304) and appropriate treatment recommendations (96.1%, 292/304). Recommendations were superior to actual management in 14.8% (45/304) and equal in 79.6% (242/304). Critical misses occurred in 7.9% (24/304), predominantly affecting rare diseases. Viral hepatitis showed highest accuracy (82.5% exact, 91.3% top-3). Confidence calibration was significant (high 60.5% vs moderate 35.8%, $p = 0.0006$).
Conclusion: LLMs demonstrate moderate accuracy but excellent clinical reasoning and guideline adherence. Despite single-timepoint limitations, LLMs showed appropriate reasoning in 96% of cases and outperformed actual recommendations in 15%. LLMs are appropriate for clinical decision support with mandatory human oversight and can enhance guideline compliance and time-to-treatment significantly. Multi-dimensional evaluation frameworks are essential for assessing medical AI beyond traditional accuracy metrics.

SAT-527
Reevaluating liver enzyme reference ranges in chronic kidney disease: a population-based study
Karem Awad[1], Benaya Rozen Zvi[2], Fadi Abu Baker[3], Mifleh Tatour[4], Abdellatif Zhalka Zhalka[5], Rawi Hazzan[6]. *[1]Department of Nephrology and Hypertension, Emek Medical Center, Afula, Israel, Rappaport Faculty of Medicine, Technion - Institute of Technology, Haifa, Israel, Afula, Israel; [2]Department of Nephrology and Hypertension, Rabin Medical Center, Petah Tikva, Israel, Gray Faculty of Medical & Health Sciences, Tel-Aviv University, Tel-Aviv, Israel, Petah Tiqva, Israel; [3]Department of Gastroenterology and Hepatology, Hillel Yaffe Medical Center, Hadera 38100, Israel, Rappaport Faculty of Medicine, Technion - Institute of Technology, Haifa, Israel, Hadera, Israel; [4]Clalit Health Services, Northern Region, Israel, Azrieli Faculty of Medicine, Bar-Ilan University, Safed, Israel, Nof hagalil, Israel; [5]Department of Internal Medicine B, Emek Medical Center, Afula, Israel, Afula, Israel; [6]Clalit Health Service, Barilan University, Nazareth, Israel*
Email: rawihazzan1@gmail.com

Background and aims: Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) are essential liver biomarkers, but consistently low values complicate their interpretation in chronic kidney disease (CKD). Current reference ranges may contribute to the underdiagnosis of hepatic disorders in this population.
Method: We conducted a retrospective, population-based cohort study using the Clalit Health Services database, which included 820,707 adult patients with a normal body mass index (BMI) and valid AST/ALT results. Patients were stratified by CKD stage and gender. The relationship between enzyme levels and estimated glomerular filtration rate (eGFR) was assessed using descriptive statistics and regression analysis.
Results: ALT and AST levels were significantly lower in CKD patients compared to the general population, with a progressive decline across CKD stages. In males, the mean ALT decreased from 24.4 U/L in Stage I to 13.5 U/L in Stage V; in females, ALT declined from 16.0 U/L to 12.8 U/L. AST values also reduced from 23.6 U/L to 15.6 U/L in males and from 19.5 U/L to 16.5 U/L in females. A strong positive correlation. was observed between ALT and eGFR, particularly in males. Enzyme variability was most significant in early CKD and narrowed in advanced stages. Non-parametric Regression models further confirmed that the association between aminotransferase levels and eGFR is modified by both age and gender, with younger patients exhibiting steeper declines in eGFR.
Conclusion: Our study highlights the urgent need for Kidney Disease-Specific thresholds for liver enzymes. We found that ALT and AST levels decline progressively with increasing severity of CKD, independent of overt liver disease, and this trend is consistent across genders. The narrowing variability and lower enzyme concentrations in advanced CKD highlights the risk of underdiagnosing liver disease when using standard Reference ranges. Implementing CKD-specific thresholds could significantly improve the detection and management of hepatic disorders in this population.

SAT-528
CT-derived spleen volume combined with routine labs accurately differentiates PSVD from cirrhosis across global cohorts
Subin Heo[1], Maxime Ronot[2], Pierre-Emmanuel Rautou[2], Pomohaci Mihai[3], In Hye Song[1], Hyo Jeong Kang[1], Youngeun Yoo[1], Lucile Moga[2], Shantha Valainathan[2], Sung-Cheol Yun[1], Won-Mook Choi[1], Seung Soo Lee[1]. *[1]Asan Medical Center, Seoul, Korea, Rep. of South; [2]Hôpital Beaujon, Clichy, France; [3]University of Medicine and Pharmacy "Carol Davila," Bucharest, Romania*
Email: dr.choi85@gmail.com

Background and aims: Porto-sinusoidal vascular disorder (PSVD) is an often overlooked etiology of portal hypertension and is commonly mistaken for cirrhosis. This study aims to evaluate differences in CT-based volumetric and laboratory characteristics between PSVD and

cirrhosis and to build and externally validate a noninvasive diagnostic model.
Method: We retrospectively analyzed 101 patients with PSVD and 202 with cirrhosis from Korea (Eastern cohort) and 45 patients with PSVD and 100 with cirrhosis from France (Western cohort), all presenting with portal hypertension and matched for its severity. Liver and spleen volumes were automatically measured on contrast-enhanced CT and normalized to individualized reference volumes. After feature comparison, a conditional logistic regression model (PSVD-VL) incorporating standardized spleen volume, aspartate aminotransferase, platelet count, and international normalized ratio was developed in the Eastern cohort and validated in the Western cohort. Rule-in and rule-out thresholds were predefined to aim for 90% specificity and sensitivity.
Results: Standardized spleen volume was markedly higher in PSVD than in cirrhosis in both cohorts (Eastern: 5.14 vs 3.59, $p < 0.001$; Western: 5.20 vs 3.46, $p < 0.001$), whereas markers of hepatic synthetic function and hepatocellular injury were comparatively preserved in PSVD. The PSVD-VL model achieved an area under the receiver operating characteristic curve of 0.86 (95% CI, 0.81–0.91) in the Eastern cohort and 0.79 (95% CI, 0.71–0.87) in the Western cohort for diagnosing PSVD. Applying the rule-in and rule-out thresholds enabled classification of 69% and 67% of patients in the Eastern and Western cohorts, respectively, with correct assignment rates of 86% and 83%.
Conclusion: Compared with cirrhosis of equivalent portal hypertension severity, PSVD is characterized by disproportionate splenomegaly and relatively preserved liver function. A model integrating CT-derived spleen volume with routine laboratory tests demonstrated consistent performance across geographically distinct cohorts and may facilitate more accurate identification of PSVD in clinical practice.

SAT-529
Malnutrition beyond BMI in chronic liver disease: a prospective study of nutritional risk, sarcopenia, and food insecurity

Benjamin Kaschube[1], Monika Rau[1], Andreas Geier[1], Hans Benno Leicht[1], Gerd Sauter[1], Florian P. Reiter[1], Lisa Duemmler[1].
[1]University Hospital Würzburg, Department of Internal Medicine II, Division of Hepatology, Würzburg, Germany
Email: kaschube_b@ukw.de

Background and aims: Malnutrition and sarcopenia are common in chronic liver disease and are associated with impaired quality of life and adverse outcomes. Food insecurity has recently been linked to MASLD, advanced fibrosis, and mortality, but data for patients with chronic liver disease in Germany are lacking. Despite their clinical relevance, systematic screening is not routinely performed. This study aimed to determine the prevalence of malnutrition, sarcopenia, and food insecurity in a large real-world cohort and to identify associated risk factors.
Method: In this prospective study, 981 outpatients with chronic liver disease attending a tertiary care center were screened for malnutrition, sarcopenia, and food insecurity between 11/22–04/24 using validated tools (LDUST, SARC-F, and FIES). Routine clinical characteristics and laboratory parameters were recorded. Descriptive analyses were performed to determine prevalence rates and to assess associations between nutritional status and patient characteristics.
Results: The cohort compromised 981 outpatients (53% female; mean age 55 years). MASLD was the most common etiology (20.5%), followed by viral hepatitis (19.0%) and cholestatic liver disease (16.6%); 18.9% had cirrhosis and 7.6% HCC. Using LDUST, 47.3% of patients were identified as being at risk of malnutrition, with highest prevalence in those with liver cirrhosis (LC), HCC, or prior liver transplantation. Malnutrition risk was not limited to low BMI, as among LDUST-positive patients, obesity (BMI >30 kg/m^2) was more frequent than BMI <25 kg/m^2 (34.1% vs. 31.5%). SARC-F screening was positive in 10.1%, predominantly in patients with ALD and LC, and was associated with older age and cardiometabolic comorbidities. Notably, 96% of patients with a positive SARC-F screening were also at risk of malnutrition. FIES screening was positive in 6.5% (n = 64) of patients, most frequently in viral hepatitis, and was associated with younger age but not with BMI, liver stiffness or cardiometabolic comorbidities. In addition, 9.7% of patients reported a worsened diet due to rising food costs since 2022.
Conclusion: Nearly half of liver outpatients were at risk of malnutrition, including many with overweight or obesity, confirming that malnutrition extends beyond low BMI. Screening for malnutrition, sarcopenia, and food insecurity identifies complementary risk profiles, while rising food costs since 2022 underscore the need to integrate nutritional and socioeconomic assessment into routine hepatology care.

SAT-530
A machine learning approach to non-invasively predict hepatic decompensation in compensated advanced chronic liver disease: the CIRI model

Georg Kramer[1,2,3], Anders Hildeman[4], Caterina Tozzi[5], Roza Maghsood[4], Vinusha Kalatharan[6], Kinga Jastrzebska[4], Hyewonnina Koo[4], Nils Svangård[4], Claire Donoghue[4], Benedikt Simbrunner[1,2,3], Benedikt Hofer[1,2,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3], Jan Oscarsson[4], Philip Ambery[4]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [3]Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [4]Data Sciences and Artificial Intelligence, BioPharmaceuticals R&D, Astra Zeneca, Gothenburg, Sweden, Gothenburg, Sweden; [5]Data Sciences and Artificial Intelligence, BioPharmaceuticals R&D, Astra Zeneca, Barcelona, Spain, Barcelona, Spain; [6]Data Sciences and Artificial Intelligence, BioPharmaceuticals R&D, Astra Zeneca, Mississauga, Canada, Mississauga, Canada*
Email: georg.kramer@meduniwien.ac.at

Background and aims: Clinically significant portal hypertension (CSPH), defined as a hepatic venous pressure gradient (HVPG) ≥10 mmHg, identifies patients with compensated advanced chronic liver disease (cACLD) at risk of hepatic decompensation. As invasive HVPG measurement is not widely available, reliable non-invasive alternatives are needed. We developed and validated the Cirrhosis Risk Identifier (CIRI), a machine-learning model based solely on 11 routine demographic and laboratory variables, trained to predict first hepatic decompensation and benchmarked it against established blood-based scores (MELD, FIB-4), HVPG and liver stiffness measurement (LSM).
Method: CIRI was trained in cACLD patients from the U.S. Optum's de-identified Clinformatics Data Mart Database (Optum) (training n = 112,618; tuning n = 18,765) and validated in an independent Optum validation cohort (n = 18,852) and a prospective European cohort from Vienna, Austria (n = 210) with paired HVPG and LSM. The endpoint was first hepatic decompensation (ascites, overt encephalopathy, variceal bleeding), with hepatocellular carcinoma and death as competing events.
Results: In the Optum validation cohort (median MELD 8 [IQR 6–12]), 3887 patients (20.6%) decompensated over 18.5 months median follow-up; in Europe (median MELD 9 [IQR 8–12]), 37 patients (17.1%) decompensated over 27.5 months. Steatotic liver disease was the predominant etiology (Optum 54.2%; Europe 44.0%). CIRI showed strong discrimination for first decompensation with time-dependent AUROCs at 1 and 2 years of 0.816 and 0.815 in Optum, and 0.836 and 0.769 in Europe, outperforming MELD and FIB-4 in both cohorts (all $p < 0.05$). In Europe, CIRI performed comparably to HVPG (all $p > 0.9$) and better than LSM (all $p < 0.01$). In Fine-Gray models, CIRI independently predicted decompensation after adjustment for non-selective beta-blockers in Optum (adjusted subdistribution hazard

ratio [aSHR]: 1.67; p < 0.001) and after adjustment for HVPG, non-selective beta-blockers, INR and etiological cure in Europe (aSHR 1.66; p = 0.017). Model performance was robust across etiologies and in sensitivity analyses including FIB-4 ≥1.3 subgroups.
Conclusion: The machine-learning-based CIRI model demonstrated robust prognostic performance and effective risk stratification in cACLD. Its predictive accuracy was validated in large U.S. and European cohorts, with discrimination of decompensation risk comparable to HVPG, supporting its potential as a non-invasive tool to identify "at-risk" cACLD patients.

SAT-531
Association between small intestinal bacterial overgrowth and chronic liver disease in patients with functional gastrointestinal disorders: a cross-sectional study in southern Vietnam
Ngan Le[1]. [1]*Tam Anh general Hospital, Gastroenterology, Ho Chi Minh, Viet Nam*
Email: bsquynhngan@gmail.com

Background and aims: Small intestinal bacterial overgrowth (SIBO) is increasingly recognized as an important factor in the gut–liver axis and may contribute to chronic liver disease (CLD). In Vietnam, and more broadly in Southeast Asia, clinical data on the association between SIBO and chronic liver disease are particularly lacking. Therefore, we conducted the first clinical study in Southern Vietnam to investigate the association between SIBO and chronic liver disease in a real-world cohort of patients with functional gastrointestinal disorders. **Aim:** To evaluate the association between SIBO and chronic liver disease in patients presenting with functional gastrointestinal symptoms.
Method: A cross-sectional study was conducted on 188 patients undergoing breath testing for SIBO. Clinical features, endoscopic findings, metabolic comorbidities, liver enzymes, and abdominal ultrasound results were analyzed. Inclusion Criteria: Completion of glucose breath test, availability of endoscopy, ultrasound, and laboratory data, No antibiotic use within 4 weeks Exclusion Criteria: Prior intestinal resection, Active malignancy, Severe systemic illness interfering with breath testing.
Results: A total of 188 patients were included in the analysis. The mean age was 47.84 ± 14.8 years (range 14–80 years), with a male predominance (107 men and 81 women). Functional gastrointestinal disorders were common in the cohort, including gastroesophageal reflux disease (16.5%), functional dyspepsia (45.7%), and irritable bowel syndrome (60.6%). SIBO was identified in 66 of 188 patients (35.1%). Chronic liver disease was diagnosed in 16 patients (8.5%). The prevalence of chronic liver disease was significantly higher among patients with small intestinal bacterial overgrowth compared with those without SIBO (55.2% vs. 44.8%, p = 0.01).
Conclusion: Small intestinal bacterial overgrowth is highly prevalent among patients with functional gastrointestinal disorders, particularly in those with functional gastrointestinal symptoms accompanied by chronic liver disease. The significant association observed between intestinal bacterial overgrowth and chronic liver disease highlights the potential role of gut dysbiosis in the gut–liver axis and in the progression of chronic liver conditions. These findings underscore the importance of considering the evaluation and management of small intestinal bacterial overgrowth in patients with functional gastrointestinal disorders, especially when chronic liver disease is present.

SAT-532
Direct prothrombin concentration as replacement for INR improves accuracy of MELD in 90-day mortality prediction in patients with acute decompensation of cirrhosis
Markus Maagaard[1,2], Nikolaj Torp[1,2], Mads Israelsen[1,2], Alastair O'Brien[3], Aleksander Krag[1,2]. [1]*Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark;* [2]*Institute of Health Sciences, University of Southern Denmark, Odense, Denmark;* [3]*Institute for Liver and Digestive Health, University College London, London, United Kingdom*
Email: markus.maagaard@rsyd.dk

Background and aims: The international normalized ratio (INR) is a core component of the Model for End-Stage Liver Disease (MELD) score. However, INR is influenced by heparins and direct oral anticoagulants (DOACs), thereby compromising its validity as a marker of hepatic synthetic function in an inpatient setting. In contrast, prothrombin concentration (CPT) is not affected by anticoagulants and may more directly reflect liver synthetic capacity. We investigated whether replacing INR with CPT improves the prognostic discrimination of MELD for 90-day mortality in patients with cirrhosis hospitalized with acute decompensation.
Method: We analysed samples from 313 patients admitted to hospital with acute onset or worsening of complications of cirrhosis. CPT was quantified from Li-Hep plasma stored at −80°C until analysis. Measurements were performed in a single 5-minute reaction step by an aptamer-based electrochemical biosensor (Solsten, DK). The primary endpoint was difference in prediction of 90-day survival between CPT and INR. We further investigated if prognostic discrimination of the MELD score, as assessed by Harrell's C, was improved by substituting INR with CPT ($MELD_{CPT}$).
Results: When comparing MELD and $MELD_{CPT}$, Harrell's C was 0.61 for the original MELD, and 0.69 for $MELD_{CPT}$ (p = 0.037). Mean cohort age was 54 years (±11), 28% were female, the dominant cirrhosis etiology was alcohol-related (90%), and 90-day mortality was 26%. The median MELD was 18 (IQR: 15–23), with median bilirubin of 5.6 mg/dL (IQR: 2.6–10.5), median creatinine of 0.78 mg/dL (IQR: 0.59–1.01) and median INR of 1.6 (IQR: 1.4–2.0). Median $MELD_{CPT}$ was 21 (IQR: 19–25), with median CPT of 843 nmol/L (IQR: 610–903). In univariable analyses both CPT (HR = 1.08, 95% CI: 1.03–1.15, p = 0.004) and INR (HR = 1.03, 95% CI: 1.02–1.05, p < 0.001) were associated with 90-day mortality. Training and validation sets were sampled as a 7:3 distribution of patients stratified only on occurrence of events. Multivariable Cox regression - replacing INR with CPT and keeping bilirubin and creatinine weighting as in the original MELD score - made an optimal prediction model expressed as: $-1.74 \times CPT + 9.57 \times \log(\text{Creatinine}) + 3.78 \times \log(\text{Bilirubin}) + 16$.
Conclusion: Using only direct measurements of CPT showed prognostic performance like established liver biomarkers. When CPT replaced INR in the MELD score, the $MELD_{CPT}$ showed greater prognostic discrimination. These findings suggest CPT as a potential prognostic biomarker in patients with decompensated cirrhosis.

SAT-533
Serum bile acids profile analysis predicts severity and progression of liver disease
Yanpei Mai[1], Qinshuo Wang[1], Suzhen Jiang[1], Linlin Cao[2], Xin Wen[1], Tianyi Xue[1], Yuxi Shi[1], Yanhui Yang[1], Huiying Rao[1], Zixing Wang[1]. [1]*Peking University Hepatology Institute, Beijing, China;* [2]*Peking University People's Hospital Laboratory Department, Beijng, China*
Email: wangzixing@pkuph.edu.cn

Background and aims: Bile acids profoundly influence the onset and progression of liver disease through signaling regulation, inflammatory responses, and interactions within the gut-liver axis. During the progression from hepatitis to cirrhosis and ultimately hepatocellular carcinoma, the bile acid profile undergoes dynamic changes. However, the association between specific bile acids and distinct stages of liver disease progression remains unclear. Identifying bile acids with stage-specific signatures holds significant value for elucidating the mechanisms of liver disease progression and establishing early warning systems.
Method: We enrolled 889 patients with liver disease from Peking University Hepatology Institute, categorized as whether of severe conditions (with irreversible liver fibrosis and cirrhosis that is related

to fundamental changes in monitoring frequency, complication risks, treatment regimens, and prognosis) and whether of advanced stages (liver function failure or malignant transformation). Predictive capability of different bile acids was initially assessed by regression model and then confirmed by random forest algorithm for outcome classification. Ten machine learning algorithms were employed to construct liver disease discriminative models. The training-to-validation ratio for each model was 7:3, with 5-fold cross-validation applied to calculate predictive performance.

Results: Among all patients, 185 (20.8%) had severe liver diseases, and 117 (13.2%) were in the advanced stage. Among the 15 bile acids, TCDCA, TCA, GCDCA, GCA, and TUDCA demonstrated the strongest predictive ability for liver disease outcomes. Variable importance derived from the random forest algorithm further validated the robust predictive efficacy of these five bile acids. Naive Bayes demonstrated the highest predictive capability for both classification outcomes, effectively distinguishing patients with severe liver disease and those with advanced liver disease with validation set AUC values of 0.873 (0.821–0.925) and 0.901 (0.854–0.948), respectively.

Conclusion: This study found that the serum bile acid profile composed of specific bile acids can effectively distinguish the severity and advanced stage of liver disease. Abnormal changes are closely associated with key pathological processes such as hepatitis, cirrhosis, and the development of hepatocellular carcinoma. Mechanistic and clinical research targeting these bile acids holds promise as a novel strategy for the assessment and treatment of liver disease.

Background and aims: It is well established that patients with cirrhosis have an increased risk of developing life-threatening complications such as hepatocellular carcinoma (HCC), decompensation, spontaneous bacterial peritonitis and variceal haemorrhage. Current international guidelines recommend the regular monitoring of patients with cirrhosis by way of biannual ultrasound scans, blood tests and screening endoscopy to enable earlier treatment and reduce mortality. However, in practice HCC surveillance remains underutilised, often due to limited hepatologist availability and thus novel strategies are required to successfully manage the increasing burden of liver cirrhosis worldwide. This study evaluated the impact of a dedicated, nurse-led hepatology surveillance service on clinical outcomes in patients with cirrhosis.

Method: We conducted a single-centre retrospective cohort study including patients diagnosed with cirrhosis between January 2020 and June 2025 (n = 409). Clinical outcomes were compared before and after implementation of a nurse-led hepatology surveillance clinic which began in June 2023, with patients receiving conventional hepatologist-led follow up or the novel nurse-led service. Outcomes of interest included adherence to 6-monthly HCC ultrasound surveillance, HCC diagnoses, variceal bleeds, liver transplant clinic referrals and overall survival times.

Results: In our study, 57.0% of patients were male, mean age was 62.3 years and mean follow-up was 25.0 months. Overall adherence to 6-monthly HCC ultrasound surveillance significantly increased following implementation of the nurse-led clinic (7.3% pre-implementation versus 54.9% post-implementation; $p < 0.001$). Survival analysis demonstrated significantly longer survival times among patients on the nurse-led surveillance pathway compared to conventional follow-up (61.6 versus 48.0 months; $p < 0.001$).

Conclusion: Implementation of our novel nurse-led surveillance pathway was associated with significantly increased HCC surveillance rates and longer survival times in patients with cirrhosis compared with conventional follow up. This study has important implications for the management of patients with Child-Pugh A cirrhosis, particularly when medical facilities have limited hepatologist capacity to maintain adequate surveillance.

SAT-538

Quantification of hepatic steatosis: a prospective multicenter head-to-head comparison of histopathology, digital pathology and MRI-PDFF

David Marti-Aguado[1], Clara Alfaro-Cervello[1], Matias Fernández-Patón[2], Gustavo Rojas-Echarry[3], Judith Pérez[3], Amadeo Ten-Esteve[3], María José Gastaldo[3], Cristina Garcia[4], Irene Navarrete-Pérez[5], Leonor Cerda-Alberich[2], Victor Merino[1], Alexandre Perez Girbes[5], Cristina Montón[1], Victor Puglia[4], Antonio Ferrández[1], Mercedes De La Torre Sanchez[6], Victoria Aguilera Sancho[5], Desamparados Escudero-García[1], Salvador Benlloch[4], Jose Miguel Carot[7], Luis Marti-Bonmati[5]. *[1]Incliva - Instituto De Investigación Sanitaria, Valencia, Spain; [2]Instituto De Investigación Sanitaria La Fe, Valencia, Spain; [3]Hospital Universitario Y Politécnico La Fe, Valencia, Spain; [4]Hospital Arnau De Vilanova, Valencia, Spain; [5]Hospital Universitari I Politècnic La Fe, València, Spain; [6]Hospital General Universitario De Valencia, Valencia, Spain; [7]Universidad Politécnica de Valencia, Valencia, Spain*
Email: davidmmaa@gmail.com

Background and aims: Accurate quantification of hepatic lipid content is essential for grading steatosis and monitoring therapeutic response. Hepatic steatosis can be assessed by liver biopsy—using conventional histopathology (invasive gold standard) or digital image analysis (DIA)—and by magnetic resonance–proton density fat fraction (MRI-PDFF), considered the non-invasive gold standard. This study critically evaluated the correlation and agreement between these diagnostic methods for hepatic steatosis quantification.

Method: This prospective, multicenter diagnostic accuracy study included patients with chronic liver disease who underwent paired liver biopsy and MRI between 2017 and 2025. Histological samples were quantitatively assessed by conventional histopathology (percentage of macrovesicular steatosis) and digitized for DIA (proportional area of lipid vacuoles). MRI-PDFF quantified liver fat content across the entire liver volume (~1000 cm^3), compared with a biopsy sample representing approximately 0.05 cm^3. Digital pathology was considered the reference standard ("ground truth").

Results: A total of 384 patients with paired biopsy and MRI were included (59% women; 62% MASLD; 32% obesity; 26% diabetes). Mean hepatic lipid content was 20.4% by conventional histopathology, 9.0% by DIA, and 8.5% by MRI-PDFF. Significant correlations were observed between all methods ($p < 0.001$): $r = 0.87$ for histopathology vs DIA, $r = 0.88$ for histopathology vs MRI-PDFF, and $r = 0.91$ for MRI-PDFF vs DIA. Linear regression analysis demonstrated a systematic overestimation of steatosis by conventional histopathology across the entire range compared with digital pathology and MRI-PDFF, which display nearly identical quantitative behaviour. Using standard histopathology cut-offs for steatosis grading (S1: 5%, S2: 33%, S3: 66%), the corresponding thresholds were non-equivalent and substantially lower when applied to quantitative reference methods: S1: 5.8% (DIA) and 4.8% (MRI-PDFF).
S2: 12.0% (DIA) and 11.2% (MRI-PDFF).
S3: 19.6% (DIA) and 18.8% (MRI-PDFF).

Conclusion: Despite evaluating vastly different liver volumes, MRI-PDFF mirrors DIA showing a linear equivalence for hepatic steatosis assessment. Conventional histopathology systematically distorts steatosis severity. These findings support MRI-PDFF as the most

accurate and reproducible reference standard for hepatic steatosis quantification, with implications in clinical practice and treatment trials.

SAT-539

The presence of mild degree steatosis does not impact the clinical course of portosinusoidal vascular disorder

Iulia Minciuna[1], Ana Maria Fit[2], Ioana Rusu[2], Oana Nicoara-Farcau[1], Corina Radu[3], Cristian Moldovan[4], Cristina Adela Iuga[4], Andreea Fodor[1], Tudor Cosma[1], Buzias Maria[1], Horia Ștefănescu[3], Bogdan Procopet[1]. *[1]Regional Institute of Gastroenterology and Hepatology "O. Fodor," University of Medicine and Pharmacy "Iuliu Hatieganu," Cluj-Napoca, Cluj-Napoca, Romania; [2]Department of Pathology, Regional Institute of Gastroenterology and Hepatology "O. Fodor," Cluj-Napoca, Romania; [3]Regional Institute of Gastroenterology and Hepatology "O. Email: Iuliabreaban@yahoo.com

Background and aims: An association between portosinusoidal vascular disorder (PSVD) and steatotic liver disease has been suggested based on shared genetic variants (i.e. PNPLA3) and disease severity (similar metabolomic profiles observed in cirrhosis vs PSVD with steatosis). However, the impact of steatosis on the clinical and histological features of PSVD remains unclear. We aimed to assess the prevalence of steatosis in PSVD and to characterize patients with both conditions.
Method: In this retrospective study, all adult patients with PSVD who underwent liver biopsy between 2015 and 2024 were included. Biopsies were blindly re-evaluated for fibrosis stage, steatohepatitis activity, and PSVD-related microvascular lesions. In 14 biopsies, NET area was assessed by confocal immunofluorescence.
Results: A total of 45 PSVD patients were included, among which 29 (64.4%) had steatosis on liver biopsy. In patients with PSVD and steatosis, 93.1% had mild steatosis, 96.5% incipient (F0-F1) fibrosis, 17.2% lobular inflammation and 27.6% portal inflammation. However, none had metabolic associated steatohepatitis. We could not find any statistically significant differences between patients with pure PSVD vs those with PSVD and steatosis in terms of clinical features: either non-specific (81.3% vs 86.2%) or specific (56.3% vs 55.2%) signs of portal hypertension, the presence of metabolic comorbidities (18.8% vs 27.6%), the median liver stiffness value (8.2 kPa (2.4–24.8) vs 6 kPa (3.6–12)), the median HVPG value (5.5 mmHg (1–15) vs 5 (2–23)); in terms of histological features either specific- obliterative venopathy (68.8% vs 72.4%), nodular regenerative hyperplasia (18.8% vs 20.7%) or non-specific- portal tract abnormalities (87.5% vs 82.8%), sinusoidal dilatation (62.5% vs 51.7%), mild perisinusoidal fibrosis (43.8 vs 58.6%); $p < 0.05$. Moreover, there was no difference in NETS area between patients with pure PSVD vs those with additional steatosis. However, patients with architectural disturbances had a higher NETS area than those without (19808 vs 10562 μm^2, $p = 0.02$).
Conclusion: The coexistence of mild degree liver steatosis with PSVD histological features was not associated with increased portal pressure gradients or a higher prevalence of clinical signs of portal hypertension, or with the development of a certain specific/non-specific histological features. The presence of NETs in PSVD patients could be linked to the development of architectural disturbances.

SAT-540

Review of palliative care involvement in advanced liver disease

David O. Sullivan[1], Lenin Ekpotu[1], Dee Noone[1], Laura Stobie[1], Monica Blount[1], Pauline Dillon[1], Matthew McKenna Barry[1], John Ryan[1]. *[1]Hepatology Unit, Beaumont Hospital, Dublin, Ireland*
Email: davidosullivan805@gmail.com

Background and aims: Advanced or decompensated liver disease carries a high symptom burden and poorer prognosis than many advanced malignancies. Despite this, many patients are not referred to palliative care until very late in the course of their disease, often until their terminal admission. We aimed to review palliative care referrals in advanced liver disease, and the duration from referral to death.
Method: A retrospective audit was performed on patients with a history of decompensated cirrhosis or hepatocellular carcinoma (HCC) attending the Liver Support Clinic (LSC) in Beaumont Hospital between 2020 and 2024. Data collected included the patient's name, date of birth, medical record number, the aetiology of their liver disease, their HCC status, their date of death, their location of death (either inpatient or out of hospital), their cause of death, whether or not a palliative care referral had been sent, and the time from referral to death.
Results: Of 513 patients attending the LSC, 57 patients died during the time period. 24 (42%) were referred to palliative care, with 18 (75%) referred during their terminal admission. The median time from referral to death was 4 days, and 62% died within one week from the referral. For those referred prior to their terminal admission, median time from referral to death was 43 days, and 2 days for those referred on terminal admission. 44% of patients with HCC were referred, compared with 42% of those without cancer; 50% of HCC patients were referred prior to their terminal admission, compared with only 17% of non-HCC patients. 52.6% died as an inpatient in an acute hospital bed; of the 23 that died out of hospital, most of these died suddenly and unexpectedly.
Conclusion: The palliative care service is under-utilised in those with cirrhosis. The majority of referrals to palliative care occur only days from death, when death is imminent. We believe this late timing severely limits the potential benefits of palliative care input. Those who were diagnosed with HCC were more likely to be referred to palliative care earlier, which is likely due to the more established role for the palliative care service in the management of advanced cancers. Overall, the findings of this audit demonstrate that referrals to palliative care in those with advanced liver disease occurs late and is usually prompted by an acute terminal event. Earlier involvement of palliative care could be used to address symptom burden, facilitate advance care planning, and improve end of life outcomes.

SAT-541

External validation of the VOCAL-Penn score for extrahepatic surgical risk assessment in cirrhosis in asian and european populations

Ana Ostojic[1], Prachiti Gokhe[2], Sai Sarada V[2], Guduru Venkat Rao[2], Petra Dinjar Kujundžić[3], Lucija Maleta[1], Ivica Grgurević[3,4], K. Rajender Reddy[5], Anand Kulkarni[2]. *[1]University Hospital Center Zagreb, Zagreb, Croatia; [2]Asian Institute of Gastroenterology, Hyderabad, India; [3]University Hospital Dubrava, Zagreb, Croatia; [4]University of Zagreb School of Medicine, Zagreb, Croatia; [5]University of Pennsylvania, Philadelphia, United States*
Email: anandvk90@gmail.com

Background and aims: Individuals with cirrhosis have higher perioperative morbidity and mortality than the general population, regardless of the type or extent of surgery. Multiple risk scores are used to support perioperative decision-making, including MELD, MELD-Na, Mayo risk score, and VOCAL-Penn score, each with distinct strengths and limitations. The VOCAL-Penn score is the more recent recommended surgical risk stratification in patients with cirrhosis as per the recent EASL clinical practice guideline. The aim of this study was to validate the performance of the VOCAL-Penn score in patients undergoing extrahepatic surgery in Asian and European tertiary hospital centers.
Method: A retrospective analysis of 182 patients with cirrhosis undergoing non-liver surgery in three tertiary hospitals (1 in India, and 2 in Croatia). For all patients, VOCAL-Penn scores were calculated. The discriminative performance of the VOCAL-Penn score in predicting 30-day and 90-day mortality was evaluated using the area under

the receiver operating characteristic (ROC) curve (C-statistics), Brier scores, and the Index of Prediction Accuracy (IPA).
Results: Most patients were male (n = 142 (77.2%)). The most common etiology of cirrhosis was MASH in India (n = 75 (64.7%)), while the leading cause in Croatia was alcohol-associated liver disease (n = 46 (69.7%)). Arterial hypertension (n = 73 (40.1%)) and diabetes (n = 68 (37.4%)) were the most frequent comorbidities. Across all three centers, most surgeries were performed electively (83.5%). The most common procedure type was open abdominal surgery (64.3%), followed by abdominal wall surgery (19.2%). Three (1.65%) patients died within 30 days and 20 (11.17%) died within 90 days after surgery. For 30-day mortality, VOCAL-Penn demonstrated good discrimination, with a C-statistic of 0.798 (95% CI: 0.512–1.000). For 90-day mortality, discrimination was strong, with a C-statistic of 0.889 (95% CI: 0.817–0.961). Brier scores were low at both time points (0.016–0.072), indicating good model calibration. The Index of Prediction Accuracy (IPA) was −1.0% at 30 days and 27.1% at 90 days.
Conclusion: In this multinational cohort, VOCAL-Penn score showed strong discrimination for 90-day mortality, while reducing the prediction error by 27% compared with a model assuming an average-risk patient. Lower discrimination for 30-day mortality might be due to few events. Model calibration remained good at both time points.

SAT-542

Evaluating artificial intelligence for the diagnosis of drug-induced liver injury in clinical practice

Anna Pocurull Aparicio[1], Martin Gómez-Loira[2], Miren Garcia Cortes[3], Marina Silveira-Balloni[1], Ernest Saenz[2], Jose Pinazo Bandera[3], Elia Canga[1], Raul J. Andrade[3], Juan Turnes[4], Xavier Forns[1]. *[1]Hospital Clinic, University of Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain; [2]Galicia Sur Health Research Institute, Pontevedra, Spain; [3]Hospital Universitario Virgen de la Victoria, University Of Málaga, IBIMA-BIONAND, CIBEREHD, Málaga, Spain; [4]University Hospital Complex of Pontevedra, Galicia Sur Health Research Institute, Pontevedra, Spain*
Email: xforns@clinic.cat

Background and aims: Drug-induced liver injury (DILI) remains a challenging diagnosis due to the absence of specific biomarkers and the need to exclude alternative causes of liver disease. This study aimed to evaluate the performance of large language models (LLM) in the causality assessment of DILI and to compare their assessments with structured expert opinion process.
Method: We evaluated eight state-of-the-art LLM (GPT-5.2 Pro, Claude Opus 4.5, Gemini 3 Pro, Gemma 3–27B, DeepSeek V3.2, Qwen3-30B, Kimi K2-Thinking, and Mixtral 8 × 22B) on 34 real-world cases. Expert opinion adjudication served as ground truth. Models received blinded clinical vignettes, comprehensive case presentations, and were required to predict both DILI diagnosis (yes/no/indeterminate) and the specific causative drug. We tested two conditions: (1) baseline assessment using only clinical vignettes task-oriented prompts, and (2) context-augmented assessment, where models received LiverTox drug hepatotoxicity entries and EASL/AASLD DILI guidelines as reference material.
Results: Based on expert opinion, 3 cases were considered non-DILI and 31 DILI. The drugs most commonly implicated were anticancer (13), antibiotics (8), analgesics (5) and lipid-lowering drugs (5); the median RUCAM score was 7 (IQR 6–8). The predominant pattern of liver injury was hepatocellular (62%), followed by cholestatic (24%). Most cases were considered of high complexity, with frequent concomitant medication: median of 6 drugs (IQR: 4–8). Experts assigned one single culprit drug in 21 cases, 2 potential drugs in 9 cases, and 3 drugs in one case. Discrepancies among experts occurred in 7 (22%) of the 31 DILI cases. Performance of the 8 language models with context-augmented assessment (measured by Matthews Correlation Coefficient, MCC) ranged from –0,04 to 1,0. Kimi-K2 achieved the highest performance (MCC = 1,0), with concordance with expert opinion in 30 cases (88%). Augmentation with external knowledge (LiverTox hepatotoxicity profiles and EASL/AASLD guidelines) substantially improved performance in 6/8 models, with a mean MCC improvement of 122%.
Conclusion: This proof-of-concept study suggests that knowledge-augmented LLM systems can effectively synthesize clinical presentations, polypharmacy patterns, and hepatotoxicity databases to support DILI causality assessment. This could simplify and standardize DILI diagnosis, especially in centers with limited expert consultation and in high complexity cases.

SAT-543

The use of non-invasive tests to detect and direct management of cirrhosis does not reduce the incidence or delay the onset of first severe decompensation events or improve survival: first report of the ELUCIDATE trial

William Rosenberg[1], Sudeep Tanwar[1], Myka Ransom[2], Annah Muli[2], Deborah Stocken[2], Paul Richardson[3], Rebecca Jones[4], Sulleman Moreea[5], Chin Lye Ch'ng[6], James Neuberger[7], Peter Selby[2]. *[1]University College London, Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom; [2]University Of Leeds, Leeds, United Kingdom; [3]Royal Liverpool University Hospital, Liverpool, United Kingdom; [4]Leeds Teaching Hospitals N H S Trust, Leeds, United Kingdom; [5]Bradford Royal Infirmary, Bradford, United Kingdom; [6]Singleton Hospital, Swansea, United Kingdom; [7]Queen Elizabeth Hospital, Birmingham, United Kingdom*
Email: w.rosenberg@ucl.ac.uk

Background and aims: Cirrhosis is often diagnosed late, limiting opportunities for surveillance and treatment of portal hypertension (PHTN) or hepatocellular cancer (HCC). ELUCIDATE, a multicentre, two arm, parallel group randomised controlled trial investigated use of the Enhanced Liver Fibrosis (ELF) test to facilitate earlier detection of cirrhosis and treatment of PHTN or HCC, to improve survival compared to standard best care (SC) in people with chronic liver disease (CLD).
Method: Thirty-seven UK centres screened 1303 CLD patients. Those eligible (ELF>8.4) were randomised to ELF guided management (cirrhosis screening if ELF>9.5) (438), or SC (440). All participants were reviewed every 6 months for 30 months with investigations for PHTN and HCC started if cirrhosis was suspected, and complications treated according to best practice. Long-term follow-up (LFU) was performed at 10 years by interrogating routine national data sources. Time from randomisation to first severe complication of cirrhosis (FSCC) due to PHTN, HCC or liver death is reported; deaths from other causes were treated as competing events. The equality of cumulative incidence functions between trial arms was investigated with Gray's test.
Results: FSCC was recorded for 122 patients (63% bacterial peritonitis), with 99 additional non-liver deaths. Median time from randomisation to FSCC was 5.1 years (IQR 1.8, 7.1) ELF v. 2.3 years (IQR 0.4, 2.9) SC, with no statistically significant difference between arms (HR_{adj} = 0.91, 95% CI: 0.63, 1.30, p = 0.60). After diagnosis of cirrhosis FSCC was recorded for 49/279 (17.6%) ELF arm and 9/18 (50%) SC patients. Baseline ELF test score predicted FSCC (HR = 1.32 [95% CI 1.2, 1.5] p < 0.001). There were 152 deaths from any cause (77 ELF, 75 SC). Median survival was 7.8 years (IQR 4.6, 9.8) with no statistically significant difference between arms (HR_{adj} = 0.89, 95% CI: 0.64, 1.24, p = 0.49). Death or incurable HCC was less frequently FSCC in the ELF arm (4/62 v 12/60); (HR = 0.28 [0.10, 0.74] p = 0.017).
Conclusion: ELF facilitated early detection of cirrhosis and risk, creating opportunities for interventions. Compared to standard care, 30 months ELF-directed cirrhosis surveillance and management was not associated with reductions in mortality, or the incidence and timing of the first severe complication of cirrhosis, even though this was less likely death or incurable HCC. Any benefits associated with early diagnosis of cirrhosis are likely to be few and modest at the cost of more invasive testing.

SAT-544

Point-of-care quadriceps ultrasound combining thickness and elastography improves detection of cross-sectional imaging-defined sarcopenia in cirrhosis

Satyam Mishra[1], Somali Ghosh[1], Akash Roy[1], Srijita Ghosh Sen[1], Surabhi Jajodia[1], Usha Goenka[1]. [1]*Apollo Multispeciality Hospitals, Kolkata, India*
Email: satyammishra1998@gmail.com

Background and aims: Sarcopenia is common in cirrhosis, but computed tomography (CT) and magnetic resonance imaging (MRI) based cross-sectional muscle assessment is has limited bedside use, is costly, and is unsuitable for serial monitoring. We evaluated quadriceps ultrasound thickness and two-dimensional shear wave elastography (SWE) stiffness against CT/MRI-derived psoas muscle index (PMI), and tested whether combining morphometric measures and elastography improves detection of CT-defined sarcopenia.
Method: In this prospective cross-sectional study, 110 individuals with underwent clinically indicated CT or MRI and bedside quadriceps assessment within one month. Rectus femoris and vastus lateralis muscle thickness were measured at standardized mid-thigh landmarks, with three measurements obtained and averaged for each muscle. Muscle stiffness of the rectus femoris (RF_ and vastus lateralis (VL) was evaluated using two-dimensional shear wave elastography (2D SWE), with three to five valid acquisitions. Sarcopenia was defined using CT/MRI-derived PMI with sex-specific cut-offs. Associations with PMI were examined using Spearman's correlation, and diagnostic performance was evaluated using receiver operating characteristic analysis and multivariable logistic regression, with area under the curve (AUC) comparisons performed using the DeLong test.
Results: CT-PMI defined sarcopenia was present in 24.5%. RF thickness correlated best with PMI ($\rho = 0.572$, $p < 0.001$), followed by VL thickness ($\rho = 0.425$, $p < 0.001$); stiffness correlations were weaker (RF $\rho = 0.22$, $p = 0.016$; VL $\rho = 0.21$, $p = 0.028$). RF thickness was lower in sarcopenic patients (median 13.5 vs 18.8 mm, $p < 0.001$) and VL thickness was also reduced ($p = 0.006$). RF thickness showed good discrimination [AUC, 0.793) with an optimal cutoff of 16.9 mm (sensitivity 85.2%, specificity 71.1%). A combined model using RF/VL thickness and stiffness improved AUC to 0.854 and significantly outperformed RF thickness alone (AUC difference 0.06, 95% $p = 0.034$). At the optimal probability cutoff of 0.183, sensitivity was 92.6%, specificity 73.5% and negative predictive value 96.8%.
Conclusion: Standardised quadriceps ultrasound, particularly RF thickness, can identify PMI defined sarcopenia in cirrhosis at the bedside. Although SWE stiffness is a weak standalone surrogate of muscle mass, its integration with morphometry improves diagnostic performance and supports a pragmatic screening strategy where cross-sectional imaging is not feasible.

SAT-545-YI

Lifetime survival and penetrance in HFE p.C282Y/p.H63D compound heterozygous and p.H63D homozygous individuals – a liver clinic cohort study

Wolfgang Straka[1], Lorenz Pammer[1], Martina Saretto[1], Bernhard Pfeifer[2,3], Sabrina Neururer[2,3], Rosa Schmidl[1], Maria Rosina Troppmair[1], Marlene Panzer[1], Sonja Wagner[1,4], Elke Pertler[1,4], Florian Kronenberg[5], Claudia Lamina[5], Herbert Tilg[1], Heinz Zoller[1,4], Benedikt Schaefer[1]. Email: wolfgang.straka@i-med.ac.at

Background and aims: Hemochromatosis is a common genetic disorder in individuals of European ancestry. In addition to the genetic cause, severity of iron overload is affected by risk factors. Penetrance and survival vary across screening and clinical cohorts. Relevance of p.C282Y/H63D compound heterozygotes and H63D homozygotes remains controversial. EASL hemochromatosis guidelines emphasize management based on phenotypic presentation and risk factors. This population-based cohort study of HFE-genotyped individuals aims to assess life expectancy, age- and sex- specific risks of disease penetrance and survival.
Method: The presented study includes individuals from Tyrol, Austria, who were referred to the liver clinic and genotyped for both the p.H63D and p.C282Y variant in HFE between 1997 and 2021. Clinical data and laboratory parameters, including risk factors and comorbidities were retrospectively assessed from the electronic health records. The long-term follow-up enabled an assessment of the life expectancy and cancer incidence. Further comparisons were made using *HFE* p.C282Y homozygotes, *HFE*-wildtype (wt) individuals and a matched propensity score, population-based control group.
Results: Inclusion criteria were met by 507 p.C282Y/p.H63D compound-heterozygotes and 301 p.H63D homozygotes which were compared with 602 *HFE*-wt and 542 p.C282Y/p.C282Y homozygous individuals as well as the matched controls. Cumulative lifetime risk for the development of provisional iron overload was significantly lower in p.C282Y/p.H63D compound heterozygotes (1.17%) and p.H63D homozygotes (0.45%) as compared to 18% in p.C282Y homozygous patients. The lowest life expectancy was found in *HFE*-wt individuals, with a median estimated survival of 81.70 years, followed by p.H63D homozygotes (82.59), p.C282Y homozygotes (86.23) and p.C282Y/p.H63D compound heterozygotes (87.35). The multivariate regression analysis showed that the genotype itself was not a statistically significant predicator for survival. Worse survival was associated with a higher rate of comorbidities.
Conclusion: Lifetime penetrance for provisional iron overload is 20 times lower in p.C282Y/p.H63D compound heterozygosity and 50 times lower among p.H63D homozygotes compared to p.C282Y homozygosity. *HFE* genotype is not an independent predicator for survival and the observed increase in mortality in p.H63D homozygous individuals is primarily driven by comorbidities.

SAT-546

Glutamate dehydrogenase outperforms transaminases and bilirubin in stratifying choledocholithiasis

Jan Sutter[1], Soleman Almadok[1], Giulia Heide[1], Julian Schulze zur Wiesch[1], Samuel Huber[1], Ansgar Lohse[1].
[1]*I. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
Email: j.sutter@uke.de

Background and aims: Choledocholithiasis (CDL) is a common condition that can lead to serious complications, requiring effective risk stratification for timely intervention. While current guidelines use clinical predictors, imaging, and laboratory markers for risk assessment, the role of glutamate dehydrogenase (GLDH) in CDL remains poorly understood. This study aims to evaluate its potential as a clinical biomarker for identifying patients with CDL.
Method: This single-center cohort study identified 23,103 patients who presented to the emergency department of the University Medical Center Hamburg-Eppendorf and underwent routine abdominal laboratory testing between May 2021 and December 2023. Patients were classified into CDL and other diagnoses. To assess the predictive value of age, sex and laboratory markers for CDL, we developed a random forest machine learning model, conducted a backward stepwise logistic regression and performed receiver operating characteristic (ROC) analysis.

Results: 152 patients were diagnosed with CDL and 22,951 with other diagnoses. In the random forest machine learning model, GLDH emerged as the most significant feature for predicting CDL. ROC analysis revealed that GLDH had the highest area under the curve of 0.93 among laboratory markers. At the upper limit of normal, GLDH demonstrated the best sensitivity (92%) compared to aspartate aminotransferase (AST), alanine aminotransferase (ALT) and bilirubin. High GLDH levels exceeding 150 U/L demonstrate the highest specificity (99%) for CDL, outperforming AST, ALT and bilirubin.
Conclusion: GLDH outperforms AST, ALT and bilirubin as a screening and predictive marker for CDL, supporting its inclusion in clinical guidelines for risk stratification.

SAT-547

Linkage of effective cirrhosis management may be critical for the realization of any benefits associated with early detection of cirrhosis: explanatory analyses from the ELUCIDATE randomised trial

Sudeep Tanwar[1], Myka Ransom[2], Annah Muli[2], Deborah Stocken[2], Paul Richardson[3], Sulleman Moreea[4], Rebecca Jones[5], Chin Lye Ch'ng[6], James Neuberger[7], Peter Selby[2], William Rosenberg[1]. *[1]University College London, Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom; [2]University Of Leeds, Leeds, United Kingdom; [3]Royal Liverpool University Hospital, Liverpool, United Kingdom; [4]Bradford Royal Infirmary, Bradford, United Kingdom; [5]Leeds Teaching Hospitals N H S Trust, Leeds, United Kingdom; [6]Singleton Hospital, Swansea, United Kingdom; [7]Queen Elizabeth Hospital, Birmingham, United Kingdom*

Background and aims: The ELUCIDATE trial found no statistically significant reduction in mortality, incidence or timing of first severe cirrhosis complications (FSCC) with Enhanced Liver Fibrosis test (ELF) guided cirrhosis detection and management, compared to standard care (SC). EASL cirrhosis surveillance guidance highlights that early treatment of varices and hepatocellular carcinoma (HCC) reduces morbidity and mortality. We hypothesised that the lack of improvement in clinical outcomes may be attributable to poor adherence to protocol-defined surveillance and interventions. We examined between-arm adherence and the association between baseline ELF score and clinical events.
Method: Case report-form review determined adherence to protocol-defined care, by arm, over 30 months from randomisation, including 6 monthly scheduled follow-up before and after diagnosis of cirrhosis; HCC surveillance (alpha-fetoprotein [AFP] testing and imaging) and interventions; endoscopic screening for varices, and prophylaxis. Association between baseline ELF score and the primary endpoint of FSCC was assessed 10 years post randomisation using routine healthcare data. Exploratory analyses examined the prognostic performance of the protocol defined ELF threshold (9.5).
Results: Baseline ELF score was a strong independent predictor of FSCC (positive predictive value of ELF>9.5 for FSCC = 26%). Each unit increase in ELF (centred at 9.5) was associated with a greater risk of FSCC (HR = 1.32, [95% CI 1.16–1.50]; p < 0.001). Adherence to protocol-defined surveillance was poor in both arms. Pre-cirrhotic and post-cirrhotic visit compliance was low but higher in the ELF arm than SC (29.8% vs 19.7% and 16.2% vs 21.1% respectively). After cirrhosis detection, compliance with timing of AFP and imaging for ELF and SC arms were 12.6% vs 11.8% and 29.5% vs 14.3% respectively. Endoscopic surveillance adherence was suboptimal with only 54.4% of ELF arm cirrhotic patients having at least one OGD compared to 60% in the SC arm. Only 56% of ELF and 43% of SC patients with varices received treatment.
Conclusion: While ELF effectively predicted risk of FSCC, poor adherence to cirrhosis surveillance and management protocols may have prevented early detection of cirrhosis translating into clinical benefit. If confirmed in the final analysis of ELUCIDATE this highlights the need to link the implementation of effective care pathways to strategies designed to improve early detection of cirrhosis.

SAT-548

Development and validation of a non-invasive model for predicting advanced liver fibrosis in patients with metabolic dysfunction-associated steatotic liver disease and dysglycemia

Zhang Xuejie[1], Feixiang Xiong[1], Chen Dandan[1], Jialiang Chen[1], Zhou Yang[1], Wu Tong[1], Ji Xiaomin[1], Yuyong Jiang[1], Yixin Hou[1]. *[1]Beijing Ditan Hospitall, Capital Medical University, Beijing, China*
Email: zhangxuejie027668@163.com

Background and aims: The confluence of metabolic dysfunction-associated steatotic liver disease (MASLD) and dysglycemia delineates a high-risk subgroup characterized by a substantially increased likelihood of progressive liver fibrosis. This study aimed to develop and validate a novel, parsimonious non-invasive model for the accurate prediction of advanced fibrosis (stage F3–F4) in this at-risk population.
Method: A retrospective analysis was conducted in 606 consecutive adults with biopsy-proven MASLD and dysglycemia from Beijing Ditan Hospital (2010–2025). The cohort was randomly split into training (n = 424) and validation (n = 182) cohorts. Multivariable logistic regression analysis identified BMI, ALT, and WBC as independent predictors for constructing a non-invasive model to assess advanced liver fibrosis in patients with MASLD and concomitant dysglycemia. The performance of the proposed model was evaluated by the area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), and compared with two validated non-invasive serum indices: the Aspartate-to-Platelet Ratio Index (APRI) and the Fibrosis-4 (FIB-4) index.
Results: Three variables were identified as independent predictors of advanced fibrosis: BMI (adjusted odds ratio [aOR] 1.40 per 1 kg/m^2 increase, 95% CI: 1.30–1.51; $P < 0.001$), ALT (aOR 1.01 per 1 U/L increase, 95% CI: 1.01–1.01; $P < 0.001$), and WBC (aOR 1.15 per 1×10^9/L increase, 95% CI: 1.01–1.31; $P = 0.035$). The model demonstrated excellent discriminative performance, with the training cohort showing an AUC of 0.865 (95% CI: 0.826–0.905), specificity of 67.8%, sensitivity of 89.9%, PPV of 84.2%, and NPV of 78%. The validation cohort exhibited an AUC of 0.900 (95% CI: 0.855–0.946), specificity of 71.4%, sensitivity of 91.6%, PPV of 85.8%, and NPV of 81.8%. It significantly outperformed both FIB-4 and APRI across all performance metrics, exhibited excellent calibration, and provided superior net clinical benefit across a wide range of risk thresholds.
Conclusion: We developed a highly accurate and validated non-invasive model based on BMI, ALT, and WBC for predicting advanced fibrosis in patients with MASLD and dysglycemia. Its simplicity and reliance on readily available parameters render it ideally suited for deployment in primary care and diabetology settings, where it could refine risk stratification and guide specialist referrals.

SAT-549

Prognostic value of handgrip strength in 1,294 japanese patients with liver cirrhosis: a large-scale multicenter cohort study from the NHO network

Hiroshi Yatsuhashi[1], Kazumi Yamasaki[1], Hayato Yamana[2], Shinobu Imai[3], Atsushi Naganuma[4], Rie Sugimoto[5], Motoyuki Kohjima[6], Tsutomu Yamashita[7], Satoru Iwamoto[8], Keisuke Ario[9], Masaaki Shimada[10], Shintaro Takaki[11], Takeaki Satoh[12], Kiyoshi Furuta[13], Ryotaro Sakamori[14]. *[1]NHO Nagasaki Medical Center, Omura, Japan; [2]Jichi Medical University, Shimotsuke, Japan; [3]Showa University Graduate School of Pharmacy, Tokyo, Japan; [4]NHO Takasaki Genral Medical Center, Takasaki, Japan; [5]NHO Kyushu Cancer Center, Fukuoka, Japan; [6]NHO Kyushu Medical Center, Fukuoka, Japan; [7]NHO Oita Medical Center, Oita, Japan; [8]NHO Kyoto Medical Center, Kyoto,*

Japan; [9]NHO Ureshino Medical Center, Ureshino, Japan; [10]NHO Nagoya Medical Center, Nagoya, Japan; [11]NHO Kure Medical Center, Kure, Japan; [12]NHO Ku, Kokura, Japan; [13]NHO Matsumoto Medical Center, Matsumoto, Japan; [14]NHO Osaka National Hospital, Osaka, Japan
Email: Yatsuhashihiroshi@gmail.com

Background and aims: Handgrip strength (HGS) has recently emerged as a critical prognostic marker in Western patients with chronic liver disease. While HGS reflects systemic muscle strength and serves as a primary indicator of sarcopenia, large-scale clinical evidence in the Japanese cirrhotic population remains limited. We aimed to investigate the impact of HGS on long-term survival in a large multicenter cohort.
Method: This study prospectively enrolled 1294 patients with liver cirrhosis (694 males, 600 females; mean age 70.7 ± 10.5 years) who visited 36 National Hospital Organization (NHO) hospitals across Japan during 2017. Baseline HGS was measured, and patients were followed for survival outcomes. Clinical characteristics included Child-Pugh class (A/B/C: 950/266/78), etiologies (HCV/HBV/ALD/MASLD/Others: 606/208/241/92/147), and HCC stages (None/I-II/III-IV: 736/405/153). Patients were stratified into sex-specific HGS tertiles: for males, High (≥34.6 kg), Intermediate (27.5–34.4 kg), and Low (≤27.4 kg); for females, High (≥20.0 kg), Intermediate (16.2–19.9 kg), and Low (≤16.1 kg).Survival analysis was performed using the Kaplan-Meier method and Cox proportional hazards models.
Results: The 5-year survival rates significantly declined as HGS decreased (P < 0.0001). • Males: High (78.0%), Intermediate (65.7%), and Low (43.5%). • Females: High (83.1%), Intermediate (72.2%), and Low (64.1%). Multivariate analysis demonstrated that 1) Age, 2) Child-Pugh classification, 3) HCC stage/progression, and 4) HGS tertiles were independent prognostic factors for survival. HGS also showed significant correlations with age, sex, and Child-Pugh score.
Conclusion: HGS is a simple, non-invasive, yet powerful independent predictor of survival in Japanese patients with liver cirrhosis. While conventional scores such as Child-Pugh and MELD provide a "static" assessment of hepatic reserve, HGS captures the "dynamic" physical vitality and systemic resilience of the patient. Integrating HGS with traditional liver-specific markers will allow for more precise risk stratification and the advancement of personalized medicine. Our findings suggest that HGS should be recognized as an essential clinical parameter for monitoring disease progression and the efficacy of therapeutic interventions.

SAT-553

A blood based diagnostic for the identification and risk stratification of fibrosis and cirrhosis based on adverse outcomes

William Young-Greenwald[1], Sam Asgarian[1], Amar Das[1], Angela Watkins[1], Craig Eagle[1], AmirAli Talasaz[1]. *[1]Guardant Health, Palo Alto, United States*
Email: byounggreenwald@guardanthealth.com

Background and aims: Liver Fibrosis/Cirrhosis affects ~4.5 million individuals in the US and can lead to adverse outcomes including death. While current blood-based diagnostics are used to identify individuals with Fibrosis/Cirrhosis, they do not adequately risk stratify those who are likely to advance in disease or have adverse health outcomes, creating an unmet medical need. Here, we present a novel blood-based diagnostic test that identifies individuals with Fibrosis/Cirrhosis at levels better/equal to commercially available tests for screening liver fibrosis. This test also provides a severity index enabling providers to identify patients at the highest risk and monitor and/or treat them before severe health events occur.
Method: A deidentified database of >50,000 individuals who underwent blood-based diagnostic testing was queried for individuals with Fibrosis/Cirrhosis diagnosed within 5 years prior to a negative Guardant Shield test. A machine learning model was trained on Guardant Shield and Infinity DNA methylation data to develop a quantitative risk score of Fibrosis/Cirrhosis disease severity and to classify individuals into disease/healthy. Classification was evaluated in 10-fold cross-validation, and risk stratification was evaluated on a separate holdout set of patients which was divided into four categories: (1) those with a clinical diagnosis of any-stage Fibrosis/Cirrhosis; (2) those not in category (1) but with fatty liver disease; (3) those in categories (1) or (2) and have had an adverse outcome (as defined by Cirrhosis, portal hypertension, HCC, Acute Myocardial or Cerebral Infarction, or Heart Failure within 12 months post-blood test); and (4) all other individuals. Risk stratification was examined by comparing the relative model AUCs of sample groups 1–3 vs group 4.
Results: Our model identified those with Fibrosis (F1–3) or Cirrhosis (F4) with an AUC of 0.79 (Kocak 2025) and 0.84 (Tamaki 2024), respectively, compared to 0.66 with the FIB4 index or 0.85 with the ELF score. Individuals who had adverse outcomes had a higher risk score from our model with AUC improvements of 0.2 and 0.08 for category 3 or 2 vs 1, respectively.
Conclusion: Here, we present a novel DNA methylation-based model for Fibrosis/Cirrhosis identification and risk stratification built on the Guardant Shield platform performing at levels equal to or better than current methods. The results warrant further study to bring more precision to this area of medicine.

SAT-554

Associations of liver steatosis and fibrosis with staging and mortality risk of cardiovascular-kidney-metabolic syndrome: evidence from two community-based studies

Email: qixiaolong@vip.163.com

Background and aims: Cardiovascular-kidney-metabolic (CKM) syndrome integrates cardiovascular, renal, and metabolic dysfunction, elevating risks of cardiovascular disease (CVD) and premature mortality. Liver steatosis and fibrosis contribute to endothelial

dysfunction, atherosclerosis, and renal injury, but remain poorly defined within the CKM framework. We aimed to investigate the associations of liver steatosis and liver fibrosis with staging and mortality risk of CKM syndrome.
Method: We analyzed two community-based studies from LiverHealth project, which enrolled adults from ten provinces across China, and the U.S. National Health and Nutrition Examination Survey (NHANES) 1999–2018. Liver steatosis and fibrosis were assessed using vibration-controlled transient elastography in LiverHealth project and the U.S. Fatty Liver Index and Fibrosis-4 index in NHANES. CKM stages were defined according to American Heart Association guidelines. Multinomial logistic regression and Cox proportional hazards models were used to assess associations with CKM staging and mortality risk, respectively.
Results: A total of 20,591 Chinese and 19,867 U.S. participants were included. In the Chinese cohort, the prevalences of steatosis stages S1–S3 were 13.0%, 6.3%, and 24.8%, respectively; fibrosis stages F1 and ≥F2 accounted for 14.8% and 4.3%, and 7.7% of participants had advanced CKM (stages 3–4). Increasing grades of liver steatosis and fibrosis were both associated with progressively higher odds of advanced CKM (P for trend <0.001). In the U.S. cohort, liver steatosis was present in 33.6% of participants, fibrosis risk was classified as low, intermediate, and high in 81.6%, 15.5%, and 2.9%, respectively, and 15.7% had advanced CKM. Both liver steatosis (OR 1.51, 95% CI 1.36–1.67) and high-risk fibrosis (OR 1.68, 95% CI 1.33–2.12) were independently associated with advanced CKM. Over a median follow-up of 10.5 years, 1,693 all-cause deaths and 497 CVD deaths occurred among participants with CKM stages 0–3. After adjustment for CKM stage, liver steatosis was not significantly associated with mortality, whereas fibrosis was associated with increased risks of all-cause (HR 1.94, 95% CI 1.64–2.31) and CVD mortality (HR 1.69, 95% CI 1.23–2.33).
Conclusion: Liver steatosis and fibrosis were associated with advanced CKM stages. Liver fibrosis but not steatosis was independently related to increased all-cause and CVD mortality in individuals with CKM stages 0–3.

SAT-555
Diagnostic value of MR elastography and MRI-proton density fat fraction in cirrhosis based on explant liver histology
Eun-Ki Min[1], Seung-Seob Kim[2], Seung Up Kim[3], Jae Geun Lee[1], Deok-Gie Kim[1]. *[1]Department of Surgery, The Research Institute for Transplantation, Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [2]Department of Radiology and Research Institute of Radiological Science, Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [3]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: mek1012@yuhs.ac

Background and aims: Accurate assessment of advanced fibrosis and steatosis is essential for prognostication in chronic liver disease. This study aimed to evaluate the diagnostic performance of MRI in assessing liver fibrosis and steatosis in patients undergoing liver transplantation (LT).
Method: Patients who underwent LT between January 2019 and December 2023 with pretransplant MR elastography (MRE) and MRI-based proton density fat fraction (MRI-PDFF) examinations were included. Explanted livers were assessed for fibrosis and steatosis, with cirrhosis subclassified using the Laennec system. Diagnostic performance was evaluated using area under the receiver operating characteristic curve (AUC) analysis.
Results: Among 187 patients (median age, 57 years), 72.2% were male. Hepatitis B virus (55%) and alcoholic liver disease (21.4%) were the most common etiologies. The median Model for End-Stage Liver Disease (MELD) score was 11. MRE detected cirrhosis (F4) with an AUC of 0.92 (95% confidence interval [CI], 0.87–0.97) and severe cirrhosis (F4c) with an AUC of 0.85 (95% CI, 0.79–0.91), at threshold values of 4.76 and 6.43 kPa, respectively. MRI-PDFF identified steatosis with an AUC of 0.83 (95% CI, 0.76–0.89) at a threshold of 2.80%. Comparisons of patients stratified by the threshold values for cirrhosis and severe cirrhosis revealed significant differences in MELD scores, history of portal hypertension-related complications, liver function parameters, and intraoperative transfusion requirements (all $p < 0.05$).
Conclusion: MRI demonstrated high diagnostic accuracy for detecting cirrhosis and steatosis in patients with advanced fibrosis undergoing LT. MRE further stratified cirrhosis severity, supporting its role in non-invasive risk assessment and prognostication.

Gut microbiota and liver disease – Liver-organ crosstalk

TOP-357
Targeting gut microbial nitrogen recycling and intestinal uptake of ammonium attenuates progression of chronic liver disease
Yinghong Zhu[1], Routing Wang[1], Ziyan Wang[1], Zhengjiang Li[1], Sile Liu[2], Jian Qu[3], Dekai Zheng[1], Puling Lai[1], Ziqi Liu[1], Yuxin Liu[1], Jingqiong Xun[4], Yue Ning[5], Jian Sun[1]. *[1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, State Key Laboratory of Multi-organ Injury Prevention and Treatment, Key Laboratory of Infectious Diseases Research in South China, Ministry of Education, Guangdong Provincial Key Laboratory for Prevention and Control of Major Liver Diseases, Guangdong Provincial Clinical Research Center for Viral Hepatitis, Guangdong Institute of Hepatology, Guangdong Provincial Research Center for Liver Fibrosis Engineering and Technology, Guangzhou, China; [2]Hunan Provincial People's Hospital and The First-Affiliated Hospital of Hunan Normal University, Changsha, China; [3]Huaihua Hospital of Traditional Chinese Medicine, Huaihua, China; [4]The People's Hospital of Guizhou Province, Guiyang, China; [5]The Quzhou Affiliated Hospital of Wenzhou Medical University, Quzhou, China*
Email: sunjian@smu.edu.cn

Background and aims: Although gut dysbiosis is linked to chronic liver disease (CLD), common microbial drivers across etiologies are poorly defined. To address this, we analyzed clinical and public cohorts encompassing metabolic dysfunction-associated steatotic liver disease (MASLD), alcohol-associated liver disease (ALD), and chronic hepatitis B (CHB) to identify shared pathogenic microbiota and their mechanisms.
Method: Fecal (n = 149) and serum (n = 397) samples from healthy donors and patients (MASLD, ALD, CHB) were collected across 4 centers. Gut microbiome profiling was conducted via shotgun metagenomic sequencing, and public single-cell datasets were analyzed to identify cell types involved in NH_4^+ transport. The role of nitrogen-recycling bacteria (NRB) and NH_4^+ in chronic liver disease was investigated using multiple mouse models (diet-induced, alcohol-induced, CCl_4-induced, HBV) and validated in intestine-specific *Slc12a2* knockout mice. *In vitro* studies employed THLE-2 hepatocytes, HIEC-6 intestinal epithelial cells (IECs), and small intestinal organoids. Analytical methods for mechanisms included serum biochemistry, histopathology, multiplex immunohistochemistry, transmission electron microscopy, Western blot, and co-immunoprecipitation.
Results: We observed a significant enrichment of NRB in CLD patients and found that the levels of their metaboliteNH_4^+ were positively correlated with the progression of CLD in both fecal and serum samples. Subsequently, we discovered NH_4^+ impaired the small intestinal barrier function and passed into the IECs via SLC12A2. In IECs, NH_4^+ was metabolized into glutamine, consuming ATP and elevating acetyl-CoA. The increased acetyl-CoA drove acetylation of the DEFA1, which reduced its ubiquitination and enhanced its

stability and secretion. Secreted DEFA1 bound to TFR1 on hepatocytes, stabilizing TFR1 and enhancing iron uptake. Increasing iron levels subsequently upregulated STEAP3 and NCOA4 and thus promoted the Fenton reaction, resulting in the ROS production and ferroptosis. Besides, we found furosemide sodium (Fus) inhibited the SLC12A2 expression of NH_4^+ surppressing the DEFA1/TFR1/ferroptosis and ultimately inhibiting CLD progression.
Conclusion: We first identify NRB and NH_4^+ as key modulators of CLD progression, unveil NH_4^+/SLC12A2/DEFA1/TFR1/ferroptosis axis for underlying disease progression in CLD patients, and reveal Fus as a potential agent for the treatment of CLD progression.

Exploring biomarkers for immunotherapy benefit in unresectable hepatocellular carcinoma based on microbiome-immunomics

Ningning Zhang[1], Kaipeng Liu[1], Shuwen Zhang[1], Wenwen Zhu[1], Xuanchen Liu[1], Hao Yu[1], Tian Liu[1], Jihui Hao[1]. [1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*
Email: haojihui@tjmuch.com

Background and aims: The immune-checkpoint inhibitors (ICIs) had significantly improved the prognosis of patients with unresectable hepatocellular carcinoma (HCC). However, only approximately 30% of patients achieve objective response from targeted therapy combined with immunotherapy. There is an urgent need to develop effective predictive biomarkers for immunotherapy efficacy.
Method: This study prospectively enrolled 137 patients with unresectable HCC who received ICI combined with targeted therapy as first-line treatment. Integrating peripheral blood flow cytometry, fecal metagenomics, and targeted metabolomics of short-chain fatty acids (SCFAs), we explored the predictive value of peripheral blood PD-1$^+$CD8$^+$T cells and the potential regulatory mechanism of the gut microbiota-SCFAs-peripheral blood PD-1$^+$CD8$^+$T cell axis.
Results: Peripheral blood PD-1$^+$CD8$^+$T cells were independent predictive factors for durable clinical benefit and overall survival (OS) in patients with unresectable HCC. Stratification of patients using a cutoff value of 5.0% showed that the sensitivity, specificity, and accuracy of predicting DCB were 82.0%, 76.1%, and 79.5%, respectively. Patients in the PD-1$^+$CD8$^+$T cells-High group had a higher rate of sustained benefit, as well as longer progression-free survival and OS, compared with those in the PD-1$^+$CD8$^+$T cells-Low group. The gut microbiota of patients in the PD-1$^+$CD8$^+$T cells-High group exhibited higher alpha-diversity and beta-diversity, along with increased abundance of SCFA-producing bacteria such as *Segatella copri*, *Faecalibacterium prausnitzii*, and *Eubacterium* sp., compared with the PD-1$^+$CD8$^+$T cells-Low group. Significant differences in fecal metabolites were observed between the two groups, with butyrate and valeric acid upregulated in the PD-1$^+$CD8$^+$T cells-High group. Multivariate correlation analysis and mediation analysis indicated that changes in the abundance of *Faecalibacterium prausnitzii* may indirectly affect the proportion of peripheral blood PD-1$^+$CD8$^+$T cells by regulating butyrate levels, with the mediating effect accounting for 17.0% of the total effect.
Conclusion: Peripheral blood PD-1$^+$CD8$^+$T cells are expected to serve as a novel peripheral blood biomarker for predicting the efficacy of immunotherapy in patients with unresectable HCC. Additionally, this study initially constructed a potential regulatory axis of "*Faecalibacterium prausnitzii* - butyrate - peripheral blood PD-1$^+$CD8$^+$T cells".

Background and aims: Bacterial infections (BI) often precipitate acute decompensation (AD) and may progress to acute-on-chronic liver failure (ACLF). However, routinely used clinical markers such as leukocyte count and C-reactive protein (CRP) do not reliably indicate the presence of BI, as they may reflect systemic inflammation rather than infection. Early detection of BI and/or its exclusion is critical to improve clinical outcomes, highlighting the need for reliable, non-invasive biomarkers. This study aimed to identify metabolomic biomarkers associated with BI in patients with AD.
Method: We investigated metabolomic and microbiome profiles in AD patients undergoing transjugular intrahepatic portosystemic shunt (TIPS) placement, with or without bacterial infection. Pairwise statistical analyses and differential metabolite expression were performed on ACLF- and sepsis-related metabolites across portal, hepatic, and cubital venous compartments. Metabolites identified as BI-associated were further evaluated in cubital vein samples by assessing concentration differences and correlations with clinical parameters. Diagnostic performance was assessed using receiver operating characteristic (ROC) curve analysis. Model performance of selected metabolites was evaluated by ROC–AUC, repeated cross-validation, and permutation testing to assess robustness and avoid overfitting.
Results: Differential analysis across circulatory compartments identified 8 metabolites as potential BI-associated metabolites. Given the clinical relevance of cubital blood sampling, these metabolites were further examined in this compartment. Two of those metabolites emerged as robust individual biomarkers for BI, demonstrating strong discriminatory power (AUC = 0.816 and 0.787, respectively). Importantly, a combined predictive model incorporating both metabolites significantly improved diagnostic performance (AUC = 0.92).
Conclusion: Two specific metabolites represent promising non-invasive biomarkers for the detection of bacterial infection in patients with acute decompensated cirrhosis and may facilitate treatment of BI, potentially improving clinical outcomes in this high-risk population.

SAT-330

Systemic inflammation aggravated by translocating environmental bacteria Aquitalea Magnusonii DNA in patients with chronic liver disease

Background and aims: Disruption of the intestinal barrier ("leaky gut") enables gut microbial components to translocate into the bloodstream and potentially also liver, potentially worsening thereby chronic liver disease. We examined the potential pathogenic role of an aquatic environmental organism *Aquitalea magnusonii* in cirrhosis which has not previously been linked to liver disease progression.
Method: We assessed *A. magnusonii* translocation across human intestinal epithelial layers (Caco-2 and HT29-MTX) *in vitro* and evaluated its dissemination across organs using alcoholic and metabolic steatohepatitis mouse models. Untargeted metabolomics identified ACLF-associated metabolites produced by the bacterium. Proteomic profiling of outer membrane vesicles (OMVs) characterized virulence-related proteins. Hepatic stellate (LX-2) cell line, myeloid and human peripheral blood mononuclear cells were with bacterial supernatants and purified pathogen-associated molecular patterns (PAMPs). Environmental water samples were screened for *Aquitalea* DNA to evaluate potential reservoir sources.
Results: *A. magnusonii* effectively invaded intestinal epithelial monolayers and disseminated to extraintestinal organs in mouse liver disease models. The bacterium produced metabolites enriched in acute-on-chronic liver failure. OMV proteomics revealed elevated levels of virulence factors, including components of flagellar machinery, type IV pili, and ABC transporters. Bacterial supernatants and PAMPs activated TLR2/TLR4-dependent signaling, inducing TNFα, IL-1β and profibrotic markers (COL1A1, TGFβ) in immune and hepatic cells. *Aquitalea* DNA detected in patient samples and tap-water sources suggests the presence of environmental reservoirs, and were associated with higher morbidity.
Conclusion: *A. magnusonii* is an environmental bacterium capable of exacerbating systemic inflammation in liver disease mouse and rat models. Its pathogenic effects involve epithelial barrier translocation, OMV- and PAMP-mediated immune activation, cytokine induction, and secretion of disease-related metabolites. These results highlight the need to consider non-commensal environmental bacteria in the pathogenesis of chronic liver disorders.

SAT-331

Characterization of the intrahepatic microbiome in patients with HBV-related end-stage liver disease

Jiyang Chen[1], Tianzhu Liang[2], Xianbin Xu[1], Xia Yu[1], Zhiwei Li[1], Sisi Yang[1], Ziqing Deng[2], Na Pei[2], Yu Shi[1], Yida Yang[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [2]BGI Research, Beijing, China*
Email: yidayang65@zju.edu.cn

Background and aims: Dysregulated microbiota is a hallmark of end-stage liver disease (ESLD). This study aimed to elucidate the composition, functional potential, and host transcriptomic correlations of the intrahepatic microbiome across various stages of hepatitis B virus (HBV)-related ESLD.
Method: We collected liver tissue samples from patients undergoing liver transplantation due to decompensated cirrhosis (DC) (n = 20) or acute-on-chronic liver failure (ACLF) (n = 24), as well as samples from donors (n = 18) who served as controls. Metatranscriptomic sequencing was performed on liver tissues to profile the intrahepatic microbiome, encompassing species composition and functional gene expression, as well as liver transcriptome. An integrated analyse was employed to investigate the correlation between microbial species and host gene expression.
Results: 2208 bacterial species were detected across 13 phyla and 165 genera. Metatranscriptomic profiling revealed that *Proteobacteria* and *Actinobacteria* dominated the intrahepatic microbiome, with *Escherichia coli* and *Pseudomonas* most prevalent across groups. Principal coordinate analysis showed distinct microbial community structures among donors, DC, and ACLF patients. Compared with donors, both groups exhibited increased abundance of *Bacteroides heparinolyticus*, *Moraxella osloensis*, and *Gardnerella vaginalis*, while ACLF patients were further enriched with *Alcaligenes faecalis* and *Burkholderia insecticola*, and DC patients had higher *B. heparinolyticus*. Most taxa originated from the gut, with additional oral- and respiratory-derived species. Despite similar abundance between groups, *E. coli* in ESLD displayed marked functional activation, including nutrient acquisition systems and virulence factors linked to adhesion, invasion, and toxin production. Integrated host–microbiome analysis revealed taxa-specific associations with impaired hepatic metabolic, immune, and structural integrity.
Conclusion: This study delineates the compositional and functional reprogramming of the intrahepatic microbiome in patients with ESLD and its coupling with liver metabolic, immune, and structural pathways. These findings suggest the intrahepatic microbiome as a promising therapeutic target for ESLD.

SAT-332

Antibiotic therapy, not disease severity, shapes the intestinal and oral microbiomes in acutely decompensated cirrhosis

Søren Damsholt[1,2,3], Lotte Lindgreen Eriksen[1,2], Johanne Sloth Lauszus[1,2], Aleksander Krag[4], Nikolaj Torp[4], Stine Johansen[4], Henriette Ytting[5], Peter Holland-Fischer[6], Stine Hansen[6], Mette Lauridsen[7], Elise Jonasson[7], Anne Grosen[8], Christian Erikstrup[8], Susan Mikkelsen[8], Astrid Hvidt[2,3], Louise Thingholm[3], Christian Hvas[1,2], Hendrik Vilstrup[2], Sidsel Støy[1,2,8], Karen Louise Thomsen[1,2]. *[1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Clinical Medicine, Aarhus Unversity, Aarhus, Denmark; [3]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark; [4]Department of Gastroenterology and Hepatology,*

Email: soerdm@rm.dk

Background and aims: Intestinal microbial disturbances are associated with advancing stages of cirrhosis, but the impact of commonly prescribed medications and disease severity in patients with decompensated cirrhosis remains unknown.
Method: We performed shotgun metagenomic sequencing on faecal and saliva samples from 100 patients with acutely decompensated cirrhosis and on faecal samples from 112 healthy faeces donors as comparators. Group differences in alpha diversity (Shannon) were tested using the Wilcoxon test and associations with disease severity and medication usage were tested using linear regressions. Differences in Bray-Curtis beta diversity were tested with PERMANOVA.
Results: The patients' mean age was 58 (±10) years, 75% were men and the median MELD score was 14.5 [11.2–17.9]. Alcohol was the dominant etiology of cirrhosis (75%) and 55% received antibiotic treatment prior to sample collection. Compared with healthy donors, patients had a 55% lower faeces alpha diversity (2.6 [2.0–3.5] vs. 4.6 [4.1–4.5], $p < 0.001$), and a significant beta diversity dissimilarity ($R^2 = 0.15$, $p < 0.001$). Correspondingly, the oral microbiome diversity was low in patient samples (2.8 [2.0–3.3]). Importantly, 26% of patients exhibited prominent single-species dominance in their faecal sample, where a single species on average accounted for 43 (±22) % of species present. These were most frequently *Enterococcus faecium* (n = 8) and *Bifidobacterium longum* (n = 6). Disease severity had no relation to microbiome diversity, whereas antibiotic treatment was associated with reduced alpha diversities in both faeces (−3.0, $p < 0.001$) and saliva (−0.6, $p < 0.001$), and also with marked beta diversity dissimilarity in both faeces ($R^2 = 0.03$, $p < 0.001$) and saliva ($R^2 = 0.02$, $p = 0.02$). Other medications (proton pump inhibitors, beta-blockers and lactulose), and type of decompensation was not associated with microbiome diversity measures when adjusted for antibiotic treatment ($p > 0.05$).
Conclusion: Patients with acutely decompensated cirrhosis exhibit a markedly reduced intestinal and oral microbial diversity, with frequent prominent single-species dominance. Antibiotic treatment, but not disease severity or type of decompensation, is associated with decreased microbial diversity in this group of patients and contribute to single-species dominance. Our findings do not support causal relation between cirrhosis stage and disturbed microbiome, which is rather ascribable to antibiotic treatment.

SAT-333

An integrated multiomics signature and network analysis differentiating metabolic dysfunction-associated steatotic liver disease and metabolic associated steatohepatitis: a pilot study

Shereen El Sobky[1], Nada El-Ekiaby[1], Injie Fawzy[1], Amira Abdelhamid[1], Heba Attia[2], Ibrahim Fayed[1], Yasser Badr[1], Mohammed Emadeldeen[3], Ahmed Nagy[4], Mohamed Negm[5], Mohamed Negm[6], Ahmed Moustafa[7], Mohamed El-Kassas[8], Mohamed Farag[9], Ramy Aziz[2], Ahmed Abdelaziz[1]. *[1]School of Medicine, Newgiza University (NGU), Giza, Egypt; [2]Department of Microbiology and Immunology, Faculty of Pharmacy, Cairo University, Center for Genome and Microbiome Research, Faculty of Pharmacy, Cairo University, Cairo, Egypt; [3]Hepatology and Gastroenterology department, National Hepatology and Tropical Medicine Research Institute, Cairo, Egypt; [4]School of Medicine, Newgiza University (NGU), Kasr Al-Ainy Viral Hepatitis Center (KAVHC), Kasr Al-Ainy University Hospital, Cairo University, Giza, Egypt; [5]Clinical and research center for intestinal disorders, Cairo University, School of Medicine, Newgiza University (NGU), Cairo, Egypt; [6]Department of Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt; [7]Department of Biology & Biotechnology Graduate Program, American University in New Cairo, Cairo, Egypt; [8]Faculty of Medicine, Helwan University, Cairo, Egypt; [9]Department of Pharmacognosy, Faculty of Pharmacy, Cairo University, Healthcare faculty, Saxony Egypt University (SEU), Badr City, Cairo, Egypt*
Email: shereen.el.sobky@gmail.com

Background and aims: Liver biopsy is the gold standard and the most reliable method, to date, to differentiate between metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic associated steatohepatitis (MASH) using NAS score. A NAS score ≥5 indicates MASH, while <5 indicates MASLD. Accordingly, there were several attempts to discover new diagnostic biomarkers that can outweigh invasive diagnostic procedures. Growing evidence has shown a causal role for gut-microbiome in MASLD onset. One way for gut-microbiome to affect MASLD is through altering intestinal lumen metabolites. Additionally, bioinformatics analysis predicted potential link between the gut-microbiome, its metabolites, and 38 host proteins in MASLD, suggesting PPARG and FXR to be among the affected host proteins. Accordingly, we aimed at performing an integrative multiomics analysis between patients with MASLD and patients with MASH to investigate potential signature that can distinguish them and determine new players that might affect their pathogenesis.
Method: Serum, stool, formalin fixed paraffin embedded (FFPE) tissue biopsies and clinical data were collected for 21 patients with MASLD and MASH. 16S NGS was performed to determine gut-microbial profile. Gas chromatography/ mass spectrometry (GC/MS) was performed for fecal and serum metabolome analysis. Immunohistochemistry was performed for the detection and quantification of subcellular localization of PPARs, FXR and their upstream regulator SIRT1. Integrative multiomics analysis was performed using mixOmics package v6.28.0 on Rstudio v2023.12.1.402.
Results: Our model identified a signature of 20 gut-bacterial genera, 10 fecal and 30 serum metabolites, and 3 host proteins to potentially discriminate between MASLD and MASH. Moreover, network and in silico analysis suggested myristic, lauric, octanoic and nonanoic acids to putatively affect PPARA and FXR, and *Coprobacter* as an important contributor in MASLD/MASH status. The same three fecal metabolites (myristic, lauric, and octanoic acids) had almost identical interaction networks with four bacterial genera (*Victivallis*, *Eisenbergiella*, *Flavonifractor*, and *Coprobacter*), serum nonaoic acid and PPARA as well as NAS and S scores.
Conclusion: Our pilot study identified potential signature that could differentiate between MASLD and MASH, and unraveled new potential players that might affect MASLD/MASH status.

SAT-334

Rifaximin ameliorates liver fibrosis and hepatocarcinogenesis in experimental MASH by inhibiting the gut–liver axis and Epiregulin–IL-8–driven angiogenesis

Kosuke Kaji[1], Norihisa Nishimura[1], Masafumi Oyama[1], Tatsuya Nakatani[1], Tadashi Namisaki[1], Hitoshi Yoshiji[1]. *[1]Department of Gastroenterology, Nara Medical University, Kashihara, Japan*
Email: kajik@naramed-u.ac.jp

Background and aims: Gut–liver axis plays a key role in metabolic dysfunction–associated steatohepatitis (MASH) progression, whereby gut-derived lipopolysaccharide (LPS) promotes hepatic inflammation, fibrogenesis, and angiogenesis through toll-like receptor 4 (TLR4) signaling. Rifaximin, a non-absorbable gut-selective antibiotic, has been shown to improve intestinal barrier function and reduce endotoxemia. This study aimed to investigate the effect of rifaximin on liver fibrosis and early hepatocarcinogenesis in MASH, with focus on the LPS–epiregulin–IL-8–angiogenesis pathway.
Method: MASH was induced in male Fischer 344 rats by feeding a choline-deficient, L-amino acid-defined high-fat diet (CDAHFD) for 12 weeks. Rifaximin (30 mg/kg/day) or vehicle was orally administered throughout the experimental period. Liver histology including

fibrosis and early hepatocarcinogenesis, portal LPS levels, Kupffer cell activation, and hepatic LPS/TLR4 signaling were analyzed. Angiogenesis-related markers, including epiregulin, IL-8, CD34-positive neovascularization, and proangiogenic gene expression, were examined. Intestinal barrier integrity was evaluated by histology, tight junction protein expression, intestinal LPS levels, and FITC-dextran permeability assays.
Results: Rifaximin significantly attenuated hepatic inflammation and fibrosis in CDAHFD-fed rats, reducing hepatic hydroxyproline content and profibrogenic gene expression. The glutathione S-transferase placental form (GST-P)-positive preneoplastic lesions were markedly decreased, accompanied by suppression of cell proliferation–related genes. Rifaximin lowered portal LPS levels and inhibited Kupffer cell activation, with downregulation of Lbp, Cd14, Tlr4, and proinflammatory cytokines. Notably, hepatic epiregulin and IL-8 expression were significantly reduced, correlating with decreased CD34-positive neovascularization and suppression of angiogenesis-related genes. These effects were associated with restoration of intestinal barrier function, including improved villus architecture, increased tight junction protein expression, and decreased gut permeability.
Conclusion: Rifaximin attenuates liver fibrosis and early hepatocarcinogenesis in murine MASH by restoring intestinal barrier integrity, limiting gut-derived LPS translocation, and suppressing the LPS–TLR4–epiregulin–IL-8–associated angiogenic pathway. These findings identify rifaximin as a potential chemopreventive strategy targeting the gut–liver axis in MASH-related hepatocarcinogenesis.

SAT-335
Acute hypobaric hypoxia remodels the intestinal metaproteome, disrupting barrier function and promoting inflammation-driven dysbiosis
Rupinder Kalra[1], Sanju Yadav[2,3], Jaswinder Maras[2], Ved Dwivedi[4], Nasir Salam[3], Narendra Sharma[1]. *[1]Banasthali Vidyapith, Newai, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India; [3]Jamia Millia Islamia, New Delhi, India; [4]ICGEB, New Delhi, India*
Email: drnarendraks@gmail.com

Background and aims: Hypoxia disrupts intestinal homeostasis and compromising barrier integrity, promoting inflammation and expansion of pathogenic microbes. These changes drive dysbiosis, increase intestinal permeability, and contributing to systemic inflammation and gut–liver axis dysfunction; however, the underlying mechanisms remain obscure.
Method: Male SD rats (n = 6/group) were exposed to simulated hypobaric hypoxia (25,000 ft) for 1, 3, or 7 days. Intestinal tissues were analyzed by metaproteomics, proteomics and metabolomics to identify differentially expressed bacterial peptides, define time-dependent taxonomic and functional signatures, and correlate microbial alterations with intestinal metabolome, intestinal barrier dysfunction and inflammation.
Results: Hypobaric hypoxia induced profound intestinal metaproteomic remodeling, with 216 differentially expressed bacterial peptides across exposure durations, of which 93 were consistently increased (FC>1.5, $p < 0.05$). These changes were associated with enrichment of 15 pathogenic taxa, including Clostridia, Salmonella, and others (FC>2.5), and Mycoplasmoides gallisepticum (FC>2.5), linked to inflammation, metabolic dysregulation, and epithelial barrier disruption. In contrast, seven commensal-associated metaproteins (e.g., Bacteroidales, Nostocaceae) were downregulated, indicating loss of colonization resistance. Intestinal metabolomics revealed marked, time-dependent metabolic reprogramming, with significant enrichment of arginine proline (FC>3.5), tryptophan metabolism (FC>3.5), pyrimidine, lysine, and purine metabolism (R^2>0.7, $p < 0.05$). Functional pathway analysis highlighted perturbations in peptidoglycan and fatty acid biosynthesis, histidine, biotin, glutathione metabolism, and prodigiosin biosynthesis, reflecting oxidative stress and enhanced microbial virulence. Concomitantly, the host intestinal proteome showed significant reduction of tight junction proteins (ZO-1, ZO-2, ZO-3; FC>3.5), adherens junction proteins (E-cadherin), and mucosal defense factors (MUC2, defensins, REG3γ; FC >1.5, $p < 0.05$) there by driving intestinal barrier failure.
Conclusion: Intestinal metaproteomics shows that hypobaric hypoxia induces time-dependent gut dysbiosis with pathogenic enrichment and commensal loss, driving metabolic rewiring, barrier dysfunction, increased permeability, microbial translocation, and gut–liver axis impairment, highlighting the microbiome as a key mediator and therapeutic target.

SAT-336
Hypobaric hypoxia induces sustained pathogenic alterations in gut microbiota and contributes to injury in a preclinical model of hypoxia
Rupinder Kalra[1], Sanju Yadav[2,3], Jaswinder Maras[2], Ved Dwivedi[4], Nasir Salam[3], Narendra Sharma[1]. *[1]Banasthali Vidyapith, Newai, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India; [3]Jamia Millia Islamia, New Delhi, India; [4]ICGEB, New Delhi, India*
Email: drnarendraks@gmail.com

Background and aims: Hypobaric hypoxia modulates liver function and remodels the gut microbiome. Stool metaproteomics reveals functional microbial shifts and metabolic pathway alterations that contribute to hypoxia-induced liver injury and inflammation.
Method: Male SD rats were exposed to simulated hypobaric hypoxia equivalent to 25,000 ft altitude for 1, 3, and 7 days in a hypoxia chamber. Stool samples were subjected to metaproteomic and metabolomic analyses. Differential protein expression profiling, followed by taxonomic and functional annotation, was performed to identify time-dependent microbial signatures and their association with liver inflammation.
Results: Hypobaric hypoxia in rats caused liver inflammation, elevated AST and ALT levels, reduced body weight, and increased liver-to-body weight ratio ($p < 0.05$). Stool metaproteomics revealed distinct α/β diversity changes and 211 differentially expressed bacterial peptides across hypoxia exposure. Hypoxia induced > 180 bacterial peptides while >10 were downregulated at all day of exposure (FC>1.5, $p < 0.05$). Comparative analysis identified 172 bacterial taxa, including 49 taxa; *Streptococcus* and *Klebsiella* associated with gut and liver inflammation and enriched in nicotinate nicotinamide and sphingolipid metabolism. These findings link hypoxia to gut dysbiosis, barrier dysfunction and increased susceptibility to secondary infections. Stool metabolome analysis validated significant dysregulation of tryptophan metabolism and carnitine dysregulation all associate to pathogenic metabolic transformation (R2>0.7, $p < 0.05$). Interestingly, increase in streptococcus correlates >0.7 with spermidine and spermine accumulation. Suggesting that hypoxia increased Streptococcus acts as a metabolic amplifier and increases accumulation of Spermidine, S-Adenosyl-L-methionine (SAM), Spermine, Putrescine >1.5 FC, $p < 0.05$ creates a pathogenic loop that contributes to inflammation and liver injury.
Conclusion: Our study shows that hypobaric hypoxia induces pronounced, time-dependent functional remodelling of the gut microbiome. Sustained enrichment of pathogenic bacteria and depletion of protective taxa may contribute to hypoxia associated gastrointestinal dysfunction and systemic inflammation, highlighting potential microbial targets for therapeutic intervention in hypoxia linked liver diseases.

SAT-337
Odoribacter splanchnicus attenuates western diet–induced MASLD by restoring hepatic lipid metabolism
Soon Sun Kim[1], Moon Gyeong Yoon[1], Se Ha Jang[2], Geum Ok Baek[1], Hyun Sun Jung[2], Jae Youn Cheong[1], Jung Woo Eun[1]. *[1]Ajou University School of Medicine, Suwon, Korea, Rep. of South; [2]Ajou University School of Medicine, Ajou University Graduate School of Medicine, Suwon, Korea, Rep. of South*
Email: jetaimebin@gmail.com

Background and aims: Metabolic dysfunction–associated steatotic liver disease (MASLD) affects both obese and non-obese individuals, and emerging evidence highlights a pivotal role of the gut microbiome in its pathogenesis. This study aimed to identify a gut microbial strain associated with MASLD prevention or treatment and to validate its hepatoprotective effects using *in vitro* and *in vivo* models.
Method: Gut microbiome profiling was performed using 16S rRNA sequencing of fecal samples obtained from healthy controls and patients with MASLD, including both obese and non-obese individuals. *Odoribacter splanchnicus* was identified as a candidate strain significantly reduced in MASLD patients. *In vitro*, the anti-steatotic effects of *O. splanchnicus*–conditioned media were evaluated in free fatty acid–treated HepG2 and Hepa1–6 cells. *In vivo* efficacy was assessed using a 13-week Western diet–induced MASLD mouse model, followed by biochemical, histological, and hepatic gene expression analyses.
Results: *O. splanchnicus*–conditioned media dose-dependently reduced lipid accumulation in hepatocyte cell lines, indicating a direct anti-steatotic effect. In Western diet–fed mice, supplementation with *O. splanchnicus* significantly improved liver enzyme levels (AST, ALT, and GGT), attenuated hepatic steatosis, inflammation, and fibrosis, and reduced macrophage infiltration. Mechanistically, *O. splanchnicus* restored the expression of key regulators of fatty acid oxidation (Ppar-α, Acox1, and Cpt1a) and bile acid signaling (Fxr), while suppressing inflammatory gene expression (Tnf-α and Tlr-4).
Conclusion: These findings demonstrate that *Odoribacter splanchnicus* exerts hepatoprotective and anti-steatotic effects by improving hepatic lipid metabolism and inflammatory responses. This strain represents a promising microbiome-based therapeutic candidate for MASLD across obese and non-obese populations.

SAT-338

The biliary metagenome in malignant cholestasis: analysis of samples obtained during EUS-guided biliary drainage

Łukasz Krupa[1], Georges Schmarz[2], Robert Staroń[1], Hartmut Schmidt[3], Jacqueline Rehner[4], Soeren Becker[4], Marcin Krawczyk[3]. *[1]Medical Department, University of Rzeszów, Rzeszów, Poland; [2]Chair for Clinical Bioinformatics, Saarland University, Saarbrücken, Germany; [3]Essen University Hospital, Department of Gastroenterology, Hepatology and Transplant Medicine, Medical Faculty, University of Duisburg-Essen, Essen, Germany; [4]Institute of Medical Microbiology and Hygiene, Saarland University, Homburg, Germany*
Email: marcinjan.krawczyk@uk-essen.de

Background and aims: Biliary obstruction is a common complication of pancreatic and hepatobiliary malignancies. In the recent years, the role of microbiota in hepatobiliary tumors has gained increasing attention. Endoscopic retrograde cholangiopancreatography (ERCP) is the standard method for biliary drainage in malignant cholestasis. However, when ERCP fails, endosonography-guided biliary drainage (EUS-BD) represents an effective alternative. This study aims to characterise biliary microbial composition in patients with end-stage malignant cholestasis undergoing EUS-BD.
Method: We prospectively enrolled 43 patients (22 women, age 33–89 years) with malignant cholestasis, predominantly due to pancreatic cancer (n = 23) and cholangiocarcinoma (n = 11). Bile samples were collected during EUS-BD (26 hepaticogastrostomies and 17 choledochoduodenostomies) following unsuccessful ERCPs. Metagenomic profiling of bile was performed using next generation sequencing (NGS).
Results: Microbial analysis was successfully performed in all samples. Four samples exhibited minimal microbial diversity with a Shannon diversity index below 0.5: two samples contained Enterococcus faecalis and Klebsiella pneumoniae and the other two samples contained Streptococcus epidermidis and Streptococcus mitis. Differential abundance analyses revealed distinct microbial signatures associated with tumor types. Patients with pancreatic cancer showed an overrepresentation of Streptococcus intermedius (q-val. = 0.032), whereas Cryptobacterium curtum was more abundant in cholangiocarcinoma (q-val. = 0.013). In patients with other malignancies, Actinomyces bouchesdurhonensis was significantly overrepresented (q-val. = <0.001). No significant association between microbial composition of bile and patients survival was observed.
Conclusion: EUS-BD allows collection of bile samples suitable for metagenomic analyses. We detected a differential abundance of species in different end-stage heapatobiliary malignancies. Larger cohorts are needed to further explore the relationship between biliary microbiota, confounding factors, tumor type and its progression.

SAT-341

Bacteroides intestinalis AM-1 reshapes the gut microbiome and preserves intestinal barrier function to mitigate acetaminophen-induced liver injury

Sushmita Pandey[1,2], Neha Sharma[1], Nupur Sharma[1], Vipul Sharma[1], Yash Magar[1], Babu Mathew[1,3], Gaurav Tripathi[1], Vasundhra Bindal[1], Sanju Yadav[1], Manisha Yadav[1], Anju Katyal[4], Shiv Kumar Sarin[1], Jaswinder Maras[1]. *[1]Institute of Liver & Biliary Sciences, New Delhi, India; [2]Dr. B R Ambedkar Center for Biomedical Research, University of Delhi, New Delhi, India; [3]Institute of Liver and Biliary Sciences (ILBS), New Delhi, India; [4]Dr. B R Ambedkar Center for Biomedical Research, University of Delhi, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Intestinal dysbiosis exacerbates liver injury, and expansion of pathogenic gut microbiota not only increases the risk of liver failure but also drives gut dysregulation, making the intestinal microbiome a key, targetable risk factor in acute liver failure (ALF). We investigate the role of intestinal and plasma metaproteomic alterations in acute liver failure (ALF) and evaluate microbiome-targeted therapeutic correction in preclinical model of ALF.
Method: Intestinal and plasma meta-proteomes were analyzed in patients with drug induced liver failure ALF (n = 116) and in an acetaminophen (APAP)-induced preclinical model. Key meta-protein alterations were identified and correlated with disease severity and clinical outcomes. Finally, the therapeutic potential of Bacteroides intestinalis AM-1 (Bi) in restoring dysregulated microbiome signatures, improving intestinal homeostasis and ALF-associated pathophysiology was evaluated in detail.
Results: Intestinal and plasma meta-proteomic analyses revealed a significant enrichment of pathogenic bacterial peptides, including Firmicutes and Enterobacteriaceae (FC >1.5; $p < 0.05$), in both ALF patients and APAP-induced preclinical models. This was accompanied by a marked reduction in beneficial commensals such as *Bacteroides* and *Lactobacillus* ($p < 0.05$), correlating with severe disruption of intestinal homeostasis. Oral Bi supplementation effectively restored microbial balance, increasing beneficial taxa while reducing pathogenic bacterial peptides, including Enterobacteriaceae and Clostridiaceae ($p < 0.05$). Bi treatment significantly improved intestinal barrier integrity through upregulation of mucosal and tight-junction proteins, including occludin, MUC2, and MUC1 (FC >2.5; $p < 0.05$). These gut-protective effects translated into marked hepatic benefits, with up to 70% reduction in hepatic necrosis and significantly lower serum AST and ALT levels ($p < 0.05$). Mechanistically, Bi activated intestinal FXR–FGF15 signaling (FC >1.5; $p < 0.05$), correcting FXR dysregulation associated with drug-induced injury and preserving intestinal mitochondrial fitness and redox homeostasis in acute liver failure.
Conclusion: Bacteroides intestinalis AM-1 restores microbiome fitness, re-established intestinal homeostasis, and attenuated experimental APAP-induced liver injury. These findings suggest Bi as a potential probiotic therapy for drug-induced hepatotoxicity.

SAT-345

Machine learning uncovers functional microbial signatures in cirrhosis patients with type 2 diabetes mellitus

In Gyu Park[1], Sang Joon Yoon[1], Sung-Min Won[1], Ki Kwang Oh[1], Un Joo Lee[2], Younglim Ham[3], Ki Tae Suk[1]. *[1]Hallym university, Institute for Liver and Digestive Diseases, Chuncheon-si, Korea, Rep. of South; [2]Hallym University, Department of Electronic Engineering, Chuncheon-si, Korea, Rep. of South; [3]Daewon University College, Department of Nursing, Jaecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Patients with comorbid liver cirrhosis and type 2 diabetes mellitus (T2DM) termed Cirrhotic Diabetes Mellitus (CDM) have worse clinical outcomes than those with either condition alone. Current taxonomic profiling approaches inadequately capture CDM-specific functional microbial interactions. We developed an interpretable machine learning framework to identify functional biomarkers that distinguish this complex comorbid phenotype.
Method: We enrolled 149 participants stratified into four groups: normal controls (NC, n = 59), T2DM (n = 46), cirrhosis (n = 30), and CDM (n = 14). Shotgun metagenomic sequencing was performed to extract both microbial taxonomic profiles and functional genes (KEGG Orthology [KO]). To address the non-linear interactions inherent in high-dimensional metagenomic data, we constructed an interpretable ML framework using XGBoost. This was coupled with Boruta feature selection and SHAP (SHapley Additive exPlanations) analysis to robustly identify key biomarkers and visualize their contribution to disease stratification.
Results: The model demonstrated robust diagnostic performance. Differentiating cirrhosis from NC, it achieved an Area Under the Receiver Operating Characteristic (AUROC) of 0.92 (discovery) and 0.79 (validation), with SHAP confirming *Dorea longicatena* and *Collinsella aerofaciens* as top predictors. Strikingly, for the challenging stratification of CDM from cirrhosis alone, the framework showed robust generalization with a validation AUROC of 0.94. Explainable AI revealed that in CDM, microbial KOs contributed significantly more than taxa. Specifically, the uracil permease gene *uraA* (K02824) was the top predictor, highlighting that functional alterations are more critical than taxonomic shifts in defining this high-risk phenotype.
Conclusion: This study establishes an integrative ML framework that successfully stratifies the complex multimorbidity of cirrhosis and diabetes. By utilizing XGBoost to capture non-linear functional interactions, we identified distinct microbial signatures associated with the CDM phenotype. These findings underscore the potential of function-based microbiome markers for precision risk stratification in advanced liver disease.

SAT-346

The interplay of serum and stool metabolomic profiles in non-progressive and progressive alcohol-related liver disease

Eemeli Puhakka[1], Krista Ahola[1], Hany Ahmed[2], Retu Haikonen[1], Sophie Leclercq[3], Kati Hanhineva[4], Luca Maccioni[3,5], Camille Amadieu[6], Marko Lehtonen[1], Ville Männistö[1], Jaana Rysä[1], Peter Stärkel[3], Olli Kärkkäinen[1]. *[1]University of Eastern Finland, Kuopio University Hospital, Kuopio, Finland; [2]University of Turku, Turku, Finland; [3]Uclouvain, Ottignies-Louvain-la-Neuve, Belgium; [4]University of Turku-Main building, Turku, Finland; [5]National Institutes of Health, Bethesda, United States; [6]University of Bordeaux, Pessac, France*
Email: epuhakka@uef.fi

Background and aims: Liver diseases are on the rise worldwide, in part due to the increase in alcohol-related liver disease (ALD) and metabolic dysfunction-associated steatotic liver disease. ALD is a progressive disease, which has large variation in the rate of progression between individuals with the same alcohol intake. The interplay between gut microbiota, intestinal permeability and liver function has been hypothesized to contribute to the metabolic processes causing ALD progression. In the present study, the aim was to examine metabolomic profiles in stool samples of non-progressive ALD and progressive ALD patients.
Method: The study was composed of 2 study groups, a non-progressive ALD group (N = 31) and an early stage progressive ALD group (N = 36). The stratification between the patient groups was done with elastography and liver function tests (aspartate aminotransferase and alanine aminotransferase). Patients with elevated liver function test results and high elastography scores were assigned to the progressive ALD group. Patient groups took part in a voluntary alcohol rehabilitation program in Brussels, Belgium between 2017 and 2019. Patients had their blood drawn and stool samples collected on the day of the admission. Both the serum and stool samples were analyzed with non-targeted liquid chromatography mass spectrometry metabolomics.
Results: In the metabolomics analysis of the stool samples, 86 identified metabolites had a p-value <0.05 and 11 identified metabolites had a p-value below the corrected alpha level (0.0009). Primary finding was that stool dopamine (Cohen's d = –0.92), phenylalanine (d = –0.92), phenylephrine (d = –0.92), tyrosine (d = –0.84) and 3-dehydroshikimate (d = –1.03) had their levels significantly lower in the progressive ALD group when compared to the non-progressive ALD group. Furthermore, stool levels of phenylalanine, dopamine, tyrosine and phenylephrine all had a moderate reverse correlation (|r|>0.4) with serum glutamate and glycine bound bile acid levels.
Conclusion: The low levels of dopamine and tyrosine in stool of the progressive-ALD point towards a shift in the bacterial species of the gut. Decreased phenylephrine levels could be linked to alterations in gut lining and permeability. The strong reverse correlation with glycine bound bile acids and glutamate indicates an interplay in disease progression. In conclusion, the metabolomic changes indicate a thorough alteration in the functional characteristics of gut lining.

SAT-347-YI

Incomplete microbial and metabolic recovery during the regression phase of carbon tetrachloride-induced liver fibrosis

Katja Sommer[1,2,3], Katharina Bonitz[1,3,4], Thomas Sorz-Nechay[1,2,3,4], Henriette Horstmeier[1], Vlad Taru[1,4], Kerstin Zinober[1], Katharina Regnat[1], Hubert Scharnagl[5], Michael Trauner[1], Philipp Schwabl[1,2,3,4], Thomas Reiberger[1,2,3,4], Benedikt Simbrunner[1,2,3,4]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria; [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [4]Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria; [5]Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria*
Email: katja.sommer@meduniwien.ac.at

Background and aims: Disruption of the intestinal barrier and subsequent microbial translocation contribute to inflammation and portal hypertension in chronic liver disease. We aimed to characterize gut-liver axis changes at carbon tetrachloride (CCl_4)–induced liver injury and after natural disease regression in mice, which may uncover therapeutic targets for strengthening gut barrier function and attenuating inflammatory cascades in liver disease.
Method: Liver fibrosis was induced in male C57BL/6J mice via bodyweight–adapted CCl_4 gavage (2 mL/kg, 3×/week as 20% olive oil solution) for 12 weeks (n = 12). Additionally, a regression group was examined after two-week CCl_4 cessation (n = 12). Control mice received only olive oil (n = 12). Portal pressure (PP) was measured and ileal and hepatic samples collected for transcriptomic profiling, histology and immune-cell phenotyping by flow cytometry. Serum samples were collected for metabolomics and ileum stool for 16S ribosomal RNA sequencing.

Results: Regression significantly reduced PP (7.15 vs. 6.10 mmHg; p = 0.010) and collagen proportionate area (7.14 vs. 4.90%, p = 0.030) compared to peak disease. Ileal immune cell profiling showed decreased $CD45^+$ intraepithelial lymphocyte proportions (−15.75%, p = 0.020) and increased $CD45^+$ lamina propria cells (+34.13%, p = 0.030) in regression. Microbial communities differed significantly between groups (PERMANOVA: p = 0.001). Peak fibrosis showed loss of *Dubosiella* and Muribaculaceae, with expansion of *Ileibacterium*, *Akkermansia*, and *Turicibacter* (in total 30% abundance) compared to controls. Microbial profiles did not normalize in regression; *Ileibacterium* remained elevated (~30% relative abundance; >2 log2-fold increase vs. peak and control), indicating persisting dysbiosis in the anaerobic niche. Serum metabolomics revealed marked alterations, with glutamic acid (log2 fold change [log2FC] = 1.00, p = 0.006) and tauro-muricholate (log2FC = 2.22, p = 0.006) elevated in peak disease compared to controls. Purine-degradation metabolites were enriched in regression compared to peak disease, including hypoxanthine (log2FC = 3.42, p = 0.127) and xanthine (log2FC = 3.34, p = 0.006) as major drivers of group separation.
Conclusion: CCl_4-induced liver fibrosis was linked to microbial, metabolic and immune disturbances, while regression was marked by persistent *Ileibacterium* overabundance and sustained metabolic stress despite partial hepatic structural recovery.

SAT-348
Diet and exercise mitigate MASLD and exert beneficial effects on skeletal muscle via organ crosstalk in diet-induced obese mice
Henrique Souza-Tavares[1], Laura Ramos-da-Silva[1], Nathan Dantas-Miranda[1], Gustavo Silva-Pereira[1], Maria Amancio-Lisboa[1,2], Gabriela Medeiros[1], Flavia Silva-Veiga[1], Vanessa Souza-Mello[1]. [1]*Rio de Janeiro State University, Rio de Janeiro, Brazil;* [2]*Instituto Federal do Rio de Janeiro-Reitoria, Rio de Janeiro State University, Rio de Janeiro, Brazil*
Email: souzatavareshenriqueuerj@gmail.com

Background and aims: Ultra-processed food intake and a sedentary lifestyle, associated with metabolic dysfunction-associated liver disease (MASLD) and sarcopenia, contribute to obesity onset. Hence, the effects of lifestyle change therapy on the muscle-liver axis merit further investigation. This study aimed to evaluate the impact of dietary intervention and physical exercise, alone or in combination, on the modulation of the muscle-liver axis in mice fed excess saturated fat and sucrose.
Method: Adult male C57BL/6J mice were fed a control diet (C) or a diet rich in saturated fat and sucrose (HFS) for ten weeks. The HFS group was then subdivided into four groups (n = 15 each), for a six-week treatment: C (control group), HFS (HFS diet group), HFS-C (C diet, mimicking a dietary treatment), HFS-Ex (HFS diet + exercise), and HFS-CEx (C diet + exercise). High-intensity interval training (HIIT) was performed on a treadmill for mice on alternate days, with each session lasting 15 minutes. At sacrifice, blood samples, triceps surae (gastrocnemius and soleus), and the liver were harvested and evaluated by biochemical, stereological, and molecular biology analyses. The differences were tested using Brown-Forsythe and Welch ANOVA with Dunnett T3 post hoc test (P < 0.05).
Results: The HFS group showed overweight, oral glucose intolerance, a proinflammatory adipokine profile, reduced lean mass, and increased hepatic steatosis volume density. All treatments (diet, exercise, or combination) led to reduced body and fat masses, increased lean mass, and improved adipokine profile. However, only the exercised groups showed increased irisin concentrations, resulting in the most pronounced MASLD reductions through AMP-activated protein kinase (AMPK)/Sirtuin-1 (SIRT1)/Peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1a) activation, improved mitochondrial dynamics, and increased oxidative capacity. All treatments increased muscle fibroblast growth factor 21 (*Fgf21*) expression, a hepatokine linked to the preserved muscle mass and improved mitochondrial dynamics markers.
Conclusion: Lifestyle change therapy (diet, exercise, or combination) improved the body composition and adipokine profile of HFS-fed mice. Enhanced skeletal muscle *Fgf21* and hepatic irisin reinforce crosstalk between these organs, preserving muscle mass and alleviating MASLD. The diet-and-exercise combination was the most effective therapy, leading to complete rescue of body composition, oral glucose tolerance, and hepatic cytoarchitecture.

SAT-349
Pharmabiotics, phocaeicola dorei, ameliorates liver fibrosis by alleviating macrophage efferocytosis of neutrophils
Ki Tae Suk[1], Jung A. Eom[1], In Gyu Park[1], Goo Hyun Kwon[1], Younglim Ham[2], Dong Joon Kim[1]. [1]*Hallym University, Institute for Liver and Digestive Diseases, Chuncheon, Korea, Rep. of South;* [2]*Daewon University, Department of Nursing, Jecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Liver fibrosis results from chronic inflammation, dysregulated immune responses, and persistent activation of hepatic stellate cells (HSCs). Increasing evidence shows that gut microbiota influence hepatic immunity and fibrogenesis. *Phocaeicola dorei* has been reported to ameliorate metabolic diseases. Its role in liver fibrosis remains unclear. We hypothesized that *P. dorei* attenuates liver fibrosis by suppressing neutrophil activation and limiting macrophage-mediated efferocytosis of apoptotic neutrophils, thereby reducing downstream HSC activation.
Method: Fecal samples were collected from healthy controls and patients (n = 285) to assess the clinical relevance of *P. dorei*. In mice models (3,5-diethoxycarbonyl-1.4-dihydrocollidine [DDC] diet and TAA [thioacetamide] injection), *P. dorei* (10^9 CFU/g twice/week) was orally administered. Fibrosis severity, collagen deposition, immune-cell infiltration, and chemokine expression were assessed by histology, Sirius Red staining, immunofluorescence, and qPCR. HSCs were isolated for RNA sequencing to identify pathway changes modulated by *P. dorei*. Primary HSCs, LX-2, THP-1, and HL-60 cell lines were used for mechanical validation.
Results: The relative abundance of *P. dorei* increased progressively with worsing liver disease in human cohort. *P. dorei* administration significantly reduced fibrosis, neutrophil degranulation and efferocytosis pathways, as indicated by decreased *Ly6g* and *F4/80* expression. In parallel, the dysregulated expression of neutrophil-associated chemokines, including *Cx3cl1*, and *Cx3cr1* was restored by *P. dorei* treatment. In vitro, *P. dorei* culture supernatant markedly inhibited macrophage-mediated efferocytosis.
Conclusion: Collectively, *P. dorei* attenuates liver fibrosis by suppressing neutrophil and macrophage infiltration and disrupting efferocytosis through interference with interactions between apoptotic bodies and macrophages. Our results identify *P. dorei* as a potential microbiome-based therapeutic candidate for liver fibrosis.

Email: j.vaquero@iisgm.com

Background and aims: Advanced chronic liver disease (CLD) is a systemic and inflammatory condition, but how molecular programs evolve across organs remains incompletely defined. Here, we examined transcriptomic changes in the liver and distant organs in experimental CLD, with a focus on the impact of liver atrophy.
Method: Male SD rats received oral carbon tetrachloride (CCl4) or vehicle for 2–12 weeks. Liver atrophy was defined as liver-to-body weight ratio < mean–1 SD of controls. Bulk RNA-seq from liver, mesentery, lung, ileum, kidney, and heart was analyzed in CLD rats without or with atrophy, and compared with controls. Differential expression and GO Biological Process GSEA were used to identify organ-specific and shared pathways.
Results: Animals with liver atrophy formed a distinct transcriptomic cluster by unsupervised PCA across all organs. In the liver, both stages of CLD showed activation of extracellular matrix programs, chemokine signaling, antimicrobial humoral responses, neutrophil recruitment, and TGF-β signatures. Concomitantly, mitochondrial/metabolic programs were repressed, including oxidative phosphorylation, electron transport chain, fatty acid β-oxidation, acetyl-CoA metabolism, and mitochondrial translation. These changes intensified with liver atrophy, which further suppressed xenobiotic/retinoid–terpenoid catabolism and NADPH-regenerating processes. Transcriptomic responses in extrahepatic organs were stage-dependent. Rats without liver atrophy showed mainly organ-restricted changes (xenobiotic/retinoid/terpenoid metabolic induction in lung, proliferative pathways in heart, no major shifts in kidney). After liver atrophy developed, multiple organs converged on innate immune activation, coupled with mitochondrial metabolic dysfunction: a) The mesentery and lung showed prominent leukocyte chemotaxis/trafficking, myeloid/neutrophil activation, and humoral immune responses, with reciprocal depletion of developmental/neurogenic programs, b) The heart and kidneys exhibited granulocyte/complement activation, phagocytosis and leukocyte–endothelial adhesion with marked repression of oxidative phosphorylation and fatty-acid β-oxidation (strongest in heart), c) The ileum preferentially upregulated extracellular matrix programs while suppressing oxidative phosphorylation/electron transport pathways.
Conclusion: Liver atrophy drives a systemic transcriptional transition in experimental CLD, from early organ-specific adaptations to late multi-organ immune activation and bioenergetic failure.

SAT-351
Integrated multi-omics analysis identifies gut microbiota – lipid - metabolite signatures associated with metabolic dysfunction – associated steatotic liver disease in overweight adults

Miloš Vratarić[1], Sofija Ignjatović[1], Bojana Mićić[1], Uroš Gašić[1], Ivana Božić -Antić[2], João Barbosa[3], Daniel Duberg[3], Anh Nguyen[4], Mark Davids[5], Amir H. Alizadeh Bahmani[5], Tuulia Hyötyläinen[3], Matej Orešič[4], Max Nieuwdorp[5], Danijela Vojnović-Milutinović[1], Ana Djordjevic[1], Nataša Veličković[1]. *[1]Institute for Biological Research "Siniša Stanković"- National Institute of Republic of Serbia, Belgrade, Serbia; [2]Euromedik Healthcare System, Belgrade, Serbia; [3]School of Science and Technology, Örebro University, Örebro, Sweden; [4]School of Medical Sciences, Örebro University, Örebro, Sweden, [5]AmsterdamUMC, University of Amsterdam, Amsterdam, Netherlands*
Email: milos.vratarić@ibiss.bg.ac.rs

Background and aims: Metabolic dysfunction–associated steatotic liver disease (MASLD) is characterized by complex interactions between the gut microbiota and host lipid metabolism, mediated by bacterial metabolites. Single-omics approach provides limited insight into these interactions, and integrated multi-omics analysis is needed for a better understanding of the gut-liver axis. This study aims to investigate differences in gut microbiota composition, and lipid and metabolite profiles characteristic of overweight adults with and without MASLD, using an integrated multi-omics approach.
Method: We conducted a cross-sectional observational study and performed fecal metagenomics analysis, as well as untargeted metabolomics and lipidomics analysis of plasma samples from overweight male and female patients with ultrasound-confirmed MASLD (n = 71) and without MASLD (n = 49). DIABLO framework was used to identify multi-omics biomarker panels of bacterial taxa, metabolites, and lipids that can distinguish overweight participants with and without MASLD.
Results: The MASLD group showed a less favorable metabolic profile, characterized by higher body mass index and waist circumference, elevated hepatic enzymes, fasting glucose and triglycerides. Single-omics block analyses provided moderate discrimination between groups, with areas under the curve (AUCs) ranging from 0.657 to 0.734. Integration of all three omics layers using the DIABLO framework improved discrimination, yielding an AUC of 0.811. Lipidomic block in Non-MASLD was dominated by lysophosphatidylcholines (LPCs), including LPC O-22:4, LPC O-20:1, LPC O-22:2, while metabolomics block featured mainly Non-MASLD- dominant contributors. In the microbiota block, Non-MASLD group showed higher abundance of *Romboutsia*, *Gemmiger formicilis*, and *Roseburia*, whereas MASLD showed higher *Acutalibacter*, *Blautia caecimuris*, the *Ruminococcus gnavus* group. Cross-layer correlation analysis identified *B. caecimuris* as the strongest cross-omics correlate, showing positive correlations with proinflammatory genera *Holdemania*, *Bilophila* and *Schaalia*, and negative correlations with beneficial *Parasutterella excrementihominis* and *Turicibacter sanguinis* in MASLD group.
Conclusion: Using a multi-omics integration approach, our study reveals microbial consortia associated with the MASLD phenotype in overweight patients. The next step will be to identify small synergistic bacterial consortia as potential therapeutic candidates for MASLD.

SAT-352-YI
Loss of crypt-adjacent barrier-supportive macrophages promotes gut barrier failure and organ injury in alcohol-related hepatitis

Joscha Vonderlin[1], Manqiang Lin[1], Juan Wang[1], Pavitra Kumar[1], Paul Horn[1], Michael Sigal[1], Frank Tacke[1], Felix Heymann[1], Moritz Peiseler[1], Cornelius Engelmann[1]. *[1]Department of Hepatology and Gastroenterology, Charité-Universitätsmedizin Berlin, Campus Virchow-Klinikum and Campus Charité Mitte, Berlin, Germany*
Email: joscha.vonderlin@charite.de

Background and aims: Patients with alcohol-related hepatitis (AH) are at high risk for progression to acute-on-chronic liver failure (ACLF). Intestinal dysbiosis and gut barrier dysfunction contribute to organ injury and inflammation, yet the underlying mechanisms remain poorly understood. We investigated gut barrier dysfunction and the role of intestinal macrophages in organ injury during acute-on-chronic metabolic injury.
Method: *CX3CR1-GFP* reporter mice were fed a Western diet with 10% ethanol for four weeks followed by ethanol binge 24 h before sacrifice. Liver injury was assessed by TUNEL staining, gut barrier dysfunction by multiplex IHC and multiphoton intravital microscopy (IVM). Immune cells were characterized by spectral flow cytometry, dysbiosis by 16 s rRNA seq. Single-cell RNA seq and 10× Xenium spatial platform was used for (spatial) transcriptional profiling. Macrophage-epithelial crosstalk was functionally tested in intestinal assembloid co-cultures. Human validation was performed with 10× Xenium spatial transcriptomics of colon biopsies from ACLF patients.
Results: Liver injury was most pronounced under acute-on-chronic stress. Whereas acute ethanol binge affected the small intestine, chronic and acute-on-chronic injury predominantly targeted the colon, resulting in impaired gut integrity, loss of barrier function,

Ly6Chi monocyte accumulation, reduced GFP$^+$ macrophage size by IVM and dysbiosis. Whilst macrophages after acute ethanol binge promoted proliferation in intestinal assembloids, this effect was abrogated in chronic and acute-on-chronic condition. Single-cell RNA sequencing revealed profound remodeling of colon macrophage compartments under chronic and acute-on-chronic stress, characterized by marked shifts in tissue-resident and monocyte-derived macrophage composition. Loss of crypt-adjacent *Retnla*$^+$*Lpl*$^+$ macrophages led to loss of barrier-supportive factors (Wnt11, PGE2), impaired epithelial regeneration, and extensive inflammatory and stress-related transcriptional reprogramming under acute-on-chronic condition.
Conclusion: The colon is a central driver of organ injury in metabolic and alcohol-related liver disease. Loss of gut function and altered colonic macrophage composition emerge as key contributors, highlighting potential targets to prevent progression to ACLF. We identify a crypt-adjacent, barrier-supportive macrophage population whose loss under chronic metabolic stress is associated with increased gut permeability and susceptibility to secondary insults in gut and liver.

SAT-353
Gut microbiota metabolite butyrate ameliorated acute-on-chronic liver failure by regulating macrophage polarization
Jing Xiao[1], Hang You[1], Zongyi Liu[1], Yong Sun[1], Yu Zhang[1], Li Wei[1], Hong Ren[1], Shiying Li[1], Peng Hu[1], Mingli Peng[1]. [1]*Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China*
Email: xiaojingabu@163.com

Background and aims: Gut microbiota dysbiosis and its metabolites disorders drive the progression of Acute-on-chronic liver failure (ACLF) through the gut-liver axis, but the specific mechanisms and intervention targets remain unclear. This study reveals the core protective role and mechanism of the microbially derived metabolite butyrate in ACLF.
Method: Blood and stool samples were collected from 50 patients with liver disease at different stages and subjected to metagenomic, metabolomic, and transcriptomic sequencing to elucidate the microbiota-metabolism-immune characteristics of ACLF. We evaluated changes in gut microbiota composition, short-chain fatty acids, intestinal barrier integrity, liver injury, and immune cell function following fecal microbiota transplantation (FMT) and butyrate supplementation, and explored specific regulatory mechanisms in ACLF mouse models and RAW264.7 cells.
Results: ACLF patients exhibited a significant reduction in gut microbial diversity, characterized by depletion of butyrate-producing bacteria (*Eubacterium, Clostridium, Ruminococcus, Blautia and Odoribacter*) and enrichment of opportunistic pathogens (*Klebsiella*, *Escherichia* and *Enterococcus*). Concurrent with decreased fecal butyrate levels, ACLF patients exhibited elevated levels of intestinal barrier markers D-lactic acid and lipopolysaccharide (LPS), and peripheral monocyte/macrophage infiltration and enhanced M1 polarization. FMT experiments confirmed that microbiota from ACLF patients could induce butyrate metabolic deficiency, barrier impairment, and exacerbated hepatic inflammation in recipient mice. Mechanistically, butyrate supplementation effectively reversed these pathological alterations. It remodeled the gut microbiota, promoting the colonization of beneficial bacteria *Odoribacter*, repaired intestinal tight junction protein expression, reduced plasm LPS levels, and significantly suppressed M1 macrophage polarization both in the liver and peripheral blood. Further investigation revealed that butyrate inhibited the phosphorylation of the mitogen-activated protein kinase signaling pathway within macrophages, thereby suppressing their polarization towards the pro-inflammatory M1 phenotype.
Conclusion: This study reveals a dysfunctional microbiota-metabolism-immune axis centered on butyrate depletion in ACLF, modulating butyrate represented a potential therapeutic strategy for ACLF.

SAT-354-YI
Bile mycobiome diversity classifies fungal peptide signature for early prediction of gallbladder carcinoma
Sanju Yadav[1], Nupur Sharma[1], Manisha Yadav[1], Neha Sharma[1], Gaurav Tripathi[1], Sushmita Pandey[1], Babu Mathew[1], Vasundhra Bindal[1], Vipul Sharma[1], Viniyendra Pamecha[1], Jaswinder Maras[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Carcinoma of Gallbladder (CAGB) has poor prognosis. While the bile microbiome and lipidome are associated with CAGB development, the contribution of fungal mycobiome is unexplored. Our study aims to investigate the fungal Mycobiome diversity and correlate it with the incidence of CAGB with classification of top fungal peptides to potentially stratify CAGB patients.
Method: Bile samples were collected from patients undergoing cholecystectomy for Gallstone (GS) disease (n = 30), patients undergoing surgery for CAGB (n = 30), and healthy liver donors (n = 20) were subjected to fungal peptide-based diversity analysis and metabolomics. Results were cross-validated in 80 patients on the plasma samples, correlated with clinical parameters, and subjected to machine learning analysis.
Results: Fungal peptide-based diversity analysis identified 6-Phyla and 24-Fungal species differentially regulated in the bile samples of the study cohort. Fungal diversity (alpha and beta diversity) was significantly higher in CAGB as compared to GS or HC ($p < 0.05$). 93 fungal peptides were upregulated and 63 were downregulated in CAGB ($p < 0.05$, FC>1.5). Linear discriminant analysis significantly segregated CAGB patients with marked increase in Aspergillus wentii (log2FC-12.21), Nosema bombycis (log2FC-11.25), Saccharomyces (log2FC-10.89), Saccharomyces cerevisiae (log2FC-10.68), and Schizosaccharomyces pombe (log2FC-10.38; $p < 0.05$) in the bile samples. Fungal-metabolite correlation analysis (r2>5, $p < 0.05$) identified Aspergillus wentii, Nosema bombycis, and others directly associated with lysine biosynthesis, taurine, and hypotaurine metabolism, fatty acid, and other in bile, and cysteine and methionine metabolism, ascorbate metabolism, purine metabolism, and others in plasma. Probability of detection (POD) calculated using fungal peptides showed a diagnostic efficiency of 96% for segregation of CAGB patients. The identified top 5 fungal peptides were validated using Single Reaction Monitoring analysis that predicted early mortality>90% accuracy/sensitivity, and specificity in a Machine Learning model.
Conclusion: CAGB patients showcase a distinct fungal diversity and identifies fungal peptide panel capable of segregation and early diagnosis of CAGB patients.

SAT-355
Microbial Streptococcal collagen like-1 protein activates fibrosis via transforming growth factor beta receptor 1 kinase in alcohol-associated liver disease
Manisha Yadav[1], Gaurav Tripathi[1], Jayesh Kumar Sevak[1], Vasundhra Bindal[1], Neha Sharma[1], Sanju Yadav[1], Nupur Sharma[1], Babu Mathew[1], Yash Magar[1], Sushmita Pandey[1], Rimsha Rimsha[1], Abhishak Gupta[2], Anupama Kumari[1], Shvetank Sharma[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India;* [2]*Artemis Hospital Gurgaon, Gurugram, India*
Email: jassi2param@gmail.com

Background and aims: Alcohol alters gut microbiota, leading to immune dysregulation and liver injury. We investigated how alcohol-related gut microbiota (AGM) reprogram hepatic kinase signaling to drive inflammation and fibrosis in alcohol related liver disease (ALD), and whether these effects can be reversed by fecal microbiota transplantation (FMT).
Method: Liver kinome and stool metaproteome changes were studied in rats (n = 6/group) colonized with severe alcohol-related

hepatitis patients stool (Group I) or ALD rats colonised with healthy human-donors stool (Group II). AGM-linked liver kinome changes were correlated with bacterial genera. Microbial protein; Streptococcal collagen-like protein 1 (Scl1) showed affinity for TGFβR1 and was screened in stool (n = 24), liver (n = 19) of SAH patients and ALD rats. The diagnostic utility of Scl1 for predicting outcome in SAH was validated in 88 patients, and FMT was employed to reduce streptococcal and Scl1 levels.

Results: Stool metaproteomics showed significant increase in *Streptococcus, Staphylococcus,* and *Clostridium* genera both in group I and group II stool (FC>1.5, $p < 0.05$) along with 34kinases associated with inflammation (Mapk14, Map3k10), fibrosis (Tgfbr1, Igf1r), lipid metabolism and regeneration (Met, Bmpr1a) in liver. FMT from healthy donors to ALD rats reversed the expression of *Streptococcus* (10-fold), *Staphylococcus* (3-fold), and *Clostridium* (5-fold), along with 18 kinases associated with inflammation (Btk, Camk4, Nuak1) and fibrosis (Tgfbr1, Col4a1, Fgfr2). Streptococcus showed strong correlation with TGFbR1 kinase. Scl1 (mimics human-collagen structurally) showed strong affinity for TGFβR1 and was significantly elevated in SAH and ALD-rat stool and liver samples (FC>2, $p < 0.05$). Expression of Scl1 was highest amongst all the known ligands for TGFβR1 such as cola1, cola2, tgfb1, and tgfb2 as its abundance was highest suggesting Scl1 as a major contributor for TGFβR1-activation Following FMT, Scl1-levels in plasma and *Streptococcus*-levels in stool significantly reduced by 2.1-folds and 1.9-folds respectively in SAH-patients and Scl1 also predicted poor response and 30-day mortality with high accuracy 0.92-AUC.

Conclusion: Alcohol-induced gut dysbiosis promotes accumulation of Streptococcal Scl1 protein in human gut which mimics human collagen thus has affinity for binding and activating TGFβR1 kinase. Scl1 also predicts poor response in SAH. FMT from healthy donors restores microbial balance and mitigates harmful host-microbe interactions.

SAT-356

Bifidobacterium pseudolongum-derived inosine mitigates polystyrene nanoplastics-induced hepatic injury by inhibiting the polarization of M1 macrophages

Kaikai Zhang[1], Yuchuan Chen[1], Jiayuan Wan[1], Jianzheng Yang[2], Lijian Chen[2], Anding Zhou[2], Qingyuan Li[2], Nian Zhou[2], Jiuyang Ding[2], Qi Wang[2], Jian Sun[1]. *[1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, State Key Laboratory of Multi-organ Injury Prevention and Treatment, Key Laboratory of Infectious Diseases Research in South China, Ministry of Education, Guangdong Provincial Key Laboratory for Prevention and Control of Major Liver Diseases, Guangdong Provincial Clinical Research Center for Viral Hepatitis, Guangdong Institute of Hepatology, Guangdong Provincial Research Center for Liver Fibrosis Engineering and Technology, Guangzhou, China; [2]Guangzhou Key Laboratory of Forensic Multi-Omics for Precision Identification, School of Forensic Medicine, Southern Medical University, Guangzhou, China*
Email: sunjian@smu.edu.cn

Background and aims: Nanoplastics (NPs) are ubiquitous pollutants that disturb gut microbiota and cause hepatic injury. Gut microbiota is considered a contributing factor to multiple hepatic injuries. However, its role in NPs-induced hepatic injury remains unclear. Here, we aims to reveal the microbial mechanisms underlying NPs-induced hepatic injury and explore possible strategies targeted at gut microbiota.

Method: 7-week-old male C57BL/6J mice were orally administered with NPs for 28 days to induce hepatic injury. Gut microbiota from NPs-adminstered mice was transplanted into recipients by fecal microbiota transplantation to investigate the role of gut microbiota. *Bifidobacterium pseudolongum* (*B.p*) colonization and its metabolite inosine supplementation were performed to explore their protection on NPs-induced hepatic injury.

Results: Exposure to NPs significantly reduced gut probiotic *Bifidobacterium pseudolongum* (*B.p*) and its metabolite inosine. Gut microbiota from NPs-adminitered mice partially reproduced NPs-related impairment of gut homeostasis and hepatic injury in recipient mice. Moreover, *B.p* colonization improved NPs-induced impairment of gut homeostasis and hepatic injury, and its protective effects were reproduced by supplementation with inosine. Mechanically, *B.p* colonization ameliorated NPs-induced decrease of hepatic inosine and subsequently normalized the expression of its target adenosine receptor A2a (A2AR). Meanwhile, increased inosine inhibited the miR155/SOCS1/NF-κB pathway and repressed NPs-induced hepatic M1 macrophage polarization. Additionally, miR155 knockout alleviated NPs-induced hepatic injury by inhibiting M1 macrophage polarization, but did not influence the suppression of NPs on A2AR. *In vitro*, CGS21680 (an agonist of A2AR) repressed lipopolysaccharide (LPS)-induced polarization of M1 macrophages by inhibiting the miR155/SOCS1/NF-κB pathway.

Conclusion: Gut microbiota partly mediates NPs-induced hepatic injury. *B.p*-derived inosine represses NPs-induced M1 macrophages polarization by inhibiting the miR155/SOCS1/NF-κB pathway via targeting A2AR. Our findings further clarifies the role of gut microbiota in NPs-induced hepatic injury and provides a potential microbial therapeutic strategy.

Single-cell and spatial transcriptomic profiling of cross-species livers: evaluating genetically engineered pig livers for clinical xenotransplantation

Siming Kong[1], Mingshuo Wang[1], Rongyan Yao[1], Yakun Liu[1], Congwen Bian[2], Bin Wang[1], Tianzi Luo[1], Hui Bai[1], Yunfang Wang[1], Zhong Zeng[2], Jiahong Dong[3]. *[1]Center for Clinical and Translational Science, Beijing Tsinghua Changgung Hospital, Tsinghua University, Beijing, China, Beijing, China; [2]Department of Organ Transplantation, The First Affiliated Hospital of Kunming Medical University, Kunming, China, Kunming, China; [3]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China, Beijing, China*
Email: ksm09410@163.com

Background and aims: Liver xenotransplantation from genetically engineered pigs holds great clinical potential to address the donor organ shortage. However, the molecular and cellular compatibility of pig livers with human physiology remains incompletely understood, particularly regarding lobular zonation and cell-type-specific gene expression. This study aims to perform an integrated single-cell and spatial transcriptomic comparison of human, macaque, wild-type, and gene-edited pig livers, in order to identify transcriptional features that may inform graft selection and immune modulation in clinical xenotransplantation.

Method: Liver tissues from healthy human donors, macaques, wild-type pigs, and multi-gene-edited pigs (8- and 10-gene edits targeting xenoantigens and immunoregulation) were analyzed. Single-cell RNA sequencing (10× Genomics) and spatial transcriptomics (Visium and Stereo-seq) were performed. Cross-species integration, cell type annotation, and zonation analysis were conducted using Seurat, Harmony, and spatial mapping tools. Comparative analyses assessed evolutionary conservation across species and transcriptional alterations in gene-edited pigs relative to wild-type and human reference livers in major hepatic cell types.

Results: Integrated single-cell and spatial transcriptomic analysis revealed a conserved architecture of major hepatic cell types across human, macaque, and wild-type pig livers. We identified distinct transcriptional gradients from periportal to pericentral zones in

metabolic and immune-related pathways common to all species, including—importantly—the first spatial characterization of zonation patterns in pig liver. Compared to wild-type pigs, livers from both 8- and 10-gene-edited pigs showed downregulation of key xenoantigen-related genes in endothelial and Kupffer cells. Spatial analysis indicated preserved lobular organization in edited livers, with intact zonation gradients and transcriptional changes in periportal regions associated with immune regulation.
Conclusion: This study establishes a cross-species transcriptional and spatial resource for liver xenotransplantation research, highlighting the potential of gene-edited pig livers to approximate human hepatic molecular and structural features. Our findings underscore the value of zonation-aware profiling in evaluating donor livers and support further preclinical validation of multi-gene-edited pigs for clinical translation.

THU-303

Dimorphic response between the classical and alternative pathways of liver bile acid synthesis after feeding a high in sucrose and fat, choline-deficient, L-amino acid defined diet to Sprague-Dawley rats

Jianing Zhou [1], Yanhao Qiu[1], Laia Vilà[1,2], Emma Barroso[1,3], Marta Alegret[1,3,4], Núria Roglans[1,3,4], Juan Carlos Laguna[1,3,4]. *[1]School of Pharmacy and Food Sciences, Universitat de Barcelona, Barcelona, Spain; [2]Barcelona, Spain; [3]IBUB, Barcelona, Spain; [4]CIBERObn, Barcelona, Spain*
Email: jclagunae@ub.edu

Background and aims: We have previously shown a clear sexual dimorphism in the fibrotic response of SD rats to a CDAA diet, with only males developing MASH (*J Hepatol* 2025 82 (Suppl 1) FRI-344). In the present work we demonstrate that the CDAA diet also modifies the liver biosynthesis of bile acids (BA) in a dimorphic way.
Method: Male (M) and female (F) SD rats were randomly distributed into 2 groups each: (1) control (CT; standard rodent chow, n = 4), and (2) CDAA (n = 8) and were fed the CT and CDAA diets for three months. At the end of the treatment, rats fasted for 2 h were sacrificed and liver tissue and faecal content were collected and properly stored. The concentrations of 10 BA (cholic acid, chenodeoxycholic acid (CDCA), deoxycholic acid (DCA), lithocholic acid (LCA), ursodeoxycholic acid (UDCA), α-muricholic acid (MCA), β-MCA, hyocholic acid (HCA), hyodeoxycholic acid (HDCA), and murideoxycholic acid (MDCA)) in rat faeces were determined by ultra-high-performance liquid chromatography coupled to tandem mass spectrometry (UHPLC-MS/MS), as described previously (Biomed&Pharmacother 177 (2024) 117067). Liver expression of pertinent genes related to primary BA synthesis was determined.
Results: Control-fed M and F SD rats showed almost no differences in their faecal BA concentrations, except in the case of DCA (×0.59 F *vs* M, p = 0.029). CDAA-fed M and F rats showed marked increases in primary, and total faecal BA concentrations with respect to CT values. However, only CDAA-fed F SD rats showed significant increases in CDCA, UDCA, DCA, LCA, HCA, HDCA, MDCA and MDCA and secondary BA. Furthermore, the total concentration of 12-OH BA (CA, DCA and MDCA) was decreased in CDAA-fed F (×0.78 F *vs* M, p = 0.012), while the total concentration of non-OH BA (CDCA, alpha and beta MCA, HCA, UDCA and LC) was increased (×2.09 F *vs* M, p = 0.0001), pointing to a shift from the classical to the alternative pathway of BA synthesis. Changes in the expression of key enzymes of BA synthesis, such as cytochrome (CYP) 7A1, CYP7B1 and CYP8B1 were in accordance with this shift in the predominant biosynthetic pathway.
Conclusion: There is a clear sexual dimorphism in liver bile acid synthesis induced by feeding a CDAA diet to SD, characterized by an increased activity of the alternative pathway of BA synthesis and an increased production of secondary BA only in F rats.
Funded by PID2023-146140OB-I00 (MICIU/AEI/10.13039/501100011033) and FEDER-UE and 2021SGR-00345.

THU-313

Expandable non-tumorigenic primary-like human hepatocytes from humanized mouse livers retain hepatic function, enable in vivo engraftment, and support robust HBV infection assays

Lennard Anders[1], Lisa Staffeldt[2,3], Lisa Groß[1], Luise Herling[1], Natalie Herzog[1], Anika Volmar[3], Götz Rövenstrunk[3], Tassilo Volz[2,4], Jan-Heiner Küpper[1], Maura Dandri[2,4], Stefan Lüth[3,5], Janine Kah[2,3,5], Sarah Kammerer[1]. *[1]Institute of Biotechnology, BTU Cottbus-Senftenberg, Brandenburg, Germany; [2]Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Faculty of Health Sciences Brandenburg, Brandenburg Medical School Theodor Fontane, Brandenburg, Germany; [4]German Center for Infection Research, Hamburg-Lübeck-Borstel Partner Site, Hamburg, Germany; [5]Department of Gastroenterology, Center for Translational Medicine, University Hospital Brandenburg, Brandenburg Medical School Theodor Fontane, Brandenburg, Germany*
Email: lennard-anders@b-tu.de

Background and aims: Freshly isolated primary human hepatocytes (PHH) are the gold standard for liver metabolism and hepatitis B virus (HBV) studies, but limited availability and rapid loss of function limit routine use. We aimed to establish expandable primary-like human hepatocytes (PLHH) from humanized mouse livers and to evaluate their drug metabolism capacity, *in vivo* behavior, and HBV permissiveness.
Method: Single donor PHH were isolated from urokinase-type plasminogen activator/severe combined immunodeficiency (uPA/SCID) mice after successful liver engraftment. Upcyte technology was used to induce proliferation, followed by clonal selection and characterization by quantitative polymerase chain reaction (qPCR) and immunofluorescence. Cytochrome P450 (CYP) activities were quantified by high-performance liquid chromatography with and without induction. Liver repopulation was tested by intrasplenic transplantation into uPA/SCID mice. Carcinogenic properties were evaluated by orthotopic transplantation of luciferase-labeled cells into NOD SCID gamma (NSG) mice. For HBV infection, cultivated cells were inoculated and extracellular HBV DNA was quantified after sequential medium washes; intracellular HBV DNA was quantified by qPCR.
Results: Selected clones proliferated with a population doubling time of 41.0 ± 1.7 h while retaining hepatocyte-like morphology and marker expression. Clones showed donor-dependent CYP expression/activity and were CYP-inducible. Human marker-positive clusters were detected in recipient uPA/SCID livers after transplantation. In NSG mice, bioluminescence signals from transplanted cells were absent or declined over time, indicating no tumour formation. In contrast, HuH7 (positive control) transplantation led to increased liver size and weight. After HBV inoculation, initial supernatant HBV DNA reached 1.4×10^9 IU/mL in Upcyte clones versus 2.7×10^8 IU/mL in HepaRG and decreased with washes to 4.96×10^6 IU/mL (Upcyte clone HU5221), 1.42×10^6 IU/mL (HepaRG) and 1.5×10^5 IU/mL (clone HU1721). Intracellular HBV DNA was up to 80 times higher in Upcyte clones than in HepaRG.
Conclusion: Expandable PLHH isolated and generated from humanized mouse livers combine proliferative capacity with maintaining CYP-dependent drug metabolism, *in vivo* liver repopulation without tumorigenicity, and are suitable for robust HBV studies. This platform can complement PHH for scalable studies on xenobiotic metabolism, HBV biology and many more.

Background and aims: Cell-type reprogramming in the liver contributes to the changes accompanying liver disease by regulating nutrient availability and producing metabolites that influence disease progression, resolution, or cancer cell growth. Mitochondria integrate cellular metabolism with cell fate decisions and play a central role in liver disease progression. Succinate dehydrogenase (SDH) functions in both the TCA cycle and the electron transport chain and is essential for tissue homeostasis and cell proliferation. This study aimed to investigate how metabolic alterations resulting from SDH deregulation influence hepatocyte plasticity, potentially revealing novel therapeutic strategies targeting metabolic vulnerabilities.
Method: Hepatocarcinoma (HCC) and control tissues (surrounding or normal liver) from two independent patient cohorts were used to investigate gene expression. A hepatocyte-specific SDH knockout mouse model (LSDH) was generated using the Cre-LoxP system. Biochemical and morphological analyses, including optical and ultrastructural studies, were performed. Mitochondrial metabolism was assessed by measuring OXPHOS protein levels and activity, Seahorse assays, and genomic and targeted quantitative liquid chromatography–mass spectrometry (LC-MS) analyses.
Results: *SDHD* mRNA expression and SDH enzymatic activity were significantly reduced in human HCC samples compared with non-tumor and healthy liver tissues. Hepatocyte-specific loss of SDH demonstrated its critical role in maintaining metabolic homeostasis. LSDH mouse livers exhibited liver damage and altered cellular bioenergetics, characterized by a metabolic shift toward increased glycolysis, glycolytic capacity, and glycolytic reserve. SDH ablation promoted pyruvate consumption to sustain maximal glycolytic flux, associated with increased pyruvate carboxylase expression and reduced pyruvate dehydrogenase activity. Metabolic remodeling induced by SDH loss activated the mammalian target of rapamycin (mTOR) pathway, enhanced lipid synthesis, enriched integrated stress response (ISR) gene expression, and impaired mitochondrial complexes I and IV. Notably, the deleterious effects of SDH inhibition were partially mitigated by a specialized diet.
Conclusion: These findings reveal hepatocyte plasticity under SDH deficiency and define a therapeutically exploitable metabolic vulnerability, enabling intervention strategies aimed at restoring metabolic homeostasis or inducing cell death, depending on the therapeutic objective.

Email: cconter@cicbiogune.es

Background and aims: Circadian misalignment, as occurs during night-shift work, challenges the liver to adjust its metabolic and transcriptional pathways in response to altered feeding times. Analysis of publicly available liver transcriptomic datasets revealed oscillatory expression of the Cyclin M1 magnesium transporter (CNNM1), a protein normally expressed at low levels in the liver, suggesting a potential role in hepatic adaptation to feeding-time shifts. Here, we investigated whether CNNM1 is required for the liver to respond to inverted feeding.
Method: Male Alb-Cre mice were assigned to three groups: ad libitum control, inverted feeding, or inverted feeding with hepatic *Cnnm1* silencing via a Cre-dependent AAV8. Inverted feeding was implemented using smart-cage feeders (8am–8pm) to simulate night-shift conditions for 3 weeks, with identical diet composition and caloric intake across groups. Liver samples were analyzed using metabolic, proteomic, and epigenetic approaches.
Results: Hepatic *Cnnm1* silencing considerably disrupted the liver's adaptive response to inverted feeding. In response to inverted feeding, livers underwent robust transcriptional and proteomic remodeling, reflecting metabolic adaptation to the shifted feeding schedule. By contrast, livers with hepatic *Cnnm1* silencing largely failed to respond to inverted feeding and instead maintained transcriptional and proteomic profiles similar to ad-libitum controls, indicating a loss of feeding-time–dependent metabolic flexibility. In particular, lipid biosynthesis, that were strongly activated in inverted-

feeding mice,remained largely unchanged in *Cnnm1*-silenced livers at both transcriptional and protein levels. Epigenetically, proteomic analysis identified KDM5A, a histone demethylase, as a downstream effector associated with CNNM1 silencing, while Western blot confirmed modulation of WDR5, a key chromatin regulator. These changes were accompanied by alterations in associated histone marks, demonstrating that CNNM1 is required for adaptive chromatin remodeling during inverted feeding.
Conclusion: CNNM1, although typically expressed at low levels in the liver, is essential for both metabolic and epigenetic reprogramming in response to circadian feeding disruption. Its absence locks the liver in a control-like state, preventing adaptation to inverted feeding and highlighting that even a decreased expressed magnesium transporter can exert a profound effect on hepatic metabolic flexibility in mice mimicking night-shift work conditions.

THU-316
When the clock breaks: H2S as a link between night shift work and metabolic health

Email: cconter@cicbiogune.es

Background and aims: Night-shift work disrupts circadian rhythms, increasing the risk of metabolic and liver dysfunction. Feeding schedules are emerging as key regulators of hydrogen sulfide (H_2S) metabolism, redox balance, and one-carbon pathways. We aimed to determine how circadian feeding disruption affects peripheral metabolism, particularly hepatic transsulfuration and related pathways, and whether a targeted plant-based diet can restore metabolic homeostasis and induce metabolic rewiring.
Method: Male C57BL/6 mice were assigned to three groups: ad libitum control feeding with chow diet, inverted feeding with chow diet, or inverted feeding with a plant-based diet composed of chickpea, pea, and lentil flours for three weeks. Inverted feeding was implemented using smart-cage feeders (8am–8pm) to simulate night-shift conditions. Hepatic and systemic H_2S production, oxidative stress, and metabolites in the transsulfuration, methionine, folate and polyamines pathways were measured. Transcript levels of the H_2S-producing enzymes cystathionine beta-synthase (CBS), cystathionine gamma-lyase (CSE), and mercaptopyruvate sulfurtransferase (MPST) were quantified.
Results: Inverted feeding increased mice body weight, fasting glucose, and insulin resistance. At the hepatic level, it reduced H_2S production, induced oxidative stress, and disrupted methionine, transsulfuration, folate, and polyamine metabolism, accompanied by significant downregulation of CBS expression. Inverted feeding with the plant-based diet restored hepatic H_2S levels, improved redox balance, and induced profound metabolic rewiring, normalizing folate- and betaine-dependent fluxes across interconnected pathways. Hepatic phosphoserine aminotransferase expression increased 185-fold, reflecting extensive adaptive remodeling of liver metabolism.
Conclusion: Our murine model of night shift work disrupts H_2S-dependent transsulfuration and alters one-carbon metabolism, leading to oxidative stress and metabolic imbalance in the liver. A legume-based plant diet effectively reverses these changes, promotes metabolic rewiring, increases H_2S availability, and restores methionine, transsulfuration, folate, and polyamine metabolism. These results highlight how night shift work may influence liver metabolism and suggest that targeted dietary interventions could help mitigate the metabolic consequences associated with night shift schedules.

Peptide-decorated DNA nanostructures enable programmable lysosomal interference in liver cells
Petra Elblová[1], Minghui Liu[2], Alicia Calé[1], Hana Andělová[3], Mariia Lunova[4], Milan Jirsa[4], Nicholas Stephanopoulos[2], Oleg Lunov[3]. *[1]Department of Optical and Biophysical Systems, Institute of Physics of the Czech Academy of Sciences, Prague, 18221, Czech Republic, Faculty of Mathematics and Physics, Charles University, Prague, 12116, Czech Republic, Prague, Czech Republic; [2]School of Molecular Sciences, Arizona State University, Tempe, Arizona 85287, United States, Biodesign Center for Molecular Design and Biomimetics, Arizona State University, Tempe, United States, Tempe, United States; [3]Department of Optical and Biophysical Systems, Institute of Physics of the Czech Academy of Sciences, Prague, 18221, Czech Republic, Prague, Czech Republic; [4]Institute for Clinical & Experimental Medicine (IKEM), Prague, 14021, Czech Republic, Prague, Czech Republic*
Email: elblova@fzu.cz

Background and aims: DNA nanostructures provide programmability at the molecular level and geometric control. Although lysosomes are an essential focus within cells for liver cell metabolism, immune response signaling, and cell death pathways, there have been no rational approaches toward manipulating lysosomal functionality. We set out with the objective of developing a simple biodegradable DNA nanostructure platform with controlled lysosomal interference within liver cell models and understanding the influences of surface chemistry and cell mechanics.
Method: A six-helix bundle DNA structure was created and electrostatically coated with either a decalysine peptide or a bioplex peptide composed of an aurein 1.2 sequence. The cell models were based on human liver cell lines, including HepG2 and Huh7, as well as an Alexander cell line. Uptake experiments were conducted under

specific geometric constraints. The effects on lysosomal localization, pH, structure, metabolism, immune response, and cytotoxicity were measured. Techniques included high-resolution confocal microscopy and Förster resonance energy transfer.
Results: Uptake of DNA nanostructures was highly dependent on actin cytoskeletal rearrangement due to geometric constraints, thus underlining the importance of cellular mechanics as a determinant for nanostructure internalization. After internalization, the nanostructures localized within lysosomes, and these lysosomes displayed responses based on surface peptide conjugation. At low doses, conjugation with decalysine-coated nanostructures caused lysosomal acidification and changes in cellular metabolism without inducing cytotoxic effects. Conversely, aurein-based peptide-coated nanostructures triggered an increase in lysosomal pH and innate immune signaling. Higher doses caused permeabilization of lysosomal membranes and mitochondrial dysfunction and death. Notably, these responses could be controlled based on concentration using the same DNA scaffold.
Conclusion: DNA nanostructures with minimal peptide decoration offer a rational and flexible platform for targeted interference in lysosomes within hepatocytes. By combining nanostructure research with cellular biomechanics, it becomes possible to have controlled modulation of lysosomal function and activity, as well as immune and cell viability responses. These research works have set fundamental guidelines for the generation of organelle-directed nanomaterials.

Email: dineshmanitripathi@gmail.com

Background and aims: Cholestasis can cause severe hepatotoxicity and increased biliary pressure leading to biliary hypertension. Dynamic changes occurring in hepatocytes in biliary pressure dependent manner remains unexplored. We aimed to investigate bile canalicular metabolic dynamics and adaptation in response to bile fluid stasis and underlying mechanisms.
Method: Primary hepatocyte isolated from bile duct ligation model (BDL) after 2 h, 4 h, 24 h, 7 d, molecular analysis, unbiased proteomics, metabolomic studies were done. Bile fluid dynamics, Biochemical, histological, imaging, SEM/TEM carried out.
Results: Increased hepatocyte CD13 expression and SEM confirmed progressive bile canalicular dilation. Multiomic profiling of primary hepatocyte post BDL reveals cellular reprogramming. At 24 h proteomics revealed early cytoskeletal destabilization (KRT6A −4, KRT14 −1.6, MACF1 −3.4, DSTN −2, ACTB −1.8 and cofilin −1.6). Suppression of junctional proteins (Connexin32 −2.3, Connexin26 −1.9, IntegrinB1 −2.1 and Claudin −1.8) indicating loss of hepatocyte polarity and canalicular integrity supported by depletion of spisulosine and sphinganine. Nuclear-deformation aligned with transmission of mechanical stress to nucleus, consistent with TEM. Metabolically, early BDL(2–4 h) induced rapid metabolic suppression, redox adaptation (GSTA1 −2.2, GLUL −3.3 and CYP2C11 −3.3), alongside metabolomic enrichment of carnitine (+3.1) and sulfur-containing metabolites. By 24 h, suppression of glycolysis (GCK −2.1, PFKFB1 −1.6) and lipid b-oxidation (CROT −2.5, ACSF2 −1.9, HSD17B12 −3.2), together with mitochondrial dysfunction (NDUFA3 +2.1, NDUFC2 +1.9, COQ3 −1.9, TIMM22 +2, GFM1 +1.5), depletion of spermine (−2.5) and PGE2 (-3.09) reflected metabolic collapse. By 7 d, hepatocytes exhibited inflammatory activation (haptoglobin +2.54, complement C3 +2.1), while persistent suppression of detoxification and failure of metabolic recovery. These alterations paralleled rising biliary pressure (12.2 mmHg immediate; 16 mmHg at 2–4 h, 14.2 mmHg at 24 h, 20 mmHg at 7d), similar to patients (12.6 mmHg), defining a pressure-driven cascade causing hepatocyte structural and metabolic failure.
Conclusion: Biliary hypertension disrupts bile canalicular membrane, drives cytoskeletal and nuclear changes and induces cellular stress with metabolic dysfunction in hepatocytes. This pressure-driven remodeling underlies cholestatic injury, and targeting early adaptive responses may limit disease progression.

THU-319
Molecular dynamics simulations reveal how hepatitis B virus preS1 haplotypes modulate the protective efficacy of the host sodium taurocholate cotransporting polypeptide S267F variant
Po-Hsien Hsu[1,2], Hsiang-Hsuan Chuang[2,3], Ding-Lian Wang[2,4], Chih-Jen Huang[2], Mei-Hung Pan[2], Hwai-I Yang[2]. [1]*Graduate Institute of Life Sciences, College of Biomedical Sciences, National Defense Medical University, Taipei, Taiwan;* [2]*Genomics Research Center, Academia Sinica, Taipei, Taiwan;* [3]*School of Medicine, Chung Shan Medical University, Taichung, Taiwan;* [4]*Graduate Institute of Life Science, National Defense Medical University, Taipei, Taiwan*
Email: ericchu102001@gmail.com

Background and aims: Chronic hepatitis B virus (HBV) infection is a global driver of hepatocellular carcinoma (HCC). Viral entry into hepatocytes relies on the interaction between the myristoylated preS1 domain and the host receptor sodium taurocholate cotransporting polypeptide (NTCP). The East Asian-predominant NTCP S267F variant confers protection against HBV infection and HCC; however, its protective efficacy shows marked inter-individual heterogeneity. While S267F impairs viral binding *in vitro*, the structural basis for how specific preS1 variants bypass this restriction to cause clinical heterogeneity remains unclear. We investigated these mechanisms using all-atom molecular dynamics simulations (MDS).
Method: Building on our prior deep sequencing analysis of the REVEAL-HBV cohort (n = 377), which identified NTCP S267F-dependent differences in preS1 haplotype distribution defined by residues 10, 17, and 35 (QSG vs. KAR), these haplotypes were selected as representative variants for structural simulation. Simulations of myristoylated preS1–NTCP complexes in phospholipid bilayer systems were prepared using CHARMM-GUI and performed using GROMACS with the CHARMM36 m force field. Four combinations (NTCP WT/S267F and preS1 QSG/KAR) were simulated with 1-μs production runs. Binding free energies and interfacial contact frequency were used to characterize binding stability and conformational dynamics.
Results: In alignment with our previous clinical findings that NTCP S267F confers protection against QSG-associated HCC risk, MDS demonstrated that the NTCP S267F substitution introduces steric hindrance, impairing binding stability for the QSG haplotype. In contrast, the KAR preS1 haplotype exhibited conformational compatibility with both NTCP variants, maintaining embedding and interfacial interactions across receptor backgrounds. Quantitative MDS metrics suggested that the KAR variant partially compensates for the structural constraints imposed by S267F, thereby preserving effective receptor engagement sufficient to avoid complete entry disruption.
Conclusion: Our results demonstrate that preS1 haplotypes defined by residues 10, 17, and 35 are critical determinants of the protective efficacy of the host NTCP S267F variant. The ability of the KAR haplotype to maintain receptor binding in the presence of S267F provides molecular-level evidence of host-driven viral adaptation and offers a mechanistic explanation for the observed heterogeneity in HCC risk reduction among carriers of this protective host genotype.

Plectin-dependent hepatocyte mechanics modulate liver fibrogenesis

Markéta Jiroušková[1], Srikant Ojha[1], Katerina Korelova[1], Lenka Sarnová[1], Herbert Schiller[2], Daniel Kytyr[3], Eva Sticova[4], Martin Gregor[1]. [1]*Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic;* [2]*Helmholtz Munich, Research Unit Precision Regenerative Medicine, Comprehensive Pneumology Center, Munich, Germany;* [3]*Institute of Theoretical and Applied Mechanics of the Czech Academy of Sciences, Prague, Czech Republic;* [4]*Institute for Clinical and Experimental Medicine, Prague, Czech Republic*
Email: marketa.jirouskova@img.cas.cz

Background and aims: The development of chronic liver disease on the background of fibrosis is associated with profound alterations in liver mechanical properties, which predispose the liver to malignant transformation. Using hepatocyte-specific deletion of the major cytolinker protein plectin as a model of altered hepatocyte cytoarchitecture, we investigated how modulation of the hepatic mechanical environment affects fibrosis development.
Method: Liver-specific plectin knockout ($Ple^{\Delta alb}$) mice and their wild-type counterparts were subjected to hepatotoxic fibrosis induced by carbon tetrachloride. Primary hepatocytes were used to characterize the consequences of plectin loss on hepatocyte mechanical properties, cytoskeletal organization and function *in vitro*.
Results: Exploratory analysis of human chronic liver disease datasets from the Gene Expression Omnibus revealed significant upregulation and dynamic regulation of plectin gene expression across fibrotic stages. Hepatocyte-specific plectin deficiency resulted in alterations of liver mechanical properties and was associated with significantly attenuated fibrosis development *in vivo*. Analysis of hepatic stellate cells demonstrated their delayed activation in the $Ple^{\Delta alb}$ hepatocyte environment both *in vitro* and *in vivo*, attributable to reduced parenchymal stiffening following hepatotoxic injury, as determined by atomic force microscopy. Furthermore, plectin loss enhanced hepatocyte keratin expression in response to injury, leading to activation of the pro-survival Akt pathway. *In vitro* analyses revealed that actin cytoskeleton dysregulation in plectin-deficient hepatocytes increased actomyosin contractility, contributing to protection against hepatotoxic injury. Consequently, portal vein-associated hepatocytes in $Ple^{\Delta alb}$ livers exhibited increased nuclear YAP localization, resulting in reduced apoptosis mediated in part by upregulated EGFR expression. Additionally, actin cytoskeleton dysregulation led to an expanded subpopulation of Annexin A2-positive migratory hepatocytes, which contributed to accelerated tissue repair following liver injury.
Conclusion: Together, our findings findings uncover a previously unrecognized role of plectin-dependent cytoskeletal organization in liver fibrogenesis and identify cytoskeleton-dependent mechanotransduction as a promising therapeutic target for limiting fibrosis progression.

THU-321

Precursor of chemically expanded hepatocytes (pre-cHep) with 1-million-fold expansion potential and liver repopulation capacity

Keisuke Kaji[1], Mylinh Huynh[1], Jakob Jeriha[1], Rebecca Granskog[1], Cherie Law[2], Yuichiro Higuchi[3], Stephen Tsui[2], Hiroshi Suemizu[3]. Email: keisuke.kaji@ed.ac.uk

Background and aims: Cryopreserved primary human hepatocytes (PHH) are indispensable for toxicology testing, drug screening, and disease modelling, but their limited lot sizes and variable quality hinder standardisation. Alternative cell sources, including pluripotent stem cell-derived hepatocyte-like cells, induced hepatocytes generated by fibroblast reprogramming, and immortalised hepatocyte lines, generally lack mature hepatocyte functions. Reprogramming mature hepatocytes into a proliferative state and organoid culture have recently emerged as promising strategies to expand fully functional hepatocytes; however, these cells have not maintained robust liver repopulation capacity beyond approximately 10^4-fold expansion. Therefore, we aimed to optimise hepatocyte expansion culture conditions to generate large quantities of fully functional hepatocytes for research and therapeutic applications.
Method: Previous studies have reported culture conditions that convert mature human hepatocytes into bipotent liver progenitors with high proliferative potential. In our hands combining these conditions resulted in loss of re-differentiation capacity to hepatocytes within one month. We therefore hypothesised that supplementing the culture medium with factors that promote hepatocyte maturation would keep the cells closer to mature hepatocytes and prolong their ability to re-differentiate.
Results: Consistent with this hypothesis, supplementation with forskolin, dibutyryl-cAMP, and IL-6 enabled reprogramming of mature human hepatocytes into precursor cells. These precursors of chemically expanded hepatocytes (pre-cHep) proliferated for over 30 days and achieved up to a 10^6-fold expansion, theoretically yielding 10^{12} cells from an initial 1×10^6, hepatocytes. Throughout this period, pre-cHep retained liver repopulation capacity comparable to cryopreserved PHH in immunocompromised mice. Moreover, pre-cHep efficiently differentiated into chemically expanded hepatocytes (cHep) in 7 days under 3D culture conditions, and these cHep exhibited global gene expression profiles closely resembling those of 3D-cultured adult PHH.
Conclusion: We successfully established pre-cHep lines from 9 of 10 donors (0–10 years old), underscoring the robustness and reproducibility of this culture system. Pre-cHep/cHep therefore represent a bona fide alternative to primary hepatocytes for diverse in vitro applications and constitute a potential cell source for future hepatocyte-based therapeutic strategies.

THU-322-YI

Liver-ETFDH deletion leads to cholestasis and glucose homeostasis disruption

Jose Maria Lanza-Arnaiz[1,2], Beñat Salegi Ansa[1,2], Tzoline Topdjian Panosian[1], Pablo Sánchez-Aguilera[1], Laura Formentini[1,2,3]. [1]*Centro de Biología Molecular Severo Ochoa (CBM), Universidad Autónoma de Madrid (UAM), Madrid, Spain;* [2]*Instituto de Investigación Hospital 12 de Octubre, i+12, Madrid, Spain;* [3]*Instituto de Biología Molecular (IUBM), Universidad Autónoma de Madrid (UAM), Madrid, Spain*
Email: jmlanza@cbm.csic.es

Background and aims: Electron transfer flavoprotein dehydrogenase (ETFDH) is a mitochondrial coenzyme Q reductase that acts as a central metabolic hub, coupling fatty acid oxidation (FAO) and amino acid catabolism to oxidative phosphorylation. Despite its fundamental role in cellular energy homeostasis and mitochondrial function, the pathophysiological relevance of ETFDH in liver biology remains largely unexplored. Therefore, our aim was to generate and characterize the first liver-specific ETFDH knockout mouse model, enabling the dissection of ETFDH-dependent metabolic and signalling pathways in hepatic pathophysiology.
Method: An albumin-Cre–driven ETFDH knockout (ETFDH–/–) mouse model was generated. Hepatic structure and function were assessed using serum biochemistry, histological analyses, transmission electron microscopy, and integrated proteomic and lipidomic profiling. Glucose and lipid metabolism were evaluated under both fed and fasting conditions using complementary in vivo and ex vivo metabolic approaches, including indirect calorimetry in metabolic cages, glucose and insulin tolerance tests, ex vivo liver slice metabolism, and blood hormone measurements.
Results: Hepatocyte-specific deletion of ETFDH caused a severe disruption of hepatic homeostasis. ETFDH–/– livers displayed

pronounced fibrosis and elevated serum alanine aminotransferase levels. Ultrastructural analysis revealed onion-like aberrant structures in bile canaliculi, indicative of intrahepatic cholestasis, further supported by elevated serum bile acid levels. Metabolic analyses revealed profound alterations in hepatic glucose and lipid metabolism, including impaired ketogenesis and FAO, leading to hypoglycaemia. Excess glycogen accumulation was observed under both fed and fasting conditions, indicating defective glycogenolysis. In vivo testing demonstrated glucose intolerance with preserved insulin sensitivity. Consistently, ETFDH−/− mice failed to secrete insulin in response to a glucose challenge, ultimately resulting in a systemic energy crisis and premature death due to severe hypoglycaemia during juvenile development.
Conclusion: Liver-specific deletion of ETFDH results in major disruptions of hepatic energy metabolism, affecting both fatty acid and glucose homeostasis. These alterations are associated with impaired cellular energy balance and secondary dysregulation of pancreatic endocrine function. Collectively, these findings identify ETFDH as a critical regulator of liver homeostasis and systemic metabolic balance.

Integrated proteomic and glycoproteomic landscape of human and pig liver: a cross-species comparative analysis
Yakun Liu[1], Rongyan Yao[1], Siming Kong[1], Mingshuo Wang[1], Congwen Bian[2], Bin Wang[1], Tianzi Luo[1], Hui Bai[1], Yunfang Wang[1], Zhong Zeng[2], Jiahong Dong[3]. *[1]Center for Clinical and Translational Science, Beijing Tsinghua Changgung Hospital, Tsinghua University, Beijing, China; [2]Department of Organ Transplantation, The First Affiliated Hospital of Kunming Medical University, Kunming, China; [3]Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China*
Email: mikeliuair@gmail.com

Background and aims: Liver xenotransplantation using pigs is limited by short graft survival. Although genetic editing has successfully eliminated major xenoantigens, profound molecular differences between pig and human livers persist. These residual incompatibilities have not been systematically interpreted from an integrated proteomic and glycoproteomic perspective. Here, we conducted the first human–pig liver proteome and glycoproteome comparative analysis to elucidate species- and gene-editing-dependent molecular incompatibilities and to assess whether unresolved protein and glycoform differences underlie limited xenograft survival.
Method: Perfused liver samples from two human donors (healthy human liver, HHL; brain-dead human liver, BDHL) and six pigs (wild-type pig liver, WTPL; 8 gene-edited pig liver, 8GEPL; 10 gene-edited pig liver, 10GEPL) were analyzed using label-free quantitative proteomics and glycoproteomics. Data-independent acquisition mass spectrometry was performed with searches against an in-house spectral library and the UniProt database.
Results: Proteomic analysis showed that HHL and WTPL share conserved core metabolic functions, whereas BDHL differs markedly. Compared with WTPL, 10GEPL upregulated defense and complement pathways while suppressing metabolism, whereas 8GEPL displayed attenuated though more variable changes. Notably, glycoproteomic profiling revealed increased fucosylation and sialofucosylation in gene-edited pig livers and aberrant glycosylation pattern in BDHL. After inspecting site-specific glycosylation differences across species, thirteen immune, metabolic, complement, and coagulation-related glycoproteins (e.g. Haptoglobin, C4A, THY1) were identified and may relate to limited xenograft survival. Specifically, elevated CD5L, a macrophage activation marker, indicated sustained immune activation in gene-edited pig livers, suggesting unintended immunogenic effects of genetic engineering.
Conclusion: This study conducted the first comparative analysis of human and pig liver proteome and glycoproteome, and revealed recipient-context differences and non-linear molecular effects of gene editing, including novel site-specific glycoform changes on key immune and hemostatic glycoproteins. Together, these findings extended the molecular definition of xenograft incompatibility beyond protein abundance and established a quantitative molecular framework for understanding xenograft incompatibility and guiding translational liver xenotransplantation.

THU-324-YI
Hyperoxidized albumin triggers proteasomal and lysosomal dysfunction compromising albumin endocytosis, degradation and recycling in alcohol-associated liver disease
Babu Mathew[1], Nupur Sharma[1], Deepanshu Sharma[2], Sushmita Pandey[1], Sadam H. Bhat[1], Vipul Sharma[1], Gaurav Tripathi[1], Vasundhra Bindal[1], Manisha Yadav[1], Neha Sharma[1], Sanju Yadav[1], Shvetank Sharma[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. *[1]Institute of Liver & Biliary Sciences, New Delhi, India; [2]National Institute of Immunology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Human serum albumin (HSA) circulates mainly as functional human mercaptalbumin (HMA), while oxidized human Nonmercaptalbumin 1 (HNA1) and human Nonmercaptalbumin 2 (HNA2) comprise about 25% and 5% respectively. In alcohol-associated liver disease (ALD), HNA1 and HNA2 are markedly increased. Although known as severity biomarkers, their intrahepatic effects on proteasomal and lysosomal activity and albumin recycling remain poorly defined.
Method: We examined the pathogenic impact of oxidized albumin isoforms using three approaches: (i) administration of HMA, HNA1, or HNA2 to healthy rats (n = 6/group) followed by proteomic, metabolomic, and albumin isoform functionality analyses in liver and plasma; (ii) repetition of these treatments in ethanol-fed ALD rats (n = 6/group); and (iii) validation in human liver biopsy and plasma from individuals with alcohol-associated cirrhosis (AAC, n = 10) and severe alcohol-associated hepatitis (SAH, n = 12) using RNA sequencing and proteomics.
Results: Exogenous HNA1 and HNA2 induced acute liver dysfunction, with HNA2 producing the greatest increases in injury markers and inflammatory mediators (FC>1.5, $p < 0.05$). HNA1 at SAH-relevant concentration (2.5 g/kg) increased lipogenesis and fibrogenic signaling (TGF-β, IL-17A), whereas HNA2 preferentially activated IL-6, MAPK, and NF-κB pathways (FC>1.5, $p < 0.05$) compared with HMA in healthy rats. Proteins mediating albumin endocytosis (Fcgrt, Cubn, Lrp2, Amn), endosomal docking (Vamp4, Stx2, Stx6), proteasomal degradation (Ecpas, Psma3, Psmb3), lysosomal function, and vesicular trafficking were reduced after HNA1 exposure and further decreased after HNA2 ($p < 0.05$), indicating impaired protein recycling and potential accumulation of pathogenic albumin. Hepatic proteasome expression reduced with increased IL-6 and TNF-α ($p < 0.05$). In ALD rats, HNA2 caused death within 2hours and suppressed proteins involved in albumin endocytosis, trafficking, and exocytosis ($p < 0.05$). These effects were confirmed in SAH plasma and biopsy, showing reduced HMA, accumulation of HNA1/HNA2, and downregulation of genes involved in albumin recycling (FC>1.5, $p < 0.05$).
Conclusion: Hyper-oxidized albumin disrupts hepatic endocytosis, endosomal docking, lysosomal function, exocytosis, and proteasome activity, leading to defective albumin recycling and degradation, thereby driving proteostasis failure, liver injury, and worsening clinical outcomes in ALD.

THU-329
Regulation of hepatic physiology and metabolism by the mitochondrial NAD+ transporter, SLC25A51
Sarmistha Mukherjee[1], Ricardo Velázquez Aponte[1], Gabriel Adzika[1], Nicole Bye[1], Hannah Vanblarcom[1], Teresa Xiao[1], Adarsh Ramamurthy[1], Joseph Baur[1]. *[1]University of Penn-Medical, Philadelphia, United States*
Email: Sarmuk@pennmedicine.upenn.edu

Background and aims: A development in the field has been the identification of SLC25A51 as a mammalian mitochondrial NAD^+ carrier by our group and others. We have recently employed modulation of SLC25A51 to alter the mitochondrial NAD^+ pool in hepatocytes and to establish that it is limiting during liver regeneration. Overexpression of SLC25A51 is sufficient to recapitulate the enhancement of liver regeneration seen with systemic NAD^+ supplementation. Studies on compartmentalization of NAD^+ within the cell will be critical to understand how it can be selectively therapeutic targeted in various metabolic disorders.
Method: We engineered tissue specific floxed mouse lines for inducible knockout of SLC25A51 to extend our studies in young adult mice as whole-body homozygous loss is embryonic lethal. Adeno-associated viral vectors expressing either Cre recombinase or enhanced green fluorescent protein (control) under the control of thyroxine-binding globulin promoter were used to generate mice with liver-specific knockout of *Slc25a51* (LKO).
Results: LKO mice trended towards hypoglycemia at baseline and had significantly lower blood glucose levels in glucose tolerance test. These mice also maintained significantly lower blood glucose when gluconeogenic substrates like pyruvate and glycerol were used. During 16 h fast and 4 h re-fed states, LKO animals showed remarkable decrease in plasma triglycerides, insulin, and cholesterol. Despite maintaining a comparable body weight, LKO mice had significantly enlarged livers and dramatic depletion of liver glycogen. Livers isolated from LKO mice showed decreased hepatic NAD^+, NADH and ATP levels. As expected, mitochondrial NAD^+ and NADH levels were significantly lower, and complex I–dependent respiration was impaired. During an exhaustive treadmill protocol, LKO mice failed to run and had lower VO_2 max. Subsequently, SLC25A51 deletion markedly compromised liver regeneration and blocked the ability of nicotinamide riboside supplementation to promote hepatocyte proliferation.
Conclusion: Our data suggest that SLC25A51 regulates hepatocyte mitochondrial energetics and hepatic redox state and is crucial for liver regeneration. We are using multi-omics approaches and stable isotope tracing experiments to determine the changes in major metabolic pathways following SLC25A51 manipulation. Overall, this study offers mechanistic insight into the role of SLC25A51 in liver physiology and provides evidence for specific functions of discrete subcellular NAD^+ pools in hepatocytes *in vivo*.

Email: ane.nieva@ehu.eus

Background and aims: Colorectal liver metastasis (CRLM) is the second leading cause of cancer-related mortality. Alterations in cholesterol (CL) metabolism are a hallmark of CRLM, where tumor cells shift between increased synthesis and uptake depending on their genetic background. Desmosterol, a CL synthesis intermediate, is elevated in several cancers, while inhibition of Δ(24)-sterol reductase (DHCR24), the enzyme regulating the balance between desmosterol and CL, is beneficial in hepatocellular carcinoma. The aims of the study were: (1) to investigate the remodeling of desmosterol and CL synthesis in human CRLM and (2) to determine if desmosterol accumulation by *Dhcr24* inhibition in hepatocytes affects CRLM proliferation.
Method: Serum, liver tumor (T) and surrounding tissue (ST) from CRLM patients (n = 20) were analyzed. CRLM was induced *in vivo* in mice fed either a chow diet or a Western diet. *Pcsk9* overexpression and *Dhcr24* inhibition in hepatocytes were achieved using ApoE-hAAT1-AAV8 and GalNAc-conjugated antisense oligonucleotides (ASO), respectively. Lipid content and protein levels were quantified. *In vitro* proliferation assays were performed using conditioned media from isolated hepatocytes.
Results: Human CRLM tumors exhibited downregulation of all enzymes involved in CL synthesis, including DHCR24, compared with ST. This proteomic remodeling was associated with increased levels of desmosterol and CL in tumors, suggesting enhanced CL uptake from circulation and accumulation of intermediates not used for *de novo* synthesis. In concordance, reduced serum LDL-CL and increased hepatic LDLR levels in both human samples and preclinical CRLM models were found. In mice, hepatocyte-specific *Pcsk9* overexpression reduced liver metastasis by inhibiting LDL-CL uptake, thereby promoting *de novo* cholesterol synthesis and reducing desmosterol accumulation in ST. Conversely, hepatocyte-specific *Dhcr24* inhibition increased desmosterol levels and promoted CRLM progression, accompanied by elevated LDL-CL. Conditioned media from *Pcsk9*-overexpressing hepatocytes, characterized by reduced desmosterol, decreased CRC cell proliferation *in vitro*. In contrast, direct treatment of CRC cells with desmosterol enhanced proliferation.
Conclusion: Dysregulation of CL synthesis and uptake in CRLM alters desmosterol levels in both hepatocytes and tumor cells. Targeting desmosterol metabolism specifically in hepatocytes may represent a promising strategy to reduce CRLM progression.

THU-331
Defining hepatocyte size–mechanotransduction set point that preserves human hepatocyte identity in vitro and in vivo

Masashi Okawa[1], Yein Woo[1], Garnik Arustamyan[1], Daniel Pinski[1], Meng Li[1], Takeshi Saito[1]. [1]*University of Southern California, Los Angeles, United States*
Email: mo_224@usc.edu

Background and aims: Cell identity maintenance is highly dependent on preserving cell size, morphology, and polarity, which are supported by the extracellular matrix (ECM). Isolation of primary human hepatocytes (HHs) involves dislodgement from the native ECM; thus, in vitro culture of HHs lacks structural support, predisposing cells to aberrant mechanotransduction and subsequent identity loss. However, the mechanisms that initiate these maladaptive responses, their kinetics, and their relationship to morphological changes leading to loss of hepatocyte identity remain elusive. This study aims to define the hepatocyte size "set point" that protects

against maladaptive mechanotransduction and preserves cellular identity.
Method: HHs were seeded at different densities as 2D monolayers to tune cell geometry, from laterally spread cells at low density to spatially confined cells at high density. Cells were also cultured on plates with varying stiffness to modulate cell–matrix tension, and then subjected to serial cellular force measurements and quantitative assessment of morphological architecture. They were compared with transcriptomic profiles generated by scRNA-seq to quantify the expression of hepatocyte identity markers and mechanotransduction pathway targets, including YAP/TAZ-associated pathways, to define the hepatocyte identity–preserving size and mechanical force set point. These readouts were benchmarked against human cirrhotic liver tissue samples.
Results: Reduction in seeding density and plate stiffness led to the emergence of distinct HH subpopulations with heterogeneous cell sizes, including compact cells within the size range observed in normal liver tissue and spread cells to variable extents. This morphological heterogeneity was correlated with the magnitude of forces from adjacent cells and was accompanied by maladaptive mechanotransduction signaling, resulting in transcriptomic heterogeneity into distinct subpopulations, including progenitor- and transdifferentiated-like cells. Genes upregulated in identity-lost cells were similarly upregulated in hepatocytes of cirrhosis individuals.
Conclusion: This study defines hepatocyte size–force set points required to preserve hepatocyte identity and provides a mechanistic framework for understanding hepatocyte dysfunction in cirrhosis. These findings are exploitable to refine HH culture strategies, thereby enhancing the quality of in vitro liver biology and disease modeling and supporting the development of regenerative medicine for liver diseases.

THU-332
Signaling through the insulin receptor induces growth via cell cycle re-entry in hepatocyte spheroids engrafted in the anterior chamber of the eye
Nuria Oliva-Vilarnau[1], Barbara Leibiger[1], Ingo Leibiger[1], Per-Olof Berggren[1], Noah Moruzzi[1]. [1]*The Rolf Luft Research Center for Diabetes and Endocrinology, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden*
Email: noah.moruzzi@ki.se

Background and aims: Monitoring of functional changes in hepatocytes, the endocrine pancreas and their crosstalk during metabolic disease development is pivotal to identify early mechanisms. The anterior chamber of the eye (ACE) is a suitable transplantation site that serves as an optical window to longitudinally monitor pancreatic islets and hepatocyte spheroids non-invasively at cellular resolution. Our aim is to implement such *in vivo* platforms to study crosstalk between endocrine pancreas and liver in metabolic disease.
Method: Murine hepatocyte spheroids and pancreatic islets are transplanted singularly or together in close proximity into the ACE of recipient mice and imaged by confocal microscopy. Recipient mice are fed an obesogenic diet to identify changes in signaling factors during disease development. Intravenously administered fluorescent probes are imaged *in vivo* to identify vascularization and FUCCI reporter hepatocytes are employed to assess cell cycle activity and number of cells in real time. The role of signaling via the insulin receptor in the crosstalk is evaluated via liver insulin receptor knockout (LIRKO) hepatocyte spheroids.
Results: Co-transplantation of murine hepatocyte spheroids and pancreatic islets in close proximity results in remarkable growth compared to spheroids transplanted without islets in the contralateral eye. Hepatocyte spheroids transplanted singularly also enlarge upon high-fat-high-fructose diet administration in recipient mice. In both cases, growth is explained by cell cycle re-entry of hepatocytes, as evidenced by FUCCI reporter hepatocytes. Hepatocytes lacking the insulin receptor show dramatically impaired growth in the experimental conditions described above, indicating insulin as the main factor at play.
Conclusion: We established a platform for longitudinal imaging of crosstalk between hepatocyte spheroids and islets *in vivo*, which enables identification of key interplay factors. Our data indicates the potent mitogenic role of insulin on hepatocytes *in vivo*, either as an endocrine or as a paracrine factor.

THU-333-YI
Role of CNNM1 in magnesium homeostasis and hepatocellular dysfunction during aging
Patricia Peña-Sanfélix[1], Leidy Estefanía Zapata-Pavas[1], Irene González-Recio[1], Naroa Goikoetxea-Usandizaga[1,2], María Luz Martínez-Chantar[1,2], Luis Alfonso Martinez-Cruz[1], Raul M. Luque[3], Ignacio Gil-Duque[3]. [1]*Liver Disease Lab, CIC bioGUNE, Basque Research and Technology Alliance (BRTA), Derio, Spain;* [2]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Carlos III National Institute of Health, Madrid, Spain;* [3]*Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Department of Cell Biology, Physiology and Immunology of University of Córdoba, Reina Sofia University Hospital, CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Cordoba, Spain*
Email: ppena@cicbiogune.es

Background and aims: Aging is associated with progressive metabolic and inflammatory dysfunction in the liver. Magnesium is essential for cellular energy metabolism and organelle function, and its deficiency has been linked to age-related diseases. CNNM1, a member of the cyclin and CBS domain divalent metal cation transporter family, has been identified as an age-regulated magnesium transporter in experimental models, while showing minimal basal expression under physiological conditions. Its upregulation with ageing suggests a pathogenic role in hepatocyte dysfunction. We investigated the impact of CNNM1 and magnesium on hepatic metabolism during ageing.
Method: Hepatic CNNM1 expression was modulated *in vivo* using AAV vectors for hepatocyte-targeted overexpression or silencing in young and aged mice. Primary mouse hepatocytes were used for mechanistic studies. Mitochondrial function, oxidative stress and metabolic flux were assessed using established assays. Systemic metabolic function was evaluated by glucose, pyruvate and insulin tolerance tests. Gene and protein expression were analysed by qPCR and immunoblotting, and tissue and cellular alterations were examined by histological and immunostaining approaches. Immune cell populations were characterised by flow cytometry.
Results: Aging was associated with increased hepatic Cnnm1 expression and a redistribution of magnesium in hepatocytes, with reduced cytosolic and increased mitochondrial magnesium levels. CNNM1 overexpression in young hepatocytes recapitulated key features of liver ageing, including impaired mitochondrial respiration, endoplasmic reticulum stress and altered magnesium compartmentalisation. CNNM1 silencing in aged hepatocytes restored magnesium balance and mitochondrial function. Systemically, overexpression impaired glucose tolerance, whereas silencing improved glucose, pyruvate, and insulin tolerance. At the cellular level, CNNM1 overexpression disrupted iron homeostasis and increased hepatic iron, while silencing attenuated iron dysregulation and lipid peroxidation. In parallel, CNNM1 knockdown reduced pro-inflammatory cytokine expression, and reshaped hepatic immune cell composition.
Conclusion: CNNM1 could be acting as a key hepatocyte-intrinsic regulator by altering magnesium and iron balance, mitochondrial function, and inflammation during liver aging. Targeting CNNM1-dependent pathways may represent a promising strategy to restore hepatocellular homeostasis in liver aging.

THU-334-YI

A human induced pluripotent stem cells-based liver assembloid platform for investigating ischemia/reperfusion injury

Riccardo Perriera[1], Clelia Ferraro[1], Minjie Zhao[1,2], Martina Morsicato[1], Salvatore Gruttadauria[3], Valentina Agnese[1], Massimo Pinzani[1], Giovanni Zito[1]. Email: rperriera@ismett.edu

Background and aims: Ischemia reperfusion injury (IRI) is one of the leading causes of liver graft failure. Although machine perfusion improves the quality of marginal donor livers, damage to the vasculature and parenchyma often leads to irreversible injury, compromising graft function. To investigate the complex interactions between endothelial cells and hepatocytes under IRI, we developed an assembloid model by combining human induced pluripotent stem cell (hiPSC)-derived liver organoids (LOs) with human umbilical vein endothelial cells (HUVECs). To identify novel IRI-associated markers, assembloids were subjected to an in vitro IRI assay, followed by transcriptomic analysis using RNA sequencing.
Method: hiPSC-LOs were generated using an established differentiation protocol in a matrix-free system combining two commercially available kits. Organoid maturation was enhanced by molecular inhibition of GSK-3 during differentiation. The maturation of hiPSC-LOs and hiPSC-derived assembloids (hiPSC-Assemb) was assessed by RNA sequencing, and compared with tissue-derived liver organoids (TLOs) and their corresponding endothelial assembloids (T-Assemb). The IRI assay was subsequently applied to both hiPSC-based and tissue-derived models to identify novel IRI-associated markers through comparative transcriptomic analysis.
Results: GSK-3 inhibition significantly increased the expression of hepatocyte markers and promoted the maturation of specific cells within hiPSC-LOs, indicating improved hepatic differentiation. In hiPSC-Assemb, interactions between hiPSC-LOs and HUVECs further enhanced hepatocyte marker expression and functional activity. RNA sequencing revealed dynamic crosstalk between parenchymal and endothelial cells within the assembloid models. Moreover, the transcriptional profile following the IRI assay identified the regulation of unrecognized genes implicated in injury and stress response pathways.
Conclusion: hiPSC-Assemb represent a versatile and powerful platform for studying liver biology and complex liver pathologies. The ability to differentiate and integrate multiple cell types within a single assembloid constitutes a key advantage of this model, enabling the investigation of multifactorial liver injuries such as IRI. Transcriptomic analysis of liver assembloids reveals liver-specific gene expression patterns and the identification of novel targets during IRI, providing a valuable framework for further mechanistic and translational studies.

Hepatic molecular pathways associated with pemafibrate treatment in a rat model of metabolic-associated steatotic liver disease

Yanhao Qiu[1], Jianing Zhou[1], Núria Roglans[1,2,3], Emma Barroso[1,2], Marta Alegret[1,2,3], Juan Carlos Laguna[1,2,3], Laia Vilà[1,2]. [1]*School of Pharmacy and Food Sciences, Universitat de Barcelona, Barcelona, Spain;* [2]*Barcelona, Spain;* [3]*CIBERObn, Barcelona, Spain*
Email: yqiuqiux231@alumnes.ub.edu

Background and aims: We have previously shown that pemafibrate (Pema) administration prevents steatosis development in an experimental model of simple metabolic-associated steatotic liver disease (MASL) in Sprague-Dawley (SD) (*Biomed Pharmacother* 2024 177:117067). Here, we investigated previously undescribed pathways that may contribute to the beneficial effects of Pema treatment in MASLD.
Method: Female SD rats were randomly assigned to three groups (n = 8 per group): (1) control, receiving standard diet; (2) high-fat diet with 10% (w/v) fructose in drinking water (HFHFr); and (3) HFHFr plus Pema at 0.5 mg/kg/day. Rats were fed the HFHFr diet for three months, while treated animals received the diet supplemented with Pema during the last month. At the end of the treatment, liver tissue was properly stored for RNA and protein extraction.
Results: Pema increased the expression of several genes involved in mitochondrial function, including Tfam, Nrf2, Sirt3, Ppargc1a, as well as mitochondrial complex IV subunits (Mt-co1, Mt-co2, and Mt-co3); PPARGC1α protein levels were also elevated. Given the link between mitochondrial function and antioxidant defences, metallothioneins Mt1 and Mt2 were evaluated, revealing increased *Mt2* expression along with higher catalase levels. As MT2 has been associated with autophagy regulation, autophagic markers were analyzed. Pema-treated rats exhibited increased phosphorylated ULK levels, reduced LC3-II/I ratio, and decreased lysosomal acid lipase expression, indicating autophagy inhibition. Finally, we assessed the expression of the vitamin D receptor (VDR), as it has been reported to modulate the expression of several genes altered in our study. Both Vdr gene and protein expression were increased in Pema-treated rats, together with enhanced expression of direct VDR target genes such as Angptl8 and Pparγ2. Further, VDR expression positively correlated with Tfam, Nrf2, Mt-co1, Mt2, and catalase expression, suggesting that VDR may contribute to some of the effects induced by Pema treatment in our MASL model.
Conclusion: Overall, our findings suggest the involvement of additional molecular pathways underlying the beneficial effects of Pema in MASL, with VDR signaling identified as a potential mediator of its hepatic actions. Nevertheless, further research is required to comprehensively clarify the underlying mechanisms. Remodeling of the bile acid connectome across the hepatitis-cirrhosis-hcc axis: network analysis reveals stage-specific hubs and potential therapeutic targets

Qinshuo Wang[1], Zixing Wang[2], Huiying Rao[3], Xin Wen[4], Tianyi Xue[4], Yanpei Mai[2], Suzhen Jiang[2], Shuo Yang[2], Yuxi Shi[4], Yanhui Yang[2], Linlin Cao[3]. Email: caoll@bjmu.edu.cn

Background and aims: While bile acids are established players in liver disease progression and are components of predictive models, the dynamics of BA networks across disease stages remain unexplored. We hypothesize that the transition from hepatitis to cirrhosis and hepatocellular carcinoma (HCC) is driven not just by changes in individual BA concentrations, but by a fundamental rewiring of BA interaction networks. This study aims to systematically map and quantify the BA network topology across this disease spectrum to identify hub BAs that may coordinate metabolic dysregulation.
Method: We prospectively enrolled 889 patients from Peking University Hepatology Institute in 2025, categorized into six groups: Hepatitis B, MAFLD, HBV-MAFLD, compensated cirrhosis, decompensated cirrhosis, and HCC. Serum levels of individual BAs were quantified using LC-MS. For each group, a BA co-abundance network G = (V,E) was constructed, where nodes (V) represent BAs

and edges (E) represent strong correlations (|Spearman's r| >0.65, capturing both synergistic and inhibitory relationships. Network topology was analyzed using density, clustering coefficient, and modularity. Cross-group comparisons of BA profiles and core identities pinpointed hub BAs whose relative changes are linked to global network restructuring.
Results: We found significant differences in network structure across the Hepatitis-Cirrhosis-HCC Axis. Specifically, network density-reflecting the frequency of interactions between bile acids- increased from 0.09–0.14 (MAFLD, HBV and overlap), 0.15–0.17 (CC and DC), to 0.22 (HCC); clustering coefficient-reflecting the degree of collaboration among BAs within functional modules-rose from 0.58 to 0.74 accordingly. Analysis of network hubs revealed that UDCA as a core BA in MAFLD, where as glycine-conjugated BAs dominated the other groups. That is, GDCA composed 6.4%–8.1% of the BA pool for HBV, and was identified as a driver for progression to CC. GCDCA becomes the hub when further progressing to DC, whereas GCA acts as a consistent hub within the networks throughout the full disease spectrum.
Conclusion: This work moves beyond individual BA quantification to define the "BA connectome" in liver disease. Identifying the dynamic hub BAs provides novel insights into the critical control points of metabolic dysregulation at each stage. These hubs represent potential biomarkers for disease monitoring and novel therapeutic targets for interrupting progression.

Integrating proteomics and metabolomics analysis identifies molecular links associated to liver injury in preclinical model of acute hypoxia stress

Sanju Yadav[1,2], Rupinder Kalra[3], Manisha Yadav[1], Gaurav Tripathi[1], Neha Sharma[1], Nupur Sharma[1], Sushmita Pandey[1], Vipul Sharma[1], Babu Mathew[1], Vasundhra Bindal[1], Narendra Sharma[3], Ved Dwivedi[4], Jaswinder Maras[1], Nasir Salam[2]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Jamia Millia Islamia, New Delhi, India; [3]Banasthali Vidyapith, Newai, India; [4]ICGEB, New Delhi, India*
Email: nsalam@jmi.ac.in

Background and aims: Acute hypobaric hypoxia induces metabolic stress, disrupting redox homeostasis and promoting liver injury; however, the molecular mechanisms linking hypoxia to hepatic dysfunction remain poorly defined. This study aimed to characterize time-dependent liver-specific proteomic and metabolomic alterations during acute hypoxic exposure.
Method: Male SD rats (n = 16/group) were exposed to simulated hypobaric hypoxia (25,000 ft) for 1, 3, or 7 days. Liver tissues were subjected to untargeted proteomic and metabolomic analyses to define temporal molecular perturbations associated with hepatic stress.
Results: Hypoxia induced significant liver injury, evidenced by elevated serum bilirubin, AST, and ALT levels and a reduced liver-to-body weight ratio ($p < 0.05$). Liver metabolomics showed a time-dependent remodelling, of 341-up, 20-down at day-1, 316 up, 22-down at day-3, and 356 up, 10 down at day-7 (FC>1.5, $p < 0.05$). These changes predominantly involved activation of inflammatory and mitochondrial redox pathways, including tryptophan (C00099, C00025), amino sugar metabolism (C00140), folate metabolism (C00576), and the TCA cycle(C00025), alongside suppression of nitrogen metabolism (C00262, C00086), indicating impaired detoxification (>2FC, $p < 0.05$). Proteomic analysis showed extensive dysregulation of (1091-up, 586-down) proteins at day-1, 1104-up and 821 down at day-3, and 453-up and 606 down at day-7 (FC>1.5, $p < 0.05$). Proteins associated with stress and lipid metabolism (FADS1, ACOX2, ACOT8), fatty acid metabolism (ACADVL, CPT1B), and calcium signalling (PTGS1) were enriched (>2FC, $p < 0.05$). Integrated multi-omics showed strong correlations between increased TCA cycle activity and inflammatory signaling pathways ($R^2>0.7$, $p < 0.05$). Network-level analysis further linked apoptotic (BAX, APAF1, CDH1, PRKCD), platelet activation (ATP2B3, PPP2R1B) and Eph–ephrin signalling (EPHA7, MYH9, LYN, EPHA3), angiotensinogen (ACE, CMA1) with altered nucleotide, amino acid, and antioxidant metabolism, identifying Eph–ephrin signalling as a key contributor to hypoxia-induced liver inflammation.
Conclusion: Acute hypobaric hypoxia induces early liver injury marked by redox imbalance, metabolic rewiring, and inflammatory activation, with coordinated proteomic–metabolomic disruptions highlighting Eph–ephrin signalling as a key driver of hypoxia-induced hepatic inflammation and a potential therapeutic target.

Type I interferon-mediated liver injury and hepatocarcinogenesis upon hepatic autophagy inhibition

Lea Aylin Yücel[1], Farina Schneider[2], Callum Hall[3], George Kassiotis[3], Marcus Krüger[4], Reinhard Büttner[2,5], Manolis Pasparakis[4,5,6], Tom Luedde[1,7], Vangelis Kondylis[1,2,5,8]. *[1]Clinic for Gastroenterology, Hepatology and Infectious Diseases, University Hospital Düsseldorf, Düsseldorf, Germany; [2]Institute for Pathology, University Hospital Cologne, Cologne, Germany; [3]The Francis Crick Institute London, London, United Kingdom; [4]Institute for Genetics, University of Cologne, Cologne, Germany; [5]Center for Molecular Medicine (CMMC), Medical Faculty and University Hospital Cologne, University of Cologne, Cologne, Germany; [6]Cologne Excellence Cluster for Aging and Aging Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [7]Center for Integrated Oncology Aachen Bonn Cologne Düsseldorf (CIO ABCD), Düsseldorf, Germany; [8]University Hospital Düsseldorf, Department of Gastroenterology Hepatology and Infectious diseases, Medical Faculty at Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany*
Email: LeaAylin.Yuecel@med.uni-duesseldorf.de

Background and aims: Liver injury drives chronic liver disease (CLD), progressively inducing inflammation, fibrosis and cirrhosis, thereby increasing the risk of hepatic malignancy. Autophagy is a catabolic process that maintains cytoplasmic quality via degradation of cellular material, and its dysregulation promotes CLD progression, such as alcoholic steatohepatitis (ASH) and metabolic dysfunction-associated steatohepatitis (MASH). In this project, we aimed to identify pathways involved in liver injury and hepatocarcinogenesis in mice with liver parenchymal cell-specific ATG16L1 ablation (LPC-KO), which develop spontaneous liver injury, progressing with age to steatohepatitis, fibrosis and tumor formation.
Method: Quantitative proteomics were used to identify early differences between ATG16L1-deficient and control livers. Transgenic mouse lines were generated to assess the role of the autophagy receptor Sequestosome-1/p62 and different mediators of type I interferon (IFN) signalling in vivo together with biochemical and (immuno)histochemical analyses. Immunoprecipitation (IP) with J2 antibody followed by RNA sequencing (RNAseq) was used to look for potential dsRNA sources activating type I IFN signalling.
Results: p62 ablation ameliorated liver injury, hepatomegaly, and delayed hepatocarcinogenesis in ATG16L1 LPC-KO mice. Proteomic analysis revealed an increased type I IFN signature, which was not normalized upon p62 deficiency. LPC-specific deletion of *Ifnar1* decreased liver injury and tumorigenesis, highlighting the involvement of type I IFN signalling in hepatocyte death. *Mavs*, but not *Sting*, deletion phenocopied the effect of Ifnar1 deficiency, indicating that aberrant accumulation of dsRNAs leads to Mavs-dependent IFN production that mediates the observed liver damage in ATG16L1 LPC-KO mice. J2 IP followed by RNAseq identified significantly altered expression in specific families of endogenous transposable elements (TEs) in livers of these mice as the potential stimuli of type I IFN signalling activation. The involvement of IFN-inducible molecules that regulate cell death, such as Zbp1, are currently being examined.
Conclusion: Our findings suggest that autophagy safeguards hepatocytes from the build-up of endogenous TEs in the context of non-viral liver disease, thus preventing the induction of type I IFN signalling that sensitizes hepatocytes to death. Possible upregulation of endogenous TEs in ASH and MASH patients needs to be elucidated.

Immune-mediated and cholestatic – Experimental and pathophysiology

Centrally-imprinted innate immune tolerance following colitis attenuates cholestatic liver disease: implications for gut-liver axis driven PSC-IBD pathogenesis

Rania Matthys[1,2], Lander Heyerick[1], Zenzi De Vos[1], Lara Morren[1], Hans Van Vlierberghe[3], Anja Geerts[3], Sarah Raevens[3], Sander Lefere[2], Xavier Verhelst[3], Frederik Berrevoet[4], Lindsey Devisscher[1].

Email: rania.matthys@ugent.be

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease frequently associated with inflammatory bowel disease (IBD). While the role of IBD in PSC remains unclear, evidence suggests a protective effect of PSC-IBD. Monocytes and macrophages are key drivers of PSC, and innate immune cells can develop long-lasting functional memory after inflammatory insults. We aim to determine how colitis shapes innate immune responses in the bone marrow and how these centrally imprinted responses translate to cholestatic liver disease severity in vivo.
Method: Acute colitis was induced in mice using 2% dextran sulphate sodium (DSS) for 5 days. Bone marrow was collected at defined timepoints post-colitis and differentiated ex vivo into bone marrow–derived macrophages (BMDMs), which were subjected to secondary stimulation and analyzed by RT-qPCR. To assess in vivo consequences, acute cholestatic liver disease was induced by common bile duct ligation (CBDL) 8 weeks after DSS exposure, with and without bone marrow transplantation (BMTx). BM of mice that underwent acute colitis was used to confirm our results.
Results: Acute colitis induced sustained elevation of pro-inflammatory cytokines (Il1b, Il6, Il12, TNFalpha) in BMDMs for up to 6 weeks, returning to baseline by 8 weeks post-colitis. Ex vivo restimulation of these BMDMs at 8 weeks post-colitis revealed reduced expression of glycolysis-related genes (mTOR, Hif1alpha, Mct1), indicating an innate immune memory state consistent with immune tolerance. In vivo, cholestatic liver injury induced 8 weeks after colitis showed a trend toward reduced hepatic inflammatory markers (Ccr2, TNFalpha, Nlrp3). Similarly, CBDL mice that received bone marrow from colitis-exposed donors displayed reduced hepatic expression of Ccr2, TNFalpha, Nlrp3, and Ccr5, along with lower hepatic mTOR and Hif1alpha levels, supporting centrally programmed immune tolerance.
Conclusion: A single episode of colitis induces innate immune memory in bone marrow derived macrophages that persists for at least 8 weeks. This memory is characterized by a tolerant phenotype, reflected by reduced inflammatory and metabolic gene expression upon restimulation. Bone marrow transplantation experiments indicate that this tolerant state is encoded at the level of hematopoietic progenitors, highlighting a central BM-driven mechanism that may contribute to innate immune dysregulation relevant to PSC-IBD.

Email: mlmartinez@cicbiogune.es

Background and aims: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are progressive cholestatic liver diseases leading to cirrhosis, liver failure, and transplantation. Existing therapies are only partially effective, leaving an urgent need for novel interventions. Magnesium (Mg^{2+}) is an essential regulator of cellular metabolism, mitochondrial function, and endoplasmic reticulum homeostasis. Dysregulated Mg^{2+} has been observed in liver injury, but its role in cholestasis remains unknown. We investigated hepatic Mg^{2+} homeostasis as a driver of cholestatic liver injury and assessed CNNM4, a Mg^{2+} exporter, as a targetable mechanism.
Method: Mg^{2+} transporters were analyzed in liver biopsies from PBC and PSC patients and in murine cholestasis models (bile duct ligation and Mdr2−/− mice). CNNM4 was silenced using GalNAc-conjugated siRNA. Liver injury, inflammation, fibrosis, and bile acid (BA) metabolism were assessed in vivo, with proteomic profiling. Translational relevance was directly tested in precision-cut human liver slices (PCLS) from patients.
Results: CNNM4 expression was consistently upregulated in human cholestatic livers and murine models. GalNAc-siCnnm4 restored hepatic Mg^{2+}, reduced inflammation and fibrosis. Mechanistically, NIRBAD confirmed that GalNAc-siRNA therapy reduces liver BA emptying time by one-third in Mdr2-/- mice, similar to wild-type mice. Proteomics revealed an antifibrotic and anti-inflammatory signature linked to Mg^{2+} restoration. Critically, in PCLS from patients, CNNM4 silencing robustly decreased fibrotic and inflammatory markers, demonstrating translational efficacy in human tissue.
Conclusion: Altered Mg^{2+} homeostasis drives cholestatic liver injury. CNNM4 inhibition restores Mg^{2+} balance, reverses hallmark features of cholestasis, and reduces fibrosis in both preclinical models and human liver slices. These findings provide compelling preclinical and human evidence supporting CNNM4-targeted therapy as a novel, liver-directed strategy for PBC and PSC.

FRI-260

RTY-406 is a dual-acting ABCB4/MDR3 and ABCB11/BSEP positive functional modulator that demonstrates efficacy in a model of primary sclerosing cholangitis

Eric Bell[1], Nathan Fuller[1], Youhwa Jo[1], Jennifer Truong[1], John Miller[1], Robert Hughes[1]. *[1]Rectify Pharmaceuticals, Boston, United States*
Email: ebell@rectifypharma.com

Background and aims: ATP binding cassette subfamily B member 4 (ABCB4/MDR3) and 11 (ABCB11/BSEP) facilitate the translocation of phosphatidylcholine (PL) and the efflux of bile acids (BA) from hepatocytes to the canalicular space, respectively. Mutations in these transporters cause monogenic cholestatic diseases (PFIC3 [MDR3 deficiency]/PFIC2 [BSEP deficiency]) and are associated with the hepatobiliary diseases intrahepatic cholestasis of pregnancy (ICP) and low phospholipid-associated cholelithiasis (LPAC), highlighting their critical role in maintaining hepatobiliary health. We have

discovered RTY-406, a novel, potent, dual-acting ABCB4/BSEP positive functional modulator (PFM) that significantly reduces cholestasis and cholangitis in an animal model of PSC.
Method: RTY-406 was evaluated with twice daily oral dosing for 6 weeks in *Abcb4* heterozygous animals fed a lithogenic diet, a model that recapitulates multiple hallmarks of PSC[1,2]. Peripheral markers of cholestasis, serum BA and alkaline phosphatase (ALP), were monitored, as well as bile components and the incidence of cholesterol crystal formation in the gallbladder. Gene expression, chemokine measurements, and histology were evaluated on liver tissue for markers of ductular reaction, cholangitis, and fibrosis.
Results: RTY-406 increased biliary levels of PL, demonstrating Abcb4 target engagement, and reduced the incidence of gallbladder crystal formation. Serum levels of BA, ALP and the levels of liver taurocholic acid (TCA) were reduced by RTY-406, indicating Bsep target engagement and efficacy on cholestatic markers. Analysis of liver tissue demonstrated RTY-406 reduced pro-inflammatory chemokines, markers of ductular reaction, monocyte/neutrophil infiltration of bile ducts, and biliary fibrosis.
Conclusion: RTY-406, a first-in-class, orally active dual PFM for ABCB4/BSEP, was characterized in a mixed genetic/diet induced model of PSC. By enhancing the function of Abcb4 and Bsep, RTY-406 conferred a beneficial impact on relevant markers of cholestasis and biliary health. These data demonstrate the potential of our dual BSEP/ABCB4 PFM to provide a benefit for hepatobiliary diseases such as PSC.

FRI-261
RTY-406, a candidate drug for primary sclerosing cholangitis (PSC), a dual-acting ABCB4/MDR3 and ABCB11/BSEP positive functional modulator, demonstrates target modulation in non-human primates
Eric Bell[1], Nathan Fuller[1], John Miller[1], Pol Boudes[1], Robert Hughes[1].
[1]*Rectify Pharmaceuticals, Boston, United States*
Email: ebell@rectifypharma.com

Background and aims: ATP binding cassette subfamily B member 4 (ABCB4/MDR3) and 11 (ABCB11/BSEP) translocate phosphatidylcholine (PL) and bile acids (BA) from hepatocytes to bile ducts, respectively. While RTY-406, a novel dual-acting ABCB4/BSEP positive functional modulator (PFM), has demonstrated efficacy in rodent models of cholestasis, validating target modulation and safety in a higher species de-risks clinical translation. We used non-human primates to assess and validate mechanism of action and hepatobiliary health serum biomarkers to support early clinical development.
Method: RTY-406 was evaluated in two independent repeat-dose studies in Cynomolgus monkeys with durations of 14 days and 28 days. Animals receiving daily oral dosing were assessed for sustained pharmacodynamic effects on peripheral markers suitable for clinical monitoring. Markers of bile acid metabolism, including total cholesterol (CHO) were used to monitor mechanism of action, while Alkaline Phosphatase (ALP), gamma-glutamyl transferase (GGT), Alanine Aminotransferase (ALT) and Aspartate Aminotransferase (AST), were used to monitor hepatobiliary health.
Results: In both the 14-day and 28-day studies, RTY-406 demonstrated a favorable profile with no adverse signals in liver function tests. ALT and AST levels confirmed the absence of hepatocellular injury. CHO, ALP, and GGT levels were all dose-dependently reduced, indicating appropriate target modulation consistent with the anticipated mechanism of action of RTY-406.
Conclusion: These 14- and 28-day studies in Cynomolgus monkeys establish a translatable biomarker profile for RTY-406. Use of bile acid synthesis markers combined with ALP, GGT, ALT, and AST provides a robust panel for parallel monitoring of target modulation and hepatobiliary health. These data de-risk translation to human studies, offering a specific set of serum biomarkers that further support clinical development of RTY-406 for PSC.

FRI-262-YI
Pathogenic MUC1$^+$ cholangiocytes drive fibrogenic crosstalk via the EFNA5–EPHA2 axis in cholestatic liver injury
Dinesh Mani Tripathi[1], Aishwarya Bhatnagar[1], Rajni Yadav[1], Himanshi Himanshi[1], Vaibhav Tiwari[1], Savneet Kaur[1], Chhagan Bihari[1], Nidhi Jalan Sakrikar[2], Shridhar Sasturkar[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Mayo Clinic, Rochester, Minnesota, United States*
Email: dineshmanitripathi@gmail.com

Background and aims: Liver injury is characterized by a ductular reaction marked by expansion of biliary epithelial cells (BECs), which contribute to both regeneration and disease progression. Pathogenicity arises from heterogeneous BEC subpopulations that remain poorly understood. We aim to define the role of MUC1$^+$ BECs in driving fibrogenesis through paracrine signaling and to identify the underlying pathways.
Method: Cholestatic injury was induced by bile duct ligation (BDL; day 2, 4, 7) and DDC diet (2 and 4 weeks). Biliary markers were analyzed by qPCR. MUC1 expression was assessed by immunohistochemistry (IHC) in murine and human liver tissue, followed by sorting of EpCAM$^+$MUC1± and EFNA5 gene expression was validated. MUC1$^+$ organoids were generated and characterized by immunofluorescence. Conditioned media (CM)–based co-culture, collagen gel contraction, and tube formation assays were performed. STRING network and protein docking analyses were conducted.
Results: Both models showed increased ductular stress and progenitor markers OPN (BDL 9-fold; DDC 5-fold), SSTR (5-fold), and ciliary remodeling by IFT27 (3-fold). IHC showed progressive expansion of MUC1$^+$ ductules from 4% - 2D, 7% - 4D, 9%- 7D, 15% - 28D. In DDC, the MUC1$^+$ increased 7% -2W; 4%- 4W. Gene analysis revealed a 12-fold increase in intrahepatic MUC1 compared with the extrahepatic compartment, and a transient increase in BCL2. At the cellular level, MUC1 increased 7-fold. MUC1$^+$ organoids increased in number (25–30 per 50,000 cells) and size (10-fold) with CK19$^+$MUC1$^+$ duct-like structures. CM showed progressive endothelin-1 elevation (23, 91, 383 pg/ml) and induced stellate cell activation (a-SMA 3-fold; COL1A1 2-fold), collagen contraction, angiogenic marker expression (TIE2, eNOS, VCAM ~2-fold), and enhanced tube formation. Direct co-culture showed an increased a-SMA population (15%). Based on prior ligand–receptor interaction studies, EFNA5 gene expression was enriched in EpCAM$^+$MUC1$^+$ BECs. EPHA2 receptor is present in activated stellate cells, supported by docking analysis. STRING analysis revealed a key fibrogenic hub linked to the PDGF and collagen pathways.
Conclusion: Cholestatic injury drives expansion of pathogenic MUC1$^+$ biliary epithelial cells that promote fibrosis through paracrine mechanisms. EFNA5 expression was detected in MUC1$^+$ cells, while its cognate receptor EPHA2, expressed on hepatic stellate cells, shows strong links to PDGFR and collagen pathways, supporting a cholangiocyte–stromal axis in fibrosis progression.

Background and aims: Primary Biliary Cholangitis (PBC) is a chronic autoimmune liver disease with strong female predominance. Variants on the X chromosome contribute to genetic susceptibility to PBC. Mosaic chromosomal alterations (mCAs), including age-related clonal hematopoiesis and loss of the X chromosome (mLOX), have been implicated in autoimmune diseases, but their prevalence and clinical relevance in PBC remain poorly defined.
Method: We detected mCAs using MOsaic CHromosomal Alterations (MoChA) caller across FinnGen (N = 520,210) and UK Biobank (UKBB; N = 482,789) to assess population-level prevalence. We identified 791 PBC patients from FinnGen and 453 from UKBB. In the FinnGen cohort, after excluding 141 males and 70 females with incomplete X chromosome data, we evaluated mLOX prevalence and clinical outcomes in 580 female PBC patients (mLOX: N = 208; no mLOX: N = 372). Age-adjusted Cox proportional hazards models assessed the impact of mLOX on death or liver transplantation in FinnGen, analyzed separately for all-cause and liver-related outcomes. UKBB data were used for prevalence validation only.
Results: Overall mCA prevalence was 28.9% in FinnGen and 12.7% in UKBB, increasing with age; the most frequent events were mLOX in females (11.9% and 5.1%) and loss of the Y chromosome (mLOY) in males (14.7% and 16.1%). Among the 580 female PBC patients analyzed, mLOX was significantly elevated compared to FinnGen participants with PBC (OR = 1.58; CI: 1.19–2.11; p = 0.0018), validated via meta-analysis with UKBB (OR = 1.60; CI: 1.22–2.08; p = 0.0006). In FinnGen, despite an increased prevalence, mLOX was not associated with increased risk of death or liver transplantation (HR = 0.80; 95% CI: 0.49–1.32; p = 0.391), nor with liver-related death or transplantation (HR = 1.23; 95% CI: 0.66–2.43; p = 0.475).
Conclusion: Female PBC patients show 60% higher rates of mLOX than population-matched controls, but mLOX does not associate with transplant-free survival. These findings suggest mLOX may contribute to PBC pathogenesis without affecting disease prognosis.

FRI-264
Endoplasmic reticulum stress-mediated PPARα-DDX3X interaction modulates Con A-induced liver injury in mice

Zihao Fan[1], 玲 徐[1], Feng Ren[1]. *[1]Beijing Institute of Hepatology/Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: fzh_925@163.com

Background and aims: Dysfunction of endoplasmic reticulum (ER) stress is involved in the pathogenesis of immune-mediated liver injury, but its molecular mechanism has not been fully elucidated. Previous studies have shown that PPARα and DDX3X play important roles in ER stress-related dysfunction. This study further explored how PPARα and DDX3X interact to regulate ER stress-related dysfunction in immune-mediated liver injury.
Method: Liver injury was induced in C57BL/6J mice via concanavalin A (Con A). DDX3X hepatocyte-specific knockout ($DDX3X^{\Delta Hep}$) mice and control ($DDX3X^{fl/fl}$) mice were utilized to investigate the role of DDX3X in liver injury. 4-PBA was used to inhibit ER stress, while siRNA, AAV-shRNA, and LV were used to regulate PPARα expression. Tunicamycin (TM) was used to induce ER stress in primary hepatocytes, and autoimmune hepatitis (AIH) patients were included for validation.
Results: Inhibition of ER stress alleviates ConA-induced liver injury by increasing PPARα expression and reducing both DDX3X levels and phosphorylation in the liver. PPARα activation attenuates liver injury and suppresses the phosphorylation of DDX3X, which is regulated by ER stress. A phospho-deficient DDX3X mutant (p.T323A) significantly reduces ConA-induced liver injury in mice. Mechanistically, phosphorylation of DDX3X promotes its cytoplasmic–nuclear translocation and hepatocyte apoptosis during ER stress. Moreover, PPARα interacts with the DDX3X helicase domain in the cytoplasm, masking the phosphorylation site (p.323), to inhibit the nuclear translocation of DDX3X and decrease the downregulation of CHOP expression. Additionally, colocalization of PPARα and DDX3X is observed in the livers of AIH patients, elevated serum DDX3X levels were linked to AIH-associated liver failure, and sustained reduction of DDX3X was correlated with a better prognosis.
Conclusion: This study highlights the role of the PPARα-DDX3X interaction in regulating DDX3X phosphorylation during ER stress and promoting DDX3X nuclear translocation and hepatocyte apoptosis. Therefore, targeting the ER stress-PPARα-DDX3X pathway represents a novel therapeutic approach for immune-mediated liver injury.

FRI-265-YI
Acetylcholine-producing B cells regulate regulatory T-cell function within the bile duct ligation–induced fibrotic liver microenvironment

Nastaran Fazel Modares[1]. *[1]University Health Network, Toronto, Canada*
Email: nastaran.fazel@gmail.com

Background and aims: Chronic cholestatic liver injury leads to progressive fibrosis driven by sustained inflammation and dysregulated immune responses. While cytokine-mediated immune regulation in fibrosis is well characterized, the contribution of neuroimmune signaling pathways remains poorly understood. Acetylcholine (ACh), traditionally viewed as a neurotransmitter, can be produced by immune cells and exerts immunomodulatory effects. Whether immune-derived ACh regulates immune homeostasis and fibrogenic pathways during chronic cholestatic liver injury is unknown.
Method: Cholestatic liver fibrosis was induced by bile duct ligation (BDL) in young mice. Acetylcholine-producing lymphocytes were identified using ChAT-GFP reporter mice, and B cell–specific cholinergic deficiency was studied using conditional ChAT knockout models. Immune cell composition and activation were assessed by flow cytometry and histological analyses, alongside evaluation of inflammatory and fibrogenic pathways.
Results: BDL-induced fibrosis was associated with a progressive decline in hepatic $ChAT^{+}$ B cells, accompanied by altered immune composition within the liver. Loss of cholinergic B-cell function correlated with reduced regulatory T-cell abundance and increased expression of profibrotic and inflammatory markers, including a-sma–associated pathways. This suggests that disruption of cholinergic immune regulation may exacerbate disease progression. Histological analyses demonstrated increased fibrotic remodeling in the absence of immune-derived acetylcholine, indicating impaired immune restraint of fibrogenic responses.
Conclusion: These findings identify immune-derived acetylcholine as an important regulator of immune balance during cholestatic liver injury. Disruption of cholinergic immune signaling contributes to

altered Treg homeostasis and enhanced fibrogenic signaling. Neuroimmune pathways may therefore represent previously unrecognized modulators of liver fibrosis and potential targets for limiting disease progression in chronic liver injury.

FRI-266

Identification of molecular targets from the interactome of primary sclerosing cholangitis and their therapeutic modulation

Claudia Fuchs[1], Oleksandr Petrenko[1,2,3], Carolina Mangana[2], Thomas Sorz-Nechay[1,2,3], Kerstin Zinober[1,3], Benedikt Hofer[1,2,3], Benedikt Simbrunner[1,2,3], Frank Assen[4], Wolfgang Weninger[4], Klaus Kaczirek[5], Georg Gyoeri[6], Gabriela Berlakovich[6], Barbara Maier[2], Espen Melum[7], Anna Katharina Frank[7], Philipp Schwabl[1,2,3], Michael Trauner[1], Thomas Reiberger[1,2,3].

Email: claudia.fuchs@meduniwien.ac.at

Background and aims: Primary sclerosing cholangitis (PSC) is a rare cholestatic liver disease characterized by chronic bile duct inflammation and fibrosis, progressing to advanced liver disease. Since the cellular and molecular drivers of PSC progression remain poorly defined, we designed a prospective-translational study to profile the PSC liver interactome at single-cell resolution to identify disease-specific molecular targets, supported by multiomics evidence, and demonstrate their therapeutic modulation via predicted small molecule ligands.
Method: We recruited three patients diagnosed with PSC cirrhosis scheduled for liver transplantation. Non-parenchymal cells (NPCs) were isolated from explanted livers and subjected to scRNA-seq and paired snRNA-seq and data were integrated with healthy and non-PSC cirrhotic controls using scVI. Differential interactions were identified using MultiNicheNet. Top ligand-receptor pairs were validated via imaging mass cytometry (IMC) and whole-tissue proteomics (with/without scaffold enrichment), cross-referencing significant transcriptomic changes in *Mdr2*$^{-/-}$ mice. Selected molecular targets underwent ligand screening with AutoDock Vina, followed by *in vitro* validations of the predicted small molecules on PSC patient-derived cholangiocyte organoids.
Results: We obtained 35501 single-cell transcriptomes from PSC livers, identifying distinct cell types (e.g., *ITGAX*/*CD1C+* dendritic cells, DC; *KRT19*/*CFTR+* cholangiocytes). PSC-specific interactions included *THBS1-CD36* between hepatic stellate cells (HSCs) and sinusoidal cells as well as HSCs and DCs. IMC confirmed increased numbers of THBS1+ HSCs and DC in fibrotic areas, as well as numbers of SLIT2+ PSC ductuli. PSC proteomics and *Mdr2*$^{-/-}$ transcriptomics further showed significant upregulation of *Thbs1*, *Nrp1*, and Slit2. bulkRNA sequencing of PSC organoids showed that treatment with ligandsTHBS1, NRP1, and SLIT2 downregulates NF-kB signature expression. GW-493838 combined with BMS270394 notably downregulated both TGF-beta and Notch signatures.
Conclusion: In advanced human PSC we discovered a range of molecular targets - by multi-molecular approaches, a reduced number of potential targets – selected by *Mdr2*$^{-/-}$ animal model validation and *in silico* drug screening. Finally, disease-modulating effects of of these predicted small molecules were investigated using PSC patient-derived cholangiocyte organoids suggesting NRP1 and THBS1 as relevant therapeutic targets.
OP and CF share first authorship; MT and TR share senior authorship.

FRI-267

Modelling the reactive cholangiocyte phenotype in cholangiopathies using human biliary organoids for evaluation of novel therapeutic compounds

Fabian Heinreichsberger[1], David Pereyra[2], Claudia Fuchs[1], Michael Trauner[1]. *[1]Hans Popper Laboratory of Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of General Surgery, Division of Visceral Surgery, Medical University of Vienna, Department of Vascular Biology and Thrombosis Research, Centre of Physiology and Pharmacology, Medical University of Vienna, Vienna, Austria*
Email: fabian.heinreichsberger@meduniwien.ac.at

Background and aims: Cholangiocytes actively contribute to inflammation during cholestatic disorders by acquiring a "reactive cholangiocyte phenotype." Multifactorial pathways involving bacterial metabolites, accumulating bile acids (BAs) or proinflammatory cytokines play significant roles in cholangiocyte activation. This study aims to (i) characterize the molecular pathways underlying cholangiocyte reactivity and (ii) explore the therapeutic effects of the hydrophilic BAs norucholic acid (NCA) and tetrahydroxylated BAs (THBA) on activated cholangiocytes.
Method: Human extrahepatic cholangiocyte organoids (ECOs) were challenged either with 10 ng/ml LPS & 100 U/L IFNγ or 50 ng/ml IL-17A & 2 ng/ml TNFa. Hydrophilic BAs (250 μM NCA or 0,1–100 μM THBA) were added to explore their therapeutic potential in preventing cholangiocyte activation. Gene expression profiles of inflammatory mediators were analyzed by qPCR.
Results: mRNA-expression profiling demonstrated that the combination of IL-17A and TNFα exerted synergistic effects, elevating Ccl20 128-fold, significantly above separated treatments (7-fold IL-17a; 21,1-fold TNFa, P < 0,0001). Co-treatment with 0.1 μM THBA significantly attenuated the IL-17A/TNFα-mediated inflammatory response, reducing Ccl2 (by 23%, P = 0,013), Cxcl2 (by 60%, P = 0,015) Il-8 (by 53%, P = 0,039) and Ccl20 (by 40%, P = 0,027) expression. NCA decreased Ccl2 (by 22%, P = 0,015), and Cxcl2 (by 45%, P = 0,05). LPS/IFNγ stimulation induced pro-inflammatory chemokine expression in ECOs 5-fold Cxcl2 (P = 0,005), 12,3-fold Ccl2 (P = 0,003), 764,9-fold Cxcl10 (P = 0,0008)). Co-treatment with THBA demonstrated dose-dependent anti-inflammatory effects, reducing Ccl2 (P = 0,0019) and Cxcl2 (P = 0,0198) back to near-baseline levels and Cxcl10 by about 50% (P = 0,001) at 0.1 μM.
Conclusion: THBA & NCA attenuate the reactive cholangiocyte phenotype arguing for their therapeutic potential in cholangiopathies.

FRI-268-YI

T helper cells influence the fate decision of facultative liver stem cells

Ben Higgins[1], Gareth Hardisty[1], Pei-Chi Huang[1], Man Chun Wong[1], Matamoana Muller[1], Hei-Ip Hong[1], Naruhiro Kimura[2], Tim Kendall[1], David Withers[3], Philip Newsome[3], Prakash Ramachandran[1], Wei-Yu Lu[1]. *[1]University of Edinburgh, Centre for Inflammation Research, Edinburgh, United Kingdom; [2]Division of Gastroenterology and Hepatology, Niigata University, Niigata, Japan; [3]Department of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom*
Email: s2263267@ed.ac.uk

Background and aims: During liver disease, a compensatory biliary regenerative mechanism, termed ductular reaction (DR), occurs. A hallmark of DR is the acquisition of a facultative stem cell phenotype by the cholangiocytes, accompanied by infiltration and proliferation of CD4$^+$ T helper cells. However, the role of these T helper cells during DR is unclear. Thus, we aimed to (1) characterise the immune composition and immune-cholangiocyte spatial organisation of the biliary niche during DR, and (2) define the influence of T helper subsets on cholangiocyte function and fate.

Method: 30-plex imaging utilising the Akoya PhenoCycler was performed on human cholestatic and steatotic explant livers to resolve the spatial immune-cholangiocyte organisation. An *Mdm2*$^{fl/fl}$ transgenic mouse model of liver injury in conjunction with antibody-based CD4 depletion was used to assess T helper cell function during DR *in vivo*. Immune- and cholangiocyte-enriched scRNA sequencing was conducted to investigate immune interactions and characterise cellular heterogeneity. The functional role of defined T helper subsets was validated using co-culture with intrahepatic cholangiocyte organoids (ICOs).
Results: T helper cells were enriched within the biliary niche, particularly in cholestatic liver diseases. Single-cell transcriptomic analysis identified distinct cholangiocyte subpopulations, including a subset marked by a stem-like transcriptional signature. T helper cell depletion disrupted this population, leading to transcriptional downregulation of key pathways involved in liver regeneration, including EGFR and Notch signalling. Co-culture experiments resulted in cholangiocytes with divergent transcriptomic profiles and phenotypes, demonstrating subset-specific regulation of cholangiocyte cell fate. Notably, Th17 cells and IL-17A promoted a stem-like cholangiocyte phenotype and induced pro-inflammatory chemokines associated with DR. Consistently, disease progression is associated with an increased Th17 to Treg ratio and enrichment of key IL-17A signalling pathways.
Conclusion: T helper cell subsets regulate the plasticity of cholangiocytes during DR. Th17-derived IL-17A programs a stem-like cholangiocyte state through modulation of regenerative and inflammatory pathways, revealing immune control of biliary regeneration.

FRI-269
Reactive biliary epithelial cells distinctly respond to toxic bile acids and favor pro-inflammatory macrophage polarization through GAS6-AXL signaling pathway in cholestatic liver
Tian Lan[1,2], Guo Yin[1], Hanyang Liu[1], Natalia Martagón Calderón[3], Franco-Leonardi Bianca[4], Yuanshui Long[2], Pavitra Kumar[1], Hilmar Berger[1], Milad Rezvani[3], Frank Schaap[5,6], Frank Tacke[1], Adrien Guillot[1]. Email: tian.lan@charite.de

Background and aims: Cholestatic liver diseases are characterized by toxic bile acid (BA) accumulation, biliary epithelial cell (BEC) activation, and macrophage accumulation. However, how the interaction between reactive BEC and toxic BA impacts macrophages remains to be fully elucidated. Growth-arrest specific protein 6 (GAS6) is a secreted protein with complex and sometimes contradictory effects on liver repair and immune response by binding to its receptor AXL. Current data shows that BECs represent a major source of GAS6. However, the role of BEC-derived GAS6 in chronic liver disease remains to be fully deciphered.
Method: Mouse intrahepatic cholangiocyte organoids (mICO) were generated from wild-type and *Mdr2*-deficient (KO) mice. Bulk RNA sequencing, seahorse assay, and multiplex immunofluorescence (mIF) were used to characterize the mICO phenotypes. BEC-specific *Gas6* knockdown mice were generated by AAV-delivered siRNA. Dissociated WT and KO mICO were seeded into the multicellular biliary-niche-on-a-chip system (BoC), together with mouse primary hepatic stellate cells, endothelial cells, and macrophages. The BoC was perfused with fresh blood circulating immune cells.
Results: KO mICO showed increased proliferation and expression of pro-inflammatory and pro-fibrotic factors when compared to WT mICO, mimicking the phenotype of reactive BECs *in vivo*. When stimulated with toxic BA, KO mICO showed higher viability and distinct transcriptomic profiles compared with WT mICO. Seahorse assays revealed that KO mICO were more metabolically active and adapted better to stress inducers. Public dataset mining and cellchat analysis revealed that BEC interacts with macrophages through GAS6-AXL signaling in cholestatic liver disease. Mouse primary macrophages treated with conditioned medium from WT and KO mICO showed pro-inflammatory polarization. This effect was partly reversed by inhibiting GAS6-AXL pathway in cell culture and in the BoC system. BEC-specific *Gas6* knockdown prevented DDC diet-induced liver injury and fibrosis, and upregulated liver cell proliferation in mice. In line, intraperitoneal injection of GAS6 protein inhibited liver cell proliferation, exaggerated liver injury and inflammation in mice fed with a CDE diet.
Conclusion: Reactive cholangiocytes have distinct transcriptomic and metabolic profiles and respond differently to toxic BA stimulation, favoring pro-inflammatory macrophage polarization and impairing liver regeneration through GAS6-AXL signaling in cholestatic liver disease.

FRI-270
Gut microbiota-bile acid axis drives pathogenic gamma delta T differentiation in autoimmune hepatitis
Junxing Li[1], Han Wang[2], Dong Xu[1]. [1]*Department of Infectious Diseases, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Hubei, Wuhan, China;* [2]*Department of Gastroenterology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Hubei, Wuhan, China*
Email: 1141539455@qq.com

Background and aims: Autoimmune hepatitis (AIH) is a chronic immune mediated liver disease driven by dysregulated hepatic immunity. Gamma delta T cells (γδT) are an important component of liver resident immune populations, yet their role in AIH and the mechanisms governing their differentiation remain unclear. This study aimed to investigate the contribution of hepatic γδT cells to AIH and to determine whether the gut microbiota bile acid axis influences their differentiation and pathogenic function.
Method: AIH was induced in mice by transfection of human autoantigen cytochrome P450 2D6 (CYP2D6). Hepatic γδT cells were characterized using single cell RNA sequencing. Human AIH liver samples were analyzed to validate findings from the mouse model. The functional role of γδT cells was assessed using γδT cell deficient mice. Transcriptional profiles of hepatic γδT cells were analyzed to identify regulatory and pro inflammatory gene programs. Liver metabolomics and 16S rRNA sequencing were performed to assess bile acid metabolism and gut microbiota composition. Antibiotic treatment was used to modulate gut microbiota and evaluate effects on bile acid metabolism, γδT differentiation and AIH severity.
Results: Single cell analysis revealed a marked accumulation of hepatic γδT cells in AIH mice, dominated by the γδT1 subset. Consistently, human AIH liver samples showed increased γδT cell infiltration with a γδT1 biased phenotype. In AIH livers, regulatory associated genes in γδT, including Nfatc1, Dusp2, Klf4, Vegfb and Bach2it1, were significantly downregulated, while pro inflammatory genes such as Bag3, Usp18 and Tab3 were upregulated. Genetic deletion of γδT cells markedly alleviated liver inflammation and fibrosis. Mechanistically, γδT1 cells were essential for effective dendritic cell antigen presentation. Metabolomic analysis indicated that γδT1 differentiation was associated with altered bile acid metabolism, which was driven by gut microbiota dysbiosis characterized by increased Allobaculum and Desulfovibrio. Antibiotic

treatment restored bile acid homeostasis, reduced hepatic γδT1 cells and ameliorated AIH severity.
Conclusion: γδT1 cells accumulate in AIH and promote liver inflammation by enhancing dendritic cell mediated antigen presentation. Their pro inflammatory differentiation is driven by bile acid metabolic dysregulation secondary to gut microbiota imbalance. Targeting the gut microbiota-bile acid-γδT1 axis may represent a novel therapeutic strategy for AIH.

Long-term effects of antibiotics in promoting liver fibrosis during cholestatic liver disease
Jack Hales[1], Cristina Lumbreras-Perales[1], Mar Moreno-Gonzalez[1], Raymond Kiu[1,2], Pablo Elizalde-Garcia[1], Shikha Saha[1], Mark Philo[1], Lindsay Hall[1,2], Naiara Beraza[1]. *[1]Quadram Institute, Norwich, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom*
Email: jack.hales14@gmail.com

Background and aims: Cholestatic liver disease is defined as an autoimmune disease with a strong genetic component, while its increased incidence point towards environmental triggers. The role of the gut microbiota during liver disease is increasingly accepted, while the mechanisms mediating its contribution to disease progression remain largely undefined. Antibiotics disrupt gut microbial communities and the potential long-term effects on liver disease susceptibility remain poorly understood. This study aimed to investigate the potential long-term effects of antibiotic-induced gut microbiome disruption on the progression of cholestatic liver disease.
Method: Mice (C57Bl/6, 8–12 weeks) received broad-spectrum antibiotics (ABx) for 7 days, with a 3-week wash-out ("recovery") period before bile duct ligation (BDL). 7 days after BDL, liver, and serum samples were collected and analysed using immunological, histological, and immunohistochemical (IHC) techniques. Shotgun sequencing and LC-MS approaches were used in faecal samples obtained from the same animals; before and after ABx, after recovery and after BDL.
Results: In ABx-treated mice, gut microbiota biomass was restored at 3 weeks post-treatment (recovery), as measured by 16 s rRNA qPCR in faecal samples. Still, shotgun sequencing revealed persistent alterations in microbiome composition, including non-recovery of commensal such as Bacteroides thetaiotaomicron (Bt), with distinct bile acids and short-chain fatty acid profiles. 7 days after BDL, ABx +recovery mice showed exacerbated liver fibrosis, assessed by Sirius Red staining, compared to mice not receiving ABx. Flow cytometry and further F4/80 IHC revealed reduced macrophage recruitment in the livers of ABx-treated mice versus untreated mice at 7 days post-BDL, accompanied by impaired phagocytic capacity and reduced expression of MMP2, indicating an altered macrophage response.
Conclusion: Antibiotics cause lasting gut microbiome alterations, including loss of key commensal bacteria that exacerbate liver fibrosis in cholestatic liver disease, despite microbiota biomass recovery. Pointing to Bt as a potential strategy to attenuate ABx-mediated aggravation in cholestatic liver disease.

FRI-272
Methyldopa reduces plasma bile acid concentrations in a murine model of estrogen-induced cholestasis
Dina Manna[1], Hana Lastuvkova[1], Jolana Schreiberova[1], Lenka Jandova[1], Milos Hroch[1], Martin Ambroz[2], Mária Krutáková[2], Martin Lenicek[3], Hirsova Petra[4], Marian Kacerovsky[5], Petr Pavek[2], Stanislav Micuda[1]. *[1]Univerzita Karlova-Lékařská Fakulta v Hradci Králové, Hradec Králové, Czech Republic; [2]Univerzita Karlova-Farmaceutická Fakulta v Hradci Králové, Hradec Králové, Czech Republic; [3]General University Hospital in Prague and First Faculty of Medicine, Charles University, Prague, Czech Republic; [4]Mayo Clinic, Rochester, United States; [5]University Hospital Olomouc, Olomouc, Czech Republic*
Email: manad@lfhk.cuni.cz

Background and aims: Intrahepatic cholestasis of pregnancy (ICP) is the most common gestational liver disorder and is characterized by elevated serum bile acid (BA) concentrations. This results in increased placental barrier penetration and adverse pregnancy outcomes, such as preterm birth and meconium-stained amniotic fluid. Epidemiological studies indicate that ICP is associated with an increased risk of preeclampsia, often requiring treatment with antihypertensive medications such as methyldopa; however, the impact of methyldopa on BA homeostasis remains unclear.
Method: We examined methyldopa in a murine model of estrogen-induced cholestasis. Female C57BL/6J mice received ethinylestradiol (10 mg/kg, s.c.) with or without methyldopa (250 mg/kg, p.o.) for 7 days. BA profiles were quantified by LC–MS across plasma, bile, liver, urine, intestine, and feces. Hepatic, ileal, and renal expression of BA-related enzymes/transporters was assessed by RT-qPCR and Western blotting.
Results: In estrogen-induced cholestatic mice, methyldopa decreased total BA concentrations in plasma and liver without increasing fecal or urinary BA excretion. This reduction was associated with upregulation of phase I/II enzymes (Cyp2b10, Ugt1a1, Sult2a1) and transporters (Abcb11, Slc10a1, Abcc3/4), consistent with transcriptional changes indicative of indirect constitutive androstane receptor (CAR) activation via p-ERK downregulation. Methyldopa also lowered hepatic free cholesterol in cholestatic mice, accompanied by downregulation of Hmgcr and upregulation of Acat2, suggesting altered cholesterol handling that limits substrate availability for BA synthesis.
Conclusion: Methyldopa lowered plasma BA concentrations under estrogen-induced stress by reducing BA synthesis and enhancing detoxification. In the context of pregnancy-related BA dysregulation, these findings suggest that methyldopa, when used to treat hypertensive disorders of pregnancy, may attenuate BA accumulation and potentially delay the onset of cholestatic phenotypes—an observation that generates hypotheses warranting clinical validation.

FRI-273
Increased miR-27b expression in early primary biliary cholangitis impairs mitophagy via prohibitin-2 suppression
Joanna Abramczyk[1], Jesus M Banales[2], Piotr Milkiewicz[3], Malgorzata Milkiewicz[1]. *[1]Department of Medical Biology, Pomeranian Medical University, 70-111 Szczecin, Poland, Szczecin, Poland; [2]Donostia University Hospital, University of the Basque Country UPV/EHU, CIBERehd, Ikerbasque, 20014 Donostia, San Sebastian, Spain; Department of Biochemistry and Genetics, School of Sciences, University of Navarra, 31008 Pamplona, Spain, San-Sebastian, Spain; [3]Department of Translational Medicine, Pomeranian Medical University, Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery of the Medical University of Warsaw, Warsaw, Poland, Szczecin, Poland*
Email: joanna.abramczyk@pum.edu.pl

Background and aims: Impaired mitophagy, a form of autophagy responsible for the degradation of damaged mitochondria, has been implicated in the pathogenesis of primary biliary cholangitis (PBC) and may contribute to the generation of disease-specific anti-mitochondrial antibodies. miR-27b is a microRNA involved in the regulation of mitophagy through modulation of the PINK1/Parkin pathway and suppression of prohibitin-2 (PHB2), a key mediator of Parkin-mediated mitophagy leading to defective clearance of damaged mitochondria. This study aimed to investigate the role of miR-27b in the pathogenesis of PBC.
Method: Expression of miR-27b and protein levels of PHB2 were analyzed in liver tissue at different stages of PBC, including early-stage PBC with fibrosis stages F0–F2 (esPBC, n = 17), advanced PBC with fibrosis stage F4 (n = 10), PSC (n = 10), and controls (n = 15). miR-27b expression was also evaluated in normal human cholangiocytes (NHC) and in H69 human cholangiocytes in culture with or without experimentally overexpression of miR-506 (H69 miR-506; a PBC cholangiocyte model). NHC were exposed to glycochenodeoxycholic

acid (GCDCA), lithocholic acid (LCA), and lipopolysaccharide (LPS). miR-27b overexpression was experimentally overexpressed by transfection with mirVana® miRNA Mimics. The role of miR-27b in autophagy was quantified by flow cytometry using the Muse® Autophagy LC3 Kit. MicroRNA, mRNA, and protein levels were assessed by qPCR and Western blot, respectively.
Results: Increased expression of miR-27b was observed only in the early stages liver tissue of esPBC (9-fold increase vs. advanced PBC, PSC, and controls), accompanied by a 30% reduction in PHB2 protein levels. Under baseline conditions, miR-506 cholangiocytes were characterized by 4-fold higher levels of miR-27b compared with controls. Incubation of NHC with GCDCA (150 µM) or LCA (100 µM), but not LPS, increased miR-27b expression (3-fold and 5.5-fold vs. control, respectively). Enhanced miR-27b expression in NHC cells led to an increased proportion of autophagic cells (1.8-fold vs. control) and an 80% reduction in PHB2 protein levels.
Conclusion: This study demonstrates that enhanced miR-27b expression at early stages of PBC and the consequent inhibition of PHB2 accumulation on damaged mitochondria may contribute to defective mitophagy, representing a potential therapeutic target in PBC.

FRI-274
Myeloid deletion of SIRT1 exacerbates cholestasis-induced liver disease by promoting inflammation and fibrosis in mice

Background and aims: Sirtuin1 (SIRT1) has been described as a key macrophage regulator during inflammation. We previously described that myeloid-specific SIRT1 overexpression contributes to cholestatic disease progression, promoting liver damage and fibrosis. Here, we investigate whether the modulation of SIRT1 in macrophages could ameliorate liver injury and fibrosis by rewiring macrophage metabolism and autophagy, regulating inflammation.
Method: Cholestasis was induced in myeloid-specific SIRT1 knockout mice (SIRT1 Mye−/−) and wild-type (WT) littermates via bile duct ligation (BDL) or 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) feeding. After 7 days, serum transaminases were measured and liver tissues were analysed by quantitative PCR (qPCR), immunohistochemistry (IHC) and immunofluorescence (IF). To evaluate autophagy, Bone Marrow-Derived Macrophages (BMDMs) from SIRT1 Mye −/− and WT mice were stimulated with labelled apoptotic bodies, and LC3B puncta were quantified.
Results: 7 days after BDL, SIRT1 Mye−/− showed increased serum Aspartate Aminotransferase (AST) and Alanine Aminotransferase (ALT) levels compared to WT. In line with this, SIRT1 Mye−/− mice had increased macrophage infiltration in the liver. IHC analysis of cytokeratin-19 (CK-19) evidenced increased biliary epithelial expansion in SIRT1 Mye−/− supporting ductular reaction. Additionally, Sirius red and αSMA staining and quantification showed increased fibrosis in SIRT1 Mye−/− 7 days after BDL compared to controls. Similarly, after 1 week of DDC feeding, SIRT1 Mye−/− mice had elevated levels of inflammatory cytokines (Il-1b, CCL2, TNFα) in the liver compared to WT controls. IHC analysis revealed increased CK-19-positive areas and increased liver fibrosis in SIRT1 Mye−/− compared to controls, as determined by Sirius red staining and αSMA IF. *In vitro*, we found decreased LC3B puncta in SIRT1-deficient macrophages after stimulation with apoptotic bodies compared to WT, indicating impaired autophagy activity.
Conclusion: SIRT1 deletion in myeloid cells contributes to the aggravation of cholestasis-mediated liver disease by promoting inflammation, ductular reaction and fibrosis. Mechanistically, SIRT1 deletion reduces autophagy in macrophages. These findings suggest that fine-tuning of SIRT1, rather than elimination, in macrophages may represent a novel therapeutic strategy for this condition.

FRI-275
Disease-specific microbiome signatures distinguish primary sclerosing cholangitis from inflammatory bowel disease
Burcin Özdirik[1,2], Daniel Fasulo[3], Peter Lee[3], Frank Tacke[2], Mark Driscoll[3], Bernd Schnabl[1]. [1]*University California San Diego, Charité - Universitätsmedizin Berlin, La Jolla, United States;* [2]*Charité-Universitätsmedizin Berlin, Berlin, Germany;* [3]*Intus - Biosciences, Farmington, United States*
Email: bozdirik@health.ucsd.edu

Background and aims: Primary sclerosing cholangitis (PSC) is an immune-related cholangiopathy lacking treatment options outside of liver transplantation. The gut-liver axis, particularly the contribution of gut microbiota, has emerged as a key pathway in PSC pathogenesis. Although PSC is frequently associated with inflammatory bowel disease (IBD), robust microbiome markers that reliably distinguish PSC from IBD alone remain elusive. In a novel approach, we employ PCR amplification of the bacterial rRNA operon to identify microbiome signatures that distinguish PSC from IBD alone and healthy controls.
Method: Microbiome profiling was performed across 96 patients with PSC (PSC-only n = 30, PSC-IBD only n = 66), 87 patients with IBD (Crohn's disease n = 42; Ulcerative Colitis n = 45), and healthy controls from two different cohorts (n = 55; n = 82). A ~2,500-base amplicon spanning the 16S and 23S rRNA genes was generated and mapped to a custom 16S–23S rRNA reference database. Marker discovery was conducted in defined training subsets, followed by classification using logistic regression and random forest models with cross-validation and independent evaluation sets.
Results: We developed a PSC-specific marker set comprising Enterobacteriaceae, Lachnospiraceae, and Oscillospiraceae that distinguishes PSC from IBD and healthy controls with 91–94% accuracy (AUC = 0.98). Further, in comparisons of PSC-IBD versus IBD-only, 27 microbial markers covering 10 taxonomic categories achieved 84% accuracy under cross validation by Random Forest. Key species included *Enterococcus faecalis*, *Klebsiella pneumoniae*, *Streptococcus thermophilus*, and *Fusobacterium ulcerans*. Incorporation of additional IBD markers improved sensitivity and subgroup performance, particularly in PSC-IBD with ulcerative colitis.
Conclusion: Distinct microbiome signatures differentiate PSC from healthy controls and from IBD alone, supporting a PSC-specific microbial phenotype with diagnostic potential.

FRI-276-YI
Modelling biliary epithelial responses to microbial signals using a bile duct on a chip platform
Sarah Peisl[1,2,3,4], Henry Hoyle[1,2,5], Enya Amundsen-Isaksen[1,2,6], Jeremy Yeoh[1,2,5,6], Stefan Krauss[5], Deborah Stroka[3,4], Espen Melum[1,2,5,6,7]. Email: sarah.peisl@unibe.ch

Background and aims: Cholangiopathies such as primary sclerosing cholangitis are characterized by chronic biliary inflammation, with increasing evidence implicating microbial products in disease pathogenesis. Cholangiocytes are exposed to microbes and microbial signals in bile and express receptors capable of sensing microbe-

associated molecular patterns (MAMP) that may engage in pro-inflammatory signalling. Mechanistic insights on how distinct microbial signals affect cholangiocyte function remain limited. We therefore aimed to integrate MAMPs with an *in vitro* bile-duct-on-a-chip model to study microbial–epithelial interactions relevant to cholangiopathies.

Method: A 3D-printed bile duct-on-a-chip with a collagen-embedded tubular channel lined by a confluent, polarized cholangiocyte layer was used. As cell source cholangiocyte organoids generated from bile duct brushings collected during ERCP were used. Lipopolysaccharide (LPS), lipoteichoic acid (LTA), and flagellin were applied apically in the chip for 24 hours at increasing concentrations with continuous flow within the channel. Epithelial responses were assessed by permeability to dextran, basal cytokine secretion (IL-8, CCL-20) by ELISA, and gene expression by qPCR, including tight junction (Claudin-2, Claudin-3) and functional markers (ASBT, CFTR).

Results: LPS, LTA and flagellin induced stimulus- and dose-dependent cholangiocyte responses. Low-dose LPS (0.1 µg/mL) was associated with an adaptive epithelial response, with unchanged permeability, upregulation of tight junction (Claudin-2 1.4-fold, Claudin-3 1.4-fold), functional markers (ASBT 5.0-fold, CFTR 2.2-fold), and suppressed IL-8 secretion (Δ –67 pg/mL). LPS 10 µg/mL was associated with increased 10 kDa dextran permeability (59% vs 15%, p = 0.007), reduced ASBT expression (0.6-fold), and IL-8 secretion (Δ +254 pg/mL). Compared with LPS, LTA and flagellin were associated with stronger inflammatory responses at low doses, with marked IL-8 induction (LTA 0.5 µg/mL: Δ +694 pg/mL; flagellin 1 ng/mL: Δ +1287 pg/mL) and CCL-20 release (LTA 5 µg/mL: Δ +251 pg/mL; flagellin 10 ng/mL: Δ +2436 pg/mL), not observed with LPS.

Conclusion: The bile duct on a chip model enables investigation of cholangiocyte responses to distinct microbial signals in a more physiological manner than previously reported. Using this platform, we identified stimulus- and dose-dependent differences in cholangiocyte sensitivity to apical MAMP, establishing the chip as relevant system to study microbial–epithelial interactions.

FRI-282

Molecular classification of Indian gallbladder cancer reveals TP53-driven and oncogene-addicted subgroups

Gayatri Ramakrishna[1], Vipin Yadav[1], Archana Rastogi[1], Vaishali Yadav[1], Varun Suroliya[2], Anupama Bhattacharya[2], Ashily Koshy[1], Abhilasha Yadav[1], Rishabh Sharma[1], Ragini Kilambi[1], Nihar Mohapatra[1], Nirupma Trehanpati[1], Viniyendra Pamecha[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India;* [2]*Artemis Hospital Gurgaon, Gurugram, India*
Email: gayatriramakrishna@gmail.com

Background and aims: Gallbladder cancer (GBC) is an aggressive biliary malignancy with high incidence in northern India. Despite known associations with gallstones and genetic predisposition, its molecular heterogeneity remains poorly defined. This study integrated genomic and immunohistochemical markers to define molecular subsets of GBC and compare tumors arising with or without gallstones.

Method: DNA from 32 gallbladder specimens was analysed using targeted next-generation sequencing using a 42-gene somatic mutation panel. Variant analysis and genetic clustering were performed using an R-based pipeline. Immunohistochemistry (IHC) was conducted for prognostic markers, including AQP1, S100P, MUC5AC, CRP, and Podoplanin.

Results: Both genders were equally represented, with gallstones present in 50% and underlying fatty liver in 59.4% cases. Histopathology revealed adenocarcinoma as the predominant subtype (78%), followed by adenosquamous carcinoma (12%). The mutation profile revealed C > T transitions as the most frequent base substitution, amongst the pathogenic variants. *TP53* was the most frequently mutated gene (56%), followed by *EGFR* (25%), *BRAF* (22%), *RB1* (19%), and *KRAS* and *PIK3CA* (12% each). Novel *RET* and *IDH1/2* variants were detected in 12% of cases. Clinically actionable targets (*IDH, ERB2, BRAF, KRAS*) were identified in 28% of tumors. Integration of mutation profiles with clinical and IHC-based prognostic markers identified three molecular subgroups of gallbladder cancer: (1) GBC1 (*TP53*-mutant): predominantly female, adverse clinicopathological features, median survival 23 months, weak podoplanin and intense AQP1 expression; (2) GBC2 (*TP53*-wild type with *RET*/*IDH* mutation): favourable prognosis, median survival 27 months, moderate AQP1 and podoplanin; (3) GBC3 (*TP53*-wild type with *EGFR*/*BRAF* mutation): predominantly male, poorest survival (13 months), intense stromal podoplanin expression. Gallstone-associated GBC exclusively harboured *IDH1* variants (19% vs 0%, p = 0.06), whereas non–stone GBC showed a higher frequency of *BRAF*/*MAP2K2* (12% vs 31%, p = 0.2) alterations.

Conclusion: In Indian patients with GBC, *TP53* inactivation defines a major subclass with moderate to good prognosis, whereas *TP53*–wild-type tumors follow an alternative oncogene-addicted pathway with poor prognosis linked to stromal podoplanin. While BRAF enrichment in non–stone tumors indicates dominance of the RAS-MAPK pathway, the IDH1 variants, which were exclusive to gallstone-associated GBC, suggest metabolic adaptation.

FRI-283

Retrieval-augmented pc-deployable small language models achieve comparable performance to frontier systems for autoimmune liver disease guideline-based decision support

Ernest Saenz[1], Martin Gómez-Loira[2], Juan Turnes[2], Indhira Pérez-Medrano[2], Ezequiel Ridruejo[3], Jimmy Daza[1], Lucia Coli[1], Timo Itzel[1], Andreas Teufel[1]. [1]*Department of Medicine II, Division of Hepatology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany;* [2]*University Hospital Complex Of Pontevedra, Pontevedra, Spain;* [3]*Hepatology Section, Department of Medicine, Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno "CEMIC", Buenos Aires, Argentina*
Email: ernest.phd@gmail.com

Background and aims: Autoimmune liver diseases expertise remains concentrated in academic centers, creating barriers to guideline concordant care in community settings. Large language models (LLMs) show promise for clinical decision support but raise concerns regarding cost sustainability, privacy and data governance. We evaluated whether smaller, locally deployable on consumer hardware models with retrieval-augmented generation (RAG) could match frontier commercial systems for autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC) clinical questions.

Method: Clinicians averaging 15 years of hepatology practice constructed a 117 question corpus addressing AIH (29.9%), PBC (35.9%), and PSC (34.2%) across diagnostic criteria, treatment algorithms, and risk stratification. Reference guidelines included EASL, AASLD, BSG, UK-PBC, APASL, DGVS, and Japanese society recommendations. Fifteen LLMs spanning 3B-1T+ parameters completed 5,265 baseline inferences. Three architecturally-diverse models (dense transformer, mixture-of-experts, hybrid state-space model (SSM); 12B-1T parameters) were subsequently evaluated with top-5 guideline passage retrieval. Outcomes included accuracy with 95% confidence intervals, inference latency, answer stability, and per-query cost and we used pairwise McNemar's tests and model per disease interaction effects.

Results: Without RAG, performance varied significantly: GPT-5.1 achieved 93.0% accuracy (95% CI: 90.2–95.3%), best local models 84.0–86.3%. With RAG, architecturally-diverse models converged: GPT-5.1 95.4%, Kimi K2 (1T MoE) 94.6%, Magistral-24B (local) 94.8%, Nemotron-12B (local) 95.0% (overlapping CIs, no significant pairwise differences). Disease-specific RAG performance: AIH 97–100%, PSC 100%, PBC 85–87% across all models. Additionally, 67/105 (63.8%) pairwise comparisons showed significant differences without RAG

versus 0/6 (0%) with RAG ($p < 0.001$ for interaction effect elimination).
Conclusion: For guideline-based autoimmune liver disease questions, small locally-deployable models with guideline retrieval demonstrated non-inferior accuracy to frontier expensive commercial systems. This approach may enable equitable access to LLM-assisted decision support while maintaining institutional data control on hospital-grade computers. Prospective clinical validation and assessment of non-guideline scenarios remain necessary before implementation.

FRI-284
A novel therapeutic strategy for cholemic nephropathy: mineralocorticoid receptor antagonists attenuate bile acid–induced renal injury in vivo and in vitro via the rac1–mineralocorticoid receptor pathway
Sigrid Schulte[1], Susanne Zweerink[1], Diran Herebian[2], Jochen Fries[3], Dirk Nierhoff[1], Christoph Neumann-Haefelin[1], Hans-Michael Steffen[1], Ulrich Töx[1]. *[1]University Hospital Cologne, Department of Gastroenterology and Hepatology, Cologne, Germany; [2]University Hospital Duesseldorf, Department of Paediatrics Neonatology and Paediatric Cardiology Metabolism laboratory, Duesseldorf, Germany; [3]University Hospital Cologne, Institute for Pathology, Cologne, Germany*
Email: sigrid.schulte@uk-koeln.de

Background and aims: Cholemic nephropathy (CN) represents an important cause of renal dysfunction in patients with cholestasis and advanced liver disease. While activation of the mineralocorticoid receptor (MR) has been implicated in renal injury, the interaction between the small GTPase RAS-related C3 botulinum toxin substrate 1 (Rac1) and MR signaling, and its contribution to CN progression, remain poorly understood. This study investigated the effects of MR antagonism on histopathological renal alterations in a bile duct ligation (BDL) rat model and examined bile acid–induced cytotoxicity in human proximal tubular epithelial cells, with a particular focus on the Rac1–MR signaling pathway.
Method: Sixty male Wistar rats were randomly assigned to three groups: sham operation, BDL without treatment, and BDL with spironolactone treatment (100 mg/kg body weight/day) for 28 days. Renal tissue was harvested for histological and immunohistochemical analysis. In parallel, the bile acid profile of a cholestatic patient with histological evidence of CN (serum bilirubin 9.3 mg/dL, creatinine 4.5 mg/L) was determined. HK-2 cells were exposed to a bile acid cocktail reflecting this patient-specific profile, with or without potassium canrenoate and/or the Rac1 inhibitor NSC23766. Cytotoxicity was assessed using the CytoTox-Glo® assay.
Results: In vivo, BDL induced characteristic histopathological features of cholemic nephropathy in untreated animals, whereas these changes were markedly attenuated in spironolactone-treated rats. Immunohistochemical analysis demonstrated reduced renal Rac1 expression in the treatment group. In vitro, exposure of HK-2 cells to the bile acid cocktail resulted in pronounced cytotoxicity after 24 hours. Co-treatment with potassium canrenoate (10 µM) and NSC23766 (100 µM) significantly reduced cytotoxicity ($p = 0.001$). Both agents alone also conferred partial protection.
Conclusion: These findings demonstrate a significant protective effect of mineralocorticoid receptor antagonists in experimental cholemic nephropathy, both in vivo and in vitro. Beyond the classical aldosterone–MR axis, activation of the Rac1–MR signaling pathway appears to play a critical role in bile acid–induced renal injury. Further studies are warranted to elucidate the therapeutic potential of targeting this pathway in cholestasis-associated kidney disease.

FRI-285
Thioredoxin reductase 1 regulates the nucleotide binding oligomerization domain containing 2-receptor interacting serine/threonine kinase 2 signaling pathway during cholestatic liver injury
Colin Shearn[1], Aimee Anderson[1], Michael Devereaux[1], Edward Schmidt[2], Ronald Sokol[3]. *[1]The University of Colorado Anschutz Medical Campus, Aurora, United States; [2]Montana State University, Hungarian Veterinary Medical University, Bozeman, United States; [3]The University of Colorado Anschutz Medical Campus, Children's Hospital Colorado, Aurora, CO, United States*
Email: Colin.Shearn@CUAnschutz.edu

Background and aims: The cholestatic liver disease primary sclerosing cholangitis (PSC), is characterized by periportal inflammation with progression to hepatic fibrosis and ultimately cirrhosis. Bacterial PAMPs have been shown to activate the Nucleotide Binding Oligomerization Domain Containing 2- Receptor Interacting Serine/Threonine Kinase 2 (Nod2-Ripk2) intracellular inflammatory signaling pathway in the intestine. Approximately 80% of PSC patients have an additional diagnosis of Crohn's disease, increasing the susceptibility of the liver to exposure of bacterial Pathogen-Associated Molecular Patterns (PAMPs) originating from the intestine. We have recently shown that Thioredoxin Reductase (TrxR1) signaling plays an important role in regulation of inflammation during cholestasis. The objective of this study was to determine if Nod2-Ripk2 signaling is upregulated in PSC and to examine the impact of pharmacological and genetic targeting of thioredoxin reductase 1 on Nod2-Ripk2 signaling in cell culture and a murine model of cholestatic liver injury.
Method: Protein and mRNA expression of the Nod2-Ripk2 signaling pathway was examined in liver tissue isolated from WT and murine models of cholestasis as well as in patients diagnosed with end stage PSC. In addition, the effect of inhibition or genetic ablation of TrxR1 signaling on Nod2-Ripk2 signaling was analyzed in cultured macrophages, cholangiocytes as well as in the bile duct ligation (BDL) model of cholestatic injury.
Results: Increased protein and mRNA expression of the Nod2-Ripk2 signaling pathway was present in human PSC as well as in liver isolated from mice following 3 day BDL as well as after feeding 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC) for 3 days. Immunohistochemical analysis of livers from human cholestatic patients as well as 3 day DDC fed and 3 day BDL mice and revealed increased hepatic Nod2 and Ripk2 staining. Pharmacological targeting of TrxRd1 inhibited Flagellin-LPS mediated Nod2-Ripk2 activation in RAW264.7 macrophages and H69 cholangiocytes. Finally, hepatospecific deletion as well as pharmacological targeting of TrxR1 inhibited BDL-dependent induction of hepatic Nod2-Ripk2 signaling.
Conclusion: These data demonstrate that the Nod2-Ripk2 inflammatory pathway is activated in murine cholestasis as well as in human PSC and implicate TrxR1-signaling as an important regulator of Nod2-Ripk2 activation.

FRI-286
cfChIP-seq liquid biopsy distinguishes autoimmune hepatitis from other liver diseases
Gavriel Fialkoff[1], Ami Ben Ya'akov[2], Issra Sharkia[1], Ronen Sadhe[1], Jenia Gutin[1], Abed Khakayla[3], Achraf Imam[3], Rifaat Safadi[4], Ophir Hay[4], Nofar Rosenberg[5], Yael Milgrom[4], Nir Friedman[1], Eithan Galun[5], Eyal Shteyer[2]. *[1]The Rachel and Selim Benin School of Computer Science and Engineering, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [2]The Juliet Keidan Institute of Pediatric Gastroenterology, Shaare Zedek Hospital, Jerusalem, Israel; [3]Department of General Surgery and Transplantation Unit, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [4]Hadassah-Hebrew University Medical Center The Liver Unit Institute of Gastroenterology and Liver Diseases, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [5]The Goldyne Savad Institute for Gene Therapy,*

Hadassah-Hebrew University Medical Center, Jerusalem, Israel
Email: eithang@hadassah.org.il

Background and aims: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease associated with substantial morbidity and mortality. Diagnosis and monitoring typically rely on liver biopsy, despite its invasiveness and limitations. Liquid biopsies show promise as noninvasive alternatives, but their utility in AIH remains underexplored. Here, we show that plasma-based chromatin immunoprecipitation followed by sequencing (cfChIP-seq) can detect hepatocyte-specific transcriptional activity in AIH and serve as a diagnostic and monitoring biomarker.
Method: We profiled circulating cell-free nucleosomes marked by H3K4me3—an active histone modification—in plasma samples from children and adults that underwent liver biopsy in two medical centers. Clinical data, lab results and histological results were recorded and correlated to the cfChip results. Diagnosis of AIH was based on the International Autoimmune Hepatitis Group scoring index. cfChIP-seq results were compared with liver RNA-seq from matched biopsies. A machine learning classifier was trained to distinguish AIH cfChIP-seq profiles from those of other liver diseases.
Results: In total, 345 patients participated in the study and were classified into distinct groups: AIH patients confirmed by biopsy (42 children and 49 adults), healthy controls (six pediatric and eight adult), and individuals with other liver conditions (35 children and 211 adults).cfChIP-seq revealed immune-related transcriptional signatures in hepatocyte-derived nucleosomes unique to AIH patients, corroborated by matched liver RNA-seq data. When tested on individuals with elevated transaminase levels, a cfChIP-seq-based classifier discriminated AIH from other liver conditions, including MASH and DILI, with high accuracy (AUC = 0.94. 79% sensitivity at 90% specificity). The cfChIP-seq signal reflected ongoing intrahepatic transcriptional activity and distinguished AIH from non-autoimmune liver injuries.
Conclusion: Plasma cfChIP-seq captures hepatocyte-specific gene activity and offers a non-invasive, accurate method for diagnosing and monitoring AIH. This approach could reduce reliance on liver biopsy, improve diagnostic precision, enable continuous monitoring of treatment response, and provide novel insights into AIH pathogenesis.

FRI-287

Renal apical sodium-dependent bile acid transporter (ASBT) inhibition increases whole-body bile acid clearance in healthy pigs by enabling renal elimination as quantified by 11C-CSar PET/CT

Michael Soerensen[1], Frederik Teicher Kirk[2], Maja Kanstrup Jørgensen[2], Mie Ringgaard Dollerup[2], Aage Kristian Olsen Alstrup[2], Dirk Bender[2], Erik Lindstrom[3], Thomas Sandahl[2]. *[1]Viborg Regional Hospital, Aarhus University Hospital, Viborg, Denmark; [2]Aarhus University Hospital, Aarhus, Denmark; [3]Ipsen, Gothenburg, Sweden*
Email: michsoer@rm.dk

Background and aims: Cholestasis, defined as decreased bile flow, can lead to systemic accumulation of bile acids (BAs). Ileal BA transporter (IBAT) inhibitors prevent reabsorption of BAs in the gut, thereby increasing fecal BA excretion and reducing systemic BA accumulation. IBAT is also expressed in proximal renal tubules, then referred to as ASBT (apical sodium-dependent bile acid transporter). Accordingly, ASBT inhibitors increase urinary excretion of BAs in bile duct ligated mice but have not been tested in larger animal models. The aim of this preclinical study was to quantify the acute effects of systemic ASBT inhibition on urinary BA excretion, whole-body BA clearance, and changes in hepatic transport kinetics in a porcine model using functional, positron emission tomography (PET) with the synthetic conjugated BA tracer ^{11}C-CSar.
Method: Eight anesthetized female pigs (Danish Landrace × Yorkshire crossbred; mean weight 42 kg) underwent two successive 60-min ^{11}C-Csar PET recordings: A baseline PET with vehicle administered as an IV bolus + infusion followed by a PET with vehicle + the ASBT inhibitor elobixibat. Arterial blood was collected successively for measurements of ^{11}C-CSar and elobixibat concentrations. Time courses of radioactivity concentrations (kBq/mL vs time in minutes) in liver and ureters were obtained. Whole-body clearance was calculated as AUC of blood ^{11}C-CSar divided by injected dose of ^{11}C-CSar. Relative change in urinary excretion was calculated as $AUC_{ureters}/AUC_{blood}$ after treatment relative to $AUC_{ureters}/AUC_{blood}$ before treatment.
Results: Arterial plasma concentrations of elobixibat ranged from 320 to 1078 (mean 673) ng/mL. Visually, pre-treatment with elobixibat clearly increased activity of ^{11}C-CSar in ureters compared to an almost non-visible excretion in vehicle-treated controls. Quantitatively, elobixibat increased urinary excretion of ^{11}C-CSar by a median of 8.2-fold ($P < 0.01$), leading to an increase in whole body clearance from mean 20.4 to 23.8 mL blood/min ($P < 0.01$). Elobixibat did not affect hepatic kinetics of ^{11}C-CSar (all parameters $P > 0.15$).
Conclusion: Intravenous administration of elobixibat increased whole-body clearance of BA in healthy pigs by enabling renal elimination. These findings provide a translational rationale for systemic ASBT inhibition as a strategy to reduce systemic bile acid exposure in patients with severe cholestasis, including patients at risk of cholaemic nephropathy.

FRI-289

Indoles are colon-dependent circulating microbial metabolites associated with prognosis in primary sclerosing cholangitis

Email: sara.tjonnfjord@gmail.com

Background and aims: Gut microbiota-derived indoles exert anti-inflammatory effects by activating the aryl hydrocarbon receptor in inflammatory bowel disease (IBD). Primary sclerosing cholangitis (PSC) typically co-occurs with IBD, and many patients undergo colectomy, which was recently associated with improved PSC survival. Here, we aimed to estimate the extent to which indole levels are altered by IBD or colectomy, and whether indoles are associated with PSC outcomes.
Method: Serum levels of indoles and the microbial metabolite trimethylamine-N-oxide (TMAO) were analysed by LC-MS/MS in a cross-sectional Norwegian PSC cohort (n = 315, median follow up 12 years). Colectomy status and IBD activity were evaluated retrospectively. Serum levels of indoles and TMAO were also assessed in a U.S. PSC cohort (n = 509, median follow up 5 years), a cross-sectional Swedish PSC cohort (n = 101), a Norwegian colorectal cancer cohort without PSC (n = 68) and healthy controls (HC, n = 100).
Results: Multiple indoles including indole-3-propionic acid (IPA) were consistently reduced in PSC compared with HC, particularly in those who had undergone colectomy. TMAO was only reduced in colectomized participants. Among people with colorectal cancer without PSC, increasingly extensive colonic resections were associated with progressively greater reductions in IPA and TMAO. Considering colon status in PSC, IPA and TMAO were almost abolished in people with proctocolectomy with ileostomy, while the impact of other types of colectomies including ileoanal pouch was weaker. In PSC with intact colon, higher concentrations of IPA were associated with better liver transplantation-free survival, while the impact of TMAO on survival was limited. There was an apparent survival benefit of high circulating IPA levels also when adjusting for the Amsterdam-Oxford model score (HR per SD increase = 0.69 (0.49–0.98) and 0.28 (0.13–0.63) in the Norwegian and U.S. cohort, respectively). Neither the indoles nor TMAO appeared to differ according to IBD status or activity.
Conclusion: IPA was reduced in people with PSC, and in those with inctact colon, the lowest levels were associated with the poorest outcome. Colectomy, and particularly proctocolectomy, was associated with depletion of key microbial metabolites, both potential disease drivers and protective factors. However, the putative benefit of gut-derived, anti-inflammatory indoles seems to be outweighed by the suggested protective role of proctocolectomy in PSC.

FRI-290-YI
Multi-omics analysis reveals zone-specific hepatocyte antigen presentation and pathogenic CD8+ T cells in autoimmune hepatitis

Han Wang[1], Shuhui Wang[1], Dean Tian[1], Mei Liu[1]. *[1]Department of Gastroenterology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*
Email: hanwang@tjh.tjmu.edu.cn

Background and aims: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease with increasing global prevalence. Progress in mechanistic and translational research has been limited by the lack of robust animal models and comprehensive characterization of the hepatic immune microenvironment. Here, we established a stable AIH mouse model and performed integrated multi-omics analyses, combining single-cell and spatial transcriptomics in both mice and human AIH samples, to provide a panoramic view of immune cell dynamics and hepatocyte-immune interactions.
Method: AIH was induced by liver-specific overexpression of the human autoantigen CYP2D6. Liver inflammation and fibrosis were assessed by H&E and Sirius Red staining, and serum autoantibodies by ELISA. Hepatic immune populations were profiled using 10× Genomics single-cell RNA sequencing and spatial transcriptomics. Human AIH liver samples were analyzed by spatial transcriptomics for cross-species validation. Stage-specific roles of $CD4^+$ and $CD8^+$ T cells were evaluated by in vivo depletion, and hepatocyte–immune cell interactions were analyzed across hepatic zones.
Results: By day 14 post-injection, periportal inflammation was evident, with serum autoantibodies detected by day 28. Peak disease at day 35 showed hallmark AIH features, including interface hepatitis, rosette formation, and fibrosis, closely resembling human AIH. Multi-omics analysis revealed dynamic remodeling of hepatic immune populations, including $CD4^+$ T cells, $CD8^+$ T cells, NK cells, and activated Tregs, with prominent immune cell interactions. Effector and tissue-resident memory $CD8^+$ T cells predominated, while $CD4^+$ T cells mainly contributed to disease initiation. Spatial transcriptomics identified zone-specific hepatocyte antigen presentation, with Zone 3 hepatocytes as the primary antigen-presenting cells, a finding validated in human AIH samples. Functional studies demonstrated that $CD8^+$ T cells are the principal pathogenic population, whereas $CD4^+$ T cells play a limited role during acute inflammation.
Conclusion: This AIH mouse model recapitulates key features of human disease and, through integrated multi-omics analyses, provides the first panoramic view of hepatic immune dynamics and zone-specific hepatocyte-immune interactions. The study clarifies stage-specific roles of $CD4^+$ and $CD8^+$ T cells, validates findings in human samples, and establishes a robust platform for mechanistic studies and therapeutic target discovery in AIH.

FRI-291-YI
Cholangiocyte-derived interleukin-15 contributes to the interaction with auto-aggressive CD8+ T cells in primary sclerosing cholangitis

Nico Will[1], Laura Liebig[2], Christian Casar[1], Sabrina Pilz[1], Silja Steinmann[1], Victor Haas[1], Franziska Mangler[1], Tobias Poch[1], Jenny Krause[1], Ulf Panzer[1], Michael Dudek[3], Percy A. Knolle[3], Norbert Hübner[2], Samuel Huber[1], Ansgar W. Lohse[1], Dorothee Schwinge[1], Christoph Schramm[1]. *[1]University Of Hamburg Medical Center Eppendorf Helipad, Hamburg, Germany; [2]Max Delbrück Center For Molecular Medicine, Berlin, Germany; [3]Institut für Molekulare Immunologie, München, Germany*
Email: c.schramm@uke.de

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive autoimmune liver disease with limited treatment options and a presumed pathogenetic contribution of the adaptive immune response. We have previously described that $CD8^+$ T cells are in close interaction with cholangiocytes. We here hypothesized that Interleukin-15 (IL-15), recently described to drive tissue-resident cytotoxic and auto-aggressive responses, may act on hepatic $CD8^+$ T cells to shape their interaction with cholangiocytes.
Method: We analyzed intrahepatic $CD8^+$ T cells using our previously generated CITE-Seq from people with PSC. Peripheral $CD8^+$ T cells from people with PSC (n = 25), PBC (n = 14), and healthy controls (n = 18) were assessed via full-spectrum flow cytometry. IL15 and IL15RA expression were profiled using single-nucleus RNA-seq (sNucSeq) from liver biopsies ($n_{total} = 52$, $n_{PSC} = 25$) and validated in human cholangiocyte organoids on protein level. Portal immune cell composition and cytokine expression were assessed by spatial transcriptomics across PSC stages and controls (n = 22).
Results: CITE-Seq-analysis of intrahepatic $CD8^+$ T cells from people with PSC showed high HLA class II, NKG2D, interferon γ and

granzyme expression, consistent with IL-15–induced auto-aggression. The upregulation of IL-15–associated phenotypic markers was confirmed in peripheral CD8$^+$ T cells from people with PSC using flow cytometry. sNucSeq analysis of liver biopsies revealed significantly increased IL15 and IL15RA-expression in cholangiocytes of PSC livers. IL-15 and IL-15Rα expression was confirmed at the transcriptional and protein levels in human-derived cholangiocyte 3D organoids and was significantly (~10-fold) upregulated upon interferon-γ stimulation. Spatial transcriptomics revealed accumulation of CD8$^+$ T cells with auto-aggressive transcriptomic profiles within portal tracts of PSC livers in proximity of cholangiocytes. Notably, cholangiocytes exhibited the highest expression of IL15 and IL15RA among all cell types of the portal tract. Blocking experiments to functionally validate those findings in mouse models are ongoing.
Conclusion: Our data support a role for IL-15 in driving auto-aggressive CD8$^+$ T cell activation in PSC. Cholangiocytes appear to serve as both source and presenter of IL-15, suggesting an antigen-independent mechanism of cholangiocyte-mediated activation of auto-aggressive CD8$^+$ T cells. The IL-15 axis may therefore represent a novel therapeutic target in PSC.

FRI-298
Integrated multi-omics approaches reveal IL-33 as a central pathogenic factor and potential therapeutic target in autoimmune hepatitis
Long Xu[1], Wanwan Shi[1], Xinghuan Fu[1], Wen-Jing Wang[1], Lin-Hui Hu[1], Xue-Ying Li[1], Yan Wang[1], Gui-Qiang Wang[1]. *[1]Department of Infectious Disease, Center for Liver Disease, Peking University First Hospital, Beijing 100034, China, Beijing, China*
Email: twinkleclinic@163.com

Background and aims: The precise source and causality of Interleukin-33 (IL-33) in autoimmune hepatitis (AIH) remain unclear. This study aims to identify the specific IL-33-producing cell subset, establish its genetic causality, and demonstrate the therapeutic efficacy of targeting IL-33 in AIH.
Method: Two-sample Mendelian randomization (MR) analysis was performed to evaluate the causal relationship between IL-33 and susceptibility to AIH. Serum IL-33 levels were measured in both AIH patients and healthy controls to investigate correlations with specific disease activity markers. To identify the cellular source of IL-33 within the liver, single-cell RNA sequencing (scRNA-seq) combined with multiplex immunofluorescence was used. Additionally, the therapeutic efficacy of an anti-IL-33 monoclonal antibody (Torudokimab) was assessed in an S100-induced AIH murine model by measuring liver injury biomarkers and immunoglobulin levels.
Results: Two-sample MR analysis revealed a causal relationship between IL-33 and susceptibility to AIH, with genetically predicted higher IL-33 levels significantly increasing AIH risk (OR = 1.457, 95% CI: 1.096–1.936, P = 0.010). Clinically, serum IL-33 levels were significantly elevated in AIH patients compared to healthy controls (P < 0.0001). Correlation analysis showed significant positive associations between IL-33 and key disease severity markers, particularly with IgG (R = 0.52, P = 0.00022) and AST (R = 0.50, P = 0.00045), followed by ALT (R = 0.44, P = 0.0023) and IgM (R = 0.40, P = 0.0077). scRNA-seq and immunofluorescence identified a specific subset of liver sinusoidal endothelial cells (LSECs), characterized by NRG3 expression, as the primary source of intrahepatic IL-33. In the S100-induced AIH murine model, treatment with Torudokimab demonstrated strong therapeutic efficacy. Compared to vehicle-treated controls, Torudokimab significantly reduced serum ALT and AST levels (P < 0.0001), effectively normalizing liver enzyme levels, and significantly alleviated the autoimmune response, as evidenced by reduced serum IgG levels (P = 0.0002).
Conclusion: This study establishes the causal role of IL-33 in the pathogenesis of AIH and identifies a specific subset of NRG3$^+$ LSECs as its primary source. Importantly, in vivo data show that targeting IL-33 effectively reverses liver injury and attenuates excessive immunoglobulin production, highlighting its potential as a novel therapeutic strategy for AIH treatment.

FRI-299
Radiocarbon dating and multi-omics of gallstones reveal prolonged residence time accompanied with microbial dysbiosis and bacterial oncometabolites linked to gallbladder cancer
Vipin Yadav[1], Rajveer Sharma[2], Vaishali Yadav[1], Ashi Mittal[1], Garima Bhatia[1], Rishabh Sharma[1], Ragini Kilambi[1], Deepti Sharma[1], Nihar Mohapatra[1], Pratibha Ramchandra Kale[1], Sherin Thomas[1], Archana Rastogi[1], Nirupma Trehanpati[1], Viniyendra Pamecha[1], Shvetank Sharma[1], Shiv Kumar Sarin[1], Gayatri Ramakrishna[1]. *[1]Institute of Liver & Biliary Sciences, New Delhi, India; [2]Inter University Accelerator Centre, New Delhi, India*
Email: rgayatri@ilbs.in

Background and aims: Gallbladder cancer (GBC) is a highly aggressive malignancy with poor outcomes and marked geographic variation, notably in northern India and Chile. Most GBCs arise in the presence of gallstones, yet the biological link between persistence of stone, composition, and malignant transformation remains unclear. This study integrated radiocarbon dating with multi-omics profiling of gallstone cores to elucidate chronological, microbial, and metabolic drivers of carcinogenesis.
Method: Thirty gallstones from patients with gallstone disease (GSD), preneoplastic lesions (PNP), and GBC were analyzed. Radiocarbon (^{14}C) dating estimated gallstone age, while LC-MS–based metabolomics and 16S rRNA sequencing identified metabolic and microbial signatures.
Results: Radiocarbon data revealed extended intracholecystic residence in GBC (median 17.5 years, range 10–55) compared with PNP (13 years) and GSD (11 years) (p < 0.03). Logistic regression confirmed increased cancer risk with longer persistence (AUC = 0.86). Metabolomics demonstrated distinct clustering by disease state. GBC stones exhibited >3-fold higher lysophosphatidylcholines, 4.2-fold elevated sulfoglycolithocholate, 6-fold enrichment of the oncometabolite trimethylamine N-oxide (TMAO), and increased leukotriene B4 and dityrosine, reflecting an inflammatory microenvironment. Conversely, protective lipids such as phosphatidylethanolamines and short-chain fatty acids (e.g., butyrate) were depleted. Metagenomic profiling identified enrichment of *Klebsiella* (FC = 2.46) and *Enterococcus* (FC = 2.20) in GBC cores, correlating strongly (r ≥ 0.7–0.9) with pro-inflammatory and lipid metabolites. Integrated analysis revealed disease-stage–specific microbial-metabolite–metabolite networks. *Klebsiella* and *Enterobacter* were positively associated with bile acids, lysophospholipids, amino-acid conjugates, and TMAO, whereas *Escherichia–Shigella* correlated with cholesterol and ceramide-rich metabolites in non-malignant stones. Butyrate showed inverse associations with pathogenic taxa.
Conclusion: Prolonged gallstone retention (>17 years) drives microbial dysbiosis and metabolic reprogramming toward pro-inflammatory, carcinogenic pathways. The gallstone core reflects the evolving gallbladder microenvironment, where altered LysoPC: PC ratios, TMAO accumulation, and enrichment of inflammatory lipids and secondary bile acids link pathogenic microbes to carcinogenic transformation.

FRI-300-YI
Developing advanced 3D models of cholangiocyte-immune crosstalk
Jeremy Yeoh[1,2,3,4], Henry Hoyle[1,2,3,4], Enya Amundsen-Isaksen[1,2,3,4], Anna Katharina Frank[1,2,4], Aleksandra Aizenshtadt[3], Stefan Krauss[3], Espen Melum[1,2,3,4,5]. *[1]Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Hybrid*

Technology Hub, Institute of Basic Medical Science, University of Oslo, Oslo, Norway; [4]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [5]Section of Gastroenterology, Department of Transplantation Medicine, Division of Surgery and Specialized Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway
Email: w.j.yeoh@medisin.uio.no

Background and aims: Cholangiopathies, such as primary sclerosing cholangitis (PSC), are driven by ongoing inflammation, where immune-cholangiocyte interactions contribute to bile duct dysfunction and liver damage. Currently, relevant human models that recapitulate biliary-immune crosstalk and cell migration are lacking, limiting studies of these mechanisms. Herein, we aimed to radically improve current methods with modified cholangiocyte organoid (CO)-immune co-cultures, as well as develop an immunocompetent organ-on-a-chip (VDUCT) incorporating perfusable primary human bile ducts and vascular channels. These systems will allow for studies of immune-related processes, such as ligand-receptor interactions and immune recruitment, in the context of bile duct physiology.
Method: Primary human cholangiocyte organoids were propagated from endoscopic retrograde cholangiopancreatography (ERCP) brushings, with human umbilical vein endothelial cells (HUVECs) and peripheral blood mononuclear cells sourced either commercially or in-house. Cholangiocytes were seeded on top of Matrigel for 14 days. The VDUCT chip consisted of two parallel hollow channels cast in hydrogel in a 3D printed chip, seeded with cholangiocytes and/or HUVECs. Fluorescent PBMCs were perfused through the vascular channel. Cell populations were visualized using brightfield and/or confocal microscopy.
Results: Surface-seeded CO-immune cell co-culture showed proximity of immune cells to cholangiocyte organoids unlike conventional embedded culture. After 24 h, surface-seeded COs exhibited loss of organoid morphology, while embedded COs largely remained intact. In the VDUCT, cholangiocytes and endothelial cells formed confluent biliary epithelia and vascular endothelia respectively after 10 days in culture, evident by actin, CK19 and CD31 staining. Perfused PBMCs adhered to the endothelium, with approximately 30% extravasated and migrated along a CXCL12 chemotactic gradient. However, no extravasation or migration of immune cells toward the biliary epithelia was observed after 48 h of co-culture, regardless of LPS stimulation.
Conclusion: In sum, our new approach to cholangiocyte-immune co-culture and the VDUCT chip will allow for a new generation of *in-vitro* studies on biliary-immune interactions with direct human and disease relevance. Furthermore, our scalable multi-cellular bile-duct on a chip will allow for parallel regulation of key parameters relevant to bile duct function and immune processes, such as flow rate and shear stress.

FRI-301
Setting-up a biliary niche-on-a-chip for the study of human liver disease-associated ductular reaction

Guo Yin[1], Marlene Kohlhepp[1], Bianca Leonardi, Tian Lan[2], Hanyang Liu[1], Hilmar Berger[1], Milad Rezvani[3], Philip Bufler[3], Frank Tacke[1], Adrien Guillot[1]. *[1]Charité-Universitätsmedizin Berlin, Department of Hepatology & Gastroenterology, Campus Virchow-Klinikum and Campus Charité Mitte, Berlin, Germany, Berlin, Germany; [2]Department of Gastroenterology, West China Hospital, Sichuan University, Chengdu, China; Charité-Universitätsmedizin Berlin, Department of Hepatology & Gastroenterology, Campus Virchow-Klinikum and Campus Charité Mitte, Berlin, Germany, Chengdu, China; [3]Charité - Universitätsmedizin Berlin, Department of Pediatric Gastroenterology, Nephrology and Metabolic Medicine, Berlin 13353, Germany, Berlin, Germany*
Email: guo.yin@charite.de

Background and aims: Ductular reaction (DR), characterized by cholangiocyte proliferation associated with inflammation and liver fibrosis, is a common hallmark of virtually all chronic liver diseases, e. g., metabolic dysfunction-associated steatotic liver disease (MASLD), and primary sclerosing cholangitis (PSC). Yet, DR implications in disease progression remain poorly understood, likely due to the lack of appropriate models. Diverse cells are involved in DR and, therefore, we aimed at developing a versatile in vitro system for cellular crosstalk investigation. We previously reported on a microfluidics-based, multicellular and primary cell-based liver-on-a-chip model mimicking the liver sinusoid and the biliary niche microenvironments. This project aims at refining the model, exploring its physiological relevance for DR studies, and setting up a human cell-based system.
Method: Intrahepatic cholangiocytes were isolated from wild-type (WT) and *Mdr2*-deficient (KO) mice by positive selection and expanded to generate 3-dimensional organoids. Total RNA sequencing and immunostaining confirmed cell identity and evidenced differences associated with DR between the two lines. Mouse or human primary hepatocytes, cholangiocytes, hepatic stellate cells, macrophages and endothelial cells were isolated from the liver and seeded to generate a biliary niche-on-a-chip (BoC). Freshly isolated blood circulating immune cells were perfused. Protein and gene expression were assessed by multiplex immunofluorescence and RT-qPCR, and immune cells were characterized by multispectral flow cytometry. Gene interference was used to knock-down genes associated with distinct pathogenic pathways.
Results: Mouse primary liver and blood cells were successfully isolated and seeded into the BoC. Inflammation and fibrogenesis increased in the BoC seeded with reactive mouse intrahepatic cholangiocyte organoids (mICOs) isolated from *Mdr2*-deficient. Transient gene expression in mICOs or macrophages modulated the BoC inflammatory response. Early results show that human primary liver cells were successfully isolated and characterized by immunofluorescence staining prior seeding in a humanized BoC.
Conclusion: The multicellular BoC is a first-of-its-kind, versatile primary cell-based model that may be used to study DR, allowing to dissect the relevance of cell-type specific molecular pathways for liver biology and pathogenesis ex vivo. Preliminary data support the feasibility of a primary, human cell-based liver-on-a-chip.

FRI-302-YI
Inhibiting cuproptosis mitigates cholangiocyte inflammation in primary biliary cholangitis

Yu-Jie Zhou[1], Nana Cui[1], Qiwei Qian[1], Bingyuan Huang[1], Tianyu Mao[1], Haoyu Wen[1], Yu Chen[1], Qiaoyan Liu[1], Leigh MacConell[2], Meng Yu[2], Liping Liu[2], Ming-Hua Zheng[3], Min Lian[1], Xiao Xiao[1], Zhengrui You[1], Ruqi Tang[1], Merrill E Gershwin[4], Xiong Ma[1]. *[1]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [2]HighTide Therapeutics, Inc., Shenzhen, China; [3]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [4]University of California at Davis, Davis, United States*
Email: maxiongmd@hotmail.com

Background and aims: Cuproptosis, a newly identified mechanism of cell death features DLAT ($PDC\text{-}E_2$) aggregation, the immunodominant mitochondrial autoantigen of primary biliary cholangitis (PBC). Hitherto therapeutic venues designed to modulate cuproptosis are lacking.
Method: We employed a multi-prong approach, using in-vitro models, and a phase II clinical study to define cuproptosis in PBC. We firstly compared susceptibility to cuproptosis among using a panel of cells. We also investigated the correlation between serum copper levels and pathology in chronic liver diseases. Similarly we investigated the relationships of $PDC\text{-}E_2$ oligomerization and cuproptosis. Then high-throughput screening of cuproptosis inhibitor was performed in cholangiocytes and the mechanism of the

inhibitory effect of berberine on cuproptosis was explored. Finally we explored the therapeutic value of berberine in patients with PBC.
Results: Cholangiocytes are more susceptible to cuproptosis than hepatocytes due to lower expression of metallothionein. Unlike in chronic hepatitis B, MASLD, and autoimmune hepatitis, serum copper was positively correlated with fibrosis stages in PBC. We observed copper overload-triggered aggregation of the DLAT (aka PDC-E_2) autoantigen in cholangiocyte mitochondria. Intriguingly, large EVs released by cuproptotic cells contained intact aggregated PDC-E_2. Co-culture of these EVs with liver-infiltrating immune cells from PBC patients potently expanded and activated PDC-E_2-specific T cells. A widely prescribed medication, berberine, was identified to inhibit cuproptosis. Mechanistically, berberine suppresses cuproptosis through promoting PDC-E_2 degradation and inhibiting pyruvate uptake to mitochondria to bypass PDC-E_2. In PBC mouse models, induction of cuproptosis exacerbated cholangitis, accompanied by increased hepatic infiltration of PDC-E_2-specific T cells, while berberine intervention mitigated cholangiocyte inflammation. Finally, in the phase 2 clinical trial in PBC patients with inadequate response to standard therapy, berberine ursodeoxycholate demonstrated reduced ALP levels at week-12 (-9.82%; 95%CI: −19.5 ~ −0.11; P = 0.048).
Conclusion: We report herein an association between cuproptosis and PBC progression. Berberine treatment represents a promising therapeutic strategy for modulating cuproptosis in associated pathologies.

TOP-277-YI
Real-world effectiveness and safety of seladelpar in primary biliary cholangitis: a nationwide electronic health record-based study

Adrielly Martins[1], Cynthia Levy[1]. [1]*University of Miami, Miami, United States*
Email: axm8717@med.miami.edu

Background and aims: Seladelpar, a selective peroxisome proliferator-activated receptor delta agonist, received United States Food and Drug Administration conditional approval in August 2024 as second-line therapy for primary biliary cholangitis (PBC). However, efficacy and safety data are lacking for patients with autoimmune hepatitis (AIH) overlap syndrome and metabolic dysfunction-associated steatotic liver disease (MASLD)—populations underrepresented in clinical trials. We evaluated the real-world effectiveness and safety of seladelpar across PBC subgroups.
Method: This retrospective cohort study used Epic Cosmos, a federated electronic health record platform. Adults with PBC prescribed seladelpar after approval were included. Patients were classified into mutually exclusive subgroups: PBC alone, PBC-AIH overlap, and PBC-MASLD. The primary outcome was biochemical response at 6 months per POISE criteria (alkaline phosphatase [ALP] less than 1.67 times upper limit of normal [ULN], 15% or greater ALP reduction, and normal bilirubin). Secondary outcomes included ALP normalization and hepatotoxicity (alanine aminotransferase [ALT] greater than 3 or 5 times ULN [xULN]).
Results: Among 666 patients with baseline ALP, 209 (31.4%) had PBC alone, 76 (11.4%) had PBC-AIH overlap, and 381 (57.2%) had PBC-MASLD. Mean age was 63.9 years and 89.8% were female. Cirrhosis was present in 35.6% overall, higher in PBC-AIH (52.6%) and PBC-MASLD (45.4%) than PBC alone (11.5%; $p < 0.001$). At 6 months (n = 248), POISE response rates were 68.8% for PBC alone, 64.2% for PBC-MASLD, and 48.5% for PBC-AIH ($p = 0.13$). Cirrhotic patients had lower 6-month POISE response than non-cirrhotic (55.6% vs 68.5%; $p = 0.04$). ALP normalization rates were 48.4%, 38.4%, and 27.3%, respectively ($p = 0.11$). ALT elevations greater than 3 xULN decreased from baseline (3.5%) to 6 months (1.1%), with no ALT greater than 5 xULN at 6 months. Mean ALT was lower at 6 months across all subgroups. No new drug-induced liver injury cases were observed. Among patients with available eGFR (14%) and creatine kinase (4%) data, no renal or muscle safety concerns were observed.
Conclusion: In this real-world study, biochemical response rates were consistent with phase 3 trial results. MASLD did not attenuate treatment response. Patients with AIH overlap showed numerically lower response rates, warranting further investigation. Seladelpar demonstrated a favorable hepatic safety profile across diverse PBC populations.

Email: diazg.alvaro@gmail.com

Background and aims: Individuals with AMA positivity are at risk of developing Primary Biliary Cholangitis (PBC), although only a minority progress to overt disease. There is limited information on their characteristics and factors associated with PBC development.
Method: Multicenter, retrospective study in 16 Spanish centers. We included individuals with AMA and/or PBC-specific antibodies who did not meet diagnostic criteria for PBC at antibody detection and who were under active follow-up.
Results: 846 individuals were included, predominantly women (82.8%). 770 (91%) were AMA+, 254 (30%) had anti-M2 antibodies, 58 (6.8%) anti-sp100, and 16 (1.9%) anti-gp210. Overall, 306 patients (36.2%) had other autoimmune diseases and 6 (0.7%) had a family history of PBC. 54 individuals (7.3%) reported at least one symptom, the most frequent being fatigue (n = 33, 3.9%) followed by pruritus (n = 11, 1.3%). All patients had alkaline phosphatase (ALP) levels below the upper limit of normal (ULN). Median values of other parameters (xULN; IQR) were AST 0.7 (0.5–0.9), ALT 0.6 (0.4–0.8), GGT 0.4 (0.4–1.6), total bilirubin 0.4 (0.3–0.6), and IgM 0.5 (0.3–0.8). Baseline elastography was available in 113 patients, with a median of 4.7 kPa (IQR 3.7–6.1). Follow-up data were available for 417 individuals. 41 patients (9.8%) developed PBC after a median of 3.2 years (IQR 1.3–6.4), yielding an incidence rate of 1.96 per 100 person-years. At baseline, those who developed PBC had significantly higher ALP (0.79 vs 0.63 × ULN, $p < 0.001$) and GGT levels (1.02 vs 0.63 × ULN, $p < 0.001$). No differences were observed in AST, ALT, bilirubin, IgM, or other parameters. In addition, patients who progressed to PBC had a higher prevalence of AMA titers >1:320 (81.6% vs 60.7%; $p = 0.011$). Baseline fatigue was significantly more frequent among those who developed PBC (14.7% vs 5%; $p = 0.014$). In univariate analysis, baseline ALP, GGT, AMA titers and fatigue were significantly associated with the risk of developing PBC. The optimal ALP × ULN cutoff was 0.73 × ULN (sensitivity 0.71; specificity 0.69). ALP ≥0.73 × ULN (HR 4.9; 95% CI 2.4–10.2), GGT >ULN (HR 2.8; 95%CI 1.4–5.6), AMA titers >1:320 (HR 3.9; 95% CI 1.7–9.3), and baseline fatigue (HR 3.7; 95% CI 1.5–9.2) were independently associated with the development of PBC in the multivariate analysis.
Conclusion: Approximately 10% of AMA-positive individuals developed PBC over a median follow-up of 3.2 years. Baseline fatigue, ALP, GGT and AMA titers were independently associated with the risk of developing PBC.

Email: montanol@ualberta.ca

Background and aims: Sex is an established determinant of prognosis in liver diseases, yet its influence on outcomes in autoimmune hepatitis (AIH) is unclear. We analyzed a large, representative multicenter Canadian cohort to determine and quantify the influence of sex on clinical course, treatment response, and outcomes in AIH.
Method: We analyzed data of 2000 AIH patients from the Canadian Network for Autoimmune Liver Diseases (CaNAL). Complete biochemical response (CBR) was defined by normalization of ALT and IgG. Poor clinical outcomes were defined as progression to cirrhosis, liver decompensation, hepatocellular carcinoma (HCC), liver transplantation (LT), or death.
Results: Our cohort, encompassing 21,204 person-years of follow-up, was predominantly female (75.0%), Caucasian (69.1%), median age 60.4 [IQR 44.6–71.0] and disease duration 8.5 [3.5–15.6] years. At diagnosis, males were younger than females (43.3 [IQR 26.2–59.1] vs. 51.1 y.o. [34.2–61.8], $p < 0.001$), presented with more severe disease (ALT 8.8 × ULN [3.1–24.1] vs. 7.6 × ULN [2.2–20.5], $p = 0.033$), and higher frequency of cirrhosis (31.3% vs. 26.4%; $p = 0.038$). Males had higher risk of not achieving CBR at 6- and 12-month (OR 1.82 [95% CI 1.34–2.46], $p < 0.001$, and OR 1.48 [1.11–1.97], $p = 0.008$, respectively), translating into lower treatment response rates (26.6% vs. 39.7%, $p < 0.001$, and 37.5% vs. 47.0%, $p = 0.008$, respectively) compared to females. Moreover, males had 1.5 times higher risk of progression to cirrhosis compared to females if they did not achieve 6-month CBR (HR 3.61 [1.27–10.24], $p = 0.016$, vs. HR 2.34 [1.45–3.78], $p < 0.001$), adjusted for age at diagnosis. Males also had a 3-fold females' risk of developing hepatic decompensation if 6-month CBR was not achieved (HR 7.97 [1.07–59.2], $p = 0.042$, vs. HR 2.72 [1.33–5.56], $p = 0.006$), adjusted for cirrhosis at diagnosis and type 2 diabetes. Male sex was associated with a higher risk of LT (HR 1.49 [1.05–2.12], $p = 0.027$), while risk of HCC, liver-related mortality, and event-free survival did not differ.
Conclusion: Males with AIH have greater disease severity, frequency of cirrhosis at diagnosis, and a lower likelihood of achieving CBR than females. Not achieving CBR places males at 1.5-fold higher risk of progression to cirrhosis and 3-fold higher risk of developing decompensation than females. This shows the importance of sex-specific risk stratification and developing targeted strategies to enhance treatment response in males with AIH.

Email: clbowlus@health.ucdavis.edu

Background and aims: Cholestatic pruritus is common in primary biliary cholangitis (PBC) and negatively impacts sleep and quality of life, yet effective treatments are lacking. In the Phase 3 GLISTEN study (NCT04950127), linerixibat, an ileal bile acid transporter inhibitor, significantly improved pruritus and pruritus-related sleep interference vs placebo over 24 weeks (wks). This analysis reports interim data from the Linerixibat Long-term Safety and Tolerability (LLSAT [NCT04167358]) Study evaluating linerixibat's long-term safety, tolerability and maintenance of itch improvement.
Method: Patients (pts) with PBC and moderate–severe pruritus when previously enrolled in Phase 3/Phase 2b linerixibat trials were eligible to enrol in this ongoing, open-label, global extension study, in which pts receive oral linerixibat 40 mg twice daily. The primary endpoint is frequency and severity of adverse events (AEs). Key secondary endpoints include: change in laboratory values; assessment of maintenance of efficacy (MOE; percent of pts who achieved an itch response [≥ 3-point reduction from baseline on 0–10 worst itch numerical rating scale (WI-NRS)] at wk 24 also achieving this threshold at wk 52). Stable concomitant PBC/itch therapy is permitted for those assessed for MOE. Analyses are descriptive.
Results: Of 241 pts enrolled up to 4 years, 222 (92%) were receiving ursodeoxycholic acid, 21 (9%) cholestyramine and 88 (37%) fibrates, seladelpar or elafibranor. AEs were reported in 88% of pts; serious AEs in 14%. The most common AE was diarrhoea (44%; led to treatment discontinuation in 7%). Among pts with an AE, 7% experienced hepatobiliary disorders, 6% alanine aminotransferase increase and 3% aspartate aminotransferase increase. Of 41 responders eligible for interim MOE assessment at wk 24 (who reached wk 52 or withdrew early), 30 (73% [95% CI: 58.07–84.31]) maintained itch efficacy at wk 52. Pts who received linerixibat for 52 continuous wks (n = 38; in GLISTEN then LLSAT) had a mean (SD) WI-NRS change from baseline of −4.87 (2.3). For those randomised to 24 wks of linerixibat then 8 wks of placebo in GLISTEN, itch returned then improved to previous levels once linerixibat restarted in LLSAT.
Conclusion: Interim analysis demonstrates that linerixibat treatment up to 4 years is generally well-tolerated with an acceptable safety profile. In addition, when assessed in a portion of pts with WI-NRS data at wks 24 and 52, linerixibat response on itch is maintained.
Funding:GSK (212358).

Email: cacouto@uol.com.br

Background and aims: Primary biliary cholangitis (PBC) outcomes are mainly reported in Caucasians, lacking data from Latin America. This study aimed to evaluate the biochemical response to ursodeoxycholic acid (UDCA) and second-line therapies using established criteria, and to assess long-term survival and prognosis for PBC in Latin America.
Method: The ALLATIN cohort is a retrospective international multicentre study that enrolled PBC patients from several Latin American countries. Biochemical response was assessed at 6 and 12 months of treatment. Deep response was defined as alkaline phosphatase (ALP)

normalization and bilirubin < 0,6 times the upper limit of normal (ULN).
Results: 2,182 PBC patients (93.3% female) were included –. At diagnosis, median age was 53 years (15–91), 18% were asymptomatic and 27% had advanced liver disease. Baseline mean ALP was 3.63 ± 3.30 × ULN and antimitochondrial antibody positivity was 73.5%. Autoimmune hepatitis and metabolic dysfunction-associated liver disease overlap were reported in 19.8% and 6.3%, respectively. UDCA was prescribed to 96.9%, with 3.6% discontinuation. UDCA response rates after 12 months were: Toronto (57.3%), Paris-2 (39.1%), POISE (38.8%) and deep-response (14.7%). Second-line therapy included fibrates in 27.8% and obeticholic acid in 0.3%. After 12 months of fibrates, response rates were Toronto (58.6%), Paris-2 (36.4%), POISE (42.1%) and deep-response (18.9%). During a mean follow-up of 7.4 ± 5.9 years, 28% developed advanced liver disease, 1.5% had hepatocellular carcinoma and 6.1% underwent liver transplantation. Five- and 10-years survival were 90.2 ± 0.9% and 81.7 ± 1.4%, respectively. Multivariate analysis showed ALP ≥5 .84 × ULN at diagnosis predicted death/transplantation (HR 1.80; 95%CI 1.37–2.34; p < 0.001), and ALP ≥1.46 × ULN at 12 months on UDCA predicted lower transplant-free survival (HR 2.20; 95%CI 1.66–2.94; p < 0.001).
Conclusion: This is the largest Latin American PBC cohort. Low rates of biochemical response to UDCA and modest indication of second-line therapy may be associated with the significant burden of advanced liver disease observed. ALP at baseline and 12-month of UDCA are independent prognostic factors for transplant-free survival. These findings support early risk stratification and timely escalation of therapy in PBC patients from Latin America.

Statin use is associated with reduced cholangiocarcinoma risk in primary sclerosing cholangitis: a national EHR cohort study
Adrielly Martins[1,2], Miki Scaravaglio[3,4], Cynthia Levy[1]. *[1]University of Miami, Miami, United States; [2]Schiff Center for Liver Diseases - University of Miami, Miami, United States; [3]Università Milano-Bicocca, Milano, Italy; [4]University of Cambridge, Cambridge, Northern Ireland*
Email: axm8717@med.miami.edu

Background and aims: Patients with primary sclerosing cholangitis (PSC) face a 10–15% lifetime risk of cholangiocarcinoma (CCA). Statins have demonstrated anti-inflammatory and antineoplastic properties in hepatobiliary cancers, but their association with CCA risk in PSC remains unclear. We evaluated the association between statin use and CCA development in a large PSC cohort.
Method: Using the Epic Cosmos database, we conducted a retrospective cohort study of PSC patients diagnosed between 2005–2025. Relevant statin exposure was defined as ≥2 prescriptions, first prescription ≥90 days after PSC diagnosis, and ≥90 days before CCA diagnosis (for CCA cases). Hazard ratios (HR) were estimated by Cox proportional hazards regression adjusting for age, sex, inflammatory bowel disease (IBD), and cirrhosis. Time-stratified analysis was performed when proportional hazards assumption was violated. Sensitivity analyses examined subgroups by IBD status, cirrhosis, and age.
Results: Of 35,453 PSC patients (mean age 52 years, 51% male, 50% IBD, 58% cirrhosis), 4,485 (13%) met statin exposure criteria and 2,041 (5.8%) developed CCA. CCA incidence was significantly lower in statin users than non-users (3.3% vs 6.1%, p < 0.001). In adjusted analysis, statin use was associated with 69% reduction in CCA risk (HR 0.31, 95% CI 0.26–0.37, p < 0.001). Time-stratified analysis revealed protection was strongest in the first 2 years (HR 0.06, 94% risk reduction), diminished over time (years 2–5: HR 0.38; years 5–10: HR 0.54), and was no longer significant beyond 10 years. In sensitivity analysis excluding CCA diagnosed within 1 year of PSC (likely prevalent disease, n = 904, 44% of cases), statin use remained significantly protective (HR 0.47, 95% CI 0.39–0.56, p < 0.001). Protection was consistent across subgroups: PSC-IBD (HR 0.33) and PSC without IBD (HR 0.28), with cirrhosis (HR 0.34) and without cirrhosis (HR 0.24), and across all age groups (p < 0.001). A dose-response relationship was observed with significant risk reduction across all prescription categories (73% reduction with 2–5 orders; trend p < 0.001).
Conclusion: In a large retrospective cohort of PSC patients, statin use was associated with a substantial reduction in CCA risk across different clinical subgroups. The protective effect was greatest in the early years after diagnosis and increased with greater exposure. These findings support further prospective evaluation of statins in PSC.

TOP-293
Liver biopsy facilitates efficient and high-quality diagnosis and evaluation of treatment outcomes in primary sclerosing cholangitis: results from the phase 3 NUC-5/PSC trial
Sandra Noh[1], Stefan G. Hübscher[2], Thomas Longerich[1], Geoffrey Chase[3], Michael Stiess[3], Peter Fickert[4], Michael Manns[5], Michael Trauner[6], Peter Schirmacher[1]. *[1]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; [2]School of Infection, Inflammation and Immunology, University of Birmingham, Birmingham, United Kingdom; [3]Dr. Falk Pharma GmbH, Freiburg, Germany; [4]Department of Medicine, Medical University of Graz, Graz, Austria; [5]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; [6]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
Email: peter.schirmacher@med.uni-heidelberg.de

Background and aims: NUC-5/PSC was a randomized, controlled, phase 3 trial investigating norucholic acid (NCA) in primary sclerosing cholangitis (PSC) at 74 sites in 16 European countries. A significant benefit of NCA was demonstrated based on the primary and several secondary endpoints comprising structured histopathological evaluation of liver biopsies. Here, we assess the suitability of liver biopsies for clinical investigations and routine diagnosis in PSC based on histological analyses in the trial.
Method: Patients with PSC were treated with NCA or placebo for 192 weeks, with biopsies collected at screening, week 96, and week 192. Eligibility criteria for the trial included confirmation of disease by cholangiography as well as hallmark signs of PSC by liver biopsy within 2 months of baseline. Biopsies were collected according to local procedures. Histological evaluation was performed centrally, with an initial examination of biopsies to confirm diagnosis, and evaluation of efficacy parameters in all biopsies after database lock. These included Ludwig, Ishak, modified Nakanuma score and PSC histoscore staging as well as digital pathology assessment of collagen proportionate area.
Results: A total of 610 biopsies from 335 patients were available at database lock for the primary analysis, with screening biopsies from 334 patients. Mean biopsy length was 21 mm (5.7% <10 mm; 21.3% 10–15 mm; 73.0% >15 mm) with 1.6% containing <6 portal tracts, 34.1% with 6–10 portal tracts, and 64.3% with >10 portal tracts. Expert histological scoring was possible for 98.5% of biopsies, while digital fibrosis assessment was possible for 98.9%. Among the 610 biopsies, 9 were not evaluable due to technical ineligibility. Furthermore, histological evaluation suggested a diagnosis other than PSC (e.g. sarcoidosis, fibropolycystic disease, primary biliary cholangitis) for 3.3% of patients, and a significant comorbid parenchymal disease (e.g. metabolic or toxic etiology) for 3.0%. Biopsy-related adverse events (AEs) were reported for 4.1% of biopsy examinations across all time points, with serious AEs reported for 1.1% and AEs for 0.7% of biopsies, and no discontinuations.
Conclusion: In this international pivotal trial in PSC, the use of locally-collected liver biopsies facilitated high diagnostic sensitivity and efficient analyses with few adverse events. Histopathology of liver biopsy is safe and informative, confirming diagnostic accuracy and therapeutic efficacy in clinical trials and for routine diagnosis of PSC.

TOP-294-YI

The number needed to treat with bezafibrate as second-line therapy to prevent liver transplantation or death in people with primary biliary cholangitis

Ellen Werner[1], Maria A. van de Vrie[1], Maria C. van Hooff[1], Adriaan J. van der Meer[1]. [1]*Erasmus University Medical Center, Rotterdam, Netherlands*
Email: e.werner@erasmusmc.nl

Background and aims: The clinical benefit of bezafibrate (BZF) in primary biliary cholangitis (PBC) has not been extensively reported in absolute measures. We aimed to assess the number needed to treat (NNT) with bezafibrate (BZF) to prevent liver transplantation (LT) or death among people with PBC.
Method: The NNT was calculated based on the LT-free survival probability among ursodeoxycholic acid (UDCA)-treated individuals with PBC included in the Dutch PBC Cohort Study and the reported adjusted HR of BZF on LT or death (aHR 0.33, 95%CI 0.19–0.55) in the Japanese Cohort Study (Tanaka et al. J Hepatol 2021). In addition, the NNT was plotted over the range of the GLOBE score (as a prognostic tool), to allow the estimation of the NNT to prevent one LT or death for the individual with BZF. The NNT to prevent one death or LT within 5 years (NNT5y) or 10 years (NNT10y) is presented.
Results: In total, 2271(63.7%) Dutch people with PBC had an ALP above the upper limit of normal (ULN) after one year of UDCA. Their median age was 57.1 years (IQR 50.1–67.0), 2003 (88.2%) were female and 187 (8.2%) had cirrhosis. During a median follow-up of 7.5 years (IQR 3.5–13.2), 76 patients underwent LT and 411 patients died without LT. Overall, the cumulative 5y and 10y LT-free survival was 90.0% (95% 88.6–91.4) and 79.4% (95% CI 77.2–81.5), respectively. This corresponded to an estimated NNT5y of 15 (95%CI 11–26) and a NNT10y of 7 (95%CI 6–13) to prevent one LT or death. According to the ALP category (1.0–1.67 × ULN, 1.67–3.0 × ULN, and ≥3.0 × ULN) at one year of UDCA, the NNT5y was 20 (95%CI 14–38), 13 (95%CI 9–26), and 7 (95%CI 5–15), and the NNT10y was 8 (95%CI 6–15), 8 (95%CI 6–16), 6 (95%CI 5–11), and 4 (95%CI 3–8), respectively. The NNT5y and NNT10y dropped below 20 from a GLOBE score above 0.19 and –0.81 (corresponding to an estimated cumulative LT-free survival of 92.3% for either 5 or 10 years), which was the case for 768/1741 (44.1%) and 1494/1741 (85.8%) people in the analyses.
Conclusion: The overall projected efficacy of continued BZF therapy in terms of the NNT to prevent LT or death was strong (NNT < 20), also in case people had a relatively favorable ALP level (1.0–1.67 × ULN) after one year of UDCA. These results highlight the potential clinical benefit of off-label BZF therapy in those without ALP normalization with UDCA therapy alone.

Email: luise.aamann@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease associated with fatigue, muscle weakness, and impaired physical performance. Sarcopenia is a known complication of chronic inflammatory diseases, but its prevalence and clinical relevance in PBC are insufficiently described. This study aimed to assess sarcopenia-related features in patients with PBC using a multimodal approach and to evaluate the feasibility of ultrasound for muscle mass assessment.
Method: Adult patients with primary biliary cholangitis were included in a cross-sectional study conducted at the outpatient clinic, Gastro Unit, Copenhagen University Hospital Hvidovre. Sarcopenia was defined according to European Working Group on Sarcopenia in Older People 2 (EWGSOP2) criteria. Muscle strength was assessed using handgrip dynamometry. Muscle mass was evaluated by appendicular skeletal muscle index (ASMI) measured by dual-energy X-ray absorptiometry (DXA), skeletal muscle mass index (SSMI) assessed by bioelectrical impedance analysis (BIA), and right-sided ultrasound measurements of the biceps brachii and rectus femoris without probe compression. Liver stiffness was assessed by transient elastography. Group comparisons were performed using independent t-tests.
Results: Forty-four patients (100% women) with a median (IQR) age of 59 (54–65) years and disease duration of 5.4 (3.0–9.4) years were included; 9% had advanced liver disease (liver stiffness > 15 kPa). Low muscle strength (< 16 kg) was present in 19%, while low muscle mass was found in 19% by DXA (ASMI < 5.5 kg/m^2) and 21% by BIA (SSMI < 6.1 kg/m^2). Disease duration and liver stiffness did not differ between patients with low versus normal muscle strength. Ultrasound measured biceps brachii muscle thickness correlated moderately with ASM ($r = 0.44$, $p = 0.004$) and SSM (0.48, $p = 0.002$) and rectus femoris muscle thickness correlated moderately with ASM ($r = 0.37$, $p = 0.02$) and SSM ($r = 0.44$, $p = 0.005$).
Conclusion: Despite a low prevalence of advanced liver disease, patients with PBC demonstrated a high prevalence of low muscle strength and muscle mass than European reference populations. These findings suggest that sarcopenia-related features occur earlier and more frequently in women with PBC and may contribute to fatigue. Muscle ultrasound appears to be a feasible and clinically useful adjunct for muscle mass assessment and may support easily accessible systematic screening.

SAT-246

High burden of depression, sleep disturbance, and anhedonia in primary biliary cholangitis independent of fibrosis stage and prognostic scores

Gupse Adali[1], Mehmet Ali Saruhan[2], Berkay Dertsiz[2]. [1]*University of Health Sciences Istanbul Umraniye Training and Research Hospital, Istanbul, Türkiye;* [2]*University Of Health Sciences, Istanbul, Türkiye*
Email: gupseadali@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic immune-mediated cholestatic liver disease associated with a substantial symptom burden. Fatigue, pruritus, sleep disturbances, and psychological symptoms are highly prevalent and may markedly impair health-related quality of life. Data simultaneously evaluating depression, sleep quality, and anhedonia in PBC, particularly in comparison with healthy individuals, are limited. This study aimed to compare depressive symptoms, sleep quality, and anhedonia between patients with primary biliary cholangitis and healthy controls using validated psychometric tests and to explore whether these tests are associated with disease severity.
Method: This cross-sectional study included 88 patients with PBC followed at a tertiary referral center and 50 healthy controls (HC)

without known liver or systemic disease. All participants underwent a standardized psychological assessment using validated self-report instruments: the Beck Depression Inventory for depressive symptom severity, the Pittsburgh Sleep Quality Index for sleep quality, and the Snaith–Hamilton Anhedonia Scale for anhedonia. Moderate-to-severe depression, poor sleep quality, and the presence of anhedonia were defined using established cutoff values.
Results: Patients with PBC had a significantly higher prevalence of moderate-to-severe depression (51.1% vs. 20.0%, $p = 0.001$), poor sleep quality (70.5% vs. 44.0%, $p = 0.004$), and anhedonia (38.6% vs. 18.0%, $p = 0.020$) than controls. Associations between PBC and psychological outcomes remained significant after adjusting for sex. Within the PBC cohort, cirrhosis was present in 9.1%, significant fibrosis in 33.0%, and advanced fibrosis in 15.9% of patients. One-third of patients were non-responders according to the Paris II criteria, 23.9% had concomitant MASLD, and 15.9% were classified as high-risk according to the GLOBE score. No significant associations were observed between quality of life measures and disease severity, including liver stiffness. Similarly, quality of life scores were not associated with the presence of MASLD, Paris II response status, or GLOBE risk category.
Conclusion: Patients with PBC exhibit a substantially higher burden of depression, sleep disturbance, and anhedonia than healthy controls. Importantly, these impairments appear to be independent of biochemical response, fibrosis severity, and prognostic risk scores, underscoring the need for systematic psychological assessment alongside routine disease monitoring in PBC.

Treatment adherence predicts lower risk of disease progression among patients with primary biliary cholangitis in the United States

Robert G. Gish[1], Michel Mendler[2], Edward Mena[2], Chong Kim[3], Yi Pan[4], Mihail Samnaliev[4], Diane Ito[4], Maria Agapova[3]. [1]*Robert G. Gish Consultants LLC, San Diego, United States;* [2]*California Liver Research Institute, Pasadena, United States;* [3]*Gilead Sciences, Foster City, United States;* [4]*Stratevi, Santa Monica, United States*
Email: rgish@robertgish.com

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease that can progress to cirrhosis, hepatocellular carcinoma, and liver failure. Real-world evidence evaluating the association between PBC treatment adherence and progression to these clinical outcomes is limited. This study aimed to evaluate the association between PBC treatment adherence with PBC disease progression.
Method: This retrospective cohort study utilized Komodo's Healthcare Map insurance claims (01/01/2016–12/19/2024). Adults aged ≥18 years diagnosed with PBC, with continuous insurance coverage, initiating ursodeoxycholic acid (UDCA), obeticholic acid (OCA) or off-label fibrates after 01/01/2017 were eligible. Proportion of days covered (PDC) with continuous treatment with UDCA, OCA and/or off-label fibrates was estimated, with ≥80% considered adherent. Discrete time-to-event models using annual and quarterly intervals as the analytic units estimated associations between adherence and the first occurrence in the data of cirrhosis, decompensated cirrhosis (DC), hepatocellular carcinoma (HC), liver transplant (LT), and all-cause mortality controlling for demographics, baseline comorbidities, and PBC treatment.
Results: The cohort included 54,034 patients with mean/median follow-up of 1,443/1,365 days (SD: 867). Patients were mostly female (84.9%), primarily Medicare-covered (51.0%), and had a mean age of 62 years. The majority (96.7%) initiated UDCA. Over 1, 3, and 5 years, 50%, 29%, and 21% were adherent, respectively. Adherence was associated with lower risk of cirrhosis (Hazard ratio [HR]: 0.88; 95% CI: 0.83–0.93), DC (HR: 0.69; CI: 0.63–0.76), LT (HR: 0.69; 95% CI: 0.58–0.81) and death (HR: 0.82; 95% CI: 0.76–0.88) (all p < .001) and was not a significant predictor of HC (HR: 0.98; 95% CI: 0.82–1.17; p = .819). When quarterly intervals were used, adherence remained associated with lower risk of cirrhosis, DC, LT and death (all p < .001).
Conclusion: In PBC, only about half of patients met the commonly accepted minimum adherence ≥80% threshold after 1 year, dropping to 1 in 5 by five years. As adherence predicts disease progression, therapy selection based on long-term tolerability and patient suitability may improve outcomes in PBC.

Recompensation and further decompensation after index decompensation in patients with autoimmune hepatitis: a real-world study

Arnav Aggarwal[1], Sagnik Biswas[1], Sarthak Saxena[1], Ayush Agarwal[1], Shekhar Swaroop[1], Vishal Chauhan[1], Shubham Jain[1], Samagra Agarwal[1], Shalimar Shalimar[1]. [1]*All India Institute of Medical Sciences, New Delhi, India*
Email: arnav272@gmail.com

Background and aims: Immunosuppression controls inflammation and can reverse fibrosis in autoimmune hepatitis (AIH), but data on hepatic recompensation in AIH-related decompensated cirrhosis are limited. We evaluated incidence and predictors of recompensation and further decompensation, and assessed the impact of recompensation on long-term survival in these patients.
Method: In this retrospective analysis of a prospectively maintained database, patients with decompensated AIH-related cirrhosis (ascites, variceal bleed or hepatic encephalopathy [HE]) treated with immunosuppression were followed from the time of biopsy-confirmed AIH. The primary outcome was cumulative incidence of recompensation, defined as per Baveno VII consensus, estimated using Fine and Gray competing-risk regression with further decompensation and death as competing risks. Secondary outcomes were all-cause mortality and further decompensation, and the effect of recompensation on mortality was assessed using a time-dependent Cox proportional hazard model.
Results: Of 112 patients (71% females; mean age 41 ± 13 years), 75% had ascites, 26% variceal bleeding and 13% HE. The median MELD-Na and CTP scores were 15.7 (11.5–22.7) and 7 (6–10) respectively. Prednisolone, azathioprine and mycophenolate mofetil were used in 89%, 62% and 21% of patients respectively. Over a median follow up of 29 months, 60 (54%) patients achieved recompensation. Younger age, lower CTP score and biochemical response at 6 months independently predicted recompensation, with biochemical response being the strongest predictor (sHR 1.76, 95% CI 1.18–3.13). After recompensation, 9 (15%) patients developed further decompensation (1- and 2-year cumulative incidence 3.4% and 8.5%), whereas among 52 non-recompensated patients, 36 (69%) developed further decompensation and 16 (31%) remained in a stable decompensated state. Recompensation was associated with reduced mortality (HR 0.26, 95% CI 0.07–0.91) compared with non-recompensated patients. Younger age, lower CTP score and biochemical response also independently predicted lower mortality.
Conclusion: More than half of treated AIH-related decompensated cirrhosis treated with immunosuppression can achieve recompensation, which is associated with reduced mortality compared with non-recompensated patients. Younger age, lower baseline CTP score, and biochemical response are key determinants of recompensation and survival.

Email: inaand@ous-hf.no

Background and aims: People with primary sclerosing cholangitis (PSC) have an increased risk of cholangiocarcinoma (CCA), a cancer with poor prognosis, highlighting the urgent need for improved biomarkers to predict CCA in PSC. We have previously shown that reduced bile acid synthesis, measured by blood 7-hydroxy-4-cholesten-3-one (C4), is associated with worse outcomes in PSC. Here, we investigated whether plasma C4 could serve as a non-invasive marker of CCA risk in PSC.
Method: C4 and bile acids in plasma profiles were analyzed by ultraperformance liquid chromatography-tandem mass spectrometry in 187 Norwegian individuals with PSC (79% male), categorized as either i) PSC with untreated CCA at sampling (PSC-CCA), ii) PSC developing CCA within two years of sampling (PSC-TO-CCA), and iii) PSC without CCA within two years of sampling (PSC-ONLY). Values are given as median (interquartile range, IQR). Group differences were calculated using Mann-Whitney-U test, and statistical analyses were performed in Stata (v18.0).
Results: In total, n = 168 were categorized as PSC-ONLY, ten as PSC-CCA and nine as PSC-TO-CCA. The distributions of sex and concurrent inflammatory bowel disease were similar in the groups. Median age at sampling was 41.2 years, median time since PSC diagnosis was 2.7 years. The median age in the PSC-ONLY group was lower than in the PSC-CCA and PSC-TO-CCA groups (39 vs. 54.7 and 55.5 years), while time since diagnosis was similar between the groups. The C4 levels were higher in the PSC-ONLY group (11.3 nmol/L, IQR 4–32.2) compared with PSC-CCA (1.8 nmol/L, IQR 1.4–2.6, $p < 0.001$) and were borderline significantly higher than in the PSC-TO-CCA group (2.8 nmol/L, IQR 1.3–8.4, $p = 0.051$). Total bile acids concentration was lower in PSC-ONLY (14.0 µmol/L, IQR 4.4–48.1) compared with PSC-CCA (78.0 µmol/L, IQR 68.0–99.3, $p < 0.001$). The total bile acids in PSC-ONLY were also numerically, but not statistically, lower than in PSC-TO-CCA (37.5 µmol/L, IQR 8.1–39.4, $p = 0.64$) and higher in PSC-CCA than in PSC-TO-CCA ($p = 0.04$). Overall, users of UDCA had lower C4 levels than non-UDCA-users (7.7 nmol/L, IQR 2.1–21.8 vs 22.5 nmol/L, IQR 8.5–45.6, $p < 0.001$). We observed no differences in C4 levels depending on use of UDCA in either group.
Conclusion: Plasma C4 was lower and total bile acids levels were higher in individuals with PSC who had established or were close to CCA development. These findings support C4 as a potential non-invasive biomarker for CCA development of PSC and warrant further investigation.

SAT-250

Long-term biochemical response is associated with a lower risk of decompensation in autoimmune hepatitis, irrespective of non-selective beta-blocker use

Email: peni.arvaniti@gmail.com

Background and aims: Baveno VII recommends non-selective beta blockers (NSBB) to prevent decompensation in compensated cirrhosis with clinically significant portal hypertension (CSPH). However, evidence supporting this strategy in autoimmune hepatitis (AIH) is lacking and it remains unclear whether NSBB provides additional benefits beyond those conferred by a long-term biochemical response (BR). We aimed to evaluate the potential of NSBB for preventing decompensation in AIH-related CSPH compared to BR.
Method: Multicentre retrospective study of 266 patients with AIH-related compensated cirrhosis and CSPH with follow-up ≥12 months. CSPH was defined by esophageal varices (EV), HVPG ≥10 mmHg, portosystemic collaterals, liver stiffness ≥25 kPa or spleen stiffness ≥50 kPa. BR was defined as sustained normalization of transaminases during follow-up. Inverse probability of treatment weighting (IPTW) was used to balance baseline covariates (age, sex, body mass index, Child-Pugh score, platelets and EV size) between patients with and without NSBB, considering death and liver transplantation (LT) as competing events.
Results: Most patients were female (66%), with a median age of 58 years (IQR 45–66) and median follow-up of 6 years (IQR 2–11). Overall, 67% (n = 177) received NSBB (propranolol = 70, carvedilol = 107), 53% as primary prophylaxis for high-risk EV. Decompensation occurred in 32% (n = 85), most commonly ascites (66%). At CSPH diagnosis, NSBB treated patients more frequently had high-risk EV (62% vs. 32%, p = 0.001) and lower platelets (108×10^9 vs. 134×10^9, p = 0.003). In IPTW-adjusted analyses, the use of NSBB did not reduce the risk of decompensation (SHR 1.10; 95%CI 0.69–1.78; p = 0.665). In contrast, BR was associated with a significantly lower risk of decompensation (SHR 0.44; 95%CI 0.28–0.72; p = 0.001), an effect that remained consistent in time-dependent analysis, after adjustment for NSBB use and for a composite endpoint of decompensation, death or LT. In stratified analyses, NSBB use was not associated with the risk of decompensation in patients with BR (HR 1.79; 95%CI 0.94–3.43, p = 0.078), whereas it was associated with a significantly lower risk in those without BR (HR 0.40; 95%CI 0.20–0.79; p = 0.009).
Conclusion: In compensated AIH-related cirrhosis, achieving long-term BR was consistently associated with lower risk of decompensation, regardless of NSBB use. This suggests that controlling the inflammatory activity of the disease plays a key role in the prognosis of AIH, even in the presence of CSPH.

SAT-251-YI

S-adenosyl-L-methionine improves health-related quality of life in patients with primary sclerosing cholangitis and inflammatory bowel disease: a subanalysis of a randomized, placebo-controlled trial

Emil Bik[1], Beata Kruk[2], Karolina Wronka[1], Jocelyn Trottier[3], Pawel Piluch[1], Olga Ciepiela[4], Joanna Raszeja-Wyszomirska[1], Olivier Barbier[3], Piotr Milkiewicz[1,5]. *[1]Department of Hepatology, Transplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland; [2]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [3]Laboratory of Molecular Pharmacology, CHU-de-Québec & Faculty of Pharmacy, Laval University, Québec, Canada; [4]Department of Laboratory Medicine, Medical University of Warsaw, Warsaw, Poland; [5]Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland*
Email: emilbbik@gmail.com

Background and aims: Patients with primary sclerosing cholangitis (PSC) frequently experience fatigue, anxiety, and impaired health-related quality of life (HRQoL). Despite the relevant impact on daily functioning, currently no therapy has been proven to effectively improve HRQoL in PSC. S-adenosyl-L-methionine (SAMe) is a key methyl donor involved in hepatocellular and neurochemical pathways and may improve well-being. This randomized, double-blind, placebo-controlled trial evaluated the effect of SAMe on HRQoL in PSC patients receiving ursodeoxycholic acid (UDCA).
Method: Sixty-eight PSC patients were randomized 1:1 to receive SAMe or placebo for six months in addition to UDCA. Five patients in the SAMe group and two in the placebo group discontinued the study, leaving 61 participants (29 SAMe, 32 placebo) included in the final analysis. HRQoL was assessed at baseline and after treatment using the State-Trait Anxiety Inventory (STAI-X1/X2), Generalized Anxiety Disorder Scale (GAD-7), Patient Health Questionnaire (PHQ-9), Modified Fatigue Impact Scale (MFIS), and the disease-specific PBC-40 questionnaire. This subanalysis focused on the subgroup of patients with concomitant inflammatory bowel disease (IBD). Changes between baseline and post-treatment values were analyzed using the Mann–Whitney U test.
Results: Among 37 patients with concomitant IBD (19 SAMe, 18 placebo), baseline HRQoL scores were comparable between treatment arms. No significant between-group differences were observed in liver biochemistry during the study period. Compared with placebo, treatment with SAMe resulted in significantly greater improvement in multiple health-related quality of life domains. Median (IQR) reductions in anxiety-related scales were −7 [−12; −3] vs−1 [−5; 3] for STAI-X1 and −7 [−10; −3] vs 0 [−4; 4] for STAI-X2 (SAMe vs placebo, respectively). General anxiety and depressive symptoms also improved (GAD-7: −3 [−4; −2] vs 0 [−2; 2]; PHQ-9: −2 [−3; −1] vs 0 [−1; 2]). Fatigue decreased more markedly in the SAMe group (MFIS: −10 [−15; −6] vs −3 [−8; 2]), and disease-specific quality of life measured by the PBC-40 improved accordingly (−9 [−13; −5] vs −3 [−9; 3]). All between-group differences reached statistical significance (p < .05).
Conclusion: In the subgroup of patients with PSC and concomitant IBD, SAMe supplementation improves anxiety, mood, fatigue, and disease-specific HRQoL.

Baseline anti-mitochondrial antibody titre in addition to gamma-glutamyltranspeptidase and alanine-aminotransferase serum levels anticipate future primary biliary cholangitis development

Davide Bitetto[1], Carlo Fabris[1], Fornasiere Ezio[1], Elisa Fumolo[1], Elena Garlatti Costa[1], Pierluigi Toniutto[1]. [1]*Hepatology and Liver Transplantation Unit, UDINE, Italy*
Email: davide_bitetto@yahoo.it

Background and aims: Antimitochondrial antibodies (AMA) serum positivity represents a major criterion for diagnosing primary biliary cholangitis (PBC). However, AMA positivity may be found in the presence of normal liver enzymes, suggesting that it could predispose to the development of PBC over time. This study aimed to evaluate the incidence and risk factors for PBC development in a cohort of AMA positive patients.
Method: This retrospective-longitudinal study, conducted from January 2014 to December 2023, enrolled all patients tested AMA positive in the central laboratory of the academic hospital in Udine (Italy), that serves a population of 537.943 inhabitants.
Results: 392 patients tested positive for AMA and 133(33.9%) of them fulfilled the diagnostic criteria for PBC. The annual incidence of AMA positivity and PBC was 5.31/100000 and 2.09/100000 inhabitants, respectively. At the time of the first AMA detection, 93/133(69.9%) patients had an established PBC. In the remaining 40 patients, PBC developed during the follow-up with a declining annual rate, ranging from 4.7% to 1%, with a cumulative 5- and 10-years incidences of 11.7% and 13.4% respectively. At the univariate and multivariate time-to-event analysis PBC occurrence was associated with baseline AMA titre>225 UI/L(O.R. 2.01, 95% C.I. 1.39–2.91, $p < 0.001$), levels of gamma-glutamyltranspeptidase (GGT) > 40 UI/L(O.R. 4.25, 95% C.I. 2.76–6.54, $p < 0.001$) and alanine-aminotransferase (AST) > 30 UI/L (O.R 1.69, 95% C.I. 1.16–2.45, $p = 0.005$).
Conclusion: In AMA positive patients, baseline AMA titre, GGT and AST serum levels anticipate the PBC development.

SAT-253

Changes in the clinical presentation of primary biliary cholangitis over the years in a university center in Argentina

Matías Bori[1], Juan Antonio Sorda[1], Ilse Pardo Ivirico[1], Andrea Curia[1], Lina Palma Cerón[1], Natalia Vera[1], Esteban Gonzalez Ballerga[1].
[1]*Hospital de Clínicas "José de San Martín" Universidad de Buenos Aires, Buenos Aires, Argentina*
Email: borimatias@gmail.com

Background and aims: The clinical presentation of primary biliary cholangitis (PBC) has changed globally over time. However, these changes have not been sufficiently analyzed in our local setting. The aim of this study was to evaluate changes in the clinical presentation of PBC over the last 40 years in a university center in Argentina.
Method: A retrospective study including 596 patients with PBC, divided into four groups according to year of diagnosis: <1990 (n = 113), 1990–1999 (n = 206), 2000–2009 (n = 151), and >2009 (n = 106). Variables analyzed included age at diagnosis, disease stage, clinical presentation (asymptomatic or symptomatic), biochemical stage (according to the Rotterdam criteria), and histological stage.
Results: The female-to-male ratio was 24:1 and remained stable over time. There was an increase in the mean age at diagnosis, from 54.3 years (±11.6) before 1990 to 57.2 years (±12.2) after 2009 ($p = 0.0185$). The symptomatic clinical variant decreased from 73.7% to 50.0% ($p < 0.001$), while early biochemical stage diagnosis increased from 18.0% to 77.4% ($p < 0.001$) over the same period. Advanced histological stages (III-IV) decreased from 60.2% before 1990 to 20.8% after 2009 ($p < 0.001$). The proportion of UDCA responders according to Paris-I, Toronto, Paris-II, Rotterdam, and GLOBE score criteria increased over the investigated decades ($p < 0.001$).
Conclusion: Over time, patients with PBC have shown a change in their clinical presentation, characterized by an older age at diagnosis, earlier biochemical and histological stages, and a predominance of asymptomatic clinical forms. These findings are consistent with global reports and may be attributable to better knowledge of the disease, greater availability and access to diagnostic tests, and possibly changes in environmental triggers over time.

SAT-254

Seladelpar effect on lipids and muscle safety with concomitant statin use in patients with primary biliary cholangitis: interim results from the open-label ASSURE study with up to 4 years of treatment

Christopher L. Bowlus[1,2], Yusuf Yilmaz[3], Ehud Zigmond[4], Victor Vargas Blasco[5], Christophe Corpechot[6], Álvaro Díaz-González[7], Sarah Proehl[8], Johnny Chew[8], Kyung Min Kwon[8], Xiangyu Liu[8], Robert Kustra[8], John M. Background and aims: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in patients (pts) with an inadequate response to UDCA or as monotherapy in pts unable to tolerate UDCA. Dyslipidaemia and use of statins are common in PBC. In the pivotal RESPONSE study (NCT04620733), SEL was associated with reductions in triglycerides (TG), total cholesterol (TC), and low-density lipoprotein cholesterol (LDL-C) at Month (M) 12 vs placebo, independent of statin use. Here, we present an interim analysis of long-term changes in lipids and muscle-related safety in pts treated with SEL from the ongoing open-label Phase 3 ASSURE study (NCT03301506).
Method: Pts from RESPONSE and legacy SEL studies enrolled in ASSURE and received open-label SEL 10 mg once daily. In this analysis, all pts in ASSURE were pooled. Baseline (BL) was defined as SEL initiation in RESPONSE or ASSURE. Post hoc, mean percent change from BL in TG, TC, and LDL-C were analysed through M36. Safety was assessed for the overall population and two subgroups (with or without BL statin use) up to M48. Muscle-related adverse events (AEs) were identified via a predefined search strategy. Data cutoff: 31 Jan 2025.
Results: Among 337 pts in ASSURE, mean BL TG was 116 mg/dL, TC 230 mg/dL, and LDL-C 130 mg/dL. In 122 pts evaluable at M36 of treatment, mean percent change from BL was −15.4% for TG, −12.0% for TC, and −18.6% for LDL-C. There were no meaningful changes in high-density lipoprotein cholesterol. At BL, 87/337 (26%) pts were on a statin. Incidences of AEs and serious AEs (SAEs) were similar in pts on a statin at BL compared with those not on a statin (AEs: 90% vs 91%; SAEs: 20% vs 18%). Muscle-related AE incidence was similar among pts on a statin (9%) vs not (9%). Creatinine kinase (CK) elevations > 3 × the upper limit of normal occurred infrequently both in pts on a statin (1%) and not on a statin (1%). Among 31 pts with muscle-related AEs, only 1 pt (not on a statin) discontinued treatment permanently due to myalgia without a CK elevation.
Conclusion: SEL treatment of pts with PBC resulted in clinically meaningful improvements in lipid profiles that were sustained through M36. Overall, SEL appeared safe regardless of statin use

and without concerns for muscle toxicity with up to 4 years of treatment.

SAT-255

Seasonal variation in intrahepatic cholestasis of pregnancy and its association with adverse pregnancy outcomes: a large retrospective cohort study

Jianghui Cai[1], Mi Tang[1], Xiao Yang[1]. [1]*Chengdu Women's and Children's Central Hospital, Chengdu, China*
Email: caijianghui@126.com

Background and aims: Intrahepatic cholestasis of pregnancy (ICP) is a liver disorder characterized by pruritus and elevated serum bile acids, which is associated with an increased risk of adverse pregnancy outcomes. Evidence suggests that seasonal variation in the onset of ICP exists worldwide. However, the influence of environmental factors, such as the season at diagnosis, on disease severity and perinatal outcomes remains underexplored in ICP. Thus, the present study aims to investigate whether the season of ICP diagnosis is associated with the risk of adverse pregnancy outcomes.
Method: This retrospective cohort study included all patients diagnosed with ICP at Chengdu Women's and Children's Central Hospital from 2015 to 2023. Patients were stratified into four groups based on the season of diagnosis: Spring (March-May), Summer (June-August), Autumn (September-November), and Winter (December-February). Primary outcomes included preterm birth, meconium-stained amniotic fluid (MSAF), asphyxia, and perinatal death. Secondary outcomes included low Apgar scores, NICU admission, peak total bile acid (TBA) levels, and length of maternal hospital stay. Statistical analyses included Chi-square, ANOVA, and multivariate logistic regression adjusting for potential confounders.
Results: Among 1216 ICP patients identified, the distribution of diagnoses across seasons was 20.23% (Spring), 16.28% (Summer), 24.1% (Autumn), and 39.39% (Winter). The incidence of preterm birth was significantly higher in patients diagnosed during winter compared to other seasons (aOR, 1.27; 95% CI, 1.06–1.51, $p < 0.05$). Similarly, rates of MSAF (aOR, 1.21; 95% CI, 1.09–1.37) and the low Apgar scores (aOR, 1.16; 95% CI, 1.07–1.25) were significantly higher in the Winter group. Peak TBA levels were also highest among patients diagnosed in Winter (129 μmol/L, $p < 0.05$). No significant independent seasonal associations were found for other perinatal outcomes, including asphyxia, perinatal death, NICU admission, or length of hospital stay.
Conclusion: The season of ICP diagnosis was significantly associated with the risk of adverse pregnancy outcomes, particularly preterm birth and MSAF. Diagnosis during winter was linked to more severe biochemical profiles and worse clinical outcomes. These findings suggest a potential role of seasonal environmental factors in modulating ICP severity. Further research is warranted to elucidate the underlying mechanisms and explore potential implications for management strategies.

SAT-256-YI

Biochemical changes and clinical outcomes after obeticholic acid withdrawal in patients with primary biliary cholangitis

Beatriz Carrillo Cubero[1], Alba Carmona Frías[1], Paloma Elma Alañón-Martínez[1,2], Jose Luis Montero[1,2,3], Pilar Barrera Baena[1,2,3], Antonio Poyato González[1,2,3], Marta Guerrero-Misas[1,2,3], Manuel De La Mata Garcia[1,2,3], Manuel Rodríguez-Perálvarez[1,2,3]. [1]*Hepatology and Liver Transplant Unit, Reina Sofía University Hospital, Córdoba, Spain;* [2]*Hepatology and Liver Transplant Unit of the Reina Sofía University Hospital, Córdoba, Spain;* [3]*Biomedical Research Center Network for Liver and Digestive Diseases (CIBERehd), Madrid, Spain*
Email: b.carrillocubero@gmail.com

Background and aims: In august 2024, the European Medical Agency revoked marketing authorization of Obeticholic acid (OA) for primary biliary cholangitis (PBC) in the European Union due to uncertainties on risks and benefits. We evaluated the evolution of liver biochemical tests and clinical outcomes in patients who withdrew OA without receiving alternative second line therapies.
Method: Observational retrospective study including adult patients with PBC who withdrew OA following regulatory authorities' recommendation. We excluded patients with decompensated cirrhosis. Patients underwent clinical visits at 6 and 12 months after OA withdrawal including liver biochemical tests. Clinical outcomes of interest were hepatic decompensation, liver transplantation, and death. Patients starting another second line therapy, including fibrates, seladelpar, or elafibranor, were excluded from that time onwards.
Results: 47 patients exposed to OA for 27 months (IQR 17–58) were recruited (97.9% women, aged 59 +/- 9.9 years old), including 29 patients (61.7%) with compensated cirrhosis. At OA withdrawal, 14 patients (29.8%) were taking 10 mg/day and 33 patients (70.2%) were receiving 5 mg/day. Six months and 12 months after OA withdrawal, 72.3% ($n = 34$) and 42.6% ($n = 20$) of patients had not received an alternative second line therapy, respectively, and were included in the liver biochemical analysis. At 6 months, median alkaline phosphatase (AP) and total bilirubin were unchanged but gamma-glutamyl transferase (GGT) raised from 59 UI/L (IQR 26–140) to 95 UI/L (IQR 49–238) ($p = 0.001$), and aspartate aminotransferase (AST) raised from 34 UI/L (IQR 23–49) to 42 UI/L (IQR 27–54) ($p = 0.043$). At 12 months, the only biochemical parameter which continued increasing was GGT at 148 UI/L (IQR 64–249) ($p = 0.002$ compared to baseline). In the whole cohort, 4 patients (8.5%) had hepatic decompensations after OA withdrawal including encephalopathy (3 episodes), ascites (2 episodes) and variceal bleeding (1 episode). Three patients required liver transplantation and one patient died due to infection during hepatic decompensation.
Conclusion: OA withdrawal was associated with a mild elevation of transaminases and a more pronounced and sustained elevation of GGT. The risk of severe hepatic decompensation within the first 12 months is not negligible and claims for caution when considering withdrawal of a second line therapy in patients with PBC, particularly in presence of advanced liver fibrosis.

Background and aims: Primary sclerosing cholangitis (PSC) is characterized by marked heterogeneity in disease progression, with variable advancement to cirrhosis, contributing to poor prognosis and challenges in accurate staging. Integrating metabolic information may improve the assessment of disease severity. This proof-of-concept study aimed to identify a serum metabolomic signature for cirrhosis detection in PSC and to evaluate its ability to predict cirrhosis development within five years.
Method: In this international multicenter study, serum samples were obtained from 216 PSC patients enrolled at nine centers across seven countries. Patients were randomly allocated (70:30) to a discovery cohort (n = 154; 22% cirrhosis) and a validation cohort (n = 62; 29% cirrhosis). Metabolomic profiling was performed using ultra-high-performance liquid chromatography–mass spectrometry (UHPLC-MS). Multivariate logistic regression adjusted for age, sex, inflammatory bowel disease, alkaline phosphatase, and bilirubin was used to identify metabolites independently associated with cirrhosis. Candidate metabolites were prioritized using bootstrap-based Elastic Net regression with cross-validation and combined into predictive models. The best-performing model was validated in the independent cohort. Stable metabolites were subsequently used to construct a model for 5-year cirrhosis prediction.
Results: Among 484 detected metabolites, 121 were significantly associated with cirrhosis, of which 27 (16 increased, 11 decreased) remained independently associated after adjustment. A seven-metabolite model differentiated cirrhotic from non-cirrhotic patients in the discovery cohort (AUC = 0.86). In the validation cohort, the model achieved an AUROC of 0.78. Among non-cirrhotic patients (n = 56), 8 (14%) developed cirrhosis during five-year follow-up, despite no baseline differences in FIB-4 scores (p = 0.15). A six-metabolite model derived from the original signature predicted 5-year cirrhosis development with high accuracy (AUROC 0.88), and demonstrated superior discrimination compared with existing prognostic scores Amsterdam-Oxford Score (0.66; p = 0.04) and revised Mayo Risk Score (0.47; p < 0.01).
Conclusion: Serum metabolomic profiles differ according to PSC disease stage, supporting metabolomics as a promising complementary tool for cirrhosis detection. Exploratory analyses indicate potential utility for predicting cirrhosis, supporting further validation in larger independent cohorts and integration into patient stratification models.

Background and aims: Primary biliary cholangitis (PBC) commonly occurs alongside extrahepatic autoimmune diseases (EADs) and cardiometabolic conditions (CMCs), yet their clinical relevance remains incompletely defined. We investigated the distribution of these comorbidities and examined whether they identify distinct phenotypic patterns of PBC.
Method: We conduct a retrospective analysis of patients enrolled in the Italian National PBC Registry (PBC322) across 57 centers. Demographics, baseline biochemical data, liver stiffness measurement (LSM), and the presence of a PBC-autoimmune hepatitis (AIH) variant were collected. The occurrence and timing of EADs, CMCs (overweight/obesity, dyslipidemia, hypertension, glucose metabolism disorders), and cardiovascular diseases (CVD: coronary artery disease, cerebrovascular disease, peripheral artery disease) were recorded. Patients with diabetes and/or metabolic syndrome were grouped as D/MS.
Results: Among 3,142 registered patients, 2,340 fulfilled inclusion criteria. The cohort was predominantly female (89%), with a mean age of 54.9 ± 4.3 years and a median disease duration of 4.9 years (IQR 1.5–10.7); mean BMI was 24.9 ± 4.3. At baseline, 23% had cirrhosis and 7% a PBC-AIH variant. EADs were present in 27% of patients, most frequently autoimmune thyroid diseases (11%), Sjogren's syndrome (7%), systemic sclerosis (4%), rheumatoid arthritis (2%), systemic lupus erythematosus (1%), vitiligo (1%) and other EADs (3%). CMCs were highly prevalent, including dyslipidemia (43%), hypertension (37%), diabetes (9%), and obesity (10%). Cirrhosis and CVD were significantly more prevalent in patients with D/MS and EADs+D/MS (cirrhosis 30% and 25%; CVD 7% and 9%) compared with those without comorbidities (23% and 3%) or with EADs alone (19% and 4%) ($p = 0.021$ and $p < 0.001$). Consistently, LSM values were higher in D/MS and EADs+D/MS (7.1 kPa [4.8–11.1] and 6.4 kPa [4.9–9.1]) than in patients with isolated EADs or no comorbidities (5.9 kPa [4.4–8] and 5.8 [4.5–8.4]) ($p = 0.005$). The PBC-AIH variant was more frequently observed in patients with EADs and EAD+D/MS (12% and 15%) than in those with D/MS alone or without comorbidities (4% and 5%; $p < 0.001$).
Conclusion: In a large national PBC cohort, CMCs and EADs delineate distinct disease phenotypes. Diabetes and metabolic syndrome identify patients with more advanced liver involvement and increased cardiovascular burden, whereas EADs are associated with a higher prevalence of the PBC–AIH variant.

SAT-259
Survival and prognostic factors in patients with autoimmune hepatitis-related cirrhosis
Yu Chen[1], Xiao Xiao[1], Xiong Ma[1]. *[1]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China*
Email: xxiao_sh@163.com

Background and aims: Long-term outcomes and prognostic factors in autoimmune hepatitis (AIH)-related cirrhosis remain poorly characterized. This study aimed to evaluate survival and identify prognostic predictors in patients with AIH-related cirrhosis.
Method: This retrospective cohort study included patients with AIH-related cirrhosis treated with immunosuppressive therapy. Transplant-free survival was analyzed using Kaplan-Meier methods and Cox proportional hazards regression. Multivariable analyses were performed separately for compensated and decompensated stages.
Results: Of the 544 patients, 379 had compensated cirrhosis and 165 had decompensated cirrhosis. During a median follow-up of 62 months (interquartile range [IQR] 38–83), decompensated group showed significantly worse survival than compensated group (60-month survival 85.9% vs. 97.3%, $p < 0.001$), with an adjusted hazard ratio (HR) of 6.26 (95% confidence interval [CI] 3.13–12.55). In the compensated group, older age (HR 1.07 per year, $p = 0.037$) and higher total bilirubin (HR 1.99, $p = 0.028$) were independent predictors of mortality. In the decompensated group, higher platelet count was associated with improved survival (HR 0.39, $p = 0.024$). Second-line immunosuppression was more frequently used among survivors in both groups.
Conclusion: Survival in AIH-related cirrhosis is strongly stage-dependent, with decompensation significantly increasing mortality risk. Age and bilirubin are key predictors in compensated disease, while platelet count is prognostic in decompensated disease. These findings support stage-adapted clinical management and risk-stratified follow-up strategies.

True seronegative autoimmune hepatitis in adults is rare and overestimated
Francesca Colapietro[1], Charlotte Slooter[2], Kalliopi Zachou[3], Daniel E. Di Zeo-Sánchez[4], Mercedes Robles-Díaz[4], Miren Garcia Cortes[4], Sara Santopietro[5], Vincenzo Ronca[6], Maria Pia Calabrese[6], Alessio Gerussi[5], Pietro Invernizzi[5], Raul J. Andrade[4], George Dalekos[3], Joost PH Drenth[2], Ynto de Boer[2], Ana Lleo[6]. *[1]ASST Papa Giovanni XXIII, Bergamo, Italy; [2]Amsterdam UMC, AGEM Institute, Vrije Universitet, Amsterdam, Netherlands; [3]General University Hospital of Larissa, Larissa, Greece; [4]Instituto de Investigación Biomédica de Málaga-IBIMA, Hospital Universitario Virgen de la Victoria, Universidad de Málaga, Malaga, Spain; [5]Università Milano-Bicocca, Milano, Italy; [6]Università Humanitas, IRCCS Humanitas Research Hospital, Pieve Emanuele, Italy*
Email: f.colapietro2@gmail.com

Background and aims: Seronegative autoimmune hepatitis (SnAIH) lacks detectable conventional autoantibodies (ANA, ASMA, anti-LKM, and anti-SLA/LP), posing diagnostic challenges. Increasing evidence suggests SnAIH in adults reflects limitations in autoantibody detection rather than a distinct variant. We systematically re-evaluated all biopsy-proven SnAIH cases in a large international multicenter AIH cohort using standardized testing.
Method: Adult patients with confirmed AIH from the International AIH Group Retrospective Registry were included. Variant syndromes were excluded. Demographic, clinical, histological and serological data were analyzed. Response to treatment at 6 and 12 months, and onset with acute severe AIH (AS-AIH) ($1.5 < INR < 2$, jaundice without encephalopathy) were recorded.
Results: We included 760 adults from five centers with available baseline liver biopsy; after excluding seropositive AIH ($n = 702$), pediatric ($n = 2$) and PBC variant ($n = 4$) cases, 52 SnAIH patients (6.8%) were identified. Of these, 25 completely lacked autoantibody testing, with only one retested (48.1%). Eighteen had partial testing, 94% without anti SLA/LP; six underwent retesting: three patients became positive, and only one remained seronegative. Overall, nine confirmed SnAIH patients (1.2%) were identified, with only one fully retested within 12 months. Median age was 56 years (20–67), 88.9% were females. Median ALT was 16.1 × ULN (6.3–46), IgG were elevated in four cases. All cases presented acutely, including one with AS-AIH. Four (44.4%) had biopsy features suggestive of autoimmune-like drug-induced liver injury (DILI-AIH); one relapsed after

corticosteroid withdrawal. Three out of seven patients (42.9%) failed to normalize ALT at six months. One patient developed cirrhosis.
Conclusion: In this large cohort, true SnAIH is rare (~1%), and less than 20% of cases underwent guideline-recommended retesting. Serological assessment was often incomplete, and nearly half had DILI-AIH-like histology. These results suggest that true SnAIH may be overestimated due to partial testing and assay variability. Strict adherence to the guidelines with standardized, comprehensive, autoantibody assays and systematic retesting in specialized laboratories are needed to clarify whether SnAIH is a distinct clinical entity in adults with AIH.

SAT-261

Postpartum alkaline phosphatase trajectory predicts magnetic resonance cholangiopancreatography based disease progression in women with primary sclerosing cholangitis

Katherine Cooper[1], Daniel Pratt[1]. [1]*Massachusetts General Hospital, Boston, United States*
Email: kcooper5@mgh.harvard.edu

Background and aims: Autoimmune diseases often flare in the postpartum period. In primary sclerosing cholangitis (PSC), identifying biochemical flares is challenged by increases in placental alkaline phosphatase (ALP). We evaluated static and dynamic ALP trajectories after pregnancy and their relation to PSC disease progression.
Method: This is a single center analysis of pregnant women enrolled in a longitudinal PSC registry. The primary outcome was PSC disease progression, defined as change in cholangiogram on magnetic resonance cholangiopancreatography (MRCP) comparing pre and-post pregnancy imaging. Pre-ALP and post-ALP were calcualted for each patient as the mean ALP in the year before pregnancy and after delivery, respectively; ΔALP was calculated as the relative change between pre- and post-ALP. Pre-ALP, post-ALP, and ΔALP were evaluated using receiver operating curves (ROC) and compared with area under the curve (AUC). They were also compared to a prior PSC flare definition, >25% increase in ALP level. To quantify cumulative cholestasis, we defined ALP-time burden as the area under the normalized ALP (ALP/pre-ALP)–time curve using trapezoidal integration.
Results: Among 23 pregnancies (median age 33, 83% IBD, 83% large duct PSC), 14 (61%) met criteria for biochemical flare and 7 (30%) demonstrated MRCP progression. More progressors had a biochemical flare (43% v 11%, p = 0.15) and fewer returned to pre-ALP baseline (0% v 44%, p = 0.05). Pre-ALP (AUC 0.54) and post-ALP (AUC 0.63) poorly discriminated progression whereas Δ ALP showed excellent discrimination at 6 months (AUC 0.94) and 12 months (AUC 0.88). The optimal ΔALP was 58%; a pragmatic threshold of Δ ALP ≥ 50% retained screening standards (sensitivity 100%, specificity 69%) and outperformed the previously used flare definition of ≥25% (AUC 0.85 v. 0.75, Delong p = 0.05). Importantly, cumulative cholestasis was higher in progressors compared to non-progressors (median ALP-time burden 745 vs 488 normalized-ALP-days, p = 0.004).
Conclusion: Our findings suggest that a majority of pregnant women with PSC meet criteria for biochemical flare after delivery. However, rather than distinct flares, the relative change in ALP levels after delivery compared to pre-pregnancy baseline seemingly best correlated with disease progression. Postpartum elevations of ALP in women with PSC warrants careful follow-up, especially when not resolved by 6 months. Larger studies are needed to validate ΔALP as a biomarker of postpartum PSC disease progression.

Email: cacouto@uol.com.br

Background and aims: Primary biliary cholangitis (PBC) shows geographical variations in presentation and prognosis. Data from

Latin America is scarce, particularly for cross-country comparisons. This study aimed to describe clinical characteristics, treatment response, and outcomes of PBC across Latin American countries.
Method: The ALLATIN cohort is a retrospective international multicentre study that enrolled 2,182 PBC patients from 13 Latin American countries. For this analysis, participants from the five largest contributing countries were selected (n = 1,980) after excluding those with concomitant liver diseases (n = 564). These were Brazil (40%), Argentina (25.1%), Mexico (17.6%), Chile (9.9%) and Colombia (7.4%), totaling 1,416 participants.
Results: Cohort was predominantly female (93.8%, lower in Argentina, 90%, p = 0.023) with a median age at diagnosis of 53 years (15–90) – subjects from Chile were slightly older (55 [28–80], p < 0.001). Antimitochondrial antibody positivity was 76.3% overall, but notably lower in Colombia (53.3%, p < 0.001). Liver biopsy was performed in 742 participants (52.4%). Hashimoto thyroiditis (14% overall) was more common in Argentina/Chile (20–21%) and less in Mexico/Colombia (8%), p < 0.001. Sjögren syndrome was observed in 9.2%, without difference across countries (p = 0.178). Asymptomatic presentation was reported in 19.3% at diagnosis, highest in Argentina (25.5%, p = 0.003). Response rates to ursodeoxycholic acid (UDCA) after 12 months varied: Toronto (59%), Paris-2 (40.1%), POISE trial (38.7%) and deep-response (14.5%) criteria. Argentina showed higher response rates by Paris-2, POISE and deep-response criteria (p ≤ 0.008). Fibrates were used as second-line therapy in 30.2%, with higher use in Mexico (37.1%) and lower in Colombia (8.6%, p < 0.001). Transplant-free survival differed significantly across countries (log-rank p < 0.001); the risk of death or liver transplantation was higher in Mexico than in Chile (HR 4.36, 95% CI 2.1–10.9, p < 0.001).
Conclusion: In the largest Latin American PBC cohort reported, there was significant heterogeneity in presentation, response to UDCA and long-term prognosis across countries. These findings highlight that even when selecting clear-cut PBC subjects, specific genetic, economic, social and cultural country-related factors influence the disease course. Regional strategies for optimal risk stratification and management should be taken into consideration.

SAT-263

Fibrates outperform obeticholic acid in biochemical response at the cost of higher early discontinuation: insights from the Italian PBC registry

Background and aims: Fibrates (FB) are used off-label as second-line (SL) therapy in primary biliary cholangitis (PBC) with inadequate response/intolerance to ursodeoxycholic acid (UDCA) and for pruritus. We evaluated the effectiveness and safety of FB versus obeticholic acid (OCA) under real-world conditions within the *Italian PBC Registry*.

Method: Patients initiating SL therapy with OCA or FB (fenofibrate/bezafibrate) have been included. Primary endpoints were ALP relative change (×ULN) and ALP < ULN at 1st biochemical assessment (12months +/- 6) after starting SL. Early discontinuation (<6 months) and toxicity were recorded. Patients who received both drugs were included in the analysis only if the 1st assessment was available before changing therapy. Factors associated with ALP < ULN were analysed trough a multivariable logistic regression.
Results: Overall, 737 patients initiated SL therapy (346 OCA, 243 FB, 148 sequential combination). Early discontinuation occurred in 39/243 (16.0%) on FB and 19/346 (5.5%) on OCA, mainly due to intolerance/toxicity ($p < 0.05$). After exclusions for missing follow-up/early therapy switch, 455 patients were included in the analysis (246 OCA, 133 FB, 76 combination therapy cases of whom 64 and 12 started with OCA and FB, respectively); 71(15.6%) had cirrhosis. Baseline ALP levels with OCA and FB were 1.92 × ULN (IQR 1.62–2.64) and 1.68 × ULN (IQR 1.23–2.54), respectively. Median time from baseline assessment to SL initiation was -29 days (IQR −9/−89), and to 1st biochemical assessment 309 days (IQR 233–372) with OCA and 300 days (IQR 224–369) with FB. Median ALP relative changes were −25% (IQR −40% to −8%) for OCA and −46% (IQR −61% to −22%) for FB ($p < 0.0001$). At baseline, 9(2.9%) and 20(13.8%) had normal ALP levels for OCA and FB groups; at first assessment ALP normalization was observed in 41(13.2%) and 88(60.7%), respectively. After adjustment for age, cirrhosis and baseline ALP level, FB therapy was associated with a higher likelihood of ALP normalization compared to OCA (OR 10.3, CI 5.8–18.1, $p < 0.0001$).
Conclusion: In this nationwide real-world cohort study including secondary and tertiary centres, FB achieved greater biochemical improvement than OCA as SL therapy for PBC, at the cost of higher early discontinuation rates. These findings reinforce FB as a potent off-label SL option while underscoring the need for vigilant long-term safety monitoring and continued real-world assessment of emerging therapeutic strategies.

Hospital Universitario Doctor Josep Trueta de Gerona, Girona, Spain*
Email: laura.cudero@gmail.com

Background and aims: The coexistence of autoimmune hepatitis (AIH) and metabolic dysfunction–associated liver disease (MASLD) may enhance inflammation, accelerate progression and worsen long-term outcomes. The aim of the study is to assess the prevalence of simple steatosis or metabolic dysfunction- associated steatohepatitis (MASH) in AIH and evaluate its impact on fibrosis, clinical course and prognosis at 3, 5 and 10 years.
Method: Multicenter retrospective study including biopsy-proven AIH (2000–2023). Patients were classified as AIH–MASH, AIH–steatosis or isolated AIH. Kruskal–Wallis, Mann–Whitney and Fisher tests were applied (p < 0.05).
Results: A total of 335 patients were included: 16.7% AIH–MASH, 14.9% AIH–steatosis and 68.4% isolated AIH. Age and sex were similar (>60% women). AIH–MASH and AIH–steatosis showed higher BMI (30.5 and 29.7 vs. 25.7 kg/m^2; $p < 0.05$) and more dyslipidemia (75% and 64% vs. 34.2%; $p < 0.05$) and diabetes (46.4% and 22% vs. 8.4%; $p < 0.05$). Significant fibrosis was more frequent in AIH–MASH (35.7% vs. 16% and 25.2%; $p = 0.01$) with higher liver stiffness (10.4 vs. 5.8 and 7.3 kPa; $p = 0.09$). Portal hypertension features were more common in AIH–MASH at diagnosis (ascites 12.5%, varices 8.9%) and follow-up (ascites 7.7–11.1%; varices 3.9–11.1%). AIH- MASH also showed higher transaminases, IgG and ultrasound signs of chronic liver disease (54.2%, 55% and 44.4% at 3, 5 and 10 years; $p < 0.05$). Hepatocellular carcinoma incidence was higher in AIH MASH (3.9%, 9.5% and 9.1%; $p < 0.05$). Overall mortality increased in AIH–MASH (9.3% vs. 2.1% and 4.8%; $p = 0.3$), with more liver-related deaths; transplant rates were similar (<10%; $p = 0.7$).
Conclusion: MASLD–AIH is associated with more advanced fibrosis, faster progression and worse long-term outcomes, including higher HCC incidence. Intensive metabolic management and surveillance are essential.

SAT-265

Primary biliary cholangitis with concurrent metabolic dysfunction-associated steatotic liver disease demonstrates comparable biochemical response to ursodeoxycholic acid: results from the ELLA-PBC cohort

Paul Yoon[1], Adriana Shen[1], Matthew Chen[1], Tara Foroohar[1], Isai Martinez Rios[1], Sade Brown[1], Jennifer Dodge[1], Brian Lee[2], Kali Zhou[1], Jeffrey Kahn[1], Saro Khemichian[1], Lily Dara[1]. *[1]Keck Hospital of University of Southern California, Los Angeles, United States; [2]Hoag Memorial Hospital, Newport Beach, United States*
Email: psyoon@usc.edu

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) commonly coexists with primary biliary cholangitis (PBC), but its impact on disease severity, treatment response, and prognosis remains uncertain, particularly in Hispanic patients who are disproportionately affected yet underrepresented in prior studies.
Method: The East Los Angeles Latinx PBC (ELLA-PBC) cohort includes predominantly Hispanic adults (≥18 years) with PBC treated at the University of Southern California Medical Centers (2006–2022). Patients initiating ursodeoxycholic acid (UDCA) with 1-year follow-up were included. MASLD was defined by hepatic steatosis plus ≥1 cardiometabolic risk factor (CMRF) with limited alcohol use. Patients were classified as PBC alone or PBC+MASLD. Predictors of 1-year alkaline phosphatase (ALP) normalization were evaluated using multivariable logistic regression. Transplant-free survival (TFS) was estimated using Kaplan-Meier methods.
Results: Of 157 UDCA-treated patients, 46 (29.3%) had PBC+MASLD. Compared with PBC alone, PBC+MASLD patients were younger (52.5 vs. 58.0 years, $p = 0.045$), more often Hispanic (80.4% vs. 61.3%, $p = 0.048$), and more often underinsured (67.4% vs. 49.6%, $p = 0.04$). BMI

was higher in PBC+MASLD (28.5 vs. 25.5 kg/m2, p = 0.009), while other CMRF were similar. PBC+MASLD patients had less advanced liver disease, with lower rates of cirrhosis, ascites, and hepatic encephalopathy and more favorable albumin, platelet, FIB-4, and APRI values (all p < 0.05). One-year biochemical response did not differ between PBC alone and PBC+MASLD (Paris II: 32.1% vs. 31.1%, p = 0.90; POISE: 39.5% vs. 42.2%, p = 0.75; ALP normalization: 18.2% vs. 13.3%, p = 0.46). MASLD was not associated with ALP normalization in the unadjusted (p = 0.47) or adjusted analyses (aOR 0.94, 95% CI 0.32–2.73, p = 0.91). GLOBE predicted more favorable survival in PBC +MASLD (5-year: 91% vs. 87%, p = 0.03), while UK-PBC risk was similar (p = 0.22). Over median 3.4 years (IQR 2.0–5.1), 25 patients experienced transplant or death. PBC+MASLD patients demonstrated numerically higher 5-year TFS (93.4% vs. 75.8%) with borderline log-rank significance (p = 0.058) and significant Wilcoxon testing (p = 0.018).

Conclusion: Concurrent MASLD was not associated with impaired biochemical response or worse early clinical outcomes in PBC. Instead, patients with PBC+MASLD presented with less advanced disease and demonstrated comparable, and potentially more favorable, prognosis. Larger longitudinal studies are needed to clarify long-term impact.

SAT-266

Cirrhosis progression in primary biliary cholangitis is higher among hispanic patients: results from the ELLA-PBC cohort

Paul Yoon[1], Adriana Shen[1], Matthew Chen[1], Tara Foroohar[1], Isai Martinez Rios[1], Sade Brown[1], Jennifer Dodge[1], Brian Lee[2], Kali Zhou[1], Jeffrey Kahn[1], Saro Khemichian[1], Lily Dara[1]. *[1]Keck Hospital of University of Southern California, Los Angeles, United States; [2]Hoag Memorial Hospital, Newport Beach, United States*
Email: psyoon@usc.edu

Background and aims: Primary biliary cholangitis (PBC) follows a progressive fibrotic course. Although ursodeoxycholic acid slows disease progression, many patients continue to advance. Hispanic patients have lower biochemical response rates in PBC and disproportionately higher mortality across chronic liver diseases, but racial/ethnic differences in cirrhosis progression for PBC remains understudied.

Method: The East Los Angeles Latinx PBC (ELLA-PBC) cohort includes predominantly Hispanic patients (≥18 years) with PBC treated at the University of Southern California Medical Centers (2006–2022). Patients with prior liver transplant or cirrhosis at presentation were excluded. The primary outcome was incident cirrhosis. Five-year cumulative incidence of cirrhosis was estimated from initial presentation using Kaplan-Meier methods and compared by race/ethnicity with the log-rank test. Cox proportional hazards models estimated hazard ratios (HR) for cirrhosis, with multivariable adjustment for covariates with univariable p < 0.10.

Results: Among 180 patients without cirrhosis at presentation, 123 (68.3%) were Hispanic, 35 (19.4%) were non-Hispanic White (NHW), and 22 (12.2%) were other non-White groups. Hispanic patients had higher rates of underinsurance (73.2% vs. 22.9% in NHW; p < 0.001) and higher baseline alkaline phosphatase (307 U/L [IQR 186–557] vs. 228 U/L [IQR 106–418] in NHW; p = 0.03), while other markers of liver disease severity (AST, ALT, bilirubin, APRI, FIB-4) were comparable across groups. Over a median 3.8 years, 34 patients developed cirrhosis. Five-year cumulative incidence was higher among Hispanic vs. NHW patients (28.6% [95% CI 20.1–39.5] vs. 6.5% [95% CI 1.7–23.9]; p = 0.02), while non-White patients had incidence similar to NHW patients (10.1% [95% CI 2.6–34.7]; p = 0.62). In univariable Cox models, Hispanic ethnicity was associated with a 4.5-fold higher risk of cirrhosis vs. NHW patients (HR 4.49 [95% CI 1.07–18.80]; p = 0.04), with no difference in non-White vs. NHW patients (HR 1.62 [95% CI 0.23–11.48]; p = 0.63). This association persisted after adjusting for baseline APRI and BMI (HR 4.17 [95% CI 0.98–17.65]; p = 0.05).

Conclusion: Hispanic patients with PBC had significantly higher 5-year cumulative incidence of cirrhosis, with elevated risk persisting even after adjustment for baseline fibrosis and BMI. These findings identify Hispanic patients as a high-risk group for cirrhosis development in PBC and support earlier therapeutic optimization and closer surveillance in this population.

SAT-267

Hepatic hilar lymphadenopathy identifies advanced fibrosis in primary biliary cholangitis

Youness Dendane[1], Rihab El Kihel[1], Ouiam Elmqaddem[1], Hajar Koulali[1], Abdelkrim Zazour[1], Ghizlane Kharrasse[1], Zahi Ismaili[1]. *[1]Department of Hepato-Gastroenterology, Mohammed VI University Hospital, Oujda, Morocco; Digestive Diseases Research Laboratory (LARMAD), Faculty of Medicine and Pharmacy, Mohammed First University, Oujda, Morocco*
Email: dendane.youness@gmail.com

Background and aims: Hepatic hilar lymphadenopathy is frequently reported on ultrasound in patients with primary biliary cholangitis, but its clinical significance remains unclear. Although often considered benign, its association with liver fibrosis has not been clearly established. This study aimed to assess the relationship between hepatic hilar lymphadenopathy, liver fibrosis severity, and systemic inflammation in primary biliary cholangitis.

Method: We conducted a retrospective study including 62 patients with primary biliary cholangitis treated with ursodeoxycholic acid (13–15 mg/kg/day) and followed for at least 24 months. Patients were classified according to the presence or absence of hepatic hilar lymphadenopathy on baseline ultrasound, defined as lymph nodes larger than 10 mm or explicitly reported by the radiologist. Liver fibrosis was assessed using transient elastography (liver stiffness ≥9 kPa) and FIB-4 score. Systemic inflammation was evaluated by C-reactive protein. Comparisons were performed using appropriate statistical tests, with significance set at p < 0.05.

Results: The mean age was 56 ± 12 years, with a female predominance (79 percent). Hepatic hilar lymphadenopathy was identified in 8 patients (13 percent). Patients with lymphadenopathy did not differ from those without regarding age or sex distribution. In contrast, advanced liver fibrosis assessed by transient elastography was nearly sixfold more frequent in patients with lymphadenopathy compared with those without (62.5 percent vs 11.1 percent; p = 0.018). A FIB-4 score ≥ 3.25 was also more common in the lymphadenopathy group (37.5 percent vs 7.4 percent; p = 0.041). No significant differences were observed in C-reactive protein levels. No cases of hepatic decompensation occurred during follow-up.

Conclusion: Hepatic hilar lymphadenopathy was associated with advanced liver fibrosis independently of systemic inflammation in patients with primary biliary cholangitis. This overlooked ultrasound finding may represent a simple warning sign for advanced fibrosis and should not be considered incidental. Prospective studies are needed to confirm its prognostic value.

Background and aims: No predictive tools for Complete Biochemical Response (CBR) in AIH are currently available. A German study proposed a score based on ferritin + IgG as a predictive marker of CBR, and its utility has been included in the AASLD guidelines. We aimed to evaluate the usefulness of this score in an international cohort of patients with AIH.
Method: International multicenter study including 430 patients from Hannover and the ColHai registry. The score (0–2) was calculated by assigning 1 point for ferritin <2.09 × ULN and another for IgG >1.89 × ULN.
Results: At baseline, patients from Hannover were younger ($p = 0.013$) and had higher transaminases, bilirubin ($p < 0.001$), ferritin ($p = 0.007$), and IgG ($p = 0.003$). In the overall cohort (ColHai + Hannover), 78% achieved CBR; however, CBR rates were higher in ColHai at 6 months (50% vs 38%; $p = 0.036$) and 12 months (67% vs 55%; $p = 0.031$). The score was associated with CBR in the Hannover cohort but showed no predictive ability in ColHai (c-statistic at 6 months: 0.51 [95% CI 0.45–0.56]; 12 months: 0.51 [95% CI 0.45–0.57]; during follow-up: 0.54 [95% CI 0.47–0.61]). We found no association with CBR at 6 months (HR 1.01; 95% CI 0.79–1.30), 12 months (HR 0.97; 95% CI 0.78–1.20), or during follow-up (HR 0.93; 95% CI 0.77–1.15). Considering baseline differences, the score was re-evaluated after IPTW-propensity score adjustment, again showing no association with CBR (HR 0.88; 95% CI 0.71–1.10). When analyzing the score components separately, the ferritin cut-off showed no predictive ability in ColHai at 6 months (HR 1.34; 95% CI 0.96–1.88), 12 months (HR 1.16; 95% CI 0.88–1.53), or during follow-up (HR 1.09; 95% CI 0.84–1.41). However, the IgG cut-off of 1.89 × ULN demonstrated predictive ability in the Hannover cohort (HR 0.42; 95% CI 0.24–0.75), in ColHai (HR 0.72; 95% CI 0.51–0.99), and in the combined cohort (HR 0.61; 95% CI 0.46–0.81).
Conclusion: We were unable to validate the usefulness of the score in the ColHai cohort. However, the proposed IgG cut-off was confirmed as a predictor of CBR.

SAT-269

Second-line treatment with novel PPAR agonists in patients with primary biliary cholangitis: real-world experience from a european tertiary care center

Miriam M. Düll[1,2], Jonas Schmid[1,2], Marcel Vetter[1,2], Markus F. Neurath[1,2], Andreas E. Kremer[3], Peter Dietrich[1,2,4].

Email: miriam.duell@uk-erlangen.de

Background and aims: A relevant proportion of patients with primary biliary cholangitis (PBC) require second-line therapy due to insufficient response or intolerance to ursodeoxycholic acid (UDCA). After withdrawal of conditional approval for obeticholic acid (OCA) in the EU, alternative treatment strategies became necessary. Elafibranor (ELA), a dual PPAR-α/δ agonist, and seladelpar (SELA), a selective PPAR-δ agonist, were recently introduced for PBC treatment. Real-world data remain limited. We aimed to assess biochemical response, patient-reported outcomes, and safety of ELA and SELA in routine clinical practice.
Method: We prospectively analyzed consecutive PBC patients treated with ELA (80 mg once daily) or SELA (10 mg once daily) at a tertiary referral center between October 2024 and December 2025. Liver biochemistry, treatment history, patient-reported outcomes (PROMIS Fatigue SF-7a and PBC-40 fatigue and pruritus domains), and safety were assessed at baseline and at 3–6-month intervals.
Results: Thirty-one PBC patients (89% female, median age 58.5 years; 29% with advanced fibrosis or cirrhosis) received ELA (n = 22) or SELA (n = 9). Among 27 patients previously treated with OCA, 17 (63%), including four on triple therapy (UDCA+OCA+bezafibrate), were switched to PPAR agonists (ELA n = 13, SELA n = 4), while one-third initiated second-line therapy de novo. All but one patient (UDCA intolerance) remained on UDCA (mean dose 14.9 mg/kg). Median treatment duration was 309 days (IQR 207–355) for ELA and 189 days (IQR 172–201) for SELA. Follow-up data were available for 20, 16, and 3 patients at 3, 6, and 12 months, respectively. At first follow-up, alkaline phosphatase (ALP) decreased in all but two patients, with a median reduction of 28%. POISE response criteria were achieved in 60%, Paris II criteria newly reached in 35%, and 26% newly showed ALP normalization. All patients with available 12-month follow-up achieved ALP normalization (baseline mean ALP 2.1 × ULN). Patients with cirrhosis showed stable or improved MELD and Child-Pugh scores. Three patients discontinued ELA due to mild intolerance; no serious adverse events occurred. Patient-reported fatigue and pruritus scores remained stable throughout treatment.
Conclusion: In this real-world cohort, elafibranor and seladelpar were associated with rapid biochemical improvement and good tolerability. Transition from OCA to PPAR agonists was feasible, including in patients with advanced liver disease, supporting their role as effective second-line options in PBC.

Interleukin-17 blockade in primary sclerosing cholangitis: results from a single-arm, open-label pilot study

Amera Elzubeir[1,2], Juliet High[2], Matthew Hammond[2], Lee Shepstone[2], Martine Walmsley[3], Palak Trivedi[4], Emma Culver[5], Guruprasad Aithal[6], Leo Alexandre[1,2], Simon Rushbrook[1,2]. *[1]Norfolk & Norwich University Hospital, Gastroenterology Department, Norwich, United Kingdom; [2]Norwich Medical School, Faculty of Medicine and Health Sciences, Norwich, United Kingdom; [3]PSC Support, Manchester, United Kingdom; [4]National Institute for Health and Care Research (NIHR) Birmingham Biomedical Research Centre (BRC); Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, University of Birmingham, Liver Unit, University Hospital Birmingham National Health Service Foundation Trust Queen Elizabeth, Birmingham, United Kingdom; [5]Translational Gastroenterology Unit, Oxford University Hospital NHS Foundation Trust; University of Oxford, Oxford, United Kingdom; [6]NIHR Nottingham Biomedical Research Centre, Nottingham University Hospitals NHS Trust and University of Nottingham, Nottingham, United Kingdom*
Email: amera.elzubeir@doctors.net.uk

Background and aims: Primary sclerosing cholangitis (PSC) has no licensed pharmacological therapy. Basic science and translational studies implicate T-helper 17 (Th17) cells and interleukin 17 (IL-17) signalling in PSC pathogenesis. We conducted a pilot study to assess the safety and feasibility of brodalumab, an IL-17 receptor A monoclonal antibody, in PSC (ISRCTN15271834).

Method: SABR-PSC was a phase 2a, single-arm, open-label, multicentre study. Adults (18–75 years) with large-duct PSC received eight brodalumab injections (210 mg) subcutaneously over 13 weeks. Primary outcomes were safety (hepatic and colonic, including post-treatment colonoscopy and histology) and feasibility (adherence, tolerability, recruitment and retention). Exploratory efficacy outcomes included change from baseline to week 16 in alkaline phosphatase (ALP), other liver biochemical analytes, liver stiffness measurements (LSM), enhanced liver fibrosis (ELF) score, 5D-Itch and health-related quality of life (HRQoL).

Results: Six participants were enrolled, and all completed the study (median age: 37.5 years; 83% male; 50% with concomitant inflammatory bowel disease [quiescent]). At baseline, the median ALP was 141 U/L (range: 63–249) and all participants had an ELF score ≥ 7.7 (range: 7.8–9.9). Treatment adherence was excellent (100%). All participants reported ≥ 1 adverse event (AE); the majority were mild. The most common AEs were fatigue, pharyngitis and abdominal pain. No serious AEs and no ALP-defined AEs occurred. At week 16, two participants (33.3%) achieved > 20% reduction in ALP, with accompanying reductions in gamma glutamyl-transferase, LSM and/or ELF; one of whom achieved a > 45% reduction in ALP and subsequent normalisation. Exploratory sub-group analysis suggested larger ALP reductions occurred among those with a baseline ELF score ≥ 9.6. No new diagnoses or exacerbations of inflammatory bowel disease were observed as assessed by faecal calprotectin, partial Mayo score, colonoscopic and histological assessment. 5D-Itch and HRQoL metrics remained stable over the treatment duration.

Conclusion: In this first-in-disease pilot study, brodalumab was safe, well-tolerated and feasible in PSC, with excellent treatment adherence and no emergent adverse gastrointestinal safety signals. Numerical improvement in exploratory efficacy outcomes (ALP, GGT, LSM/ELF) were observed in a subset of patients. A larger-scale randomised controlled trial to further evaluate brodalumab's safety, tolerability and efficacy in PSC is warranted.

Efficacy and tolerance of second line treatments for autoimmmune hepatitis: a multicentric french real life FILFOIE study

Ahmad Kattan[1], Marie-Noëlle Hilleret[2], Teresa Antonini[1], Kerstin Hartig[1], Yasmina Chouik[1], Christine Chambon-Augoyard[3], Sylvie Radenne[1], Francois Bailly[1], Charlotte Costentin[2], Olivier Guillaud[3], Francois Villeret[1], Fanny Lebosse[1], Mathias Ruiz[4], Vincent Leroy[2], Jérôme Dumortier[3], Domitille Erard[1]. *[1]Hepatology, Hospices Civils de Lyon, Lyon, France; [2]Service d'hépato Gastro Entérologie, CHU de Grenoble, Grenoble, France; [3]Federations des Spécialites Digestives, HCL, Lyon, France; [4]Service d'hépato Gastro Entérologie Pédiatrique, Hopital Mère Enfant, Hospices Civils de Lyon, Lyon, France*
Email: domitille.erard@chu-lyon.fr

Background and aims: Autoimmune hepatitis (AIH) is a rare, chronic inflammatory liver disease. First-line treatment is well established, combining steroids and azathioprine to maintain remission. However, 20% of patients do not respond or do not tolerate first-line treatment. The objectives of this study were to describe second-line treatments for AIH, their efficacy and tolerance, in a large French cohort of adult and pediatric patients.

Method: Between 2000 and 2025 in two expert centers, patients followed for AIH who received second-line treatments due to intolerance or ineffectiveness of first-line therapy were retrospectively included.

A complete biochemical response was defined as normalization of transaminases and IgG at 6 months of treatment.

Results: A total of 142 patients were included, with a median age at diagnosis of 42 years and a majority of women (70.4%). A quarter of patients (26.1%) had an associated overlap syndrome. At diagnosis the median cytolysis level was 10.7 ULN (IQR: 4.2–22.4) for AST and 10.0 ULN (IQR: 4.0–20.4) for ALT. A liver biopsy was performed in 124 (87.3%) patients, with cirrhosis in 36 patients (25.4%); 14.7% of patients had severe acute hepatitis (INR > 1.5). First-line treatment was steroids (100%) combined with azathioprine (89.4%). Azathioprine treatment was discontinued in 115 patients (90.6%), mainly due to intolerance (56.5%) and ineffectiveness (34.8%). Mycophenolate mofetil was used as second-line treatment in 90 patients (63.4%), mainly due for intolerance (67.8%). At 6 months, 42.2% of patients had a complete biochemical response (CBR) and 33.3% had discontinued treatment. Tacrolimus was used in 82 patients (57.7%), mainly due to first-line therapy failure (79.3%). At 6 months, 39% of patients had a CBR and 28.0% had discontinued treatment. Among other treatments, 12 patients (8.5%) were treated with cyclosporine, 8 (5.6%) with mTOR inhibitors, 6 (4.2%) with rituximab, and 3 with plasma exchange. During follow-up, a majority of patients (65.5%) received two second-line treatments, and 26.8% received three treatments. At the last follow-up (median duration of 6 years), 70 patients (49.3%) had a complete biochemical response, 101 (71.1%) had cytolysis <1.5 ULN, and 112 (78.9%) had cytolysis <2 ULN. Thirteen patients (9.2%) underwent transplantation, and 4 (2.8%) died.

Conclusion: Second-line treatment of AIH is based on MMF and tacrolimus with good efficacy and few severe clinical events observed during follow up.

SAT-272-YI

Spleen stiffness predicts clinical event-free survival in primary biliary cholangitis: a prospective cohort study

Ilkay Ergenc[1], Hasan Basri Yapıcı[2], Caglayan Keklikkiran[3], Coskun Ozer Demirtas[4], Haluk Kani[4], Michael Heneghan[1,5], Yusuf Yilmaz[3]. *[1]The Roger Williams Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Department of Internal Medicine, School of Medicine, Marmara University, Istanbul, Türkiye; [3]Department of Gastroenterology, School of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye; [4]Department of Gastroenterology, School of Medicine, Marmara University, Istanbul, Türkiye; [5]School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom*
Email: ergencilkay@gmail.com

Background and aims: Spleen stiffness measurement (SSM) using 100-Hz transient elastography is a promising non-invasive tool to

predict clinically significant portal hypertension (PHT). In Primary Biliary Cholangitis (PBC), PHT can develop before cirrhosis in the early stages due to granulomatous inflammation and cholestasis. PHT is associated with poor prognosis. The aim of this study was to evaluate SSM as a predictor of clinical event-free survival in patients with PBC.
Method: Consecutive PBC patients meeting EASL criteria were invited to participate. Consenting patients with reliable SSM were followed every six months with clinical assessment and liver function tests, and annually with abdominal ultrasound. SSM was performed with FibroScan® Expert 630 by same experienced hepatologist. Elevated SSM was defined as >26.5 kPa, based on published thresholds for probable CSPH. Event-free survival was defined as absence of ascites, variceal bleeding, encephalopathy, spontaneous bacterial peritonitis, hepatorenal syndrome, hepatocellular carcinoma, transplantation, or death.
Results: Of 108 enrolled patients, 98 had reliable SSM and were followed for a median of 51 months (8–57). All had at least one positive diagnostic marker; 52 (48%) had previous liver biopsy. Most were female (94.4%); mean age was 50.4 ± 11 years; median disease duration was 4.6 years (1.7–7.5). Twenty-eight (26.2%) were non-responders by Paris II, and 15 (14%) had cirrhosis. Elevated SSM (>26.5 kPa) was present in 37 (35.7%). SSM correlated weakly with liver stiffness ($r = 0.494$, $p < 0.01$). The prevalence of cirrhosis, biochemical remission, metabolic syndrome, and steatosis was similar between elevated and normal SSM groups. Ten clinical events occurred: 2 (3.2%) in the normal SSM group and 8 (22.9%) in the elevated SSM group ($p = 0.06$), including variceal bleeding ($n = 5$), hepatorenal syndrome ($n = 1$), and ascites ($n = 1$). Six patients died: two due to variceal bleeding, two due to sepsis, one due to ovarian cancer, and one sudden death of unknown cause. Median event-free survival was longer with normal versus elevated SSM (53.1 vs 48.1 months; log-rank $\chi^2 = 9.976$, $p = 0.02$).
Conclusion: Elevated SSM identified patients at higher risk of clinical events and mortality with shorter event-free survival. SSM may improve risk stratification and guide monitoring in PBC.

SAT-273

Clinical outcomes of mycophenolate mofetil as first-line therapy in autoimmune hepatitis: a real-world cohort study

Rut Fernández[1], Eunate Muga[1], Ander García[1], Alex Bausela[1], Maria Senosiáin[1], Patricia Salvador[1], Javier Bustamante[1], José Ramón Fernández[1]. [1]*Hospital Universitario Cruces, Barakaldo, Spain*
Email: fernandezbezanillarut@gmail.com

Background and aims: Standard first-line therapy for autoimmune hepatitis (AIH) consists of corticosteroids (CS) with azathioprine, although intolerance, delayed response and steroid-related toxicity remain major limitations. Mycophenolate mofetil (MMF) has recently emerged as an effective and well-tolerated alternative, supported by the randomized controlled CAMARO trial, but real-world evidence remains limited. We aimed to evaluate the effectiveness and safety of MMF as first-line treatment for AIH in routine clinical practice.
Method: We conducted a retrospective observational study including consecutive immunosuppression-naïve adult patients with newly diagnosed AIH treated with MMF plus CS as first-line therapy at a tertiary referral center between October 2016 and October 2024. Baseline demographic, clinical, biochemical and histological data were collected. Complete biochemical remission (CBR) was defined as normalization of alanine aminotransferase (ALT) and immunoglobulin G (IgG) levels. Outcomes included CBR at 6 and 12 months, time to CBR, CS tapering, relapses, treatment changes and adverse events.
Results: Thirty-two patients were included (mean age 60 years; 69% female). At presentation, 75% had acute hepatitis without severity criteria, 16% acute severe hepatitis and 9% acute decompensation of advanced chronic liver disease. At baseline, median ALT was 991 U/L, median IgG was 1865 mg/dL and median MELD score was 15. CBR was achieved in 90.6% (95% CI 80–100%) at 6 months and 96.9% (95% CI 91–100%) at 12 months, with a median time to remission of 43 days (IQR 21.5–135.3). At 6 months, 22% of patients were receiving CS doses ≤2.5 mg/day, increasing to 65.6% at 12 months. One relapse (3.1%) occurred during follow-up. MMF was discontinued in three patients (9.4%), none due to lack of efficacy. Adverse events occurred in 28.1% (9/32), mainly mild gastrointestinal symptoms; only one patient required permanent MMF withdrawal. No patient required liver transplantation and no deaths were recorded during follow-up.
Conclusion: CBR rates and the safety profile of MMF in this real-world cohort were at least comparable to those reported in randomized trials and large prospective cohorts, including the CAMARO trial and published Greek series. The use of MMF in AIH enables rapid and sustained remission with low CS requirements, limited toxicity and minimal relapse rates, supporting its use as a first-line option for AIH in routine clinical practice.

SAT-274-YI

Long term prognostic impact of persisting histological activity despite biochemical remission in autoimmune hepatitis (AIH)

Sarah Flatley[1], Asha Dube[1], Barbara Hoeroldt[1], Laura Harrison[1], Elaine Wadland[1], Dermot Gleeson[1]. [1]*Sheffield Teaching Hospitals, Sheffield, United Kingdom*
Email: s.flatley@nhs.net

Background and aims: We previously reported that persistent histological activity despite biochemical remission (BR) was found in 45% of AIH patients and was associated with reduced long-term survival. Whether this remains true in more contemporary cohorts and in patients achieving complete biochemical remission (CBR) is unclear. We aimed to reassess the long-term prognostic significance of persistent histological activity despite BR in AIH.
Method: Single-centre cohort study of 496 patients (79% female, age 57 [2–87] years, follow-up 9 [0–36] years) with AIH (1999 IAIHG criteria) presenting 1987–2023 and followed until death/liver transplantation. 445 patients had a diagnostic liver biopsy; 260 underwent follow-up biopsy after a median of 29 months. All biopsies were examined by a single histopathologist (AKD) according to a pre-designed proforma. BR was defined as normal ALT, AST and globulin; CBR additionally required normal IgG. Histological remission was defined as Ishak histological activity index (HAI) ≤3 .
Results: At follow-up biopsy, 205/260 (79%) patients were in BR, and 95/130 (73%) with available IgG data were in CBR. Persistent histological activity (HAI ≥4) was present in 99/205 (48%) patients in BR and 51/95 (54%) patients in CBR. Histological remission was more frequent in patients achieving BR (52% vs 15%, $p < 0.001$) and CBR (46% vs 10%, $p < 0.001$). Serum IgG was not independently associated with histological remission after accounting for BR.
Overall, 20-year death/transplantation rates were 54 ± 3% (all-cause) and 20 ± 3% (liver-related). In the overall cohort, achievement of BR within 12 months was associated with reduced all-cause death/transplantation (HR 0.25, 95% CI: 0.06–0.98, $p = 0.045$), adjusting for other known prognostic variables. CBR showed a similar but non-significant association (HR 0.71, 95% CI: 0.20–1.36, $p = 0.079$).
Among patients achieving BR, mortality did not differ by IgG normalisation (HR 0.71, 95% CI: 0.09–5.34, $p = 0.747$) and persistent histological activity was not associated with all-cause (HR 1.07, 95% CI: 0.59–1.94, $p = 0.837$) or liver-related (HR 1.83, 95% CI: 0.62–9.40, $p = 0.391$) death/transplantation.
Conclusion: 1. BR was significantly associated with improved outcomes, but additional serum IgG normalisation was not of further prognostic value.
2. Persistent histological activity was common despite BR and CBR but was not independently associated with inferior long-term survival. In patients achieving BR or CBR, routine repeat liver biopsy solely for prognostication may not be needed.

SAT-275

Long-term extrahepatic mortality in autoimmune hepatitis: a cohort study

Sarah Flatley[1], Asha Dube[1], Barbara Hoeroldt[1], Laura Harrison[1], Elaine Wadland[1], Dermot Gleeson[1]. [1]*Sheffield Teaching Hospitals, Sheffield, United Kingdom*
Email: s.flatley@nhs.net

Background and aims: Autoimmune hepatitis (AIH) is associated with excess long-term mortality, historically attributed to liver disease. The contribution and causes of extrahepatic deaths remain incompletely defined. We aimed to quantify extrahepatic mortality in AIH compared with the general population and to describe its major causes.
Method: Single-centre retrospective/prospective cohort study of 496 patients (79% female, age 57 [2–87] years, follow-up 9 [0–36] years) with AIH (1999 IAIHG criteria) presenting 1987–2023 and followed until death/liver transplantation or 31/12/23. Causes of death were determined from clinical records and death certificates. Standardised mortality ratios (SMR) for extrahepatic death were calculated using age- and sex-matched regional population data, adjusted for calendar year and to exclude background liver-related mortality.
Results: During follow-up, 168 patients died and 11 underwent liver transplantation. Of 168 deaths, 121 (72%) were extrahepatic. Extrahepatic mortality exceeded that of the general population (SMR 1.31; 95% CI: 1.08–1.75). Extrahepatic deaths were due to cancer (31%; SMR 1.38 [95% CI 0.94–1.83]), infection (24%; SMR 7.77 [4.88–10.66]), vascular disease (21%; SMR 1.44 [0.86–2.02]), frailty or dementia (11%), renal failure (3%), other causes (10%), and unknown causes (2%). On multivariate analysis, older age at diagnosis, diabetes mellitus, and failure to normalise ALT within 12 months, but not the presence of cirrhosis, were independently associated with extrahepatic mortality. Excess infection-related mortality persisted in patients without cirrhosis (n = 324; SMR 7.39 [3.62–11.08]). Causes included pneumonia (n = 19), Covid-19 (n = 3), urosepsis (n = 3), and infective endocarditis, listeria meningitis, and invasive aspergillosis (n = 1 each). At infection onset, 22/26 informative patients (85%) were receiving immunosuppressive therapy, including prednisolone, budesonide, azathioprine and mycophenolate, with no exposure to biologic agents.
Conclusion: In this long-term AIH cohort, most deaths were due to extrahepatic causes and overall extrahepatic mortality exceeded that of the background population. Non-liver deaths were predominantly related to malignancy, vascular disease and infection, emphasising the importance of long-term management of AIH beyond control of liver inflammation alone.

SAT-276

Risk of cancer in patients with autoimmune liver disease treated with acetylsalicylic acid

Paulina Flis[1,2], Hannes Hagström[1,3], Staffan Rosenborg[2,4], Annika Bergquist[1,3], Axel Wester[1,2]. [1]*Gastroenterology and Nutrition Unit, Karolinska Institute, Stockholm, Sweden;* [2]*Division of Clinical Pharmacology, Karolinska University Hospital, Stockholm, Sweden;* [3]*Division of Hepatology, Department of Upper Gastrointestinal Diseases, Karolinska University Hospital, Stockholm, Sweden;* [4]*Department of Laboratory Medicine, Karolinska Institute, Stockholm, Sweden*
Email: paulina.flis@ki.se

Background and aims: Primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), and autoimmune hepatitis (AIH) are the major autoimmune liver diseases (AILD) and are associated with an increased risk of cancer. Epidemiological studies suggest that acetylsalicylic acid (ASA) may have protective effects against several cancers. We therefore investigated the potential cancer-protective effect of ASA in patients with AILD.
Method: Using the population-based DELIVER cohort, Swedish national registers were used to identify all patients with a hospital-based AILD diagnosis between 2006 and 2021. Patients were classified as ASA-exposed (≥180 days of ASA dispensed within 365 days after diagnosis of AILD, based on defined daily doses) or non-exposed. Follow-up started 365 days after AILD diagnosis. Propensity score matching was done to balance potential confounders, including sex, age, education, comorbidities and co-medications. Cox regression was used to estimate hazard ratios (HRs) and 95% confidence intervals (CI) for any cancer. The cumulative incidence of cancer was calculated while accounting for the competing risk of non-cancer death.
Results: We included a total of 698 AILD-patients with a median age of 72 (IQR 63–79) of whom 542 (78%) were female and 106 (15%) had cirrhosis at baseline. 322 (46%) had PBC, 267 (38%) had AIH and 109 (16%) had PSC. During a median follow-up of 3.7 years (IQR 1.5–7.8), any cancer occurred in 37/182 (20%) of ASA-exposed patients and 100/516 (19%) of unexposed patients. Cancer incidence rates per 1000 person-years were similar between ASA-exposed patients (42.7) and comparators (39.2) (HR 1.1, 95% CI 0.7–1.6). The 10-year cumulative incidence of any cancer was 25% (95% CI 18–34%) in ASA-exposed patients and 24% (95% CI 20–29%) in unexposed patients. The incidence of major bleeding did not differ between groups (HR 1.0, 95% CI 0.7–1.5), with 10-year cumulative incidences of 27% (95% CI 19–35%) in ASA-exposed and 24% (95% CI 19–28%) in unexposed patients.
Conclusion: ASA use was not associated with a reduced risk of cancer in patients with AILD, and no increased risk of major bleeding was observed among ASA-exposed patients.

Email: mfrey@courpharma.com

Background and aims: Primary biliary cholangitis (PBC) is a progressive autoimmune liver disease with significant unmet needs. Current therapies target bile acid regulation without addressing the underlying autoreactive T-cell mediated pathology. CNP-104 is a first-in-class tolerogenic nanoparticle encapsulating the PBC autoantigen PDC-E2, designed to restore antigen-specific immune

tolerance. Here we report exploratory prognostic risk scores from a Phase 2a study of CNP-104 in PBC.
Method: This randomized, double-blind, placebo-controlled trial enrolled 42 patients with PBC with an incomplete response to ursodeoxycholic acid. Patients were randomized 2:1 to receive two IV doses of CNP-104 (4 or 8 mg/kg) or placebo, one week apart. Exploratory analyses included prognostic risk scores (UK-PBC, GLOBE, and ALBI) and their components. Presented are the pooled CNP-104 (n = 25) and go-forward 4 mg/kg CNP-104 (n = 11) cohorts versus placebo (n = 16).
Results: UK-PBC and ALBI scores worsened in the placebo group but stabilized in both the pooled CNP-104 group (p = 0.014 and p = 0.001, respectively) and the 4 mg/kg group (p = 0.010 and p < 0.0001, respectively) through Day 270. This stabilization indicates a reduced risk of poor clinical outcomes. GLOBE scores increased similarly in the placebo and pooled CNP-104 arms (p > 0.05), but stabilized in the 4 mg/kg group compared to placebo (p = 0.0125). These results reflect the differential impact of CNP-104 on the unique components/weights used in each model (UK-PBC: ALP, bilirubin, ALT, albumin, platelets; ALBI: albumin, bilirubin; GLOBE: age, ALP, bilirubin albumin, platelets). Albumin levels were maintained in pooled CNP-104 and 4 mg/kg cohorts compared to a decrease in placebo at Day 180 (p = 0.040 and p = 0.014, respectively), suggesting albumin as a driver of improvements in prognostic scores. ALP and platelet levels were stable over the course of this analysis. Together, this data suggests that CNP-104 initially has a larger impact on hepatic function than on cholestasis early in the treatment course.
Conclusion: The significant improvement in key prognostic scores with CNP-104 demonstrates early evidence of disease-modifying activity and provides insight into the unique impact of CNP-104 on hepatic function compared to other PBC treatments. These findings support CNP-104 for development as a mechanistically distinct treatment for PBC in larger randomized trials.

Email: gatselis@me.com

Background and aims: Primary biliary cholangitis (PBC) is the most common autoimmune liver disease, with significant impact on quality of life and survival. We aimed to analyze Greek PBC patients, assess to treatment response during the first year, and explore correlation with outcomes.
Method: Prospectively-collected data were retrospectively analyzed. Response to ursodeoxycholic acid (UDCA) at first year was classified according to alkaline phosphatase (ALP): complete response (ALP ≤ 1 × ULN), partial response (1.67 × ULN ≥ ALP > 1 × ULN), and non-response (ALP > 1.67 × ULN).
Results: Overall, 1385 patients were included (85.6% female; median age 56.4 years). Median delay in diagnosis was 19 months. At baseline, 719/1385 (51.9%) were asymptomatic, 171/1385 (12.3%) had cirrhosis, including decompensation [70/171 (40.9%)]. Fatigue and pruritus at diagnosis were present at 176/1385 (12.7%) and 281/1385 (20.3%), respectively. At month 12 of treatment, 62.2% showed complete response, 27.5% partial, and 10.3% non-response. During follow-up [median (interquartile range): 7 (11) years], 93/1214 patients (7.7%) developed cirrhosis, and 71/194 (37.2%) decompensation. Baseline symptoms were not associated with outcome (decompensation, liver-related-death or liver transplantation). Both non-responders (HR:10.0;95%CI:4.8–20.9; p < 0.001) and partial responders (HR:2.7;95%CI:1.3–5.7; p = 0.007) had increased risk of decompensation. Liver-related-death or liver transplantation occurred in 93/1385 patients (6.7%). Non-response (HR:6.8;95% CI:3.6–12.7; p < 0.001) and partial response (HR:2.2;95%CI:1.2–4.2; p = 0.011) were associated with liver-related mortality.
Conclusion: Cirrhosis at diagnosis is relatively uncommon in PBC, yet it remains a significant concern. Approximately 40% of patients do not achieve ALP normalization after one of UDCA, which is associated with poor prognosis. Therefore, early identification and prompt initiation of second-line therapies seem essential. [on behalf of the Hellenic Autoimmune Liver Diseases Study Group]

Outcomes of cirrhotic patients at the presentation of autoimmune hepatitis and the role of biochemical response as a predictor of survival
Elze Maria Gomes Oliveira[1], Maria Lucia Gomes Ferraz[2], Ana Cristina Amaral[2], Antonio Eduardo Benedito da Silva[2], Patrícia Marinho C Oliveira[3], Lucas Carvalho[4], Luiza Lacks[5], Felipe Oliveira Carvalho[6], Maria Chiara Chindamo[7]. *[1]Centro Universitario Lusiada UNILUS, Santos, Brazil; [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [3]Fleury Medicina e Saude, Sao Paulo, Brazil; [4]Endosoni, Centro Universitario Lusiada, Santos, Brazil; [5]Hospital Beneficência Portuguesa, Santos, Brazil; [6]Hospital Ana Costa, Santos, Brazil; [7]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*
Email: elzeoliveira@terra.com.br

Background and aims: Autoimmune hepatitis (AIH) generally responds well to immunosuppressive therapy and is associated with a favorable prognosis. Treatment aims to delay fibrosis progression, prevent liver transplantation, and improve survival. Cirrhosis is present at diagnosis in approximately 30% of patients and has been associated with poorer treatment response and worse outcomes. Failure to achieve biochemical remission has been linked to increased rates of liver transplantation and liver-related mortality. This study aimed to evaluate the frequency of cirrhosis at AIH presentation and to assess the impact of biochemical response and liver function at diagnosis on patient survival.
Method: A total of 114 patients with AIH diagnosed according to International Autoimmune Hepatitis Group criteria were included. Cirrhosis was defined by histology or by clinical signs of liver failure and/or portal hypertension. All patients were treated with prednisone combined with azathioprine. Loss of liver function was defined as prothrombin activity <70% and albumin <3.5 g/dL. Biochemical response was defined as normalization of ALT, AST, gammaglobulin, and bilirubin levels.
Results: Among the 114 patients evaluated, 60 (53%) had cirrhosis at diagnosis. Ninety-five percent were female, with a mean age of 28 ± 17 years. Among cirrhotic patients, 57% achieved a biochemical

response. Data from 51 of the 60 cirrhotic patients were available for analysis regarding the presence or absence of biochemical response, disease course with or without decompensation, and survival over a mean follow-up period of 8 ± 4.5 years. Among cirrhotic patients with biochemical response, 29 of 30 (97%) remained free of decompensation, compared with 12 of 21 (57%) cirrhotic patients without biochemical response (p = 0.001). Mean survival time was 14 years in patients with biochemical response and 9 years in those without response (p = 0.03). In patients who achieved biochemical response, comparative analysis according to disease presentation (cirrhosis with or without liver function impairment) showed no significant impact of liver function at diagnosis on survival (10.6 ± 1.1 vs. 10.2 ± 1.2 years; p = 0.86).
Conclusion: The achievement of biochemical response is a strong predictor of decompensation-free survival and improved overall survival in patients with cirrhosis at the time of AIH diagnosis. This favorable prognosis appears to be independent of liver function status at presentation.

Email: lorenz.grossar@ugent.be

Background and aims: Follow-up of disease activity in subjects with autoimmune hepatitis (AIH) mainly relies on normalization of transaminases (TA) and immunoglobulin G (IgG). Complete biochemical response is defined by the international autoimmune hepatitis group consensus criteria as normalization of TA and IgG within six months after induction treatment, and correlates with superior liver-related survival. The association of IgG with survival outcomes is more contested than TA normalization. In a recent retrospective, multicenter cohort, no significant difference in cirrhosis development was observed between subjects with AIH after persistent TA normalization, according to their IgG evolution. We aimed to replicate these findings in our own cohort.
Method: We performed a subset-analysis from our own real-world, multicenter, retrospective cohort of subjects with AIH and identified those with persistently normal TA, and without cirrhosis at initial diagnosis. All available IgG levels were recorded allowing classification of subjects with either persistently normal IgG (IgGn), fluctuating IgG (IgGf), and persistently elevated IgG (IgGe). Development of cirrhosis was assessed by suggestive clinical, laboratory and imaging findings, and/or follow-up biopsy.
Results: From an initial cohort of 213 subjects with AIH, 95 without cirrhosis and with persistently normal TA could be identified. According to IgG evolution, 76 (80.0%) had persistently normal IgG, whereas 17 (17.9%) and 2 (2.1%) were classified as IgGf and IgGe, respectively. During a median follow-up of 8.1 years (interquartile range: 1.2–15.1 years), seven (7.4%) subjects developed cirrhosis. When comparing proportions according to IgG evolution, the proportion of subjects with persistently normal IgG who developed cirrhosis was significantly lower than in those with either persistently elevated or fluctuating IgG: 3/76 (4.0%) versus 1/2 (50%) and 3/17 (17.6%), respectively. Fisher's exact test p-value for differences in proportions between IgGn, IgGf, and IgGe = 0.01635.
Conclusion: In our subset-analysis, development of cirrhosis occurred significantly less in subjects with persistently normal TA and IgG, compared to those with abnormal IgG in follow-up. Our findings are in contrast with a recent publication suggesting no role of IgG in cirrhosis development, emphasizing the importance of large datasets with long-term follow-up when outcome incidence is low.

Background and aims: Primary sclerosing cholangitis (PSC) is an enigmatic chronic cholestatic disease that results in a disproportionate burden of transplant activity across the globe. Herein, we characterize a globally representative cohort of patients (pts) with PSC who underwent liver transplantation (LT) and report burden of recurrent PSC (rPSC), re-transplantation, and malignancy on explant.
Method: Descriptive statistics were used to describe baseline characteristics. Summary statistics were reported as proportions and medians with interquartile ranges. Kaplan-Meier analyses were used to evaluate time dependent regional differences in risk of rPSC.
Results: In total, 1546 pts were included in the analysis from Africa (n = 114), Northern Europe (NE) (n = 405), Mediterranean Europe (n = 61), Oceania (n = 117), North America (NA) (n = 791) and South America (SA) (n = 58). The mean age of PSC diagnosis was 36 (25–48) years (yrs), 65% were male, 55% Caucasian, 76% had IBD, and 10% labelled with an autoimmune hepatitis variant. Mean age at LT was 44 yrs (32–57) and median MELD 14 (8–21). Surgically, 61% had a donation after brain death graft, 9% had a donation after cardiac death graft, 16% had a living donor graft, and 55% had a Roux-en-Y anastomosis. UDCA was used in 39% of pts pre-LT and 22% in the first year post LT. Tacrolimus (83%) and mycophenolate mofetil (52%) were the most common immunosuppressive agents used post LT. Malignancy was detected in 6.2% of all explants (n = 96), with cholangiocarcinoma in 3.2% (n = 50), gallbladder cancer in 1.2% (n = 18) and hepatocellular cancer in 2% (n = 28). Excluding pts referred for LT with indication of neoplasia (n = 60), 4.5% (n = 67) of the cohort had incidental malignancy on explant. The cumulative incidence of rPSC was 2.1% at 1 year, 13.7% at 5 yrs and 26.8% at 10 yrs. There was a lower risk of rPSC in Africa compared to the other regions ($p < 0.05$) but no significant difference in rPSC across Mediterranean or NE, NA, SA, and Oceania. Re-LT occurred in 14.1% (n = 219) a median of 2.3 (0.2–8.6) yrs after first LT, and a third LT was performed in 1.9% (n = 30) pts after a median of 2.6 (0.8–11.5) yrs from second LT. A fourth LT was performed in 3 pts, all from NE at a median of 6.9 (4.8–7.5) yrs from 3rd LT.
Conclusion: PSC pts undergoing LT are at high risk of malignancy on explant, rPSC, and re-transplantation. Understanding predictors of such impactful outcomes remains an important priority.

SAT-287

Efficacy and safety of seladelpar in patients with primary biliary cholangitis and cirrhosis, including those with clinical signs of portal hypertension: interim results from the open-label ASSURE study with up to 4 years of treatment

Aliya Gulamhusein[1], Pietro Invernizzi[2,3], Andrea Galli[4], Francesca Carubbi[5], Sarah Proehl[6], Robert Kustra[6], Jie Liu[6], Kyung min Kwon[6], Daria B. Crittenden[6], Palak J. Email: sgordon3@hfhs.org

Background and aims: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in patients (pts) with an inadequate response to UDCA or as monotherapy in pts unable to tolerate UDCA. In the pivotal RESPONSE study (NCT04620733), SEL had similar efficacy in pts with or without compensated cirrhosis and safety generally similar to placebo. Here, we present an interim analysis of the efficacy and safety of SEL in pts with compensated cirrhosis in the ongoing open-label Phase 3 ASSURE study (NCT03301506).
Method: Pts from RESPONSE and legacy SEL studies enroled in ASSURE and received SEL 10 mg once daily. Pts with cirrhosis per protocol at baseline (BL) were pooled. BL was defined as SEL initiation in RESPONSE or ASSURE. Post hoc, cirrhosis pts were identified as having features of portal hypertension (PHT) if they met ≥ 1 criterion at baseline (BL): platelets < 140×10^3/uL, low albumin, elevated total bilirubin (TB), ascites, or medical history of varices or PHT. Efficacy endpoints through month (M) 36 included composite biochemical response (CBR; alkaline phosphatase [ALP] < 1.67 × the upper limit of normal [ULN], ≥ 15% decrease in ALP, and TB ≤ 1.0 × ULN), ALP normalisation, and other laboratory changes. Safety was also assessed. Data cutoff: 31 Jan 2025.
Results: 53/337 (16%) pts had cirrhosis at BL; most were Child-Pugh (CP)-A, with 4 (8%) CP-B. At BL, mean ALP was 267.5 U/L, TB 0.98 mg/dL, and liver stiffness 20.6 kPa. 29/53 (55%) pts with cirrhosis had features of PHT. Among evaluable pts, 25/51 (49%) achieved CBR at M12, with a similar proportion meeting this endpoint at M36 (9/19 [47%]). Mean percent change from BL in ALP was −35% at M12 and −28% at M36. 15/51 (29%) pts achieved ALP normalisation at M12, and 3/19 (16%) with available data had normal ALP at M36. Adverse events were reported in 50/53 (94%) pts. Four pts experienced events meeting the criteria for a PBC clinical outcome; no events were assessed as related to SEL. No pts with abnormal aspartate aminotransferase (AST) or alanine aminotransferase (ALT) at BL experienced an AST or ALT ≥ 2 × BL.
Conclusion: SEL continues to demonstrate sustained biochemical efficacy and a favourable safety profile in cirrhosis pts with PBC, including pts with features of PHT, with up to 4 years of treatment.

SAT-288

Increased risk of non-Hodgkin lymphoma in autoimmune hepatitis: a large retrospective cohort study

Mifleh Tatour[1], Fadi Abu Baker[2], Tarek Saadi[3], Rawi Hazzan[4]. *[1]Clalit Health Service, Faculty of Medicine, Bar Ilan, Safed, Tel aviv, Israel; [2]Department of Gastroenterology and Hepatology, Hadera, Israel; [3]Rambam Health Care Campus, Haifa, Israel; [4]Clalit Health Service, Azrieli Faculty of Medicine, Bar-Ilan University, Tel aviv, Israel*
Email: rawihazzan1@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease that usually requires long-term immunosuppressive therapy. Thiopurines and mycophenolate mofetil (MMF), commonly used in AIH, have been associated with an increased risk of lymphoma in other autoimmune diseases. However, data regarding the risk of non-Hodgkin lymphoma (NHL) in AIH patients are limited. This study aimed to evaluate the incidence of NHL in AIH patients treated with immunosuppressive agents compared with the general population.
Method: We conducted a retrospective population-based cohort study using Clalit Health Services data from 2000–2020. Adult AIH patients treated with azathioprine, 6-mercaptopurine (6-MP), or MMF were included. Patients with inflammatory bowel disease, other

autoimmune diseases, prior lymphoma, or additional chronic liver diseases were excluded. Incident NHL cases were identified through linkage with the Israeli National Cancer Registry. Standardized incidence ratios (SIRs) were calculated by age and sex to compare observed versus expected NHL cases.
Results: A total of 685 AIH patients were included (83.5% female; mean age 53.1 years), with a mean follow-up of 7.5 years. Nine patients developed NHL, all aged ≥45 years at diagnosis. The overall SIR for NHL was 36.5, indicating a markedly increased risk compared with the general population. Six cases occurred in patients treated with azathioprine and two in those treated with MMF; no cases were observed in patients treated exclusively with 6-MP. No statistically significant association was found between specific immunosuppressive agents and NHL risk.
Conclusion: AIH patients treated with standard immunosuppressive regimens exhibit a substantially increased risk of NHL compared with the general population, independent of the specific agent used. These findings highlight the need for heightened clinical awareness and possibly tailored surveillance strategies for lymphoma in AIH. The elevated risk likely reflects a combination of chronic immune dysregulation inherent to AIH and prolonged immunosuppressive therapy, underscoring the importance of balancing long-term treatment benefits against potential malignancy risks. Further large-scale and mechanistic studies are warranted to elucidate causal factors and guide optimal management approaches.

SAT-289

Long-term risk of inflammatory bowel disease in autoimmune hepatitis: over a 20-year population-based study

Mifleh Tatour[1,2], Fadi Abu Baker[3], Tarek Saadi[4], Rawi Hazzan[2,5]. *[1]Clalit Health Service, Faculty of Medicine, Bar Ilan, Safed, Tel aviv, Israel; [2]Bar Ilan University, Safed, Israel; [3]Department of Gastroenterology and Hepatology, Hadera, Israel; [4]Rambam Health Care Campus, Haifa, Israel; [5]Clalit Health Service, Azrieli Faculty of Medicine, Bar-Ilan University, Tel aviv, Israel*
Email: rawihazzan1@gmail.com

Background and aims: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease frequently associated with other autoimmune conditions, including inflammatory bowel disease (IBD). Although coexistence of AIH and IBD has been described, the long-term incidence of IBD after AIH diagnosis and its impact on liver outcomes remain insufficiently defined. This study aimed to evaluate the long-term risk of IBD among AIH patients and to assess its influence on cirrhosis and liver-related complications.
Method: We conducted a retrospective, population-based cohort study using Clalit Health Services data, including adult patients diagnosed with AIH between 2000 and 2024. Patients with pre-existing IBD, other chronic liver diseases, or cirrhosis before AIH diagnosis were excluded. Incident IBD cases were identified during follow-up. Demographic, clinical, and treatment variables were analyzed. Kaplan–Meier analysis was used to estimate cumulative IBD incidence, and multivariable logistic regression identified predictors of IBD development. Liver-related outcomes were compared between patients with and without IBD.
Results: Among 1284 AIH patients (80.5% female; median age 51.5 years), 126 (9.8%) developed IBD during a mean follow-up of 4.8 years, most commonly Crohn's disease. The cumulative probability of remaining IBD-free declined progressively to 79.7% at 20 years. Smoking was independently associated with increased IBD risk (adjusted OR 1.76, 95% CI 1.10–2.83). Cirrhosis was significantly more prevalent in AIH patients with IBD compared with those without IBD (73.9% vs 26.3%, $p < 0.0001$). However, rates of major liver-related complications, including ascites, variceal bleeding, hepatic encephalopathy, and hepatocellular carcinoma, did not differ between groups.
Conclusion: IBD develops in a substantial proportion of AIH patients over long-term follow-up, with risk increasing over time. Smoking is a modifiable independent risk factor for IBD development. Although AIH–IBD overlap is associated with a higher prevalence of cirrhosis, it does not appear to increase the risk of advanced liver-related complications. These findings support long-term vigilance for IBD in AIH patients and emphasize the importance of smoking cessation.

SAT-290-YI

Timing matters: prognostic impact of biochemical response assessment in autoimmune hepatitis (AIH)

Helena Hernández-Évole[1], Ana Pascual-Dapena[2], Marta Sánchez-Ric[1], María Fernández-Aguilera[3], Empar Moreno-Penades[3], Nuria Florensa[2], David Heitmann[2], Diogo Simas[2], Fernando Diaz[4], Sara Lermo[4], María Del Barrio[5], Pinelopi Arvaniti[1], Ignasi Olivas[2], Álvaro Díaz-González[6], Magdalena Salcedo Plaza[7], Mar Riveiro Barciela[8], Sergio Rodriguez-Tajes[1], María Carlota Londoño[1]. *[1]Hospital Clínic De Barcelona, Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas CIBEREHD), Madrid, Spain; IDIBAPS, Barcelona, Spain; [2]Hospital Clínic De Barcelona, Barcelona, Spain; [3]Vall d'Hebron, Barcelona, Spain; [4]Gregorio Marañón, Madrid, Spain; [5]Hospital Valdecilla, Santander, Spain; [6]Hospital Valdecilla, Clinical and Translational Research in Digestive Diseases Group, Valdecilla Research Institute (IDIVAL), Santander, Spain, Santander, Spain; [7]Gregorio Marañón, Gregorio Marañón Health Research Institute (IiSGM), Madrid, Spain; CIBERehd, Madrid, Spain; [8]Vall d'Hebron, CIBERehd, Barcelona, Spain*
Email: hernandez.ievole@gmail.com

Background and aims: Current AIH guidelines define complete biochemical response (CBR) as normalization of transaminases and IgG at 6 months, although the optimal timing for response assessment remains uncertain. We aimed to evaluate whether the timing of CBR or biochemical response (BR; transaminase normalization) assessment influences its prognostic value for future liver-related events (LRE) in patients with AIH.
Method: Retrospective cohort of 423 biopsy-confirmed AIH patients treated with first-line therapy at four Spanish hospitals. Patients with cirrhosis at diagnosis, prior decompensation, variant forms, or fulminant presentation were excluded. LRE was defined as cirrhosis development, decompensation, hepatocellular carcinoma, liver transplantation, or liver-related death. Landmark analyses at 3, 6, 9, and 12 months were performed using Cox proportional hazards assessed the association between CBR and BR with LRE at 3, 6, 9 and 12 months, adjusting for age and sex.
Results: Most patients were women (64.3%) with median age of 55 years (IQR 42–65) and median follow-up (FU) of 6.3 (IQR 3.1–9.7). CBR was achieved in 83% of patients after a median time of 6.5 months (IQR 2.9–14.4) from treatment initiation. CBR rates at 3, 6, 9, and 12 months were 20%, 37%, 50%, and 57%, respectively. During the FU 36 patients developed LRE, none occurred before 9 months and only one by 12 months of treatment. Landmark Cox regression showed that achieving CBR at 6 months was linked to a reduced risk of LRE (HR 0.37, 95% CI 0.14–0.98, $p = 0.044$), with the strongest prognostic value at 9 months (HR 0.35, 95% CI 0.15–0.81, $p = 0.014$). CBR at 3 and 12 months were not significantly related to outcomes.BR was achieved in 87% of patients after a median time of 5.7 months (IQR 2.3–11.8). BR rates at 3, 6, 9 and 12 months were 25%, 43%, 57%, and 65%, respectively. The strongest association between BR and reduced LRE risk was at 9 months (HR 0.45, 95% CI 0.21–0.96, $p = 0.038$).
When compared to BR, CBR resulted in a slight, non-significant improvement in Harell's C statistics at 6 (0.77 vs. 0.76, $p = 0.625$) and 9 months (0.75 vs. 0.77, $p = 0.464$).
Conclusion: In non-cirrhotic patients with AIH, assessing treatment response at 9 months identifies late responders without increasing early clinical risk and provides optimal prognostic discrimination for LRE. BR based on transaminase normalization performs similarly to CBR, suggesting limited added prognostic value of IgG normalization.

SAT-291

Reduced symptom prevalence but significant quality of life impact in patients with primary biliary cholangitis in Spain

Email: hernandez.ievole@gmail.com

Background and aims: Fatigue and pruritus are common symptoms of primary biliary cholangitis (PBC) and can occur at any disease stage. Previous studies report prevalence rates of pruritus, fatigue, and cognitive impairment in PBC at 80%, 60%, and 35%, respectively. This study aimed to evaluate symptom severity and associated clinical factors in Spanish PBC patients.
Method: A multicenter cross-sectional study at 11 sites used electronic questionnaires (PBC-40, 5D-Itch, EQ-5D-5L) to measure symptoms and quality of life (QoL). Moderate-to-severe (M-S) symptoms were defined as fatigue ≥29, cognitive impairment ≥16, and pruritus ≥9. Clinical and epidemiological data were then collected.
Results: 191 patients were included: 91% women, median age 60 years (IQR 52–66), 88% AMA positive, and 7% with cirrhosis. Most (88%) received UDCA alone; 30.9% had second-line therapy. Based on PBC-40, 30% of patients had pruritus; with 12% experiencing M-S symptoms. Of these, 33% were untreated and 25% denied pruritus upon questioning. The 5D-itch scale identified pruritus in 49%, although 40% denied it. The correlation between 5D-itch and PBC-40 was moderate ($r = 0.648$, $p < 0.001$). Pruritus was linked to higher liver stiffness (OR 1.22, IQR 1.1–1.4) and younger age (OR 0.94, IQR 0.89–0.99). Those who reported no pruritus but were detected by PBC-40 had lower QoL than those without pruritus (0.92 vs 1.00; $p = 0.002$). M-S fatigue was reported by 41% of patients and cognitive impairment by 30%, with neither associated with clinical or biochemical features. M-S fatigue was associated with pruritus (OR 3.5, IQR 1.02–11.86). Patients with cognitive impairment received more psychotropic medications without higher rates of depression or anxiety. Pruritus significantly reduced quality of life (QoL) ($p < 0.0001$), even when mild, and M-S fatigue had a similar impact ($p < 0.0001$). When both symptoms coexisted, QoL was lowest (0.790 vs 0.923, $p < 0.05$). Increased fatigue scores were linked to higher chances of work leave or disability pension (OR 1.08, 95% CI: 1.02–1.14, $p = 0.011$), regardless of average income per consumption unit.
Conclusion: Fatigue, although less common in our Spanish cohort than previously reported, was the primary symptom of PBC and the key factor contributing to reduced QoL and socioeconomic burden. Its strong association with pruritus underscores the importance of using validated scales to detect underreported symptoms. PBC-40 detects early mild pruritus impacting QoL, identifying patients who may benefit from treatment.

SAT-298

Diagnosis, treatment and outcomes of primary biliary cholangitis – insight from 801 patients enrolled for 20 years in the Polish registry of two tertiary centres

Maciej Janik[1], Beata Kruk[1], Ewa Wunsch[2], Karolina Wronka[1], Magdalena Jaroszek[1], Jacek Tomczuk[1], Sebastian Jędruszek[2], Kaja Kozłowska[2], Joanna Raszeja-Wyszomirska[1], Piotr Milkiewicz[1,2]. *[1]Medical University of Warsaw, Warszawa; [2]Pomeranian Medical University, Szczecin, Poland*
Email: mjanik24@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is a rare cholestatic liver disease with limited but expanding treatment options. Data on PBC from Central/Eastern Europe remain scarce. Here, we evaluated diagnosis, treatment and outcomes from a 20-year Polish registry of patients with PBC.
Method: We analysed a cohort of 801 patients with PBC prospectively recruited between 2005 and 2025 at two tertiary centres (Warsaw and Szczecin) collaborating within ERN RARE-LIVER. The registry comprised clinical and patient-reported data at the time of diagnosis, at inclusion, and during follow-up.
Results: The cohort included 719 women (90%), with a median age at diagnosis of 53 years (range: 22–88), and no differences in age compared to males. AMA and ANA antibodies (including, but not limited to, anti-sp100 and anti-gp210) were present in 79% and 68%, respectively. At diagnosis, median (range) ALP and bilirubin levels were 270 (37–2700) IU/mL and 0.9 (0.1–40.5) mg/dL, respectively. Liver biopsy (LB) was performed in 49% of patients (with younger age and/or with worse liver injury markers (ALT, AST, ALP, all $p < 0.01$)), due to suspicion of autoimmune hepatitis (AIH) variant and/or advanced fibrosis. Liver cirrhosis (assessed by LB, liver stiffness or clinical signs) and PBC/AIH variant were diagnosed in 31% and 8% of patients, respectively. More than half of patients (56%) reported any pruritus at diagnosis. These subjects had higher ALP ($p < 0.001$), but no differences in liver cirrhosis status ($p = 0.08$). At the registry inclusion (median 2 (0–27) years after diagnosis), significant fatigue (>33) and itch (>6) were evaluated by PBC-40 in 40% and 39% patients, respectively. Drug regimens comprised of UDCA (98%) and fibrates (43%). Indications for fibrates were: insufficient UDCA response (63%), pruritus (17%), hypertriglyceridemia (11%) or multi-indication. After a median of 6 (0.5–32) years from the diagnosis, 55% had normalised ALP, 35% had ALP 1.0–1.67, and 10% had ALP > 1.67, the upper limit of normal. During the follow-up, 27% patients underwent liver transplantation (LT), and 12% died. Patients who received LT were diagnosed at a younger age, in a non-tertiary centre (82%, both $p < 0.001$), with higher ALP and ALT (both $p < 0.05$), but not bilirubin.
Conclusion: This large Polish PBC cohort provides comprehensive real-world data on diagnosis, symptom burden, treatment patterns and long-term outcomes. Despite widespread UDCA use, many patients required second-line or symptom-relief therapy.

SAT-299

The majority of fatigued primary biliary cholangitis patients do not have clinically significant itch

David E. Jones[1], Jessica Leighton[1], Aaron Wetten[2], Magnus Doverskog[3], Jessica Dyson[2]. *[1]Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Newcastle Upon Tyne Hospitals Nhs Foundation Trust, Newcastle upon Tyne, United Kingdom; [3]Umecrine Cognition, Solna, Sweden*
Email: david.jones@newcastle.ac.uk

Background and aims: Quality of life (QoL) impairment in primary biliary cholangitis (PBC) is significant with the symptoms of itch and fatigue (with and without cognitive symptoms) predominating. Recent advances in itch treatment through the development of the iBAT inhibitors and appreciation of the beneficial effects of the

fibrates and PPAR agonists has, together with the intuitive view that night-time itch that disturbs sleep must contribute to fatigue, led to a view that targeting itch is the key route to symptom improvement in PBC. This study aimed to address the question of whether fatigue in PBC is, indeed, simply a downstream consequence of itch, with the implication that effective itch treatment will address the problem of fatigue at a population level.

Method: The PBC-40 questionnaire was completed by 1964 well-characterised patients in the UK-PBC national cohort. Established cut-offs for moderate/severe symptom severity (ie clinically significant symptoms) vs mild/none (non-clinically significant) were used for each symptom domain (itch, fatigue and cognitive symptoms).

Results: 644 (33%) participants had significant itch. Of these, 520 (81%) also had significant fatigue. 336 (52%) had significant cognitive symptoms and 333 (52%) had fatigue with cognitive symptoms (the form of fatigue with the greatest impact on QoL). Of the 1320 participants with no/mild itch, 608 (46%) had fatigue and 363 (28%) had cognitive symptoms. Overall, 1128 (57%) of the cohort had fatigue, but of those 54% did not have itch. Likewise, of the 699 (36%) of the population with significant cognitive symptoms 52% did not have itch.

Conclusion: Fatigue and cognitive symptoms are common in PBC patients with clinically significant itch. It is therefore logical to target itch treatment as a priority in this group. However, the majority of PBC patients with fatigue and/or cognitive symptoms do not have itch, so we can't expect improvement in their fatigue through itch reduction. Hence, to support a more individualized treatment approach, there is a clear need to develop specific fatigue-targeting therapies to address the quality-of-life issues in this group of patients.

SAT-300

Long-term treatment with elafibranor improves markers of immune response and inflammation in primary biliary cholangitis

David E. Jones[1], Cynthia Levy[2,3], Kris V. Kowdley[4,5], Christopher L. Bowlus[6], Darren Asquith[7], Nuno Antunes[8], Nathan Touati[9], Jörn M. Schattenberg[10]. *[1]Translational and Clinical Research Institute and NIHR Newcastle Biomedical Research Center, Newcastle University, Newcastle Upon Tyne, United Kingdom; [2]Schiff Center for Liver Diseases, University of Miami, Miami, United States; [3]Division of Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, United States; [4]Liver Institute Northwest, Seattle, Washington, United States; [5]Elson S. Floyd College of Medicine, Washington State University, Washington, United States; [6]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, United States; [7]Ipsen, London, United Kingdom; [8]Ipsen, Cambridge, Massachusetts, United States; [9]Ipsen, Paris, France; [10]Department of Internal Medicine II, Saarland University Medical Center, Homburg, Germany*
Email: david.jones@newcastle.ac.uk

Background and aims: Primary biliary cholangitis (PBC) is a rare autoimmune disease characterised by progressive destruction of small intrahepatic bile ducts. Chronic inflammation results in liver injury, fibrosis and cirrhosis. Markers of immune response (immunoglobulin [Ig]-G and IgM) and inflammation (haptoglobin and C-reactive protein [CRP]) are associated with disease activity. Elafibranor (ELA), a PPARα/δ agonist, significantly improved markers of cholestasis in the phase III ELATIVE® trial (NCT04526665). Here, markers of immune response/inflammation from the trial and ongoing open-label extension (OLE) are presented.

Method: 161 patients (pts) were randomised 2:1 to receive ELA 80 mg or placebo (PBO) daily in the double-blind period (DBP). Pts who completed the DBP could enter the OLE and receive ELA 80 mg. Change from baseline (CfB) in IgG, IgM, haptoglobin and CRP were assessed using a mixed model for repeated measures (adjusted for baseline/stratification factors) at Week (W) 26 and 52 of the DBP and were presented descriptively from OLE start to W156. OLE data are reported for pts who continued ELA (continuous pts [W156 ELA exposure]; baseline at DBP start) and pts who switched from PBO to ELA (crossover pts [W104 ELA exposure]; baseline at OLE start).

Results: 108 pts received ELA and 53 received PBO in the DBP. 138 pts entered the OLE (continuous pts: n = 93; crossover pts: n = 45); 113 remained at W156. In the DBP, significant reductions in IgG, IgM and haptoglobin were observed with ELA vs PBO at W26 and sustained to W52 (W52 IgG least squares [LS] mean CfB: –0.365 g/L [n = 95] vs 0.333 g/L [n = 46, p = 0.009]; IgM LS mean CfB: –0.558 g/L [n = 95] vs 0.025 g/L [n = 46, p < 0.001]; haptoglobin LS mean CfB: –0.166 g/L [n = 93] vs –0.001 g/L [n = 47, p = 0.008]). CRP increases were smaller with ELA vs PBO (W52 LS mean CfB: 0.81 mg/L [n = 93] vs 1.02 mg/L [n = 47, p = 0.051]). In the OLE, reductions in IgG, IgM and haptoglobin were sustained in continuous pts to W156 (W156 mean CfB IgG: –0.556 g/L [n = 72]; IgM: –0.676 g/L [n = 72]; haptoglobin: –0.204 g/L [n = 73]). Reductions in all markers were reproduced in crossover pts (W156 mean CfB IgG: –1.361 g/L; IgM: –0.663 g/L; haptoglobin: –0.231 g/L; CRP: –0.71 mg/L [n = 33 for all]).

Conclusion: Long-term ELA treatment leads to sustained and reproducible reductions in levels of markers of immune response/inflammation, providing a potential role for ELA in influencing mechanistic changes to autoimmune processes in PBC and slowing disease progression.

SAT-301

Investigating the burden of illness in primary sclerosing cholangitis (PSC): a multinational study

Deepak Joshi[1], Guy Lacey[2], Jolan Terner-Rosenthal[2], Lucia Quadrado[2], Robin Howard[2], Jane Moorhouse[3], Oliver Webb[3], Sarah Smart[3], Donna Rowen[4], Philip A. Powell[4], Brian Thorsen[5], Ingo Van Thiel[6], Martine Walmsley[7], Angela Leburgue[8], Francesca Scarpa[9], Marlyn J. Mayo[10]. *[1]King's College Hospital, RW-ILS, London, United Kingdom; [2]Mirum Pharmaceuticals, Inc., Foster City, California, United States; [3]Initiate Consultancy, Ltd., Northampton, United Kingdom; [4]Sheffield Centre for Health and Related Research, University of Sheffield, Sheffield, United Kingdom; [5]PSC Partners Seeking a Cure, Denver, Colorado, United States; [6]Deutsche Leberhilfe, eV, Cologne, Germany; [7]PSC Support, Manchester, United Kingdom; [8]ALBI France, Versailles, France; [9]AMAF Italia (Associazione Malattie Autoimmuni Del Fegato), Muggio, Italy; [10]UT Southwestern Medical Center, Dallas, Texas, United States*
Email: d.joshi@nhs.net

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, chronic liver disease associated with progressive damage to hepatic bile ducts and cholestasis-related symptoms such as pruritus and fatigue, which can impair health-related quality of life (HRQoL). This study aims to better characterize the burden of illness in symptomatic PSC patients.

Method: A survey of patients with PSC matched to a general population sample was initiated in the US, UK, France, Germany and Italy. The web-based survey sent through patient advocacy groups with links to questionnaires contained both quantitative and qualitative elements, including validated outcome measures (e.g., PROMIS Fatigue, SF-36). Pruritus severity was measured by the Adult ItchRO (0–10 scale; 0 = no itch; 10 = worst itch). T-statistics and linear regression analyses were performed to examine the relationship between pruritus severity and HRQoL. Only survey data from the US, UK, and France were available at the time of submission.

Results: 242 individuals (38% male; mean [SD] age 42.3 [12.3] years) were included of which 121 were patients with PSC currently experiencing pruritus (US: n = 50, UK: n = 50, France: n = 21) and 121 from an age- and sex- matched general population cohort (US: n = 50; UK: n = 50; France: n = 21). The median (SD) ItchRO in patients with PSC was 5 (2.30) indicating moderate severity, with 62% of patients reported having to make lifestyle adjustments due to fatigue. Pruritus severity (ItchRO) and fatigue (PROMIS fatigue) were significantly correlated (r = 0.243, p = 0.007) and this relationship remained

significant when controlled for country, age, and sex. Overall, patients with PSC had significantly ($p < 0.05$) lower HRQoL scores across the majority of SF-36 domains vs. the general population. Furthermore, an increase in pruritus severity was associated with worsening HRQoL across the physical component summary, role-physical, bodily pain and social functioning SF-36 domains. PSC symptoms negatively impacted patients' ability to work in half of the population.
Conclusion: Initial findings demonstrate that PSC is associated with debiliating physical, emotional, and social burden, with pruritus severity linked to fatigue and reduced physical function. These symptoms continue to be present and inadequately managed despite multiple medications used, underscoring an unmet need in the treatment of PSC.

SAT-302

The mean corpuscular volume (MCV) is a surrogate for therapeutic azathioprine metabolites in patients with autoimmune hepatitis

Guan Sen Kew[1,2], Yu Jun Wong[2], Shagani Thisairajah[2], Ellina Lytvyak[2], Aldo J Montano-Loza[2]. *[1]Woodlands Health Campus, Singapore, Singapore; [2]University of Alberta Hospital, Edmonton, Canada*
Email: kewguansen@gmail.com

Background and aims: Azathioprine (AZA), combined with prednisone, is still considered the first-line treatment for autoimmune hepatitis (AIH). Recent guidelines suggest testing 6-thioguanine nucleotides (6-TGN) in patients with incomplete biochemical response, intolerance, or non-adherence to therapy, proposing a therapeutic level of >223 pmol/8 × 10^8erythrocytes. However, access to 6-TGN testing can be costly and limited in many countries, leading to the consideration of surrogate blood indices such as mean corpuscular volume (MCV) and white blood cell (WBC) count. This study aims to evaluate the clinical utility of these blood indices in predicting therapeutic 6-TGN levels.
Method: We included 111 patients with AIH who were tested for 6-TG and 6-MMP (6-Methylmercaptopurine) levels because of incomplete biochemical response between 2004 and 2025. Data collected included baseline demographics, hematological and biochemical indices, azathioprine dosage, and corresponding 6-TGN levels, which were analyzed.
Results: 68.5% were female, and 29.7% had cirrhosis. A total of 211 6-TGN samples were collected, with a median value of 278 pmol/8 × 10 8 erythrocytes (IQR 182–490). The median azathioprine dose was 1.31 mg/kg (IQR 0.99–1.67), and 59.7% of samples were collected while patients were also on prednisone. Patients with MCV higher than 94.5 fL (OR = 2.93, $p = 0.004$) and an increase in MCV from baseline (OR = 2.71, $p = 0.004$) are more likely to have therapeutic 6-TGN levels. In contrast, WBC was not a significant predictor (OR = 0.96, $p = 0.516$) of therapeutic 6-TGN levels. Higher azathioprine doses (mg/kg) did not predict higher 6-TGN levels (B = 13.6, $p = 0.718$), but were significantly associated with higher 6-MMP levels (B = 3103.05, $p < 0.001$). The optimal MCV and change in MCV from baseline for predicting therapeutic 6-TGN levels were 94.5 fL, with a sensitivity of 69.4% and specificity of 63.6% (Youden index = 0.33), and +4.5 fL, with a sensitivity of 59.2% and specificity of 79.7% (Youden index = 0.39), respectively.
Conclusion: MCV higher than 94.5 fL and an increase in MCV from baseline were the strongest indicators of therapeutic 6-TGN levels in our cohort of AIH patients. Our findings suggest MCV might be useful in clinical practice as surrogate indicators to assess therapeutic 6-TGN levels, especially in regions where access to 6-TGN testing is limited.

SAT-303

Healthcare resource utilisation and costs associated with alkaline phosphatase normalisation and composite biochemical response among adults prescribed ursodeoxycholic acid for primary biliary cholangitis

Robert G. Gish[1,2], Robert Wong[3], Yi Pan[4], Mihail Samnaliev[4], Diane Ito[4], Chong Kim[5]. *[1]Robert G. Gish Consultants, LLC, San Diego, United States; [2]Hepatitis B Foundation, Doylestown, United States; [3]Division of Gastroenterology and Hepatology, Department of Medicine, Stanford University, Stanford, United States; [4]Stratevi, Santa Monica, United States; [5]Gilead Sciences, Inc., Foster City, United States*
Email: chong.kim9@gilead.com

Background and aims: Patients (pts) with primary biliary cholangitis (PBC) experience a substantial clinical and economic burden. Response to first-line ursodeoxycholic acid (UDCA) in clinical trials varies, and evidence linking biochemical response to economic outcomes is unclear. We aimed to evaluate the association between biochemical response and healthcare utilisation (HCRU) and costs in pts with PBC receiving UDCA.
Method: This observational, retrospective cohort study used Komodo Health data to identify pts with PBC from 1/9/2018 to 30/3/2023. Inclusion criteria: ≥ 1 UDCA prescription (excluding pts receiving obeticholic acid), continuous insurance enrolment for 12 months pre- and post-index, and baseline alkaline phosphatase (ALP) ≥ 1.67 × upper limit of normal (ULN). Post-index ALP normalisation was defined as ALP ≤ 1 × ULN; composite biochemical response (CBR) was defined as ALP < 1.67 × ULN, ALP decrease ≥ 15%, and total bilirubin ≤ 1 × ULN. Regression-adjusted models compared the association on HCRU and costs for pts achieving ALP normalisation or CBR.
Results: At baseline, 4013 pts had ALP ≥ 1.67 × ULN. Two cohorts of 1015 pts and 935 pts were analysed for post-index ALP normalisation and CBR, respectively. Pts achieving ALP normalisation (173/1015 [17%]) or CBR (600/935 [64%]) were older and more likely to be of White race or non-Hispanic ethnicity. In regression-adjusted sensitivity analyses (n = 941), ALP normalisation was associated with significantly fewer inpatient (IP) admissions (rate ratio [RR], 0.26; 95% CI, 0.11–0.64; $p = .003$) and outpatient (OP) visits (RR, 0.85; 95% CI, 0.73–0.99; $p = .036$). Differences in emergency room (ER) visits and prescription use were not significant. Achieving CBR (n = 865) was associated with significantly fewer IP visits (RR, 0.35; 95% CI, 0.20–0.59; $p < .001$), while OP visits, ER visits, and prescription use showed no significant differences. Each 10% reduction in ALP levels was associated with 21% lower IP, 6% lower OP, and 13% lower ER visit rates (all $p < .001$). Costs were significantly lower both for pts with ALP normalisation (–$8250; $p < .001$) and with CBR (–$5691; $p < .001$).
Conclusion: In pts with PBC receiving UDCA, achieving ALP normalisation or CBR was associated with substantial reductions in HCRU and costs. These findings underscore the importance of monitoring biochemical response and considering timely treatment escalation for non-responders to improve clinical outcomes and reduce the economic burden on pts and the healthcare system.

SAT-304

Sustained alkaline phosphatase normalisation and biochemical response are associated with reduced disease progression and clinical outcomes among adults prescribed ursodeoxycholic acid for primary biliary cholangitis

Robert G. Gish[1,2], Robert Wong[3], Yi Pan[4], Mihail Samnaliev[4], Diane Ito[4], Chong Kim[5]. *[1]Robert G. Gish Consultants, LLC, San Diego, United States; [2]Hepatitis B Foundation, Doylestown, United States; [3]Division of Gastroenterology and Hepatology, Department of Medicine, Stanford University, Stanford, United States; [4]Stratevi, Santa Monica, United States; [5]Gilead Sciences, Inc., Foster City, United States*
Email: chong.kim9@gilead.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic, autoimmune liver disease associated with long-term liver injury,

fibrosis, and clinical outcomes including cirrhosis and liver transplantation. Up to 40% of patients (pts) with PBC have inadequate treatment response to first-line ursodeoxycholic acid (UDCA), and incomplete treatment response (eg, alkaline phosphatase [ALP] > the upper limit of normal [ULN]) is associated with worse outcomes. This study evaluated the association of disease progression with sustained biochemical response in pts with PBC treated with UDCA in real-world settings.

Method: This observational, retrospective study used Komodo Health data to identify adults with PBC from 1/9/2018 to 30/3/2023. Key inclusion criteria were ≥ 1 UDCA prescription, 12 months (M) of continuous pre-index insurance coverage, and baseline (BL) ALP ≥ 1.67 × ULN. Pts were assessed for ALP normalisation (ALP ≤ 1 × ULN) and composite biochemical response ([CBR]; ALP < 1.67 × ULN, ≥15% ALP decrease from BL, and total bilirubin ≤ 1 × ULN) at 12 M (± 6 M) following UDCA initiation; pts who achieved either biochemical response but failed to maintain it through the end of follow-up (up to 30 M) were excluded. Cox Proportional-hazard (PH) regression models assessed clinical outcomes following biochemical response, including a composite endpoint of death or liver transplantation.

Results: At BL, 4013 pts had ALP ≥ 1.67 × ULN; 1015 and 935 pts were evaluated for ALP normalisation and CBR at 12 M (± 6 months), respectively. Pts achieving sustained ALP normalisation (173/1015 [17%]) or CBR (600/935 [64%]) were older and less likely to be of African American race or Hispanic ethnicity and more likely to have Medicare coverage. BL cirrhosis was lower for pts who achieved CBR vs those who did not (17% vs 39%; p < .001). In adjusted Cox PH models, CBR was associated with reduced risk of cirrhosis (hazard ratio [HR], 0.52; 95% CI, 0.33–0.83; p = .006), decompensated cirrhosis (HR, 0.20; 95% CI, 0.06–0.63; p = .006), ascites (HR, 0.12; 95% CI, 0.04–0.36; p < .001) and mortality (HR, 0.28; 95% CI, 0.13–0.57; p < .001).

Conclusion: Pts with PBC treated with UDCA who achieve sustained ALP normalisation or CBR had reduced risk of disease progression and fewer clinical outcomes. Incorporating ALP normalisation and CBR into PBC treatment decisions (eg, escalation to second-line options to enhance biochemical response) may help mitigate complications.

SAT-305

Metabolic syndrome drives small dense low-density lipoproteins in primary biliary cholangitis: a lipoprint-based analysis

Tomáš Koky[1], Sylvia Dražilová[1], Martin Janicko[1], Slavomíra Komárová[1], Beáta Hubková[2], Ivana Tóthová[2], Mária Mareková[2], Peter Jarčuška[1]. *[1]2nd Dept of Internal Medicine, PJ Safarik University, Faculty of Medicine and L Pasteur University Hospital, Košice, Slovakia; [2]Dept of Medical and Clinical Biochemistry, PJ Safarik University, Faculty of Medicine, Košice, Slovakia*
Email: tomaskoky1@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is associated with cholestasis-related dyslipidaemia considered largely non-atherogenic. However, concomitant metabolic syndrome may promote atherogenic lipoprotein alterations not captured by conventional lipid parameters. Small dense LDL (sdLDL) is a key atherogenic LDL subfraction, but its determinants in PBC remain unclear. We investigated associations between metabolic syndrome, liver disease characteristics and Lipoprint-derived sdLDL in PBC.

Method: In this cross-sectional single-centre study, patients with PBC underwent Lipoprint-based LDL subfraction analysis. sdLDL was defined as LDL-3–7. Metabolic syndrome and metabolic dysfunction–associated steatotic liver disease (MASLD) were defined by standard criteria, and liver fibrosis as non-advanced (F0–2) or advanced (F3–4) measured by transient elastography (VCTE). Due to skewed distribution, sdLDL was ln-transformed. Associations were assessed using univariable analyses, multivariable linear regression adjusted for relevant metabolic and clinical confounders and logistic regression for detectable sdLDL.

Results: Among 148 patients with PBC, metabolic syndrome was present in 39%. Ln-transformed sdLDL levels were higher in patients with metabolic syndrome than in those without (−2.87 ± 1.53 vs −3.58 ± 1.19; p = 0.004; Cohen's d = 0.53), while no association was observed with MASLD (p = 0.324) or advanced fibrosis (p = 0.155). In multivariable linear regression, metabolic syndrome remained independently associated with higher ln-transformed sdLDL levels (standardized β = 0.26, p = 0.005), with consistent results after adjustment for statin and fibrate therapy (standardized β = 0.27, p = 0.003) and in sensitivity analyses using waist circumference (p = 0.010). In logistic regression, metabolic syndrome was independently associated with detectable sdLDL. Although sdLDL levels were higher in patients with complete biochemical response (CBR), stratified nonparametric analysis showed that in the CBR+ subgroup ln(sdLDL) was higher in patients with metabolic syndrome (Mann–Whitney U = 544.5, p = 0.012), with a similar trend in the CBR− subgroup indicating no effect modification by biochemical response.

Conclusion: In PBC, small dense LDL is driven by metabolic syndrome rather than MASLD, liver fibrosis, or biochemical response to therapy. Lipoprint-based sdLDL profiling may improve cardiovascular risk stratification in this population.

SAT-306

Demographic and clinical characteristics of United States real-world patients with primary biliary cholangitis and alkaline phosphatase between 1 and 1.67 vs ≥ 1.67 × upper limit of normal despite ursodeoxycholic acid treatment

Rachel H. Mackey[1,2], Steve Gao[1], Charlotte Carroll[1], Fang Xia[1], Nirali Kotowsky[1], Lisa Albert[1], Grace M. Chee[1], Susheela Carroll[1], Daria B. Crittenden[1]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]University of Pittsburgh School of Public Health, Pittsburgh, United States*
Email: nirali.kotowsky@gilead.com

Background and aims: For ursodeoxycholic acid (UDCA)-treated patients (pts) with primary biliary cholangitis (PBC), alkaline phosphatase (ALP) ≥ 1.67 × upper limit of normal (ULN) is a recognised threshold warranting second-line (2L) treatment initiation. However, given increasing evidence that any ALP > ULN increases risk of adverse clinical outcomes, we characterised real-world pts with PBC and ALP between 1 and 1.67 × ULN.

Method: Adult pts with PBC were identified in a United States laboratory-linked claims database (HealthVerity Marketplace) from 1/1/2015 to 5/15/2025 at earliest of 2+ PBC diagnosis (dx) codes or an anti-mitochondrial antibody-positive result with either 1+ PBC dx code or any ALP ≥ 1.5 × ULN. ALP index date was the first ALP > ULN on/after PBC dx date directly preceded by ≥ 6 months of UDCA (and no 2L) treatment. Pts with liver cancer, failure or transplant, decompensated cirrhosis, or lack of 12 months continuous medical enrolment on/before ALP index date were excluded. Pts were categorised based on first ALP between 1 and 1.67 × ULN vs pts at first ALP ≥ 1.67 × ULN. Due to overlap between the two groups, no statistical testing was performed.

Results: Characteristics for pts with ALP between 1 and 1.67 × ULN (n = 796) vs ALP ≥ 1.67 × ULN (n = 341) were: male 10% vs 13%, mean age of 58 vs 55 years, prior UDCA duration of 2.5 vs 2.3 years, proportion with portal hypertension 5% vs 7%, diabetes 23% vs 19%, chronic kidney disease 10% vs 11%, osteoporosis 14% vs 11%, fatigue 22% vs 20%, sleep disorders 11% vs 11%, hypertension 49% vs 40%, hyperlipidaemia 56% vs 49%, statin use 32% vs 26%, obesity 23% vs 16%, depression or anxiety 33% vs 27%, and pruritus 7% vs 13%. In pts with ALP between 1 and 1.67 × ULN vs pts with ALP ≥ 1.67 × ULN, 68% and 89%, respectively, had ≥ 1 characteristic associated with worse outcomes, including compensated cirrhosis (23% vs 30%), albumin < lower limit of normal (7% vs 16%), total bilirubin > 0.6 × ULN (25% vs 44%), increased alanine or aspartate aminotransferases (ALT > ULN [37% vs 67%] or AST > ULN [26% vs 66%]), APRI ≥ 1.5 (2% vs 10%), FIB-

4 ≥ 3.25 (9% vs 13%), advanced PBC (Rotterdam criteria: 2% vs 8%), or GLOBE > 0.3 (24% vs 39%).
Conclusion: UDCA-treated pts with PBC with elevated ALP between 1 and 1.67 × ULN have a substantial burden of comorbidities, symptoms, and abnormal liver biochemical and clinical risk factors for disease progression, similarly seen in pts with ALP ≥ 1.67 × ULN. This supports considering 2L therapy in pts with any ALP elevation.

SAT-307
Factors associated with second-line treatment initiation among real-world, second-line–eligible patients with primary biliary cholangitis in the United States
Nirali Kotowsky[1], Oluwadamilola Onasanya[1], Rongjun Shen[1], Steve Gao[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: nirali.kotowsky@gilead.com

Background and aims: Evidence is limited on the frequency of second-line (2L) treatment initiation among United States (US) adults with primary biliary cholangitis (PBC) who are 2L eligible. Clinical characteristics that drive 2L initiation within these groups in the real world are poorly understood.
Method: This was a retrospective cohort study of adults with PBC in the US HealthVerity Marketplace database, with 2L eligibility based on alkaline phosphatase (ALP) ≥ 1.67 × upper limit of normal (ULN) or ALP > 1 to < 1.67 × ULN after completing 12 months (M) of ursodeoxycholic acid (UDCA) from 1/1/15 to 1/5/25. Eligible patients (pts) had continuous insurance enrolment ≥ 12 M before and ≥ 6 M after ALP test date (index), ≥ 80% UDCA adherence over the first 12 M of treatment, and no 2L treatment at baseline (BL). BL characteristics were assessed at index date. Follow-up continued until disenrollment, outcome (2L initiation), mortality, or end of study period. A Cox model was used to estimate the adjusted hazard ratio (HR) and 95% confidence intervals (95% CIs) of 2L initiation among pts with ALP > 1 to < 1.67 × ULN, relative to pts with ALP ≥ 1.67 × ULN.
Results: Among 1031 pts with PBC identified, 315 (30.6%) and 716 (69.4%) had ALP ≥ 1.67 × ULN, or ALP > 1 to < 1.67 × ULN at index, respectively. Overall, 22.9% of the cohort initiated 2L treatment during follow-up; 37.5% and 16.5% had ALP ≥ 1.67 × ULN, or ALP > 1 to < 1.67 × ULN, respectively. Most (79.2%) 2L initiators added a 2L treatment to UDCA, while the remainder switched from UDCA to 2L. Median time from index date to 2L add-on was shorter for the ALP ≥ 1.67 × ULN vs ALP > 1 to < 1.67 × ULN group (280 vs 865 days, p < .01). Across both groups, those who initiated 2L treatment were more likely to be younger (40–64 years). In the ALP ≥ 1.67 × ULN group, comorbid chronic kidney disease was a negative risk factor for 2L initiation (2.5% vs 8.1%, p < .01). In the ALP > 1 to < 1.67 × ULN group, comorbid hypertension was a negative risk factor for 2L initiation (27.1% vs 39.5%, p < .01); Cox regression showed a 0.3 × lower hazard of 2L initiation with ALP > 1 to < 1.67 × ULN vs ALP ≥ 1.67 × ULN (HR [95% CI] = 0.3 [0.2–0.4]).
Conclusion: Despite available 2L treatments for PBC, about 63% of pts with ALP ≥ 1.67 × ULN and 84% of pts with ALP > 1 but < 1.67 × ULN do not receive 2L. Given emerging evidence that any elevated ALP increases the risk for liver transplant or death, these data raise concerns about undertreatment of PBC among US patients.

SAT-308
Characteristics and treatment patterns of primary biliary cholangitis: real-world insights from a linked claims–electronic medical records database
Nirali Kotowsky[1], Oluwadamilola Onasanya[1], Rongjun Shen[1], Steve Gao[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: nirali.kotowsky@gilead.com

Background and aims: With the approval of 2 new therapies for primary biliary cholangitis (PBC), understanding real-world treatment patterns is increasingly important. This retrospective study aims to characterise patient characteristics by the treatment option initiated after diagnosis among patients (pts) with PBC in the US.
Method: This retrospective cohort study used the US HealthVerity Marketplace database to identify adults (at index) from 1/1/2016 to 30/11/2024. The index date was the first PBC case-defining event: a positive anti-mitochondrial antibody (AMA) test, positive antinuclear antibody test preceded by a negative AMA test, PBC diagnosis code, the first of 2 elevated alkaline phosphatase (ALP) test results ≥ 6 months (M) apart, or first-line (1L) ursodeoxycholic acid (UDCA) or second-line (2L; fibrates, obeticholic acid, elafibranor, or seladelpar) treatment for PBC. Eligible pts with PBC were required to have continuous insurance enrolment for M12 before and M6 after index and were classified into 3 groups at baseline (BL; untreated, UDCA only, and 2L treated) defined by their treatment post-index.
Results: Among 12,230 pts with PBC, 19% untreated, 70% UDCA only, and 11% 2L-treated pts were identified. Mean (SD) age in the untreated, UDCA-only, and 2L-treated groups was 55 (15), 57 (13), and 53 (11) years, respectively, with a greater proportion of pts ≥ 65 years in the untreated (27%) vs the 2L-treated group (12%; p < .01). Medical and mental health comorbidities (hypertension, 52%; diabetes, 24%; major depressive disorder, 27%; anxiety disorder, 33%) were significantly more prevalent in the untreated vs the UDCA-only (37%, 16%, 16%, 20%, respectively) and 2L-treated (32%, 15%, 17%, 21%, respectively) groups (p < .01). There was no significant difference in the proportion of comorbid metabolic dysfunction-associated steatohepatitis, autoimmune hepatitis, or alcoholic liver disease between the 3 groups. About 17% of the 2L-treated vs 14% and 13% of the UDCA-only and untreated groups had BL concomitant use of adjunctive anti-itch medications (p < .01). Of the 2L-treated group, ~ 18% had a BL ALP ≥ 1.67 × upper limit of normal (ULN) vs 9% and 7% of the UDCA-only and untreated groups.
Conclusion: Pts untreated for PBC had similar rates of comorbid liver conditions but more cardiovascular and mental health conditions than treated pts with PBC. Despite BL ALP ≥ 1.67 × ULN, ~ 1 in 10 pts with PBC were not receiving PBC treatment nor escalating to 2L treatment.

Email: miriam.duell@uk-erlangen.de

Background and aims: Pruritus is a frequent and burdensome symptom in chronic liver diseases, significantly impairing quality of life; however, its anatomical distribution across etiologies remains poorly characterized. Standardized body mapping provides a patient-friendly, language-independent approach to systematically capture itch patterns and may help identify disease- or patient-specific phenotypes. We aimed to characterize the anatomical distribution of

pruritus in patients with chronic liver diseases and explore differences across etiological subgroups.
Method: In a cross-sectional study at a tertiary hepatology center, pruritic patients completed front- and back-view body maps indicating current and habitual itch sites. Demographic, clinical, and etiological data were collected. Patients were categorized into immune-mediated and cholestatic liver diseases (ICLD), steatotic liver diseases including MASLD, MetALD, ALD (SLD), and viral liver diseases (VLD). Itch intensity and impact were assessed using mean and worst itch NRS and the 5-D Itch scale. Body maps were digitized and analyzed using automated, observer-independent quantitative image analysis.
Results: Among 656 participants, 173 (26.4%) reported pruritus; complete body maps were available for 150 patients (67.7% female). ICLD represented the largest subgroup (n = 71; 40.7%). Mean itch was 3.8 ± 2.7, worst itch 4.4 ± 2.9, and median 5-D Itch score 11 (IQR 8.5–15). Pruritus predominantly affected the extremities, particularly volar forearms and anterior lower legs, followed by the back. In contrast to previous literature, involvement of the palms and soles was rare. Current and habitual itch patterns were highly concordant. Patients with cirrhosis reported less frequent upper-body involvement than non-cirrhotic patients. Female patients reported itch across more regions than males. No disease-specific exclusive patterns were identified, but extremity-dominant distribution was consistent across all subgroups.
Conclusion: Standardized body mapping reveals a reproducible, extremity-predominant pattern of pruritus in chronic liver diseases, largely independent of etiology. ICLD patients demonstrated the most extensive distribution. These findings support shared pathophysiological mechanisms in hepatobiliary pruritus and underscore body mapping as a robust, complementary approach for itch phenotyping, offering spatial insights beyond conventional intensity-based assessments and potentially greater ease of use for patients.

SAT-314
Genetic predisposition increases the gallstone risk in patients with PSC: single center, prospective analysis

Beata Kruk[1,2], Susanne Weber[3], Frank Lammert[4], Piotr Milkiewicz[5], Marcin Krawczyk[6]. *[1]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Centre for Preclinical Research, Medical University of Warsaw, Warsaw, Poland; [2]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [3]Department of Medicine II, University Hospital Saarland, Homburg, Germany; [4]Center for Health Research Economics Hannover (CHERH), Hannover Medical School (MHH), Hannover, Germany; [5]Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Division of Gastroenterology, Department of Translational Medicine, Pomeranian Medical University in Szczecin, Warsaw, Poland; [6]Department of Gastroenterology, Hepatology and Transplant Medicine, Medical Faculty, University of Duisburg-Essen, Essen, Germany*
Email: beata.kruk@wum.edu.pl

Background and aims: Gallstone disease (GD) is common in primary sclerosing cholangitis (PSC), affecting up to 25% of patients (*Said et al. J Hepatol 2008*). Its development is linked to disturbances in bile acid homeostasis, chronic cholestasis, and impaired gallbladder motility, all frequent in PSC (*Cazzagon et al. J Hep. Rep. 2022*). Here, we investigate the prevalence of GD in a large PSC cohort and assess both clinical and genetic risk factors, including the common polymorphism in the hepatobiliary sterol transporter ABCG8.
Method: A total of 663 adults with PSC (218 women, age 18–74 years, BMI 15.6–39.5 kg/m^2) were prospectively recruited. Data on GD, cholecystectomy and gallbladder cancer were extracted from clinical records, abdominal sonography, and/or MRI. The *ABCG8* p.D19H (rs11887534) polymorphism was genotyped using TaqMan assays.
Results: Among 663 patients, a total of 93 (14%) had history of GD: sixty-six had gallstones and gallbladder *in situ*, whereas 27 had been cholecystectomised before inclusion. Six patients had diagnosis of gallbladder cancer (three before inclusion and three during follow-up). The minor allele frequency *ABCG8* p.D19H was higher in those with GD than in those without (8.6% vs. 4.5%). The variant was associated an approximately twofold increased risk of GD (OR = 2.06; 95% CI, 1.13–3.75; P = 0.018). Among non-genetic risk factors, GD was associated with age (P < 0.001), but not with BMI, sex, or ulcerative colitis (all P > 0.05). In multivariate analysis, both the *ABCG8* p.D19H polymorphism (P = 0.015) and age (P < 0.001) remained independently associated with GD. One of six patients with gallbladder cancer was heterozygous for the transporter variant.
Conclusion: GD-PSC is a multifactorial condition, more common in older patients and those with genetic predisposition. These results further underscore the use of ursodexycholic acid in PSC to mitigate the risk of developing gallstones and their complications in predisposed patients.

SAT-315
Blood extracellular vesicle proteins predict ursodeoxycholic acid response in primary biliary cholangitis

Email: ainhoa.lapitz@biodonostia.org

Background and aims: Ursodeoxycholic acid (UDCA) is the standard first-line therapy for primary biliary cholangitis (PBC), improving liver biochemistry and long-term outcomes. However, approximately one-third of patients exhibit incomplete response and require alternative therapies. While clinical criteria may aid to assess response after treatment initiation, reliable pre-treatment biomarkers to predict UDCA efficacy are lacking. This proof-of-concept study aimed to explore baseline proteomic differences in serum extracellular vesicles (EVs) between UDCA non-responders and responders to non-invasively predict treatment response.
Method: 24 serum samples from patients with PBC with elevated alkaline phosphatase (ALP > 1.5× upper limit of normal, ULN) prior to UDCA initiation were included. Treatment response after one year was defined as ALP < 1.5 × ULN, classifying patients as responders (n = 9) or non-responders (n = 15). Serum EVs were isolated by differential ultracentrifugation and analyzed using mass spectrometry–based proteomics. Associations between EV protein abundance and UDCA response were assessed, and candidate biomarkers were integrated into a predictive model using Elastic Net-penalized logistic regression.
Results: Pre-treatment clinical characteristics revealed that non-responders were younger compared to responders, with no significant differences in cirrhosis or biochemical parameters. Proteomic analysis of serum EVs identified 23 proteins with altered abundance in non-responders at baseline. These proteins were functionally related to polyclonal B-cell activation, immune trafficking, and early fibrotic remodeling, reflecting a pre-existing more aggressive immune-driven and fibrogenic disease phenotype in non-responder patients that is not primarily bile acid–dependent. A machine learning six-protein predictive model (HV333, KV230, IGE, LV214,

KVD13 and KV228) distinguished responders from non-responders with an AUC of 0.985 (95% CI 0.947–1.000, p < 0.001), 93.3% sensitivity, and 100% specificity. Patients exhibiting this signature were approximately 184-fold more likely to be non-responders to UDCA.
Conclusion: Serum EV proteins are promising pre-treatment biomarkers to predict UDCA response in PBC. After further validation in larger cohorts, they may enable a personalized medicine approach, identifying patients at high risk of non-response at baseline and guiding tailored treatment strategies, including early consideration of second-line therapies.

SAT-316

Efficacy and safety of seladelpar in patients with primary biliary cholangitis and alkaline phosphatase levels between 1 and 1.67 × upper limit of normal: interim results from the open-label ASSURE study

Cynthia Levy[1,2], Jeong Heo[3], Michael Galambos[4], Xin Qi[5], Justin Smith[5], Susheela Carroll[5], Kyung Min Kwon[5], Sarah Proehl[5], John M. Vierling[6]. *[1]Division of Digestive Health and Liver Diseases, Miller School of Medicine, University of Miami, Miami, United States; [2]Schiff Center for Liver Disease, Miller School of Medicine, University of Miami, Miami, United States; [3]Department of Internal Medicine, Pusan National University and Biomedical Research Institute, Busan, Korea, Rep. of South; [4]Digestive Healthcare of Georgia, Atlanta, United States; [5]Gilead Sciences, Inc., Foster City, United States; [6]Baylor College of Medicine, Houston, United States*
Email: vierling@bcm.edu

Background and aims: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in patients (pts) with an inadequate response to UDCA or as monotherapy in pts unable to tolerate UDCA. The pivotal RESPONSE (NCT04620733) study evaluated SEL in pts with alkaline phosphatase (ALP) ≥ 1.67 × the upper limit of normal (ULN). Here, we report data from an interim analysis of pts with lower baseline (BL) ALP levels between 1 and 1.67 × ULN in the ongoing Phase 3 ASSURE study (NCT03301506).
Method: Pts from RESPONSE and legacy SEL studies enroled in ASSURE and received open-label SEL 10 mg once daily. Data for this post hoc analysis included pts from legacy studies with ALP levels between 1 and 1.67 × ULN at BL in ASSURE. BL was defined as SEL initiation in ASSURE. Endpoints for this analysis included composite ALP normalisation response (ALP ≤ 1 × ULN and ≥ 15% ALP reduction) and change from BL in laboratory parameters through month (M) 24. Safety was also assessed. Data cutoff: 31 Jan 2025.
Results: A total of 50 pts from legacy SEL studies enroled in ASSURE with ALP levels between 1 and 1.67 × ULN, and 47 reached M24 of treatment as of the data cutoff. At BL, 24% had cirrhosis, and 44% were aged < 50 years at PBC diagnosis. BL means were ALP 156 U/L, gamma-glutamyl transferase (GGT) 117 U/L, total bilirubin (TB) 0.64 mg/dL, and alanine aminotransferase (ALT) 28 U/L. Composite ALP normalisation was achieved by 83% (40/48) and 74% (35/47) of pts at M12 and M24. SEL treatment reduced mean ALP by −40% at 12 M and −35% at M24. GGT and ALT also declined (mean change, respectively: −40% and −23% at M12; −39% and −24% at M24), while TB remained stable overall. No pts had adverse events (AEs) leading to treatment discontinuation; 2 pts (4%) had serious AEs, which were unrelated to treatment.
Conclusion: In pts with PBC enroled in ASSURE with ALP levels between 1 and 1.67 × ULN, treatment with seladelpar up to 24 M led to sustained reductions in markers of cholestasis and high rates of ALP normalisation, which is increasingly recognised as an optimal treatment goal for PBC. SEL appeared overall safe and well tolerated in this population.

SAT-317

A novel machine learning-based diagnostic tool for distinguishing between primary sclerosing cholangitis and IgG4-related cholangitis: an international asian study in China and Japan

Chenyi Jiang[1], Min Lian[2], Atsushi Tanaka[3], Xiong Ma[1]. *[1]Division of gastroenterology and hepatology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Institute of aging & tissue regeneration, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Division of gastroenterology and hepatology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [3]Teikyo University School of Medicine, Tokyo, Japan*
Email: ceciliacy2021@126.com

Background and aims: Primary sclerosing cholangitis (PSC) and IgG4-related cholangitis (IRC) are two distinct autoimmune cholangitis that share similar biochemical and imaging features. Distinguishing between them remains a significant clinical challenge. We aimed to develop and validate a machine learning-based diagnostic tool to improve the diagnostic accuracy for PSC and IRC in Asian populations.
Method: This international study includes data from China and Japan. The Chinese data were derived from a multicenter observational cohort study of PSC and IRC (NCT05463445), which enrolled adult patients with imaging-evidence of sclerosing cholangitis from 13 hospitals. Patients with secondary sclerosing cholangitis were excluded. Data from the leading center (n = 382) were used for model development. A separate prospective cohort from the same center (n = 94) was used for temporal validation, and data from the other 12 hospitals (n = 337) were used for external validation. The Japanese data were obtained from nationwide epidemiological studies, comprising 881 patients (524 IRC, 357 PSC) with complete diagnostic data for external validation. The eXtreme Gradient Boosting (XGB) algorithm was used to construct the final model based on four routinely available clinical variables: serum IgG4, age at diagnosis, ALT, and ALP. Model performance was evaluated by the area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, and decision curve analysis.
Results: A total of 1694 patients (813 Chinese, 881 Japanese) were included. The XGB model achieved an AUROC of 0.98 (95% CI 0.96–0.99) in the Chinese development cohort, 0.98 (95% CI 0.95–1.00) in the Chinese temporal validation cohort, 0.96 (95% CI 0.94–0.98) in the Chinese external validation cohort, and 0.91 (95% CI 0.89–0.93) in the Japanese nationwide validation cohort. The model showed good sensitivity (0.78–0.94) and high specificity (0.91–0.97) across all validation cohorts. Decision curve analysis demonstrated a consistent net benefit across a wide range of threshold probabilities in all cohorts, supporting the model's clinical utility.
Conclusion: We developed and validated a simple, four-variable XGB-based diagnostic tool that accurately distinguishes IRC from PSC in Asian populations. The tool will be made publicly available as a web-based calculator, which can assist clinicians in making accurate diagnoses and guide appropriate management decisions.

18F FAPI PET/CT as a non-invasive assessment in autoimmune liver diseases: a prospective pilot study

Zhuwan Lyu[1], Shuxian An[1], Tianyu Mao[1], Xiting Pu[1], Bo Li[1], Jun Zhang[1], Jianjun Liu[1], Xiong Ma[1], Min Lian[1]. *[1]Shanghai Jiaotong University School of Medicine Affiliated Renji Hospital, Shanghai, China*
Email: sophialian24@163.com

Background and aims: Autoimmune liver diseases (AILD), characterized by chronic inflammation and progressive fibrosis, still rely on the invasive liver biopsy as diagnostic method in practice. Our study aims to evaluate the feasibility of fibroblast activation protein inhibitor positron emission tomography/computed tomography (FAPI PET/CT) in quantifying inflammation and fibrosis in AILD patients as a non-invasive method for assessing disease activity.

Method: This prospective pilot study enrolled 15 AILD patients and 3 metabolic dysfunction-associated steatotic liver disease (MASLD) patients. All participants underwent FAPI PET/CT imaging. Hepatic FAPI uptake was quantified using maximum standardized uptake value (SUVmax) and liver-to-background uptake ratio (LBR). All the liver sections were assessed using the Scheuer scoring system. FIB-4 and APRI score were calculated for comparing the predictive accuracy with SUVmax or LBR. Immunohistochemistry and multiplex immunofluorescence characterized FAP expression patterns and spatial relationships with immune cells.
Results: We found that FAPI expression was significantly upregulated in AILD patients compared to that in control groups. The FAPI uptake showed strong correlations with fibrosis stage and inflammatory grade. Clinically, FAPI uptake is related to liver stiffness as well as several serological markers (including platelet number and international normalized ratio) but not autoantibodies (such as antinuclear antibody). FAPI PET/CT demonstrated superior diagnostic performance for detecting significant fibrosis ($S \geq 2$) with an AUROC of 0.992, outperforming transient elastography, FIB-4, and APRI. Histological analysis revealed disease-specific spatial patterns that fibroblast activation protein expression was accumulated in periportal/lobular regions in autoimmune hepatitis (AIH) while in peribiliary areas in primary biliary cholangitis (PBC). Spatial analysis showed closer proximity between FAP+ fibroblasts and T cells or macrophages in AIH compared to PBC.
Conclusion: Our study reveals that FAPI PET/CT directly visualizes active fibroblasts in AILD, demonstrating superior diagnostic performance compared to established tools, suggesting its potential for early intervention and non-invasive monitoring in AILD.

Email: montanol@ualberta.ca

Background and aims: Liver stiffness measurement (LSM) represents a valuable noninvasive tool for the prediction of outcomes in patients with chronic liver disease; however, evidence in autoimmune hepatitis is still scarce. Our study aimed to explore the prognostic potential of LSM in predicting clinical outcomes in autoimmune hepatitis (AIH), accounting for demographic, clinical, and lifestyle factors.
Method: From the nationwide Canadian Network for Autoimmune Liver Diseases registry, we analyzed data of 1148 AIH patients with ≥ 1 reliable LSM at/after diagnosis but before occurrence of any events. We performed landmark analysis using the first LSM and follow-up until the outcome. The primary composite outcome was time to the first onset of liver-related events (LRE), defined as hepatic decompensation, liver transplantation, hepatocellular carcinoma (HCC), or death. LSM cut-offs were established using the highest Youden's index. Complete biochemical response (CBR) was defined as normalization of both ALT and IgG. Predictive performance of models was evaluated using Harrell's C-index, with comparison conducted via a non-parametric bootstrap approach with 1000 replicates.
Results: The majority were females (74.3%) and Caucasians (72.4%). Median age was 59.7 (IQR 42.6–70.9) years, time from diagnosis to first LSM 2.9 years (range 0–43.7), LSM value 8.1 kPa (IQR 5.5–14.2) and CBR at 6 months was present in 58.4%. LSM was associated with reaching the composite endpoint (HR 1.03 [1.01–1.05], $p = 0.007$), after adjusting for cirrhosis at diagnosis (HR 7.01 [2.78–17.66], $p < 0.001$), type 2 diabetes (HR 2.75 [1.19–6.31], $p = 0.017$), age at diagnosis, and lack of CBR at 6-month and at the time of LSM. Addition of LSM increased Harrell's C-index by 0.02 [0.001–0.06] to 0.88 (SE 0.06). Patients with LSM ≥ 11.0 kPa (best cutoff) had 3 times higher risk of reaching composite endpoint [HR 3.23 [1.03–10.1], $p = 0.045$], adjusted for cirrhosis at diagnosis (HR 6.89 [2.78–17.08], $p < 0.001$), type 2 diabetes (HR 2.63 [1.15–6.05], $p = 0.023$), age at diagnosis, and lack of CBR at 6-month and at the time of LSM.
Conclusion: LSM improves the prediction of clinical outcomes in AIH beyond treatment response and other factors. LSM ≥ 11.0 kPa carries a 3-fold higher risk of development of decompensation, HCC, LT, or liver-related death. The incorporation of LSM into routine assessment has the potential to improve risk stratification and to guide individualized treatment and surveillance strategies in AIH.

SAT-320

Impact of metabolic dysfunction-associated steatotic liver disease on treatment response, clinical outcomes and prognosis in primary biliary cholangitis: findings from a large multicenter longitudinal GLOBAL PBC registry

Email: montanol@ualberta.ca

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly common, but data on its concomitance with primary biliary cholangitis (PBC) are limited. We aimed to evaluate the impact of MASLD on treatment response, clinical outcomes, and their prediction in people with PBC.
Method: We analyzed 1209 PBC patients across 21 centers in North America, Europe, and Asia, who had ≥ 1 reliable controlled attenuation parameter (CAP) by vibration-controlled transient elastography (VCTE), measured before occurrence of any events, and ≥ 6 months of follow-up. MASLD was defined as CAP ≥ 270 dB/m or histologically confirmed steatosis, plus ≥ 1 cardiometabolic risk factor and no history of heavy alcohol use. Treatment response was measured by conventional criteria. Clinical outcomes included liver decompensation, hepatocellular carcinoma, liver transplantation (LT), or death.
Results: 90.7% were females, with mean age 62.9 ± 11.7 years, and MASLD was diagnosed in 26.6%. Proportion of females (29.1% vs. 26.4%), age at diagnosis (53.3 ± 11.9 vs. 52.4 ± 12.2 y.o.), and time from VCTE to follow-up (2.6 ± 1.6 vs. 2.7 ± 1.7) did not differ between PBC-MASLD and PBC. Liver stiffness measurement (LSM) was higher among PBC-MASLD (10.9 ± 11.3 vs. 9.1 ± 8.3 kPa; p = 0.014), as well as prevalence of diabetes (52.5% vs. 23.9%; p < 0.001) and obesity (54.5% vs. 19.8%; p < 0.001). Treatment response achievement was more frequent in PBC-MASLD, as per Paris-2 (30.7% vs. 20.7%, p = 0.007), Toronto criteria (31.4% vs. 19.7%, p = 0.002), ALP normalization (34.8% vs. 22.2%, p = 0.001), and deep biochemical response (38.7% vs. 21.9%, p < 0.001), with a similar trend for GLOBE score (28.5% vs. 20.0%, p = 0.075). MASLD was not associated with poorer outcomes overall (HR 0.68, p = 0.192) or in the high-risk group (LSM ≥ 15.0 kPa, HR 0.89, p = 0.747). Adjustment for MASLD did not alter the predictive value of LSM, GLOBE, UK-PBC, APRI, or FIB-4 (HR 1.05, p < 0.001; HR 3.15, p < 0.001; HR 2.27, p < 0.001; HR 1.68, p < 0.001; and HR 1.38, p < 0.001), respectively. Probability of LT and liver-related death was similar between PBC-MASLD and PBC (5-year: 2.5 ± 4.7% vs. 3.1 ± 5.6%, p = 0.280; 10-year: 7.4 ± 11.7% vs. 9.1 ± 12.7%, p = 0.213; 15-year: 12.3 ± 16.3% vs. 14.8 ± 17.4%, p = 0.150).
Conclusion: In people with PBC, MASLD is associated with higher treatment response rates and does not negatively affect clinical outcomes or the predictive value of LSM and established prognostic scores.

SAT-321

Development and temporal validation of a perioperative prediction model for secondary sclerosing cholangitis in critically ill cardiac surgery patients

Samy Mady[1], Michael Schoerghuber[1], Lukas Gulden[1], Theresa Lind[1], Florian Rainer[1], Matthias Egger[1], Michael Kolland[1], Peter Fickert[1], Vanessa Stadlbauer[1,2], Nikolaus Schreiber[1]. *[1]Medizinische Universität Graz, Graz, Austria; [2]Center of Biomarker Research CBmed GmbH, Graz, Austria*
Email: vanessa.stadlbauer@medunigraz.at

Background and aims: Secondary sclerosing cholangitis in critically ill patients (SSC-CIP) is a rare but devastating complication after cardiac surgery with very high mortality. The aim was to develop and validate a parsimonious perioperative laboratory-based prediction model to enable early risk stratification of SSC-CIP.
Method: A retrospective observational study included adult patients undergoing cardiac surgery between 2020 and 2024. Case status was

assigned by independent chart review of two clinical experts, classifying patients as definitive SSC-CIP (endoscopic retrograde cholangiography or magnetic resonance cholangiography) or very likely SSC-CIP (prolonged intensive care stay with invasive ventilation, prolonged inotropic support or extracorporeal membrane oxygenation and a typical rise in gamma-glutamyl transferase and alkaline phosphatase after exclusion of other causes). Standard laboratory parameters obtained at postoperative ICU admission were evaluated as candidate predictors. Patients operated between 2020–2022 formed the development cohort, and those operated between 2023–2024 formed an independent validation cohort. Predictor selection and model tuning were conducted in the development cohort using stability selection with L1-penalized logistic regression on bootstrap samples, followed by optimization of model complexity with L2-regularized logistic regression. Model performance was assessed using the area under the receiver operating characteristic curve (AUROC) and the Brier score with uncertainty quantified by non-parametric bootstrapping (2000 resamples).

Results: Among 1769 patients, 976 (15 SSC-CIP) were in the development cohort and 793 (14 SSC-CIP) in the validation cohort. The final model comprised six postoperative laboratory predictors selected via stability-based feature selection: potassium, gamma-glutamyl transferase, platelet count, arterial oxygen partial pressure, procalcitonin and serum osmolality. In the validation cohort, bootstrap resampling yielded a median AUROC of 0.77 (95% confidence interval 0.61–0.92) and a Brier score of 0.22, indicating acceptable discrimination and moderate calibration.

Conclusion: The model based on routine perioperative laboratory parameters showed acceptable discriminative performance for SSC-CIP, but estimates were constrained by the small number of events inherent to this rare condition. Multicenter collaboration and centralized registries are needed to refine predictive accuracy and support clinically actionable risk stratification.

SAT-322

Patient navigation and patient-reported outcomes assessment in primary biliary cholangitis and primary sclerosing cholangitis reveal quality-of-life differences and early indicators of adverse clinical outcomes: a multi-year registry analysis

Ana Marenco-Flores[1,2], Victoria Abadi-Ron[2], Natalia Rojas-Amaris[2], Ava Tsapatsaris[1], Esteban Garita[3], Romelia Barba[4], Leandro Sierra[5], Behnam Saberi[2], Vilas Patwardhan[2], Alan Bonder[2]. *[1]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, United States; [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States; [3]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, United States; [4]Texas Tech University, Lubbock, United States; [5]Cleveland Clinic, Twinsburg, United States*
Email: ana_marenco@hms.harvard.edu

Background and aims: Patient-reported outcomes (PROs) offer insight into the burden of chronic liver disease. The Chronic Liver Disease Questionnaire (CLDQ) measures quality of life (QoL) across fatigue, activity, emotional function, abdominal, and systemic symptoms. We examined patient navigation data, CLDQ domain trends, and their association with hepatic decompensation in primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) to determine whether PRO patterns and navigation data help identify early indicators of adverse outcomes.

Method: We conducted a retrospective study using a long-standing registry at a tertiary hepatology center (2018–2025). Patients with PBC or PSC completed the CLDQ at baseline and follow-up. We assessed domain scores, completion rates, and changes over time by disease type and compared retained patients with those who dropped out due to death, liver transplantation, or hepatic decompensation. Domain scores required ≥ 50% item completion. Biochemical–QoL associations were examined using Spearman's correlation, and yearly domain scores with SD were plotted to assess longitudinal patterns. Analyses were performed in Stata and Python.

Results: Among 311 patients (183 PBC, 128 PSC) with 1223 visits, retention was 78.1%, with 21.9% dropout from hepatic decompensation (10.9%), liver transplantation (9.0%), or death (1.9%). PSC patients reported higher QoL across most domains, including fatigue (5.48 vs 5.05, $p < 0.001$), systemic (5.41 vs 5.05, $p = 0.008$), activity (5.71 vs 5.44, $p = 0.03$), and abdominal symptoms (5.95 vs 5.69, $p = 0.02$), with similar emotional function ($p = 0.12$). Overall CLDQ scores were higher in PSC (5.68 vs 5.38, $p < 0.001$). Longitudinal plots showed improvement in PSC (+12.5%) and stable scores in PBC. Dropout patients had lower QoL than retained patients (5.29 vs 5.54, $p = 0.02$), with deficits in fatigue ($p = 0.04$) and systemic symptoms ($p = 0.01$). Higher alkaline phosphatase correlated with lower QoL ($r = -0.22$), strongest for fatigue ($r = -0.25$), and declines in activity often preceded hepatic decompensation ($r = -0.34$).

Conclusion: This registry showed strong retention and higher QoL in PSC than in PBC. Hepatic decompensation primarily caused dropouts, with lower fatigue and systemic symptom scores distinguishing non-continued participants. The ALP–QoL relationship supports the use of the CLDQ, and longitudinal domain tracking may help identify patients needing earlier intervention.

SAT-323

Impact of imaging surveillance on outcomes after cholangiocarcinoma diagnosis in primary sclerosing cholangitis

Adrielly Martins[1], Miki Scaravaglio[2], David Goldberg[1], Cynthia Levy[1]. *[1]University of Miami, Miami, United States; [2]University of Cambridge, Cambridge, Northern Ireland*
Email: axm8717@med.miami.edu

Background and aims: Patients with primary sclerosing cholangitis (PSC) carry a lifetime cholangiocarcinoma (CCA) risk of 10–15%, prompting recommendations for systematic surveillance. However, evidence supporting survival benefit from surveillance is limited. We aimed to determine if imaging surveillance improved the overall survival of patients with PSC-CCA.

Method: Using the Epic Cosmos database, we conducted a retrospective cohort study of PSC patients with CCA diagnosed between 2005 and 2025, at least one year after PSC diagnosis. Patients with colorectal cancer were excluded. Surveillance was defined as two or more abdominal imaging studies (magnetic resonance imaging, computed tomography, or ultrasound) performed 6–36 months before CCA diagnosis to distinguish surveillance from diagnostic workup. The primary outcome was all-cause mortality after CCA diagnosis. Cox proportional hazards regression was used, adjusting for age at PSC diagnosis, sex, ulcerative colitis, cirrhosis, and colectomy status. Sensitivity analyses addressed informative censoring by excluding patients lost to follow-up >2 years and by assuming these patients died.

Results: A total of 1031 PSC-CCA patients were included (mean age at CCA 57 years, 61% male, 70% with inflammatory bowel disease, 78% with cirrhosis). Among them, 536 (52%) received surveillance and 495 (48%) did not. Patients in the surveillance group had higher rates of cirrhosis (86% vs 70%, $p < 0.001$) and prior colectomy (50% vs 24%, $p < 0.001$). During a median follow-up of 1.43 years (IQR 0.48–3.64), 352 patients (34%) died and 72 (7%) underwent LT. LT rates were higher in the surveillance group (9.0% vs 4.8%, $p = 0.011$). In the main adjusted analysis, surveillance appeared associated with higher mortality (hazard ratio 1.32, 95% confidence interval [CI] 1.06–1.65, $p = 0.014$). However, this association attenuated and became non-significant in sensitivity analyses excluding patients lost to follow-up (hazard ratio 1.23, 95% CI 0.98–1.53) and assuming lost patients died (hazard ratio 1.12, 95% CI 0.92–1.36).

Conclusion: In this large retrospective cohort of patients with PSC-CCA, imaging surveillance was not associated with improved survival after CCA diagnosis. However, surveillance was associated with

higher LT rates, possibly reflecting earlier detection at transplant-eligible stages, warranting further investigation.

SAT-324

Latent class analysis identifies three distinct patient phenotypes in primary sclerosing cholangitis: implications for clinical trial access and mental health screening

Adrielly Martins[1], Patricia Moreno[1], Joshua Korsenik[2], Christopher L. Bowlus[3], Cynthia Levy[1]. [1]*University of Miami, Miami, United States;* [2]*Harvard University, Cambridge, United States;* [3]*University of California - Davis, Davis, United States*
Email: axm8717@med.miami.edu

Background and aims: Primary sclerosing cholangitis (PSC) patients experience variable symptom burden and psychological distress, yet care approaches often do not account for this heterogeneity. We used latent class analysis (LCA) to identify distinct patient phenotypes and examine associations with quality of care measures.
Method: We analyzed data from 238 PSC patients who completed an online survey (response rate 75%). LCA was performed using 8 indicators: 5 physical symptoms (fatigue, itch, abdominal pain, brain fog, nausea), PROMIS Depression and Anxiety scores (categorized as low/moderate/high), and care confidence. Models with 2–5 classes were compared using Bayesian Information Criterion (BIC). Multinomial logistic regression examined predictors of class membership. Chi-square tests compared quality of care outcomes across classes.
Results: Three phenotypes were identified (N = 220, mean posterior probability = 0.96): [1] Low Symptom Burden (34%): minimal physical symptoms, moderate psychological burden, high care confidence; [2] Physical Burden (26%): high fatigue (89%), moderate other symptoms, high anxiety (73%) but low depression, high care confidence; [3] Physical & Psychological Burden (41%): high fatigue (92%), elevated symptoms across all domains, with 95% moderate/high depression and 100% moderate/high anxiety. IBD prevalence did not differ significantly across phenotypes ($p = 0.78$). There was a trend toward association of cirrhosis with both higher burden phenotypes (OR 2.34–2.44, $p = 0.06$–0.07); and female sex trended toward association with the high-burden group ($p = 0.09$). Patients in the Physical & Psychological Burden group were less likely to report being offered clinical trial participation ($p = 0.024$), and this disparity persisted after adjusting for cirrhosis, female sex, and IBD ($p = 0.046$). Mental health screening was uniformly low across all phenotypes: only 26–31% were asked about depression and 26–28% about anxiety, despite near-universal psychological burden in the highest-risk group.
Conclusion: Over 40% of PSC patients experience major physical and psychological burden. These patients were less likely to report being offered clinical trials, though further investigation is needed to determine whether this reflects eligibility criteria, access barriers, or other factors. Mental health screening rates are low across all phenotypes. Phenotype-based approaches may help identify patient-sin need of psychological support and could inform strategies to optimize clinical trial recruitment.

SAT-361

Bridging the gap in primary sclerosing cholangitis care: results from a patient survey

Adrielly Martins[1], Patricia Moreno[1], Joshua Korsenik[2], Christopher L. Bowlus[3], Cynthia Levy[1]. [1]*University of Miami, Miami, United States;* [2]*Harvard University, Cambridge, United States;* [3]*University of California - Davis, Davis, United States*
Email: axm8717@med.miami.edu

Background and aims: Primary sclerosing cholangitis (PSC) is a rare, chronic liver disease often associated with inflammatory bowel disease (IBD), for which effective treatments are lacking. Prior research suggests significant variability in care delivery, but the patient perspective remains underexplored. This study aimed to assess patients' perceptions of PSC care, including symptom burden, psychological well-being, and alignment between clinical practice and guideline-based recommendations.
Method: An anonymous online questionnaire was distributed through the PSC Partners registry (March–June 2025). Adults with PSC were invited to complete a 52-question survey capturing symptom burden, access to care, adherence to surveillance, and perceptions of care. Validated PROMIS forms assessed anxiety and depression. Analyses examined associations between social deprivation index (SDI), clinical factors, and outcomes.
Results: A total of 238 patients completed the survey (median age 54 years; 52% female; 75% US residents); 67% had concomitant IBD—ulcerative colitis (73%) – and 24% had cirrhosis. Most were followed by a hepatologist (79%) at a university-affiliated center (65%). Fatigue (60%) was the most commonly reported symptom, followed by brain fog (37%), abdominal pain (37%), and pruritus (34%). While physicians frequently asked about physical symptoms (fatigue 70%, pruritus 76%, abdominal pain 78%), inquiries about anxiety (28%) and depression (28%) were less common. PROMIS T-scores indicated mild depression and anxiety. Higher SDI was associated with increased depression ($p = 0.01$) and anxiety ($p = 0.01$), as was cirrhosis with depression ($p < 0.01$). Among patients with IBD, 68% reported annual colonoscopy; and 99% of all respondents reported having undergone at least one colonoscopy. Annual imaging was reported by 89%, and lifetime testing included bone densitometry (74%) and fibrosis assessment through vibration-controlled transient elastography (70%). Scheduling challenges (31%) were the most commonly reported barrier to imaging. Fifty-five percent had been invited to participate in clinical trials and 77% rated their overall care as good or excellent.
Conclusion: Findings from this survey highlight high adherence to recommended surveillance practices but reveal gaps in mental health assessment. SDI and cirrhosis were associated with worse psychological outcomes. These findings emphasize the need for structured mental health screening and attention to social determinants of health in PSC care.

Email: clbowlus@health.ucdavis.edu

Background and aims: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in patients (pts) with an inadequate response to UDCA or as monotherapy in pts intolerant to UDCA. The pivotal Phase 3 RESPONSE (NCT04620733) study excluded pts with metabolic-

associated steatohepatitis. Pts with steatotic liver disease (MASLD) were allowed without formally collecting hepatic steatosis data. We describe the efficacy and safety of SEL in pts with PBC and evidence of concurrent metabolic syndrome (MetS) as a proxy for MASLD in the RESPONSE trial.

Method: Pts with PBC were randomised 2:1 to SEL 10 mg or placebo (PBO) for 12 months (M). In this post hoc subgroup analysis, pts were classified as having MetS if they met ≥ 3 of the following criteria at entry: body mass index (BMI) > 27.6 kg/m^2, elevated triglycerides, low high-density lipoprotein, current treatment for hypertension or diabetes, or elevated blood pressure or fasting glucose. Efficacy endpoints included composite biochemical response (CBR; alkaline phosphatase [ALP] < 1.67 × upper limit of normal [ULN], total bilirubin ≤ ULN, ALP reduction ≥ 15% from baseline [BL]), ALP normalisation, and changes in ALP and other laboratory parameters at M12. Safety was also assessed.

Results: Of 193 pts enrolled, 22% had evidence of MetS at BL (SEL: 24 [19%]; PBO: 18 [28%]). At BL, pts with MetS vs pts without had higher mean BMI (30.4 vs 26.2 kg/m^2), ALP (324.5 U/L vs 311.5 U/L), and liver stiffness (11.5 kPa vs 8.9 kPa), and were more likely to have cirrhosis (24% vs 11%). The percentage of pts achieving a CBR (95% CI) at M12 in the SEL arm was similar in pts with and without MetS (MetS: 42% [22–63]; no MetS: 66% [56–75]) compared with PBO (MetS: 17% [4–41]; no MetS: 21% [11–36]), as was ALP normalisation (SEL: MetS, 17% [5–37] vs no MetS, 27% [19–37]; PBO: MetS, 0% [0–19] vs no MetS, 0% [0–8]). ALP reduction with SEL at M12 was similar regardless of MetS status (mean percent change from BL for SEL vs PBO: MetS, −41% vs 2%; no MetS, −44% vs −9%). Incidence of adverse events (AEs), including cardiovascular AEs, was similar between the SEL and PBO arms irrespective of MetS presence.

Conclusion: MetS was a frequently observed comorbidity in pts with PBC enrolled in RESPONSE. The efficacy and safety profile of SEL was similar in pts with and without MetS. Further studies are needed to better understand the impact of MASLD on PBC management.

SAT-363

Efficacy and safety of seladelpar in patients with primary biliary cholangitis and risk factors for progression including younger age at diagnosis or higher liver stiffness in the pivotal response study

Marlyn J. Mayo[1], Gideon M. Hirschfield[2], Michael Galambos[3], Ira Jacobson[4], Richard Aspinall[5], Christopher L. Bowlus[6], Mitchell Shiffman[7], George Dalekos[8], Kyung min Kwon[9], Lulu Wang[9], Sarah Proehl[9], Daria B. Crittenden[9]. Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Seladelpar (SEL) is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC). In the Phase 3 RESPONSE trial (NCT04620733), SEL significantly improved cholestasis biomarkers and pruritus vs placebo (PBO) in patients (pts) with PBC. Younger age at diagnosis and higher liver stiffness measurements (LSM) are risk factors for PBC progression. Here, we report data on the high-risk subgroups of pts in RESPONSE.

Method: Pts with PBC were randomised 2:1 to SEL 10 mg or PBO for 12 months (M). Two high-risk subgroups were defined post-hoc: age < 45 years (yrs) vs ≥ 45 yrs at PBC diagnosis, and LSM ≥ 10 kPa vs < 10 kPa at baseline (BL). Efficacy endpoints at M12 included composite biochemical response (CBR; alkaline phosphatase [ALP] < 1.67 × upper limit of normal [ULN], ALP decrease ≥ 15%, and total bilirubin ≤ ULN) and mean percent change in ALP. Safety was also assessed.

Results: Among 193 pts enrolled, 65 pts were age < 45 yrs at diagnosis (SEL, 40; PBO, 25) and 52 pts had a BL LSM ≥ 10 kPa (SEL, 36; PBO, 16). Pts aged < 45 yrs vs ≥ 45 yrs at diagnosis had a mean age at entry of 48 vs 61 yrs; cirrhosis was present in 17% vs 13% of pts per group, respectively, with similar ALP (mean 316 vs 313 U/L). Pts in the younger diagnosis subgroup treated with SEL had a CBR of 45% vs 12% with PBO; in the older diagnosis group, CBR was 69% vs 25% with SEL vs PBO. Mean ALP percent change from BL in the younger group was −35% vs 2% for SEL vs PBO, while in the older age group it was −47% vs −11%. Pts with BL LSM ≥ 10 kPa had a higher prevalence of cirrhosis vs the < 10 kPa group (44% vs 2%) and higher ALP (mean 350 vs 300 U/L). Pts with a higher LSM treated with SEL had a CBR of 47% vs 13% with PBO, with this endpoint observed in 67% vs 24% in the lower LSM group. Mean percent change from BL in ALP was similar in both groups: higher LSM, SEL −40% vs PBO −15%; lower LSM, −43% vs −3%. No treatment-related serious adverse events (AEs) were reported in any pts; liver-, muscle-, and renal-related AEs were similar in both high-risk groups.

Conclusion: SEL improved cholestatic markers in two subgroups of pts with PBC and risk factors for progression based on younger age at diagnosis and elevated liver stiffness. Safety was similar for pts with or without high-risk characteristics. Overall, these results suggest SEL may benefit pts with PBC across clinical risk levels.

SAT-364

Long-term improvements in lipid profiles with elafibranor treatment, and favourable safety with concomitant statin use, in patients with primary biliary cholangitis during the open-label extension of the phase III ELATIVE® trial

Marlyn J. Mayo[1], Christopher L. Bowlus[2], Kris V. Kowdley[3,4], Mark Pedersen[1], Nuno Antunes[5], Darren Asquith[6], Nathan Touati[7], Cynthia Levy[8,9]. [1]*Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, Texas, United States;* [2]*Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, California, United States;* [3]*Liver Institute Northwest, Seattle, Washington, United States;* [4]*Elson S. Floyd College of Medicine, Washington State University, Washington, United States;* [5]*Ipsen, Cambridge, Massachusetts, United States;* [6]*Ipsen, London, United Kingdom;* [7]*Ipsen, Paris, France;* [8]*Schiff Center for Liver Diseases, University of Miami, Miami, Florida, United States;* [9]*Division of Digestive Health and Liver Diseases, University of Miami School of Medicine, Miami, Florida, United States*
Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Patients (pts) with primary biliary cholangitis (PBC) may have increased risk of cardiovascular (CV) disease and dyslipidaemia which may require lipid-modifying therapies. In ELATIVE® (NCT04526665), elafibranor (ELA) led to significantly improved biomarkers of cholestasis in PBC and was associated with atherogenic lipid improvements through 52 weeks (wks). Here, long-term lipid data from the ongoing open-label extension (OLE) are evaluated.

Method: Pts who completed the ELATIVE® double-blind period (DBP) could enter the OLE and receive ELA 80 mg daily. Data are reported for pts who continued ELA treatment (continuous pts) and pts who switched from placebo to ELA (crossover pts). For continuous pts, baseline (BL) was DBP start; for crossover pts, BL was last measurement at/before first ELA dose. Mean change from BL (CfB) in total cholesterol, low-, very low-, high-density lipoprotein cholesterol (LDL-c, VLDL-c, HDL-c) and triglycerides, and CV risk score, are reported through 208 and 104 wks of ELA treatment in continuous and crossover pts, respectively. New muscle-related

adverse events (AE) occurring in the OLE are reported for both groups, and for pts receiving statins.
Results: Overall, 138 pts entered the OLE (93 continuous pts; 45 crossover pts). In continuous pts, improvements in lipids observed at Wk 52 were maintained through Wks 156 (n = 73) and 208 (n = 15), with mean CfB (mg/dL) of: total cholesterol (Wk 156: −25.4; Wk 208: −37.1), LDL-c (Wk 156: −18.8 [n = 72]; Wk 208: −23.2 [n = 14]), VLDL-c (Wk 156: −5.1 [n = 72]; Wk 208: −8.5 [n = 14]) and triglycerides (Wk 156: −28.1; Wk 208: −55.3). In crossover pts, early improvements were sustained through 104 wks of ELA treatment (mean CfB [mg/dL]; n = 33): total cholesterol (−29.3), LDL-c (−18.1), VLDL-c (−4.6) and triglycerides (−23.3). HDL-c mean CfB (mg/dL) remained stable in both continuous (Wk 156: −1.0; Wk 208: −0.3) and crossover (Wk 104: −6.5) pt groups. BL mean CV risk score was low and remained stable in both pt groups. To data cut-off, 4 muscle-related AEs occurred in the OLE (2 continuous ELA; 2 crossover ELA), none treatment-related. In pts receiving statins (continuous ELA: 19 [20.4%]; crossover ELA: 10 [22.2%]), no new muscle-related safety signals were detected.
Conclusion: Long-term ELA treatment in pts with PBC, including crossover pts, was associated with sustained improvements in atherogenic lipids. CV risk remained stable. There were no new treatment-related muscle-related AEs, including in pts receiving statins.

SAT-365
Real-world survey assessing pruritus in PSC in France, Germany, Italy and the United States: results from a matched patient and their treating physician cohort
Marlyn J. Mayo[1], Marco Carbone[2], Will Johnson[3], Lena Amari[3], Guy Lacey[4], Jolan Terner-Rosenthal[4], Lucia Quadrado[4], Robin Howard[4], Verena Keitel-Anselmino[5]. *[1]UT Southwestern Medical Center, Dallas, Texas, United States; [2]University of Milano-Bicocca, Milan, Italy; [3]Adelphi Real World, Bollington, United Kingdom; [4]Mirum Pharmaceuticals, Inc., Foster City, California, United States; [5]University Hospital Magdeburg, Magdeburg, Germany*
Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic, progressive liver disease characterized by damage to intra- and extrahepatic bile ducts. While studies indicate that almost 90% of patients with PSC experience pruritus at some point in their lives, a recent physicians survey reported that 42% of their patients with PSC had pruritus and almost all physicians (90%) believe that pruritus has a profound impact on a patient's quality of life (QoL). The purpose of the current study is to describe the reported frequency and assessment of pruritus in a matched cohort of patients with PSC to their treating physicians to determine if there are alignment or differences between what physicians and patients report.
Method: Data were extracted from the Adelphi Real World PSC Disease Specific Programme™, a cross-sectional survey with retrospective data collection of physicians and their adult patients (≥18 years old) with PSC in France, Germany, Italy, and the United States from November 2024 to April 2025. The current presentation is focused on physicians' and patients' perceptions and attitudes around their management of PSC. Analyses of the matched cohorts used symmetry significance testing.
Results: Results from physicians (n = 157) and patients with PSC (n = 151) were included in this analysis. There was agreement between physicians and their patients regarding the most common current symptoms (pruritus [68% vs. 68%; p = 1.00]; sleep disturbance due to pruritus [15% vs. 19%; p = 0.2008]), although physicians reported fatigue signficantly less than patients (68% vs. 75%; p = 0.0499). There was also agreement between physicians and patients regarding the most bothersome PSC symptoms (fatigue [77% vs. 74%; p = 0.4497], pruritus [76% vs. 77%; p = 0.8348], sleep disturbance due to pruritus [13% vs. 17%; p = 0.2253]). Physicians were less likely to think their patients' pruritus was mild vs. patients (58% vs 72%; p = 0.0104). Physicians were less likely to believe that current PSC treatments could relieve pruritus (27% vs. 48%). However, both physicians and patients reported that improving pruritus was still a key goal for treatment (72% vs. 69%; p = 0.2482).
Conclusion: While there was agreement on the prevalence of pruritus between physicians and patients, perspectives on the burden of symptoms appeared to differ. These initial data highlight the importance of more explicit assessment of pruritus during clinical encounters and improved physician/patient communication to bridge perceptual differences.

SAT-366
Use of maralixibat for the treatment of cholestatic pruritus in late-onset PFIC
David Bernstein[1], Maly Tiev[1], Jeffrey Crippin[2], Fabian Rodas[3], Adebowale Adeyemi[4], Natasha Chandok[5], Marlyn J. Mayo[6]. *[1]Gastroenterology and Hepatology Ambulatory Network, NYU Grossman School of Medicine, NYU Langone Health, New York, New York, United States; [2]Department of Medicine, Washington University School of Medicine, St. Louis, Missouri, United States; [3]University of Texas Health Science Center San Antonio-UTHSCSA, The Texas Liver Institute, San Antonio, Texas, United States; [4]Division of Gastroenterology, Department of Pediatrics, Nemours Children's Hospital, Wilmington, Delaware, United States; [5]Department of Medicine, McMaster University, Hamilton, Ontario, Canada; [6]UT Southwestern Medical Center, Dallas, Texas, United States*
Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Progressive Familial Intrahepatic Cholestasis (PFIC) has traditionally been characterized as a pediatric cholestatic condition. More recently, it has been recognized that PFIC can be diagnosed at any age. Maralixibat (MRX), an ileal bile acid transporter inhibitor (IBATi), is indicated for the treatment of cholestatic pruritus in patients with PFIC ≥1 year in the US, and for the treatment of PFIC in patients ≥3 months in the EU. However, its use in late-onset PFIC has not been widely reported. Here we describe the efficacy, tolerability, and safety of MRX in late-onset PFIC.
Method: Clinicians treating patients (≥18 years) with a diagnosis of PFIC completed an electronic case report form including clinical and biochemical data. Pruritus was assessed with the Clinician Scratch Scale (CSS), a 0–4 scale where 0 = no evidence of pruritus and 4 = cutaneous mutilation, bleeding or scarring; ≥1-point reduction is considered clinically meaningful. Data are presented using medians and min/max, and categorical variables are as counts and percentages.
Results: Data on 6 patients (2 males) from 6 centers were included: 1 (17%) *ATP8B1*, 2 (33%) *ABCB11*, 2 (33%) *ABCB4*, and 1 (17%) multi-gene deletion at 17q12. Median age at initiation of treatment was 26 (range 10–60) years and duration of treatment was 9 (range 2–129) months. One was being assessed for liver transplant (LT) and 1 was waitlisted. Before treatment, 3 (50%) had CSS of 4, 1 (17%) had a CSS of 3, and 2 (33%) had CSS of 2. Following treatment, all had a clinically meaningful reduction in CSS, with 3 (50%) achieving complete resolution (CSS = 0). Pre- and post-treatment sBA levels were available for 4, 3 (75%) with a substantial reduction in sBA levels (212 to 14, 352 to 16, and 81 to 60 μmol/L). Bilirubin and liver enzymes remained stable or decreased in the majority. Notably, the 2 being evaluated or waitlisted for LT were delisted following clinical improvement. AEs were reported in 3 including diarrhea (n = 3; 50%), transaminase increase that normalized by last clinical follow-up (n = 2; 33%), increase in bilirubin (n = 1; 17%), and abdominal pain (n = 1; 17%). There were no discontinuations or severe liver events (e.g., decompensation).
Conclusion: MRX led to significant improvements in pruritus and sBA in patients with late-onset PFIC, suggesting IBATi may offer benefit in this group. Additional studies evaluating longer follow-up in a larger cohort would allow for better characterization of the benefits of IBATi in late-onset PFIC.

SAT-367

Comparative clinical and immunological features of drug-induced autoimmune-like hepatitis, drug-induced liver injury, and autoimmune hepatitis

Yao Meng[1], Zikun Ma[1], Yuhong Suo[1], Lina Wu[1], Tiantian Guo[1], Mengmeng Zhang[1], Xu Fan[1], Xinyan Zhao[1]. [1]*Beijing Friendship Hospital, Capital Medical University, Beijing, China*
Email: mengyao2954@163.com

Background and aims: Distinguishing drug-induced autoimmune-like hepatitis (DIALH) from drug-induced liver injury (DILI) and autoimmune hepatitis (AIH) is challenging due to overlapping clinical features. We aimed to identify discriminative characteristics through a comparative analysis of clinical indicators and peripheral T-cell subsets.
Method: Clinical and immunological characteristics were compared across three groups: DIALH, DILI, and AIH. Peripheral blood T-cell subsets were analysed by flow cytometry. Group differences were assessed using the Kruskal–Wallis test, followed by pairwise Wilcoxon tests, with $p < 0.05$ considered statistically significant.
Results: A total of 6 cases of DIALH, 38 cases of DILI and 42 cases of AIH were included in the study. The DIALH group exhibited markedly higher peak levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) compared to the AIH group [ALT: 588.5 (330.3–789.0) vs. 87.0 (51.0–120.0) U/L, $p < 0.001$; AST: 459.7 (287.8–512.6) vs. 93.0 (56.9–186.8) U/L, $p < 0.001$]. The DILI group showed significantly higher bilirubin levels (TBIL, DBIL) compared to DIALH [TBIL: DILI 72.2 (32.3–146.0) vs. DIALH 18.8 (10.1–27.8) μmol/L, p = 0.007; vs. AIH 23.9 (15.2–65.2) μmol/L, $p < 0.001$]. Serum immunoglobulin G (IgG) levels were significantly higher in both the DIALH and AIH groups compared to the DILI group [DIALH: 1815.0 (1477.5–1912.5), AIH: 1760.0 (1580.0–2070.0), vs. DILI: 1110.0 (971.0–1310.0) mg/dL; DIALH vs. DILI p = 0.009, AIH vs. DILI $p < 0.001$], while levels between DIALH and AIH were comparable ($p = 0.762$). Flow cytometry analysis identified differences in several T-cell subsets. Th2-like Tregs and CCR4+ Memory-Tregs were significantly reduced in DIALH compared to DILI and AIH [both $p < 0.05$].
Conclusion: DIALH shares a predominantly hepatocellular injury pattern with DILI and elevated IgG levels with AIH, but is distinguished by a reduced proportion of Th2-like and CCR4+ memory Tregs, suggesting a specific peripheral immune signature that may aid in its differentiation.

Background and aims: Differentiating autoimmune hepatitis (AIH), from primary biliary cholangitis (PBC), and their variant syndrome (VS) is challenging due to overlapping histological and clinical features. The ALNE deep learning (DL) model has shown promise in AIH–PBC discrimination but has not been validated in large cohorts or applied to VS. We aimed to develop and externally validate a histopathology-based DL model for discriminating AIH, PBC, and characterizing VS using a large, ethnically diverse, multicenter cohort.

Method: We conducted a multicenter study including a training cohort of 1216 patients with AIH (n = 900, mean age at diagnosis 53 ± 16 years, 66% female) and PBC (n = 316, mean age at diagnosis 52 ± 11 years, 73% female). Digitized liver biopsy slides and clinical data were collected from 21 international centers across Europe, Asia, North and South America and processed using the UNI2 foundation model to extract histopathological features. ALNE 2.0, a binary classification model (AIH vs. PBC), was developed using 5-fold cross-validation and externally validated on 207 patients (AIH n = 162, mean age at diagnosis 53 ± 17 years, 67% female; PBC n = 45, 52 ± 9 years, 91% female) from two additional centers. The model was then applied to 198 VS cases from 17 countries (mean age at diagnosis 51 ± 14 years, 53% female), generating a probability score. Logistic and linear regression analyses examined clinical variables associated with AIH vs PBC classification probabilities.

Results: In 5-fold cross-validation (training cohort: AIH n = 900, PBC n = 316), ALNE 2.0 achieved a mean AUROC of 0.92 (95% CI 0.88–0.96), with average precision of 0.97 (95% CI 0.96–0.99) for AIH and 0.79 (95% CI 0.68–0.91) for PBC. In independent external validation (AIH n = 162, PBC n = 45), performance remained high: AUROC of 0.94, average precision of 0.98 for AIH and 0.83 for PBC. In VS cases (n = 198), predictions were evenly distributed (AIH 46.5%, PBC 53.5%), with probabilities polarizing toward AIH or PBC phenotypes rather than intermediate values. Cases classified as AIH had significantly higher alanine aminotransferase levels (OR 1.18, 95% CI 1.02–1.38, p = 0.031) at presentation, while those classified as PBC more frequently exhibited GP210 antibody positivity (coeff. −0.154, 95% CI −0.305 to −0.004, p = 0.045).

Conclusion: ALNE 2.0 accurately discriminates AIH and PBC in a large, ethnically diverse multicenter cohort and provides quantitative assessment of the dominant disease phenotype in VS cases.

Email: alessio.gerussi@unimib.it

Background and aims: Autoimmune liver diseases (AILDs) have a significant impact on health-related quality of life (HRQoL). Using artificial intelligence (AI), we explored HRQoL and related constructs to identify patient phenotypes that transcend traditional diagnostic categories.
Method: A total of 1388 patients with autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC), or variant syndromes were recruited from 12 European centers (mean age 52 ± 16 years; 71% female). Data included nine validated HRQoL questionnaires assessing physical functioning, fatigue, emotional distress, somatic symptom burden, and illness-related cognitions, along with sociodemographic and clinical variables. Unsupervised K-means clustering was applied to identify homogeneous subgroups based solely on HRQoL profiles, with cluster stability confirmed through internal validation (617 patients, mean age 51.5 ± 16.6 years, 72.0% female). Feature ranking determined the variables most responsible for cluster differentiation.
Results: Clustering identified five distinct HRQoL-based patient clusters transcending diagnostic categories. Cluster A included older, comorbid patients with cirrhosis, moderately impaired physical health but preserved psychological health. Cluster B (predominantly female) showed the lowest HRQoL, marked by fatigue, physical limitations, poor health perception and somatic preoccupation. Cluster C represented clinically stable patients with balanced HRQoL. Cluster D showed moderate disease severity but high emotional burden and strong medication beliefs. Cluster E included younger, mainly male patients with minimal comorbidities and the highest HRQoL. Self-rated health, fatigue and somatic preoccupation were the strongest discriminators. A rule achieving 90% coverage in Cluster B was defined by the following criteria: European Quality-of-life 5-Dimension (EQ-5D) "usual activities" > 1, EQ-5D "health today" ≤ 52, 8-item Somatic Symptom Scale (SSS-8) tiredness/low energy > 0, and Somatic Symptom Disorder-B Criteria Scale (SSD-12) behavioural subscale > 2.
Conclusion: This AI-based, multidimensional analysis identified five HRQoL phenotypes across AILDs, independent of diagnosis. The identification of a severely affected subgroup, identifiable through a simple four-item rule, highlights opportunities for targeted, transdiagnostic interventions.

SAT-370

Symptom experience in patients with primary biliary cholangitis: pilot survey results

Robert Mitchell-Thain[1], Mo Christie[1], Rebecca West[1], William Lobb[2], Nekshan Dalal[3], Alexa Ashton[2], Magnus Doverskog[4], David E. Jones[5]. *[1]PBC Foundation, Dunfermline, United Kingdom; [2]Indegene, Princeton, United States; [3]Indegene, London, United Kingdom; [4]Umecrine Cognition, Solna, Sweden; [5]Newcastle University Hospital, Newcastle Upon Tyne, United Kingdom*
Email: robert@pbcfoundation.org.uk

Background and aims: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease with significant impact on quality of life. This study aimed to capture symptom burden in PBC, and gain patient perspective on the need for new therapeutic options.
Method: 103 adults with PBC were surveyed using an online instrument on the PBC Foundation app. Respondents were predominantly female (98%) with majority aged 51–70 years (70%). 39% were employed full-time/part-time by choice, 18% were employed part-time or retired due to illness and 9% were unable to work due to illness. 96% of patients were on UDCA with 49% being responders, 6% non-responders, and 44% unsure/not told if they were responders. Only 9% of patients were told they had cirrhosis.
Results: Majority of patients reported experiencing central fatigue (84%) followed by dry eyes/dry mouth (72%), bone/joint pain (71%), peripheral fatigue (69%) and itching/pruritis (45%) in the last 4 weeks. 60% of patients reported experiencing both central and peripheral fatigue. 84% of patients reported moderate to severe fatigue on the PBC-40 questionnaire (48% moderate- score of 29 to 39 and 37% severe- score of ≥40). Central fatigue was patients' most burdensome/severe symptom (51%), followed by peripheral fatigue (41%) and bone ache (37%). Nearly half (49%) of patients reported experiencing their worst days due to central fatigue almost daily. Only 60% patients experiencing central fatigue and 45% experiencing peripheral fatigue discussed it with their clinicians believing fatigue to be "normal" (23%) and that clinicians cannot help (17%). When asked to choose only one symptom to treat, central fatigue overwhelmingly

dominated patient priorities (58%), followed by peripheral fatigue: 15%, all other symptoms combined: 27%.
Conclusion: Fatigue is commonly reported as one of the most prevalent symptoms of PBC. This survey highlights the importance of central (characterized by a lack of self-motivation) and peripheral fatigue (muscle weakness and dysfunction) constructs and the dominance of central fatigue as the most burdensome symptoms for which patients seek treatment. These findings underscore an urgent need for targeted interventions and a patient-focused approach to fatigue management to improve quality of life in PBC.

SAT-371
Nebokitug modulates gut–liver inflammatory and tissue-remodeling signatures in PSC patients with coexisting IBD
Revital Aricha[1], Tom Snir[1], John Lawler[1], Chris Cirillo[1], Dave Weiner[1], Adi Mor[1]. [1]*Chemomab Therapeutics Ltd., Tel Aviv, Israel*
Email: revital.aricha@chemomab.com

Background and aims: Primary sclerosing cholangitis (PSC) co-occurs with inflammatory bowel disease (IBD) in over 60% of affected individuals, reflecting intertwined gut–liver immune pathways. In the Phase 2 SPRING trial of nebokitug, a monoclonal antibody targeting the chemokine CCL24, 62% of enrolled PSC patients had concomitant ulcerative colitis (UC) or Crohn's disease (CD). We evaluated whether CCL24 inhibition modulates inflammatory and tissue-remodeling signatures relevant to PSC-IBD pathogenesis.
Method: SPRING study enrolled adults with PSC, with or without concomitant IBD. UC patients) were required to have emission or mild disease (Partial Mayo ≤2–3; no item >1), and and CD patients had to be in remission (CDAI <150). Concomitant IBD therapies were required to be stable for ≥12 weeks. Patients were treated with nebokitug (10 or 20 mg/kg) vs placebo once every three weeks for 15 weeks. Serum proteins were quantified using the Olink proteomic platform at baseline and Week 15. Biomarker analyses focused on inflammatory cytokines, chemokines, monocyte/macrophage markers, epithelial injury markers, and tissue-remodeling proteins previously associated with UC and CD activity.
Results: Nebokitug treatment led to modulation of inflammatory pathways shared between PSC and IBD. Significant reductions were observed in TNFRII, CXCL9/10/11, IL-6, CD14, IL-18, and IL-17, cytokines known to be strongly linked to IBD activation, mucosal immune recruitment and epithelial injury. Nebokitug also decreased multiple proteins associated with stromal and epithelial remodeling in IBD progression, including S100A12 (UC severity correlate), YKL-40 (IBD activity marker), resistin (predictor of Crohn's disease inflammation), CD38 (UC mucosal inflammation), and VEGF (angiogenesis in CD). Nebokitug demonstrated a significant elevation in MST-1, a negative regulator of inflammation that has been linked to genetic susceptibility and disease modulation in IBD, highlighting potential relevance to intestinal inflammatory pathways.
Conclusion: Treatment with nebokitug for up to 15 weeks resulted in improvements across inflammatory and tissue-remodeling pathways relevant to PSC with coexisting intestinal inflammation. These findings suggest that CCL24 inhibition may beneficially impact shared gut–liver inflammatory circuits.

SAT-372
Nebokitug down-regulates core fibrotic and immune pathways defined by single-cell liver profiling
Revital Aricha[1], Tom Snir[1], John Lawler[1], Chris Cirillo[1], Dave Weiner[1], Adi Mor[1]. [1]*Chemomab Therapeutics Ltd., Tel Aviv, Israel*
Email: revital.aricha@chemomab.com

Background and aims: Primary sclerosing cholangitis (PSC) is an immune-mediated biliary disease with no approved treatments. Recent single-cell analyses of human liver tissue identified four PSC-specific gene expression programs (GEPs), including extracellular matrix (ECM) remodeling, macrophage activation, fibrosis/myofibrosis, and immune-activation pathways. These GEPs are upregulated in livers from patients with PSC compared with those with metabolic dysfunction–associated steatohepatitis (MASH) and healthy controls. We assessed the effects of nebokitug, a CCL24-blocking monoclonal antibody in clinical development for PSC, on these GEPs by examining corresponding protein changes in serum from the SPRING Phase 2 trial.
Method: Serum proteins were quantified using the Olink proximity extension assay (PEA) in patients with PSC enrolled in the SPRING study who were treated with nebokitug 10 mg/kg (n = 21), nebokitug 20 mg/kg (n = 27), or placebo (n = 18). We analyzed the association between the four GEPs and disease severity (defined by elastography >8.7 kPa) and evaluated the effects of nebokitug vs placebo on these protein related GEPs.
Results: Proteins corresponding to all four PSC-related GEPs, reflecting fibrosis-related collagens, fibrotic macrophage activity, myofibroblast pathways, and immune-activation signaling, were significantly elevated in patients with moderate to advanced disease compared with those with mild PSC. Treatment with nebokitug led to dose-dependent reductions in serum proteins associated with these GEPs, with the greatest effects observed in patients with moderate to advanced disease.
Conclusion: Nebokitug treatment was associated with dose-dependent reductions in serum protein signatures linked to key fibrotic and immune pathways implicated in PSC. These findings support CCL24 blockade as a mechanism-based therapeutic approach targeting core molecular drivers of PSC pathogenesis.

SAT-377
AI-driven proteomic profiling differentiates composite improvement following treatment with nebokitug in PSC
Tom Snir[1], Revital Aricha[1], John Lawler[1], Chris Cirillo[1], Dave Weiner[1], Adi Mor[1]. [1]*Chemomab Therapeutics Ltd., Tel Aviv, Israel*
Email: tom.snir@chemomab.com

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease, characterized by persistent and progressive inflammation and fibrosis. The phase 2 SPRING study of nebokitug, an anti-CCL24-monoclonal antibody, showed anti-inflammatory, anti-fibrotic, and anti-cholestatic activity in PSC patients. We present a machine-learning model trained on treatment-associated proteomic changes to characterize nebokitug's impact on the liver. In addition, integration with a liver-specific atlas proteome allows evaluation of coordinated liver-derived protein changes following treatment.
Method: Serum protein levels in patients with PSC were quantified by Olink explore HT, before and after 15 weeks treatment with nebokitug (10 mg/kg; n = 21, 20 mg/kg; n = 27). All measured proteins were used to model a composite improvement outcome requiring reductions in ELF score, transient elastography, and PRO-C3, using penalized logistic regression (Elastic Net). Feature importance was aggregated from 500 iterations of repeated 5-fold cross-validation. Consensus was defined by features selected in ≥50% of iterations. Model performance was evaluated via AUROC and validated using permutation testing. Pathway and network analyses were performed on contributing proteins. PCA was performed on sub-groups of proteins shown to be liver specific.
Results: The model accurately differentiated patients who met the composite improvement criterion from those who did not, achieving a mean AUROC of 0.92 in repeated cross-validation. Permutation testing confirmed the model's validity, outperforming random noise models (mean null AUROC 0.59; $p < 0.05$). Stability analysis resulted in a protein signature consistently selected across iterations. Pathway analysis showed metabolic, catabolic and extracellular matrix related pathways, predominantly expressed in the liver. Analysis of baseline-to-week 15 changes using a liver-specific atlas proteome allowed clear discrimination between the groups, as shown by PCA.
Conclusion: AI work based on proteomics was successful in distinguishing a composite efficacy improvement outcome to treatment with nebokitug in patients with PSC. Patients who meet

the criteria showed differential expressions of liver proteins, with functional liver related proteins as the main drivers of this change. This analysis highlights treatment-associated improvement following nebokitug therapy, as well as the importance of CCL24 blockade in liver diseases and PSC pathology.

SAT-378-YI

The italian primary biliary cholangitis registry: insights from a nationwide cohort study

Eugenia Nofit[1,2], Laura Cristoferi[1], Alessio Gerussi[1,2], Daphne D'Amato[2], Marco Mario Giacomo Festa[1], Emanuela Bonaiuto[3], Vito Di Marco[4], Francesco Azzaroli[5], Elton Dajti[5], Francesca Colapietro[6], Pietro Lampertico[7], Elisabetta Degasperi[7], Stefano Fagiuoli[2,8], Mauro Viganò[8], Antonino Castellaneta[9], Antonella De Feudis[9], Edoardo Giannini[10], Sara Labanca[10], Francesca Terracciani[11], Giovanni Raimondo[12], Carlo Saitta[12], Maurizio Russello[13,14], Mariarita Cannavò[13], Ester Vanni[15], Alessandra Risso[15], Filomena Morisco[16], Valentina Cossiga[16], Cristina Rigamonti[17], Giulia Francesca Manfredi[17], Gabriele Missale[18], Alessandra Orlandini[18], Raffaele Cozzolongo[19], Francesco Losito[19], Armando Curto[20], Andrea Galli[20], Luca Maroni[21], Maurizia Brunetto[22], Barbara Coco[22], Federica Cerini[23,24], Francesco Pavan[23], Francesco Bellanti[25], Stefano Quiete[25], Lucia Napoli[26], Francesco Giuseppe Foschi[26], Andrea Mega[27], Monica Zoeschg[27], Alessandro Granito[28], Fabio Piscaglia[28], Giovanni Vitale[29], Maria Cristina Morelli[29], Valeria Pace Palitti[30], Marcello Persico[31], Tommaso Sarcina[31], Lorenzo Surace[32], Elisabetta Falbo[32], Raffaella Viganò[33], Federico D'Amico[33], Silvia Nardelli[34], Domenico Montecalvo[34], Gerardo Nardone[16], Alba Rocco[16], Giovanni Vettori[35], Luisa Moser[35], Chiara Ricci[36], Paolo Poisa[36], Fabrizio Bronte[37], Andrea Affronti[37], Alessandro Federico[38], Fiammetta Di Nardo[38], Clara Agnolon[39], Giuliano Alagna[40], Mariaconsiglia Bragazzi[41], Ilaria Cavalli[42], Alessandra Mangia[43], Francesca Fianchi[44], Filippo Gabrielli[45], Teresa Zolfino[46], Grazia Anna Niro[47], Luca Fabris[48], Saveria Lory Croce'[49], Luchino Chessa[50], Anna Meneghetti[51], Luigi Muratori[52], Leonardo Baiocchi[53], Eleonora Grassi[54], Francesca Capelli[55], Ludovico Abenavoli[56], Anna Maria Baragiotta[57], Fabio Marra[58], Nadia Dal Bo'[59], Susanna Schianchi[60], Roberto Chiavaroli[61], Nora Cazzagon[3], Vincenza Calvaruso[4], Ana Lleo[6], Umberto Vespasiani-Gentilucci[11], Marco Marzioni[21], Marco Carbone[2,33], Pietro Invernizzi[1]. *[1]Fondazione Irccs San Gerardo dei Tintori di Monza, Università degli Studi di Milano-Bicocca, Monza, Italy; [2]Università degli Studi di Milano-Bicocca, Milano, Italy; [3]Azienda Ospedale Università Padova, University of Padova, Padova, Italy; [4]Azienda Ospedaliera Universitaria Policlinico Paolo Giaccone, University of Palermo, Palermo, Italy; [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna Policlinico Sant'Orsola, Bologna, Italy; [6]Istituto Clinico Humanitas, Rozzano, Italy; [7]Fondazione Irccs Ca Granda Ospedale Maggiore Policlinico, Milano, Italy; [8]ASST Papa Giovanni XXIII, Bergamo, Italy; [9]Azienda Ospedaliero Universitaria Consorziale Policlinico, Bari, Italy; [10]Ospedale San Martino, Genova, Italy; [11]Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy; [12]Azienda Ospedaliera Universitaria di Messina Gaetano Martino, Messina, Italy; [13]Azienda Ospedaliera di Rilievo Nazionale e di Alta Specializzazione Garibaldi, Catania, Italy; [14]LIVER UNIT, ARNAS GARIBALDI-NESIMA, CATANIA; [15]Azienda Ospedaliera Città della Salute e della Scienza, Turin, Italy; [16]Azienda Ospedaliera Universitaria Federico II, Napoli, Italy; [17]Azienda Ospedaliero Universitaria Maggiore della Carità, Novara, Italy; [18]Azienda Ospedaliero-Universitaria di Parma, Parma, Italy; [19]IRCCS S. Email: eugenia.nofit@irccs-sangerardo.it

Background and aims: Primary biliary cholangitis (PBC) is a rare autoimmune liver disease. Epidemiological data in Italy are limited. To address this the Italian PBC Registry was established in 2019 to collect retrospective and prospective data. This study provides an overview of the Registry and its collected data.

Method: The Registry includes demographic, biochemical, staging, and treatment data. Tests at diagnosis are those performed 3 months before to 30 days after diagnosis; tests at 1 year after UDCA were performed 11–15 months after treatment initiation. Categorical variables are reported as frequencies (%), continuous variables are reported as mean ± SD or median and interquartile range. ALP, AST, ALT, GGT are expressed as ratios of their ULN, bilirubin as mg/dL.

Results: From 2019 to 2025 enrolment increased from 128 to 3310 (37 ± 22 patients/month). 3199 were analyzed (111 excluded for missing data). The Registry involves 69 active centers, 61 entering data across Italy (40 North, 9 Center, 20 South/Islands). 2836 (89%) were female with mean age 55.3 ± 12 years, BMI 24.96 ± 4.64, 3067 (96.7%) were Caucasian. Median follow-up was 6.9 years [3.1,12.6]. 2018 (80.3%) reported no alcohol consumption, 456 (18.1%) consumed <10/20 g/day (women/men) and 40 (1.6%) consumed >10/20 g/day (women/men). Never-smokers were 1724 (70%), former 423 (17.2%), current 315 (12.8%). At diagnosis, among 1840 patients (57.5%) with available tests, the mean values were: ALP 1.59 [1.07,2.67], AST 1.25 [0.83,2.10], ALT 1.32 [0.80,2.18], GGT 3.90 [1.89,7.49], bilirubin 0.65 [0.50, 0.92] mg/dL. Liver biopsy was performed in 666 (20.8%) patients and transient elastography in 653 (20.4%) with a median liver stiffness of 6.6 kPa [5.0,9.1]. After one year of UDCA 809 (25.3%) patients had: ALP 1.11 [0.78,1.64], AST 0.78

[0.59,1.06], ALT 0.70 [0.48,1.10], GGT 1.26 [0.70,2.78], bilirubin 0.60 [0.44,0.83] mg/dL. Elevated ALP (>1.67) was observed in 185 (22.9%). However, considering the entire cohort, 923 (28.8%) patients initiated second-line therapy: 429 (46.5%) with Obeticholic Acid (OCA), 277 (30%) with fibrates, 163 (17.7%) with combination therapy (OCA and fibrate). Regarding the new PPAR-targeted therapies, 125 (13.5%) patients initiated Elafibranor and 52 (5.6%) initiated Seladelpar.
Conclusion: The Italian PBC Registry provides a national picture of PBC, supporting disease monitoring and management. Continued commitment from participating centers will enhance data completeness and strengthen the reliability of future analyses.

Alkaline phosphatase and bilirubin levels at one year of fibrate therapy predict long-term outcomes in patients with primary biliary cholangitis receiving second-line treatment

Satoko Ohfuji[1], Kyoko Kondo[2], Keiji Tsuji[3], Mayumi Yamaguchi[4], Yuki Yamashita[5], Hironao Okubo[6], Kazufumi Dohmen[7], Hideyuki Tamai[8], Masaya Tamano[4], Masanori Abe[9], Atsumasa Komori[10], Atsushi Tanaka[11]. *[1]Department of Public Health, Graduate School of Medicine, Osaka Metropolitan University, Osaka, Japan; [2]OMU Core Facilities Life Sciences Section, Osaka Metropolitan University, Osaka, Japan; [3]Department of Gastroenterology, Hiroshima Red Cross Hospital and Atomic-bomb Survivors Hospital, Hiroshima, Japan; [4]Department of Gastroenterology, Dokkyo Medical University Saitama Medical Center, Koshigaya, Japan; [5]Department of Medicine, Division of Gastroenterology, Shinshu University School of Medicine, Matsumoto, Japan; [6]Department of Gastroenterology, Juntendo University Nerima Hospital, Tokyo, Japan; [7]Gastrointestinal and Hepato-Biliary-Pancreatic Center, Chihaya Hospital, Fukuoka, Japan; [8]Department of Hepatology, Wakayama Rosai Hospital, Wakayama, Japan; [9]Department of Community and General Medicine, Ehime University Graduate School of Medicine, Ehime, Japan; [10]NHO Nagasaki Medical Center, Nagasaki, Japan; [11]Department of Medicine, Teikyo University School of Medicine, Tokyo, Japan*
Email: satoko@omu.ac.jp

Background and aims: In patients with primary biliary cholangitis (PBC) treated with ursodeoxycholic acid (UDCA) monotherapy, alkaline phosphatase (ALP) and total bilirubin (T-Bil) levels are well-established predictors of prognosis. However, their prognostic utility in patients receiving combination therapy with UDCA and fibrates remains unclear. This nationwide Japanese retrospective cohort study aimed to validate biochemical response criteria at one year of fibrate therapy as a predictor of transplant-free survival in patients with PBC receiving fibrates as second-line therapy.
Method: Patients with PBC who received bezafibrate (BZF) or pemafibrate (PMF) as second-line treatment due to an incomplete response or intolerance to UDCA between 2001 and 2024 were included. By using laboratory data at one year after starting fibrate treatment, the proportions achieving 1) ALP < 1.67×the upper limit of normal (ULN) and ≥ 15% ALP reduction and T-Bil normalization, 2) both ALP and T-Bil normalization, 3) ALP normalization and T-Bil < 0.6 × ULN were assessed. Then, the association between each biochemical response criteria and transplant-free survival was analyzed by using Kaplan-Meier and Cox proportional hazard models.
Results: A total of 558 patients (BZF: 344, PMF: 214) were included. The median age was 60 years (IQR: 50–68 years), and 460 (82%) were female. At 1 year of fibrate treatment, the median ALP level (×ULN) was 0.81 (IQR: 0.57–1.60), and the median T-Bil level (×ULN) was 0.50 (IQR: 0.40–0.67). 315 (57.3%) achieved 1) ALP < 1.67 × ULN and ≥ 15% ALP reduction and T-Bil normalization, 326 (59.3%) achieved 2) both ALP and T-Bil normalization, and 261 (47.5%) achieved 3) ALP normalization and T-Bil < 0.6 × ULN. During a median follow-up of 4.9 years, 27 (4.8%) patients underwent death or liver transplantation. In the univariate analysis, all three criteria were significantly associated with outcomes. After adjustment of potential confounders, achieving 1) ALP < 1.67 × ULN and ≥ 15% ALP reduction and T-Bil normalization was only a significant predictor, which showing a 69% reduction in hazard (HR = 0.31, 95%CI: 0.11–0.83).
Conclusion: This nationwide Japanese cohort study demonstrates that the ALP and T-Bil levels at one year after initiation of fibrate therapy are valuable predictors for transplant-free survival in patients with PBC receiving fibrates as second-line treatment.

Clinical utility of thiopurine methyltransferase (TPMT) genotype and azathioprine (AZA) metabolites in the management of autoimmune hepatitis (AIH)

Ignasi Olivas[1,2], Judit Julian[3], Ana Maria Lizana[3], Pinelopi Arvaniti[1,2,4], Helena Hernández Evole[1,2,4], Sergio Rodriguez-Tajes[1,2,4], Jaime Sainz[3], Mercè Brunet[3,5], María Carlota Londoño[1,2,4,6]. *[1]Liver Unit, Hosptial Clínic Barcelona, Institut d`Investigació Biomedica August Pi y Sunyer (IDIBAPS), Barcelona, Spain; [2]Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomèdiques August Pi Sunyer (FRCB-IDIBAPS), Barcelona, Spain; [3]Department of Biochemistry and Molecular Genetics, Section of Pharmacology and Toxicology, Hospital Clínic Barcelona, Barcelona, Spain; [4]Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain; [5]Universitat de Barcelona, Barcelona, Spain; [6]Universitat de Barcelona, Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas (CIBEREHD), Institut d`Investigació Biomedica August Pi y Sunyer (IDIBAPS), Barcelona, Spain*
Email: ignasiolivasalberch@gmail.com

Background and aims: Current AIH guidelines recommend monitoring AZA metabolites, 6-thioguanine (6-TG) and 6-methylmercaptopurine (6-MMP), to optimize therapy. Evidence for their clinical utility is limited, and the relationship between TPMT genotype and AZA metabolites remains unclear. This study evaluated the impact of TPMT genotyping and 6-TG/6-MMP monitoring on the management of AIH.
Method: This prospective study included 112 AIH patients treated with AZA and prednisone. TPMT polymorphisms (*3A, *3B, and *3C) were assessed by qPCR. Erythrocyte 6-TG and 6-MMP concentrations were measured using ultra-high-performance liquid chromatography–mass spectrometry. Therapeutic ranges were defined as 6-TG 235–450 pmol/8 × 10^8 erythrocytes and 6-MMP <5700 pmol/8 × 10^8 erythrocytes. Continuous data are expressed as median (IQR).
Results: Most patients were women (67%), Caucasian (89%), age 55 years (38.9–64.8). Time from AZA initiation to first metabolite measurement was 3.3 years (0.98–6.53) and AZA dose was 100 mg/d (75–125). Testing was performed for insufficient response (IR) in 50 patients (45%) and for AZA dose adjustment in 62 patients (55%) with complete biochemical response (CBR). Among 96 patients with TPMT genotyping, seven (7%) were heterozygous for *3A and the remainder were wild type (WT). Median 6-TG and 6-MMP levels were 386 pmol/8 × 10^8 erythrocytes (IQR 259–566) and 1541 pmol/8 × 10^8 erythrocytes (IQR 0–3976). No differences in 6-TG levels were found between WT and heterozygous patients, while 6-MMP levels were significantly lower in heterozygous patients ($p < 0.001$). AZA dose correlated positively with 6-TG levels in WT ($\rho = 0.34$; 95% CI 0.15–0.52; $p < 0.001$) and heterozygous patients ($\rho = 0.89$; 95% CI 0.40–1.00; $p = 0.012$). 6-TG levels were not associated with CBR, anaemia, or leukopenia ($p > 0.05$). Metabolite-guided management led to treatment changes in 34 patients: in 19 with CBR and 6-TG or 6-MMP above range, AZA was reduced; in 9 with IR and 6-TG below range, AZA was increased; in 6 with IR and 6-TG above range, AZA was switched to MMF. Four patients with IR and undetectable 6-TG were identified as non-adherent.
Conclusion: TPMT genotyping and AZA metabolite monitoring showed interindividual variability and adherence issues, prompting therapeutic adjustments in a substantial proportion of patients with AIH. The lack of association between 6-TG levels and CBR or toxicity

suggests metabolite monitoring may be mainly useful in patients with IR.

SAT-381

Impact of metabolic syndrome on clinical outcomes in primary biliary cholangitis: a retrospective cohort study

Jade Pace[1], Michael Attanasi[1], Brittany Kwait[1], Christopher Dorizas[1], Bryana Belin[2], Maham Ghani[1], Sanjaya Satapathy[1]. *[1]Northwell Health, Manhasset, United States; [2]Donald & Barbara Zucker School of Medicine at Hofstra, Hempstead, United States*
Email: jpace1@northwell.edu

Background and aims: Metabolic syndrome is an increasing area of interest among patients with chronic liver disease and has been associated with adverse outcomes in several conditions. However, its impact on clinical outcomes in primary biliary cholangitis (PBC) remains unclear. We investigated the association between metabolic syndrome and hepatic decompensation and mortality in a retrospective cohort of patients with PBC followed at a tertiary care center. We hypothesized that the comorbidity of metabolic syndrome confers a worse prognosis.
Method: Inclusion criteria consisted of patients at least 18 years of age with an ICD-10 code diagnosis of PBC and positive anti-mitochondrial antibody titer ≥ 1:40 that were admitted over the past 10 years. Metabolic syndrome was defined using established clinical criteria at index admission. Body mass index ≥ 30 kg/m^2 and A1c ≥ 5.6% were used as surrogates for elevated waist circumference and fasting glucose. The primary outcomes were time to first hepatic decompensation (ascites, bilirubin > 3.0, encephalopathy, or esophageal gastrointestinal bleed) and all-cause mortality. Survival was assessed using Kaplan-Meier methods, and Cox proportional hazards models were used to evaluate associations after adjustment for age, sex, and Model for End-Stage Liver Disease (MELD) score where available.
Results: A total of 401 adults with PBC were included. Among this cohort, 137 patients (34%) met criteria for metabolic syndrome. Liver disease severity markers such as bilirubin levels and MELD score were similar between groups. During follow-up, 140 patients (35%) developed hepatic decompensation and 68 patients (17%) died. In multivariable models adjusted for age and sex, metabolic syndrome was not independently associated with hepatic decompensation (hazard ratio [HR] 0.83; 95% confidence interval [CI] 0.63–1.10) or mortality (HR 1.18; 95% CI 0.64–1.82). In MELD-adjusted mortality models (n = 310), metabolic syndrome remained unassociated with mortality (HR 1.08; 95% CI 0.64–1.82). Older age, male sex, and higher MELD score were independently associated with increased mortality.
Conclusion: In this large cohort of patients with PBC, metabolic syndrome was not independently associated with hepatic decompensation or mortality after adjustment for established disease severity markers. These findings suggest that traditional indicators of liver disease severity, rather than metabolic comorbidity burden, primarily drive adverse outcomes in PBC.

SAT-382

Utility of spleen stiffness measurement for the detection of esophageal varices in primary biliary cholangitis (PBC)

Email: marlenepadillamd@gmail.com

Background and aims: In primary biliary cholangitis (PBC), clinically significant portal hypertension (CSPH) may develop even in precirrhotic stages due to a presinusoidal component, potentially limiting the accuracy of Baveno VII (BVII) criteria for predicting esophageal varices (EV). We aimed to evaluate the utility of spleen stiffness measurement (SSM) in predicting EV and varices needing treatment (VNT) in patients with PBC.
Method: This multicenter cross-sectional study included patients from 14 centers with PBC fulfilling at least one of the following criteria: Liver stiffness measurement (LSM) ≥8 kPa, splenomegaly, platelet count ≤150 × 10^9/L, or ultrasonographic signs of cirrhosis or portal hypertension. LSM and SSM were assessed using transient elastography. Laboratory tests, ultrasound (±6 months from the SSM), and upper endoscopy (±12 m) were collected.
Results: We included 126 patients, 87% women, with a median age of 64 years (IQR 58–71). Overall, 82% had a LSM ≥8 kPa, 48% thrombocytopenia, 49% splenomegaly, and 65% cirrhosis. Median LSM and SSM values were 13.6 kPa (IQR 9.1–21.3) and 36.6 kPa (IQR 25.2–48.6), respectively. EV were present in 39% of patients, of whom 28% had VNT. The prevalence of VNT was significantly higher in patients with LSM >15 kPa (24%) compared with those with LSM 8–15 kPa (4%) or <8 kPa (0%; p = 0.002). For EV prediction, BVII criteria (LSM ≤ 15 kPa and platelet count ≥150 × 10^9/L) showed moderate diagnostic accuracy (AUC 0.71), with a sensitivity (Se) of 85%, specificity (Sp) of 55%, and negative predictive value (NPV) of 85%. LSM alone demonstrated comparable performance (AUC 0.74, Se of 94%, Sp 48% and NPV of 93%) at a cut-off of 9.8 kPa. Platelet count also showed moderate accuracy (AUC 0.70, Se 55%, Sp 82%, NPV 74%) using a cut-off of 127.5 × 10^9/L. SSM achieved the highest diagnostic accuracy for EV detection (AUC 0.79, Se 78%, Sp 74%, NPV 84%) at a cut-off of 37 kPa. Combining SSM ≥37 kPa with a platelet count <127.5 × 10^9/L further improved diagnostic performance (AUC 0.81, Se 45%, Sp 88%, NPV 72%). For VNT prediction, SSM was the strongest predictor (AUC 0.85, Se 93%; Sp 65%; NPV 99%), at a cut-off of 39 kPa, outperforming BVII criteria, LSM, and platelet count (AUC 0.68, 0.74, and 0.77, respectively).
Conclusion: SSM showed superior diagnostic accuracy for predicting esophageal varices and varices needing treatment in patients with

PBC, improving BVII criteria. Its use may enable more accurate risk stratification, including in precirrhotic stages.

SAT-383

Beyond fibrosis: clinical relevance of histological inflammatory patterns in autoimmune hepatitis

Ana Pascual-Dapena[1], Marta Sánchez-Ric[1], Helena Hernández Evole[1], Diogo Simas[1], Nuria Florensa[1], David Heitmann[1], Ignasi Olivas[1], Pinelopi Arvaniti[1], Sergio Rodriguez-Tajes[1], María Carlota Londoño[1]. *[1]Liver Unit, Hospital Clinic Barcelona, Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Ciberehd, Barcelona, Spain*
Email: mlondono@clinic.cat

Background and aims: Autoimmune hepatitis (AIH) exhibits diverse histological features. Beyond fibrosis, the implications of these patterns in terms of disease presentation, progression, and outcomes remain inadequately defined. We aimed to assess the clinical and prognostic implications of different histological inflammatory patterns in patients with AIH.
Method: We retrospectively evaluated 349 diagnostic liver biopsies from patients with AIH. Histology was classified into four inflammatory patterns: predominant portal inflammation (PI), predominant lobular inflammation (LI), mild portal and lobular inflammation (mPLI), and moderate-to-severe portal and lobular inflammation (m-sPLI). The presence of ductular reaction (DR) was also assessed. Liver-related events (LRE) were defined as cirrhosis development, decompensation, hepatocellular carcinoma, liver transplantation, and liver-related death. Complete biochemical response (CBR) was assessed during follow-up.
Results: Most patients were women (71%), with a median age of 53 years (IQR 42–63) and a median follow-up of 8 years (IQR 5–12). At diagnosis, 33 patients had PI, 34 LI, 84 mPLI, and 112 m-sPLI. DR was present in 41 patients. Patients with predominant LI and m-sPLI showed higher median AST (873 and 710 vs. 217 and 382 U/L), ALT (1015 and 834 vs. 274 and 430 U/L), and bilirubin levels (7 and 5.4 vs. 1.0 and 1.7 mg/dL) compared with PI and mPLI phenotypes (all $p < 0.05$), and more frequently presented with acute AIH (67% and 58% vs. 35% and 43%, respectively; $p = 0.013$). Patients with DR had higher GGT (193 vs. 135 U/L, $p < 0.001$), alkaline phosphatase (236 vs. 155 U/L, $p = 0.004$), and bilirubin levels (7.0 vs. 2.6 mg/dL, $p = 0.021$). CBR rates were 47% at 6 months, 57% at 12 months, and 78% at last follow-up, with no significant differences across histological phenotypes. After excluding patients with cirrhosis at diagnosis ($n = 37$), 66 patients developed LRE during follow-up. Predominant LI was associated with a lower risk of LRE compared with other histological phenotypes (6% vs. 23%; OR 0.21, 95% CI 0.05–0.89; $p = 0.035$), and this association persisted after adjustment for baseline fibrosis (OR 0.22, 95% CI 0.05–0.97; $p = 0.048$).
Conclusion: Distinct histological inflammatory patterns in AIH are associated with different clinical presentations and long-term outcomes. Predominant lobular inflammation identifies a subgroup of patients with a more favourable disease course. Recognition of histological patterns at diagnosis may improve risk stratification in AIH.

SAT-384

Statins are underutilized for cardiovascular disease in patients with PBC

Mark Pedersen[1], Gemma H. X. Weijsters[2], Adriaan J. van der Meer[2], Ellina Lytvyak[3], Allison Mella[3], Sergio Rodriguez-Tajes[4], Helena Hernández Evole[4], Cláudia Couto[5], Henriette Ytting[6], Xavier Verhelst[7], Agnes Paradissis[7], Cynthia Levy[8], Adrielly Martins[8], Marco Carbone[9], Eugenia Nofit[9], Álvaro Díaz-González[10], Konstantinos Papantoniou[11], Christos Triantos[11], Conrado Fernandez-Rodriguez[12], Gideon M. Mayo[1]. *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, United States; [2]Erasmus MC, Rotterdam, Netherlands; [3]University of Alberta, Edmonton, Canada; [4]Hospital Clínic De Barcelona, Barcelona, Spain; [5]Universidade Federal De Minas Gerais, Belo Horizonte, Brazil; [6]Hvidovre Hospital, Hvidovre, Denmark; [7]UZ Gent, Gent, Belgium; [8]University of Miami Miller School of Medicine, Miami, United States; [9]Università degli Studi di Milano-Bicocca, Milano, Italy; [10]Hospital Universitario Marqués De Valdecilla, Santander, Spain; [11]Division of Gastroenterology, Department of Internal Medicine, University of Patras, 26504, Patras, Greece, Patras, Greece; [12]Universidad Rey Juan Carlos, Madrid, Spain; [13]UHN - Toronto General Hospital - Elizabeth St Garage, Toronto, Canada*
Email: mrpeders@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic, cholestatic liver disease that is associated with dyslipidemia. Retrospective studies have suggested that dyslipidemia in PBC is not associated with increased risk of major adverse cardiovascular events (MACE), or is associated only in the presence of another cardiovascular risk factor. We use data from the multinational Global PBC Study group to examine the treatment patterns of dyslipidemia in PBC.
Method: Retrospective chart review was performed at 13 separate clinical sites in the Global PBC Study group. Data were collected on prior diagnoses of dyslipidemia, hypertriglyceridemia, hypertension, chronic kidney disease (CKD), pharmacotherapy of dyslipidemia, revascularizations (cardiac, cerebral, or peripheral) and MACE (defined as ST-elevation myocardial infarction [STEMI], non-ST-elevation myocardial infarction [NSTEMI], unstable angina, cerebrovascular accident, and transient ischemic attack).
Results: Data were collected on 1926 patients from 9 countries. 799 (24.6%) of these patients carried a diagnosis of dyslipidemia, 652 (20.1%) hypertension, and 136 (7.1%) chronic kidney disease. There were 81 MACE events (5.3%), with 45 of these being cardiac (STEMI, NSTEMI, or unstable angina). Only 40.5% of patients with dyslipidemia and hypertension were on a statin as primary prophylaxis of MACE. Of the 106 patients who had either a MACE or revascularization event for non-MACE reasons (e.g. high-risk coronary lesions), only 58.4% patients ever received a statin.
Conclusion: In this large, multinational population, only 40.5% of patients with two identified risk factors for MACE were prescribed a statin as primary prophylaxis, as is suggested by current AASLD and EASL guidelines. Further, only half the patients with a strong indication for statin use (history of MACE or revascularization procedure) were prescribed a statin. Though further work is needed to define which patients with PBC are at increased risk for MACE, the present data suggest that statins are underutilized in patients with PBC.

Identifying primary biliary cholangitis in the general population: a laboratory based look back exercise

Isobel Phillips[1], Molly Thorpe[1], Abdullah Alhouri[1], Grace Hutchinson[1], Angharad Clements[1], Joanna Gould[1], Molly Flint[1], Eleanor Godward[1], Andrew Yeoman[1]. *[1]Aneurin Bevan University Health Board, Newport, United Kingdom*
Email: andrew.yeoman@wales.nhs.uk

Background and aims: PBC is typically diagnosed via the combination of a positive anti-mitochondrial antibody (AMA) and raised alkaline phsophatase (ALP) levels. The true prevalence is probably underestimated due to a lack of awareness of the disease in non specialist settings. We set out to evaluate whether there are a significant number of patients within our region of Gwent, Wales, that possess the laboratory features that are highly suggestive of PBC but who are currently undiagnosed.
Method: A retrospective search was undertaken within the clinical laboratory system within the Aneurin Bevan University Health Board utilsing data from 1st April 2104 to 30th March 2024. We identified all

pateints with a positive AMA and corrleated this with whether the ALP was elevated, either at the same time as AMA postitivity or at any time point during future follow up. Patients with an existing diagnosis of PBC were also identified via notes review.
Results: A total of 974 unique individuals had a raised AMA, 378 of which have a confirmed diagnosis of PBC given a population prevalence of 69/100,000. Of the remaining 596 individuals without a diagnosis of PBC, 132 (22%) had an eleavted ALP synchronous to the AMA positivity. Of these individuals 65% were referred and assessed by Hepatology and PBC had been excluded. In addition, 464 had a normal ALP of whom 109 (23%) had been referred and seen for specialty assessment. Of the 464 with a normal ALP at time of AMA positivity, 225 (48%) subsequently had at least 1 elevation in the ALP and in 163 (35%) this was persistent. Specilaist clinical review occurred in 60/163 (37%) of this cohort. Overall, there were 149 individuals whose AMA and ALP would be suggestive of PBC prompting specialist assessment but who have not been referred for such.
Conclusion: Despite a high PBC prevalence, around 2/3rds of positive AMAs in our region over a decade are not asscoiated with a confirmed diagnosis of PBC. Furthermore 149 of these individuals (25%) have not been formally reviewed by Hepatology to confirm a diagnosis. Work is now currently underway to identify how many of these individuals have PBC.

SAT-386

Prevalence and clinical impact of metabolic dysfunction-associated steatotic liver disease in primary biliary cholangitis: a tertiary-center experience

Riccardo Plebani[1], Maria Pia Calabrese[1,2], Antonella Ruiu[1,2], Pietro Meschisi[1,2], Stella De Nicola[1,2], Nicola Pugliese[1,2], Vincenzo Ronca[1,2], Alessio Aghemo[1,2], Ana Lleo[1,2]. *[1]Department of Biomedical Sciences, Humanitas University, Department of Gastroenterology, Division of Internal Medicine and Hepatology, IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy; [2]Department of Gastroenterology, Division of Internal Medicine and Hepatology, IRCCS Humanitas Research Hospital, Rozzano, Italy*
Email: ric.plebani@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is frequent among general population, as such might coexist with other chronic liver condition such as primary biliary cholangitis (PBC). However, its clinical relevance remains uncertain. While current management effectively targets cholestasis, it is unclear whether patients with concomitant MASLD differ in disease progression. We aimed to assess MASLD prevalence in a tertiary-care PBC cohort, assessing their treatment response and disease course compared with PBC alone.
Method: We conducted a single-centre, retrospective, observational study of consecutive patients with PBC. MASLD was defined by evidence of hepatic steatosis on imaging in the presence of cardiometabolic risk factors. Fibrosis stage was assessed by liver biopsy or liver stiffness measurement. Metabolic dysfunction–associated steatohepatitis (MASH) was defined histologically. Clinical outcomes were assessed at the last available follow-up.
Results: Among 160 patients with PBC, 50 (31%) had concomitant MASLD. Baseline alkaline phosphatase levels were comparable between patients with and without MASLD (median 220, IQR 145–321 vs median 211, IQR 151–381 respectively, $p = 0.80$), while gamma-glutamyltransferase levels were higher in MASLD patients without being statically significant (median 224, IQR 123–438 vs median 274, IQR 167–538, respectively, $p = 0.30$). Liver stiffness measurements were similar between groups, whereas CAP values were significantly higher in patients with MASLD (median 201, IQR 181–233 vs median 255, IQR 227–293, $p < 0.05$). Response to UDCA did not differ between groups. Cirrhosis was less frequent among patients with MASLD compared with those without MASLD (14% vs 32%, $p = 0.029$). Hepatic decompensation occurred in 4% of patients with MASLD and 12% of those without MASLD, without a statistically significant difference between groups. Among patients with MASLD, 8 (18.6%) had fibrosis stage F2–F3; histological MASH was identified in 3 patients.
Conclusion: MASLD was a common overlapping condition in patients with PBC, yet its presence was not associated with clear differences in cholestatic treatment response or short-term clinical outcomes in this cohort. These findings raise the hypothesis that MASLD may have a limited impact on the clinical course of established PBC, although longer follow-up and larger prospective studies are needed.

SAT-387

Meaningful within-patient change on the 5-D itch scale in patients with primary biliary cholangitis experiencing pruritus

David E. Jones[1], Andreas E. Kremer[2], Milena Anatchkova[3], Mary Kate Ladd[3], Anne Skalicky[3], Shubhram Pandey[4], Marvin Rock[5], Susheela Carroll[5], Caroline Burk[5]. *[1]Newcastle University, Newcastle, United Kingdom; [2]University Hospital Zürich, University of Zürich, Zürich, Switzerland; [3]Thermo Fisher Scientific, Waltham, MA, United States; [4]Pharmacoevidence, Mohali, India; [5]Gilead Sciences, Foster City, CA, United States*
Email: david.jones@newcastle.ac.uk

Background and aims: Pruritus is a prominent symptom in primary biliary cholangitis (PBC). In the phase 3 RESPONSE trial (NCT04620733), seladelpar (SEL) vs placebo (PBO) significantly and meaningfully reduced pruritus in patients with PBC as measured using the pruritus numerical rating scale (NRS), the established regulatory standard for pruritus assessment in PBC studies. Findings were supported by consistent results from the 5-D Itch scale, a validated patient-reported measure of pruritus severity and impact. However, a meaningful within-patient change (MWPC) threshold on the 5-D Itch was not established. Here, RESPONSE patient data were analyzed to establish an MWPC threshold on the 5-D Itch.
Method: RESPONSE was a 12-month, double-blind, placebo-controlled trial. The 5-D Itch was completed bi-weekly from run-in to Month (M) 6 and monthly to M12. Anchor-based analyses of the intent-to-treat population (ITT) at M6 and M12 examined the 5-D Itch total score's sensitivity to change and identified an MWPC threshold; all ITT patients with data were evaluated. Patient Global Impression of Severity (PGI-S) and Change (PGI-C) scales (completed at baseline, M6, M12) served as anchors. Spearman's correlation coefficients between 5-D Itch total and PGI-S/PGI-C change scores verified anchor suitability. A distribution-based estimate (0.5 × SD at baseline) supported anchor-based findings. Proportions of 5-point responders for the 5-D Itch were evaluated in the ITT and the subgroup with moderate to severe pruritus (MSPN; baseline Pruritus NRS ≥ 4).
Results: RESPONSE enrolled 193 patients (128 SEL; 65 PBO). PGI-S and PGI-C were deemed suitable anchors ($|\text{Spearman's } \rho| > 0.30$). In patients with a 1-point PGI-S improvement, mean (SD) change in 5-D Itch total was –4.21 (3.64) at M6 and –3.70 (3.47) at M12 (median –5 for both). In patients reporting "moderately better" on the PGI-C, mean (SD) change was –3.49 (4.38) at M6 and –2.38 (3.94) at M12 (median: –2.5 at M6; –3.5 at M12). The distribution-based estimate was 2.39. At M6, 24% on SEL vs 14% on PBO were 5-point responders in the ITT, and 45% on SEL vs 26% on PBO were 5-point responders in the MSPN. At M12, 23% on SEL vs 9% on PBO were 5-point responders in the ITT, and 43% on SEL vs 17% on PBO were 5-point responders in the MSPN.
Conclusion: An MWPC threshold range of –3 to –5.5 points on the 5-D Itch in patients with PBC in RESPONSE was established. Higher proportions of patients on SEL than PBO were 5-point responders at M6 and at M12.

SAT-388

Primary biliary cholangitis education significantly improves competence in recognising which patients would most likely benefit from second line therapy

S Christy Rohani-Montez[1], Marinella Calle[1], Margaux Le Berre[1], Marlyn J. Mayo[2], Mark Swain[3], María Carlota Londoño[4]. [1]*Medscape Education Global, London, United Kingdom;* [2]*UT Southwestern Medical Center, Dallas, TX, United States;* [3]*University of Calgary, Calgary AB, Canada;* [4]*Hospital Clinic Barcelona, Barcelona, Spain*
Email: srohani@medscape.net

Background and aims: Best practices in the management of primary biliary cholangitis (PBC) are evolving with the recent availability of peroxisome proliferator-activated receptor (PPAR) agonists. We sought to improve physician competence according to the Moore's Outcomes Framework, in recognizing who would potentially benefit from these second-line therapies, and to improve knowledge regarding PPAR agonist clinical trial data by providing expert-led accredited education.
Method: Physicians participated in a 55-minute, video-based online CME activity divided into 4 main discussions with different speakers and synchronized slides (available at www.medscape.org/viewarticle/1002582). Education effects were assessed using a 3-question, repeated pairs, pre-/post-assessment study design. One question assessed confidence. Pre- to post-assessment differences were evaluated using the McNemar's test. $P \leq 05$ was considered significant. The activity launched in June 2025, and data collected through October 2025.
Results: Overall significant improvements were seen after participation for gastroenterologists/hepatologists (gastro/heps) with a correct response rate of 44% at pre-assessment vs 62% post-assessment ($p < .001$, Cohen's $d = 0.68$, $N = 272$), and for primary care physicians (PCPs) with a correct response rate of 44% at pre-assessment vs 57% at post-assessment ($p < .001$, Cohen's $d = 0.51$, $N = 457$). Case-based questions assessing when to consider second-line therapy showed significant improvements. The largest gap in knowledge was regarding the therapeutic expectations of PPAR agonists based on current clinical data, specifically how quickly ALP reductions should be expected, but this also significantly improved post-education. After participating, 32% of gastro/heps and 35% of PCPs had measurable improvements in confidence in deciding when to start second-line PBC therapy. When asked what challenges are most often encountered when assessing the need for second-line PPAR agonists amongst inadequate UDCA responders, 30% of gastro/heps and 42% of PCPs said lack of knowledge on PPAR agonist clinical data and 44% of gastro/heps and 43% of PCPs said lack of or limited access to these therapies. Only 8% of gastro/heps and 5% of PCPs said they were not convinced that PPAR agonists would benefit these patients.
Conclusion: This study demonstrates the success of online video-based education in improving competence and confidence in implementing second line PPAR agonists for patients with PBC.

SAT-393

From real patients to digital twins: synthetic cohorts for evidence generation in UDCA-treated primary biliary cholangitis

Vincenzo Ronca[1], Sara Baccino[2], Ferrari Ivan[2], Eugenia Nofit[3], Alessio Gerussi[4], Laura Cristoferi[3], Saverio D'amico[2], Matteo Della Porta[1,2], Pietro Invernizzi[3,4], Marco Carbone[4,5], Ana Lleo[1,2]. [1]*Department of Biomedical Sciences, Humanitas University, Department of Gastroenterology, Division of Internal Medicina and Hepatology, IRCCS Humanitas Research Hospital, Milan, Italy;* [2]*IRCCS Humanitas Research Hospital, Milan, Italy;* [3]*Fondazione IRCCS San Gerardo dei Tintori di Monza, Monza, Italy;* [4]*Department of Medicine and Surgery, University of Milano-Bicocca, Division of Gastroenterology, Center for Autoimmune Liver Diseases, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Monza, Italy;* [5]*Hepatology and Gastroenterology Unit, Grande Ospedale Metropolitano Niguarda, Milan, Italy*
Email: Vincenzo.ronca@hunimed.eu

Background and aims: Second-line therapies expanded treatment options for primary biliary cholangitis (PBC) patients who are non-responders to ursodeoxycholic acid (UDCA) and at risk of disease progression; however, regulatory approval has relied on biochemical surrogate endpoints rather than hard clinical outcomes. Outcome-based trials remain challenging due to slow disease progression and constraints on placebo use in the presence of approved therapies, highlighting the need for alternative evidence-generation frameworks. We aimed to generate and validate high-fidelity synthetic cohort of UDCA-treated PBC patients.
Method: A total of 1016 UDCA-treated PBC patients were derived from the Italian PBC retrospective registry. Demographics, laboratory test, comorbidities, and clinical outcomes were collected. A patented AI-based generative model was trained on baseline and follow-up variables to generate a synthetic cohort at a 1:1 ratio. Fidelity was assessed by comparing summary statistics, standardised mean differences (SMD), principal component analysis, distance- and correlation-based metrics, and a composite Clinical Synthetic Fidelity (CSF) score. Privacy protection was evaluated by the 5th percentile distance to closest record (DCR) and nearest neighbour distance ratio (NNDR). Biochemical trajectories were compared. Transplant-free survival according to UDCA response, defined by POISE criteria, was analysed in real and synthetic cohorts.
Results: The synthetic cohort closely reproduced baseline demographics and clinical features. Median age was 57 years (IQR 50–66) in both cohorts, with comparable sex distribution and laboratory values. Transplant-free survival curves and hazard separation between synthetic and real cohorts in UDCA responders and non-responders were preserved. All SMDs were <0.05, indicating good balance. Fidelity metrics were high (CSF 0.896; correlation score 0.945; numerical and categorical distance scores 0.878 and 0.886; PCA score 0.877). Privacy analyses showed similar 5th percentile DCR values for real–synthetic (6.02) and real–real (5.58) comparisons, with NNDR values of 0.896 and 0.857. Longitudinal biochemical trajectories overlapped over five years.
Conclusion: High-fidelity synthetic patient-level data accurately reproduce demographic, longitudinal biochemical, and outcome patterns in UDCA-treated PBC. Synthetic cohorts offer a scalable complement to traditional evidence generation, enabling external control arms and exploratory regulatory analyses in slow-progressing diseases.

SAT-394

Frequency of PFIC-associated genetic variants across different adult cholestatic phenotypes

Vivian Rotman[1], Andreia Evangelista[1], Aline Moura Ferraz Pereira[1], Cibele Franz[2], Luciana Agoglia[3], Renata Perez[1], Maria Chiara Chindamo[1]. [1]*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil;* [2]*UNIRIO, Rio de Janeiro, Brazil;* [3]*Federal Fluminense University, Rio de Janeiro, Brazil*
Email: vrotman@gmail.com

Background and aims: Progressive familial intrahepatic cholestasis (PFIC) comprises a group of autosomal recessive disorders caused by pathogenic variants in genes encoding bile acid transport proteins and may progress to advanced liver disease. In adults, PFIC-associated variants are often linked to milder phenotypes and are frequently identified in the heterozygous state, challenging the traditional view of strict recessive inheritance. Data on the prevalence and clinical impact of PFIC-related variants in Brazilian adults remain limited. This study aimed to describe the frequency of PFIC-associated genetic variants and the clinical and demographic characteristics of adults with cholestatic phenotypes.
Method: Adult patients evaluated for cholestatic liver disease underwent genetic analysis of 18 cholestasis-related genes using

next-generation sequencing (Illumina HiSeq 2500/4000) on buccal swab samples. Variants were classified according to ACMG criteria and HGVS nomenclature as pathogenic (P), likely pathogenic (LP), or variants of uncertain significance (VUS). Clinical, laboratory, and demographic data were retrospectively collected from medical records.
Results: Fifty-five patients were included: 64% female with mean age at symptom onset of 36.1 ± 14.5 years. Chronic cholestasis was the predominant clinical phenotype (87.3%), and cirrhosis at diagnosis was observed in 14.5% of patients. PFIC-associated variants were identified in 31 patients (56.4%), predominantly involving the *ABCB4* gene (93.5%). Among these, 22 variants occurred in simple heterozygosity (14 variants were classified as pathogenic, 3 as LP, and 5 as VUS) and 7 in compound heterozygosity (one patient carried VUS in both alleles, while six patients carried a VUS in one allele combined with another variant). *ABCB11* variants were identified in one patient (3.2%) in compound heterozygosity, and *CFTR* variants were also detected in only one patient (3.2%). Typical cholestatic symptoms were frequently observed among individuals carrying VUS.
Conclusion: *ABCB4* variants were highly prevalent among Brazilian adults with cholestatic liver disease. The predominance of simple heterozygosity supports the possibility of alternative inheritance mechanisms or the presence of undetected variants. The association between VUS and classical cholestatic manifestations suggests a potential for future reclassification of some of these variants as pathogenic.

SAT-395
Tacrolimus as second-line therapy in pediatric autoimmune hepatitis: remission and response outcomes in a single-center cohort
Saurabh Saurabh[1]. [1]*Ilbs Pharmacy, New Delhi, India*
Email: saurabh394@gmail.com

Background and aims: A subset of children with autoimmune hepatitis (AIH) remain refractory or intolerant to standard therapy with corticosteroids and azathioprine, constituting a difficult-to-treat phenotype. Evidence for calcineurin inhibitors in this population is limited. We evaluated the efficacy and safety of tacrolimus as second-line immunosuppression in pediatric AIH.
Method: A retrospective cohort of 16 children (age 3–18 years) with AIH (type 1/ 2 or seronegative) treated with tacrolimus were analyzed. Indications included incomplete biochemical response, azathioprine intolerance, or persistent disease activity despite optimized therapy. Tacrolimus dosing targeted trough levels of 4–8 ng/mL. Outcomes assessed were (i) biochemical remission (normal ALT and IgG), (ii) biochemical response (>50% improvement), time to remission, and (iii) adverse events. Median follow-up was 8 months.
Results: Of 16 children receiving tacrolimus, 7 (43.7%) achieved complete biochemical remission, with a median time to remission of 5 months. An additional 5 children (31.2%) demonstrated partial biochemical response. Overall, 12/16 (75%) showed meaningful biochemical improvement. Four children had minimal/no response. Among responders, corticosteroid tapering was feasible in the majority, with several achieving steroid minimization. Tacrolimus was generally well tolerated. Reported adverse events included mild tremors (n = 2), transient hypertension (n = 1), and reversible nephrotoxicity (n = 1).
Conclusion: Tacrolimus is an effective and safe second-line immunosuppressive option in pediatric AIH, achieving remission or substantial biochemical improvement in three-quarters of treated children. These findings support consideration of tacrolimus in difficult-to-treat pediatric AIH and highlight the need for multicenter prospective studies to standardize dosing and long-term surveillance.

Email: joern.schattenberg@uks.eu

Background and aims: Patients (pts) with primary biliary cholangitis (PBC) have a higher risk of osteoporosis and fractures. Elafibranor (ELA) demonstrated no negative impact on bone health through 52 weeks (wks) of the phase III ELATIVE® trial (NCT04526665). Here, data from the ongoing open-label extension (OLE) are presented.
Method: Data are reported for pts who completed the double-blind period (DBP) and continued daily ELA 80 mg into the OLE; baseline (BL) was defined as DBP start. Dual energy X-ray absorptiometry (DEXA), the gold standard for assessing bone mineral density (BMD), was used to measure the femoral neck, lumbar spine and total hip regions. Mean (standard deviation [SD]) change from BL (CfB) in BMD absolute values and T-scores are reported through Wk 182. Due to staggered OLE entry, data were pooled for Wk 104 and 130 (Wk 104|130) and Wk 156 and 182 (Wk 156|182). Bone fractures are reported from OLE start to data cut-off (DCO; May 2025).
Results: 93/108 (86.1%) pts continued ELA into the OLE; at BL, 87/93 (93.5%) were female, 34/93 (36.6%) had osteoporosis or osteopenia and mean (SD) age was 56.7 (8.3) years. At BL, mean (SD) femoral neck BMD absolute value was 0.79 g/cm^2 (0.15) which remained stable at Wk 52 (CfB: 0.00 g/cm^2 [0.05]), 104|130 (CfB: 0.00 g/cm^2 [0.03]) and 156|182 (CfB: −0.03 g/cm^2 [0.05]). Mean (SD) lumbar spine BMD absolute value at BL was 0.99 g/cm^2 (0.18); this was stable at Wk 52 (CfB: 0.00 g/cm^2 [0.04]), 104|130 (CfB: 0.00 g/cm^2 [0.05]) and 156|182 (CfB: −0.01 g/cm^2 [0.07]). Mean (SD) total hip BMD absolute value was 0.84 g/cm^2 (0.14) at BL and remained stable at Wk 52 (CfB: 0.00 g/cm^2 [0.04]), 104|130 (CfB: +0.01 g/cm^2 [0.03]) and 156|182 (CfB: +0.04 g/cm^2 [0.18]). Mean (SD) BMD T-scores at BL for femoral neck, lumbar spine and total hip regions were −1.36 (1.1), −1.24 (1.45) and −1.14 (1.16), respectively; these remained stable at Wk 52 (CfB: −0.04 [0.40]; −0.03 [0.49]; +0.03 [0.51]), 104|130 (CfB: −0.01 [0.29]; −0.11 [0.44]; +0.05 [0.36]) and 156|182 (CfB: −0.16 [0.70]; −0.06 [0.77]; +0.00 [0.64]). From OLE start to DCO, 9 fractures occurred in 8/93 (8.6%) pts; most fractures were associated with a fall (7/9 [77.8%]) or trauma (1/9 [11.1%]) and 7/8 (87.5%) pts had confounding factors.
Conclusion: After up to 3.5 years of ELA treatment, BMD remained stable in pts with PBC. Few pts experienced fractures, and most had confounding factors; the observed proportion was consistent with the expected rate in a PBC population, suggesting ELA has no negative impact on bone health.

Email: peter.schirmacher@med.uni-heidelberg.de

Background and aims: Norucholic acid (NCA) was recently shown to confer a significant benefit for patients with primary sclerosing cholangitis (PSC) in the NUC-5/PSC trial. This benefit was demonstrated using endpoints incorporating paired liver biopsies. Here, we present detailed results of histopathological evaluations conducted in the trial.
Method: The NUC-5/PSC trial compared 1500 mg NCA versus placebo (PBO) in patients with PSC over a 192-week double-blind phase, with the primary analysis performed at week 96. Biopsies were collected at screening as well as weeks 96 and 192 according to local procedures. Histological analyses were carried out at the primary analysis, with 201 patients having at least one screening and one post-baseline biopsy (NCA: 144, PBO: 57). Histological evaluation was performed centrally by hematoxylin and eosin and Sirius red staining as well as cytokeratin 7 immunohistochemistry. All biopsies were assessed centrally for multiple histological scores by two expert liver pathologists blinded to treatment allocation and biopsy sequence. Collagen proportionate area (CPA) was evaluated by semiquantitative digital pathology.
Results: Significantly more patients exhibited no worsening in histological disease stage with NCA than PBO as assessed by Ludwig staging (risk difference [RD] 20.7, $p < 0.001$), modified Nakanuma score (RD 16.8, $p = 0.006$), PSC histoscore (RD 16.7, $p = 0.006$), and Ishak staging (RD 18.9, $p = 0.002$). The treatment effect by no worsening in Ludwig stage was consistent across disease severity at baseline, as defined by baseline ALP levels (<2.5x ULN: RD 26.7; ≥2.5x ULN: RD 12.4), liver stiffness by Fibroscan (F0: RD 31.1; F4: 22.0), or Ludwig stage (stages 1+2: RD 22.1; stages 3+4: RD 20.1). Fibrosis as assessed by CPA increased with Ludwig stage: mean (±SD) CPA at baseline was 3.7% (±2.1%) in all patients with Ludwig stage 1, 5.7% (±2.8%) for Ludwig stage 2, 10.0% (±4.2%) for Ludwig stage 3, and 25.4% (±11.6%) for Ludwig stage 4. Mean CPA changed from 8.9% (±6.3%) at baseline to 8.0% (±6.8%) at week 96 among NCA patients compared with 7.8% (±6.7%) to 9.3% (±8.7%) among placebo patients with evaluable biopsies at both time points.
Conclusion: Detailed histological analyses revealed significant antifibrotic treatment effects of NCA in PSC, which were consistent across all different staging systems and degrees of baseline disease severity. In line with staging results, CPA analysis by digital pathology confirmed positive effects of NCA on liver fibrosis.

SAT-398

The burden of fatigue in primary sclerosing cholangitis: results from the WIND-PSC prospective cohort

Christoph Schramm[1], Gideon M. Hirschfield[2], Christopher L. Bowlus[3], Brian Thorsen[4], Bettina E. Hansen[5], Mary Vyas[6], Kidist Yimam[7], Daniel Pratt[8], Craig Lammert[9], Sayed Obaidullah Aseem[10], Aldo J Montano-Loza[11], Michael Li[12], Zuha Jeddy[4], Sammantha Fuller[13], Julia Van Dyke[13], Stephen Rossi[4], Cynthia Levy[14].
[1]UKE - University Medical Center Hamburg-Eppendorf, Department of Medicine, Hamburg, Germany; [2]University of Toronto - UHN, Autoimmune and Rare Liver Disease Programme, Toronto, Canada; [3]University of California at Davis, Department of Medicine, Sacramento, United States; [4]PSC Partners Seeking a Cure, Greenwood Village, United States; [5]Erasmus University Medical Center, Erasmus, Netherlands; [6]PSC Partners Seeking A Cure - Canada, Toronto, Canada; [7]California Pacific Medical Center, Division of General and Transplant Hepatology, San Francisco, United States; [8]Massachusetts General Hospital, Autoimmune and Cholestatic Liver Center, Boston, United States; [9]Indiana University, Department of Medicine, Indianapolis, United States; [10]Virginia Commonwealth University, Department of Medicine, Richmond, United States; [11]University of Alberta, Department of Medicine, Edmonton, Canada; [12]University of California at San Francisco, Department of Medicine, San Francisco, United States; [13]Arbor Research Collaborative For Health, Ann Arbor, United States; [14]University of Miami, Department of Medicine, Miami, United States
Email: clevy@med.miami.edu

Background and aims: Fatigue is a burdensome but poorly understood symptom of primary sclerosing cholangitis (PSC) that significantly impacts quality of life. Data on its persistence and relationship to other symptoms is lacking. WIND-PSC is a global prospective observational study evaluating clinical outcomes, biomarkers and symptom burden in adults with PSC. We report an interim analysis on the incidence, severity, and persistence of fatigue and its correlation to other symptoms.
Method: Adult patients with large duct PSC were prospectively enrolled at 9 sites in North America and Europe. A patient-reported categorical symptom screening tool assessing the frequency, severity and persistence of abdominal pain, anxiety, brain fog, fatigue, insomnia, liver pain, nausea, and pruritus is administered at baseline and every 12 weeks. Evaluation criteria required baseline and a Week 12 and/or 24 assessment.
Results: A total of 261 patients met symptom screening criteria with patient demographics and disease characteristics consistent with other PSC cohorts. Cirrhosis was present in 12% of patients based on a liver stiffness measurement (LSM) >15 kPa and clinical data. Fatigue was the most prevalent symptom at baseline (75%) with severe and frequent/constant symptoms in 18% and 29%, respectively. Other less frequent symptoms were insomnia (62%), anxiety (58%), brain fog (46%), abdominal pain (46%), pruritus (44%), liver pain (36%), and nausea (27%). Most patients had ≥ 2 symptoms at baseline (69%) and only 12% reporting no symptoms. Presence and severity of fatigue at baseline was most strongly correlated (r_S) with insomnia (0.58) followed by brain fog (0.52) and abdominal pain (0.50). Fatigue was not associated with LSM, IBD status, duration of PSC, or any patient demographics. At Week 24, fatigue persisted for 31%, worsened for 13%, newly emerged for 12%, remained absent for 13%, improved for 14%, and resolved for 11% of patients. Change in fatigue at Week 24 was moderately associated with directional change or persistence in brain fog ($p < 0.001$), anxiety ($p < 0.05$), insomnia ($p < 0.05$), and abdominal pain ($p < 0.05$), and aligned with the associations at baseline.
Conclusion: Fatigue is a frequent but poorly understood symptom in people with PSC, independent of disease stage or demographics and linked to the presence and persistence of other symptoms. These data support further studies to understand the factors leading to the occurrence and persistence of fatigue and its impact on health-related quality of life.

SAT-399

Anti-HK1 and Anti-KLHL12 antibodies in primary biliary cholangitis: diagnostic relevance but no prognostic impact

Mirjam Kolev[1], Basil Ummel[1], Henning Nilius[2], Florian Kollert[3], Michael Mahler[4], Gary Norman[5], Chelsea Bentow[4], Michael Horn[2], Michael Nagler[2], Nasser Semmo[1]. *[1]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Switzerland, Bern, Switzerland; [2]Department of Clinical Chemistry, Inselspital, Bern University Hospital, University of Bern, Switzerland, Bern, Switzerland; [3]Department of Rheumatology and Immunology, Bern University Hospital, University of Bern, Switzerland, Bern, Switzerland; [4]Research and Development, Autoimmunity, Werfen, San Diego, CA, USA, San Diego, United States; [5]Research and Development, Autoimmunity, Werfen, San Diego, CA, San Diego, United States*
Email: mirjam.kolev@insel.ch

Background and aims: Novel antibodies against hexokinase 1 (HK1) and kelch-like 12 (KLHL12) have been proposed as highly specific diagnostic markers for primary biliary cholangitis (PBC) and as potential prognostic indicators. We aimed to assess their diagnostic and prognostic value in a contemporary PBC cohort.
Method: In this retrospective single-center cohort study, 96 PBC patients and 269 non-PBC controls underwent extended serological profiling, including anti-MIT3 (M2), anti-gp210, anti-sp100, anti-HK1, and anti-KLHL12. Diagnostic performance was evaluated using receiver operating characteristic (ROC) curves and area under the curve (AUC) analysis. Transplant-free survival was analyzed with Kaplan–Meier estimates and Cox regression.
Results: Among the 96 PBC patients, 84% were female, with a median age of 56 years (IQR 45.5–65). Median follow-up was 8.3 years (IQR 4.3–12.3). Anti-HK1 and anti-KLHL12 antibodies were detected in 50.0% and 21.9% of patients, respectively. Established markers were positive in 86.5% (anti-MIT3), 19.5% (anti-gp210), and 24% (anti-sp100). Anti-MIT3 alone showed a sensitivity of 86.5% (95% CI, 78.0–92.6%) and specificity of 94.3% (95% CI, 88.1–97.9%). Considering all antibodies together, sensitivity increased to 91.7% (95% CI, 84.2–96.3%) with a modest decrease in specificity to 90.6% (95% CI, 83.3–95.4%). Fifteen patients either died from liver-related events or underwent transplantation. No statistically significant differences in transplant-free survival were observed for anti-HK1, anti-KLHL12, anti-gp210, or anti-sp100 positivity (all $p > 0.05$).
Conclusion: Anti-HK1 and anti-KLHL12 antibodies are common in PBC and provide complementary diagnostic information when added to established serological markers, modestly improving overall sensitivity. However, they were not associated with transplant-free survival, indicating their primary utility is diagnostic rather than prognostic in contemporary PBC patients.

Goldin[3], Pierre Allaume[2], Julien Calderaro[1], Vincent Leroy[1]. *[1]Hôpitaux Universitaires Henri Mondor, Paris-Est Créteil University, Medicine, Créteil, France, Inserm, U955, Team 18, Créteil, France, Créteil, France; [2]Chu Pontchaillou Rennes, Rennes, France; [3]Imperial College of Science Technology & Medicine, St Mary's Hospital, London, United Kingdom; [4]Hôpital Saint-Antoine Ap-Hp Par Chartier Dalix, University of Pisa, Paris, France; [5]Saint Mary's Hospital, London, United Kingdom; [6]Hôpital Civil, Strasbourg, France; [7]Hôpital Avicenne, Bobigny, France; [8]Azienda Ospedaliera Careggi, Firenze, Italy; [9]Azienda Ospedaliero Universitaria Careggi, Firenze, Italy; [10]Clinica Universidad de Navarra, Pamplona, Spain; [11]Faculté de Santé-Upec, Créteil, France*
Email: asessa1990@gmail.com

Background and aims: Lack of treatment response and cirrhosis are associated with hepatic events in autoimmune hepatitis (AIH), yet predictors of treatment failure available at diagnosis remain poorly defined. We aimed to identify baseline predictors of treatment failure in a large multicenter AIH cohort and to externally validate a simple risk stratification.
Method: This retrospective longitudinal study included a training cohort of 351 consecutive patients with AIH and liver biopsy at diagnosis with at least 1 year of follow up treated in 4 French, 1 Italian, and 1 Spanish tertiary centers (2010–2023). An external validation cohort comprised 65 UK patients (2012–2024). Complete biochemical response (CRB) was defined according to EASL guidelines. Candidate predictors were restricted to baseline variables and selected using LASSO. A simple clinical risk score was derived in the training cohort and applied to the validation cohort.
Results: Training and validation cohorts were comparable for age (54 years in both), gender (68% and 78% female), prevalence of cirrhosis (28% and 31%) and treatment regimens (azathioprine + corticoids 88 vs 79%). Compared with the training cohort, UK patients had significantly lower ALT levels (232 vs 495.5 IU/L, $p = 0.001$) and higher IgG levels (25 vs 20 g/L, $p = 0.008$). CBR within one year was achieved in 76% and 81% of patients, while refractory disease occurred in 10% and 9%, respectively. IgG levels and cirrhosis emerged as the main predictors of treatment failure, defining three baseline risk groups: low (IgG <25.9 g/L), intermediate (IgG ≥ 25.9 g/L without cirrhosis), and high risk (IgG ≥25.9 g/L with cirrhosis). In the validation cohort, response rates decreased stepwise across risk groups (88%, 81%, and 64%), mirroring the pattern observed in the training cohort (85%, 63%, and 47%). High-risk patients had reduced odds of response (OR 0.26, 95% CI 0.05–1.17) and increased odds of refractory disease (OR 3.54, 95% CI 0.59–21.21). When used to identify treatment failure, the score demonstrated a specificity of 78% in the validation cohort (89% in the training cohort), a sensitivity of 50% (vs 35%), and a high negative predictive value (94% vs 92%). Incorporating early ALT response status into the baseline score did not improve discrimination.
Conclusion: A simple baseline IgG–cirrhosis score provides reproducible stratification of treatment failure risk in AIH and may have clinical utility for individualized therapeutic strategies.

SAT-401-YI
Early real-world experiences of Elafibranor in primary biliary cholangitis (PBC)
Charlotte Sewell[1,2], Nadir Abbas[2], Diane Lloyd Madden[2], Ahmed M Elsharkawy[2], Amanda Smith[2], James Ferguson[2], Palak Trivedi[1,2]. *[1]University of Birmingham, Birmingham, United Kingdom; [2]Liver Unit, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*
Email: charlottesewell@nhs.net

Background and aims: Elafibranor (Ela), a next-generation peroxisome proliferator-activated receptor (PPAR) alpha/delta agonist, was approved for the treatment of PBC in 2024. Herein, we evaluate early real-world experiences in using Ela as a second-, third-, or fourth-line treatment for PBC.
Method: The effectiveness, safety and tolerability of Ela was evaluated in patients (pts) initiating therapy in combination with ursodeoxycholic acid (UDCA), obeticholic acid (OCA), and amongst those switching from bezafibrate (BZF).
Results: From Dec 2024 to Nov 2025, 54 pts initiated Ela (49 women, median age 57y, median transient elastography score 11.5 kPa). 18 pts had cirrhosis, 47 continued UDCA, 16 combined Ela with OCA and 29 switched from BZF to Ela. To date, n = 45, 33 and 17 have completed 1-, 3- and 6-months follow-up, respectively. 8, 4, and 2 pts discontinued Ela at the same timepoints, principally for gastrointestinal side effects (n = 7). However, 5 pts were able to restart later. In pts continuing Ela, median alkaline phosphatase (ALP) decreased from 2.47x upper limit of normal (ULN) at baseline, to 1.64x, 1.49x and 1.36x ULN at 1, 3 and 6 months respectively ($p < 0.0001$), with 2, 4 and 3 pts attaining normal ALP at the same points. Alanine aminotransferase (ALT) decreased from 0.99x ULN at baseline, to 0.87x, 0.80x and 0.84x ULN at 1,3 and 6 months ($p < 0.03$). Bilirubin was 0.62x ULN at baseline and remained stable at 1, 3 and 6 months. Pts on Ela without OCA showed similar reductions in ALP (from 2.94x ULN at baseline to 1.65x, 1.50x, and 1.32x ULN at 1, 3, and 6 months; $p < 0.001$) to the Ela + OCA group (ALP lowered from 1.88x ULN to 1.44x ULN at 1 month and 1.2x ULN at 3 months; $p < 0.02$). In pts who switched to Ela from BZF, ALP decreased from 2.68x ULN to 1.68x, 1.21x and 1.94x ULN at 1, 3 and 6 months ($p < 0.008$). ALP reductions were similar to those with no prior BZF exposure (2.26x ULN at baseline to 1.65x, 1.50x and 1.15x ULN at 1, 3 and 6 months; $p < 0.008$). No significant reductions in ALT

were observed in the sub-group of pts on Ela+OCA combination therapy, nor in those with prior BZF exposure. In all, n = 21/40 pts with pruritus at baseline reported improvement, 11 no change, and 4 worsening of itch. 24 pts who switched from BZF reported pruritus at baseline, and 12 reported improvement on Ela.
Conclusion: Treatment with Ela in real-world PBC settings is associated with early biochemical and symptomatic improvement, including in pts previously treated with BZF, and in combination with OCA.

SAT-402

MSC-mediated modulation of the IL-4/CD39 Axis in treg cells restores immune tolerance and improves treatment outcomes in steroid-resistant autoimmune hepatitis

Wanwan Shi[1]. [1]*Peking University First Hospital, Beijing, China*
Email: wanwanshi198@163.com

Background and aims: Autoimmune hepatitis (AIH) is an immune-mediated liver disease that poses significant challenges in treatment, particularly for patients who are steroid-resistant. Recent studies have highlighted that reduced CD39 expression on Treg cells, leading to impaired immunosuppressive function, is one of the key pathogenic mechanisms in AIH. Mesenchymal stem cells (MSCs) has demonstrated promising results in treating immune-related diseases. This study aims to explore the role of MSCs in restoring Treg cell function by modulating the IL-4/CD39 axis, providing a novel therapeutic strategy for steroid-resistant AIH patients.
Method: We assessed the expression of IL-4 in peripheral blood mononuclear cells from steroid-resistant AIH patients using flow cytometry, and investigated the correlation between IL-4 expression and CD39 in Treg cells. Additionally, immunofluorescence staining was performed to examine the distribution of CD39 and IL-4 in liver tissue from these patients. To investigate the causal relationship between IL-4 and AIH susceptibility, we conducted a two-sample Mendelian randomization (MR) analysis. Furthermore, we evaluated the therapeutic effects of MSCs in a ConA-induced AIH mouse model by measuring liver injury biomarkers, immunoglobulin levels, and Treg cell subtypes and function, with a focus on the regulation of the IL-4/CD39 axis.
Results: In PBMCs from steroid-resistant AIH patients, we observed significantly elevated IL-4 levels ($P < 0.01$), which correlated negatively with CD39 expression on Treg cells ($R = -0.42$, $P = 0.02$). MR analysis confirmed a significant causal relationship between IL-4 and AIH susceptibility. The analysis using the Inverse Variance Weighted method showed statistical significance (OR = 1.459027, 95% CI: 1.006–2.115, $P = 0.046$) suggesting that IL-4 may increase the risk of AIH. These findings demonstrate a critical link between IL-4, CD39 deficiency, and impaired immune suppression in Treg cells. In AIH mouse models, MSC treatment significantly reduced ALT, AST, and IgG levels ($P < 0.0001$), indicating effective immunoregulation. MSC treatment also significantly increased the proportion of Treg cells, restored CD39 expression and decreased IL-4 expression, suggesting that MSCs restore Tregs function by modulating the IL-4/CD39 axis.
Conclusion: Our findings demonstrate that MSCs can modulate the IL-4/CD39 axis in Treg cells to restore immune tolerance for AIH. This approach represents a novel strategy for treating autoimmune liver diseases.

SAT-403

Analysis of structured and unstructured data from a large electronic health record system identifies frequent pruritus and fatigue in patients with PSC

Anthony Perez[1], Ashley Jaksa[1], Sarah Sidhu[2], Douglas B. Mogul[2], Shannon Vandriel[2], April LaRow[2], Michael Fried[1]. [1]*Target RWE, Durham, North Carolina, United States;* [2]*Mirum Pharmaceuticals, Inc., Foster City, California, United States*
Email: sarah.sidhu@mirumpharma.com

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease featuring bile duct strictures that lead to hepatic injury, cirrhosis, and liver failure. Pruritus and fatigue may occur, but reported prevalence varies widely across studies. We used large electronic health record (EHR) databases, TARGET-LD and TARGET-GASTRO, with over 800,000 patients with liver and gastrointestinal disease that contain both structured and unstructured data to assess dataset robustness and frequency of patient-reported pruritus and fatigue in PSC patients.
Method: PSC patients were identified in TARGET-LD/GASTRO using ICD-10 K83.0. Baseline characteristics, amount of liver enzyme results [alanine aminotransferase (ALT); aspartate aminotransferase (AST); alkaline phosphatase (ALP)], MRCP testing, and diagnoses of pruritus and fatigue were described. For a subset of patients who had unstructured data available (i.e., provider notes), we evaluated the EHR text for positive mentions of pruritus, fatigue, and MRCP testing, using a purpose-built natural language processing (NLP) system to improve prevalence estimates relative to traditional code-based enumeration alone.
Results: We identified a cohort of 3958 PSC patients. Patients had mean age of 54 years at first PSC ICD-10 code and 53% were male. In both the inpatient and outpatient setting, more than 2600 patients (>66%) had at least one lab result for each major liver enzyme (ALT, AST and ALP). Over a third of patients had >4 outpatient lab values for ALT (33.5%, n = 1326), AST (33.7%, n = 1332), and ALP (38.5%, n = 1523). A subgroup of 1427 patients had additional available unstructured data. In this subgroup, structured data identified MRCP in less than half of patients (41%, n = 594), while inclusion of unstructured data revealed twice as many (82%, n = 1080). Structured data rarely identified pruritus (17%, n = 235) and fatigue (20%, n = 216), though frequency was greater with the addition of unstructured data for both pruritus (53%, n = 758) and fatigue (66%, n = 944).
Conclusion: We identified one of the largest reported US EHR datasets of PSC patients with robust data on laboratory values and imaging. While pruritus and fatigue were infrequently coded, additional analysis of unstructured data markedly increased their identification and indicate these are important, prevalent symptoms in PSC. Use of both structured and unstructured elements may provide a new opportunity to understand the natural history of this rare disease.

SAT-404

Concomitant metabolic-dysfunction associated steatotic liver disease in primary biliary cholangitis: no adverse liver outcomes but increased cardiovascular risk in a large real-world cohort

Jarell Jie-Rae Tan[1], Ellina Lytvyak[2], Shao Wei Sean Lam[3], Aldo J Montano-Loza[2], Yu Jun Wong[1,3]. [1]*Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, Singapore;* [2]*Division of Gastroenterology and Hepatology, University of Alberta, Edmonton, Canada, Edmonton, Canada;* [3]*Duke-NUS Medical School, Singapore, Singapore, Singapore*
Email: wongyujun1985@gmail.com

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly prevalent among patients with primary biliary cholangitis (PBC), but it's impact on long-term clinical outcomes remains unclear. We evaluated whether concomitant MASLD modifies clinical outcomes in PBC.
Method: We performed a retrospective nationwide cohort study using TriNetX (deidentified, patient-level, electronic health records from >110 US healthcare organizations). MASLD was defined as hepatic steatosis plus ≥1 cardiometabolic risk factor. Patients with other chronic liver diseases were excluded. Adults with PBC were classified as PBC-MASLD or PBC alone, and propensity-matched (1:1) on demographics, cirrhosis, ALP, and metabolic comorbidities. Secondary analysis evaluated MASLD patients with new onset of PBC. Outcomes were assessed using time-to-event analyses. Biochemical response was defined as ALP normalization at 1-year.

Primary outcome was hepatic decompensation (HD); secondary outcomes included major adverse cardiovascular events (MACE), liver transplantation (LT), HCC, and all-cause mortality.
Results: Among 3711 PBC patients (86.3% female; mean age 60.6 ± 15 years), 1327 (35.8%) had concomitant MASLD. After matching, 1216 PBC patients were included per group with good balance across matched variables (SMD < 0.10). Over an average follow-up of 4.1 years, PBC-MASLD was not associated with increased risk of HD (HR 1.02, 95%CI: 0.77–1.36), LT, and HCC. Results were consistent in landmark analyses excluding early events. In contrast, PBC-MASLD had a significantly higher risk of MACE than PBC alone (HR 1.31, 95% CI: 1.05–1.63, p = 0.018). ALP normalization at 1-year was more common in PBC-MASLD than PBC alone (55.8% vs 43.8%, p < 0.01). All-cause mortality was higher in PBC/MASLD despite comparable liver-specific outcomes (HR 1.64, 95%CI 1.31–2.05). These findings were consistent in sensitivity analyses that excluded patients without cardiometabolic risk factors and those with a high cardiometabolic burden. In MASLD patients with new-onset PBC, risks of HD and MACE were similar to those of MASLD alone.
Conclusion: Concomitant MASLD did not worsen liver-related outcomes in PBC but was associated with higher cardiovascular risk and poorer survival, challenging the assumption that PBC-MASLD is clinically benign. This suggests excess risk in PBC-MASLD is driven by cardiometabolic disease rather than liver progression, highlighting the need for integrated cardiovascular risk assessment and management.

SAT-409-YI
The burden of cholangiocarcinoma in primary sclerosing cholangitis: a high-volume north american transplant and hepatobiliary surgical center perspective
Natassia Tan[1,2], Robert Grant[3], Jennifer Knox[3], Chaya Shwaartz[4,5], Arndt Vogel[2,3], Ian Mcgilvray[4,5], Laura Dawson[6], Trevor Reichman[4,5], Gonzalo Sapisochin[7], Aruz Mesci[6], Nazia Selzner[5], Gideon M. Hirschfield[1,2], Aliya Gulamhusein[1,2]. *[1]The Autoimmune and Rare Liver Disease Programme, Toronto General Hospital, University Health Network, Toronto, Canada; [2]Toronto Centre for Liver Disease, Toronto, Canada; [3]Princess Margaret Cancer Centre, Toronto, Canada; [4]Division of General Surgery, Toronto General Hospital, Toronto, Canada; [5]Ajmera Transplant Center, University Health Network, Toronto, Canada; [6]Department of Radiation Oncology, Princess Margaret Cancer Centre, University Health Network, Toronto, Canada; [7]Department of General and Abdominal Surgery, Vall d'Hebron University Hospital, Barcelona, Spain*
Email: natassiapinpintan@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is associated with a high burden of cholangiocarcinoma (CCA). Optimal management of PSC-CCA is challenging due to strict eligibility criteria of protocols for liver transplant (LT) and risks associated with extensive surgery and/or immunochemotherapy in patients (pts) with significant hepatobiliary (HB) disease. Herein, we describe the management of PSC-CCA in a high-volume PSC, HB, and LT center.
Method: We conducted a single-center retrospective study of all pts with PSC-CCA followed at the University Health Network between January 1st, 2000, to December 31st, 2024.
Results: Of 881 pts with PSC, 54 cases (6%) of PSC-CCA were identified, the majority male (n = 35, 64.8%). Median age of diagnosis of PSC was 38 (IQR 30–47) years (yrs) and 48 (IQR 39–59) yrs for CCA. Perihilar CCA (pCCA) was most common (n = 20, 37%), followed by intrahepatic CCA (iCCA) (n = 17, 31.4%), and distal CCA (dCCA) (n = 8, 14.8%). 40% (8/20) pts were enrolled in the Mayo protocol for LT-pCCA, 50% dropped out due to progressive disease and 50% had LT, one with subsequent Whipple for positive margins. 25% (5/20) of pts with pCCA ineligible for LT had primary resection with adjuvant capecitabine (80%) – with 75% 3-yr overall survival (OS). 50% (10/20) were ineligible for surgery and managed with palliative chemotherapy (CT) (60%) or supportively (40%) with 54% 1-yr and 27% 3-yr OS. Of those with PSC-iCCA, 17.6% (3/17) were managed with LT, 1 with mixed CCA-hepatocellular carcinoma as standard of care, 1 with iCCA <2 cm pre-LT, and 1 with multifocal CCA stable on neoadjuvant CT. 41% (7/17) pts with iCCA had a primary resection with neoadjuvant and/or adjuvant CT with 100% 1-yr OS and 50% 2-yr OS. 35.2% (6/17) pts with iCCA were ineligible for surgical intervention and managed with palliative CT (50%) or supportively (50%) with 55% 1-yr OS. Of the 7 pts with CCA that had LT, median follow up was 1.7 yrs (IQR 1–2.4), with 42% 5-year OS. All pts with dCCA had a Whipple procedure and adjuvant CT, with 75% 1-yr and 37.5% 5-yr OS. In the entire cohort, 29 (53.7%) pts died with 31.1% 5-yr OS after CCA diagnosis.
Conclusion: PSC-CCA carries a dismal prognosis yet selected pts may benefit from aggressive surgical intervention, though management remains heterogeneous even in high volume centers. Optimizing outcomes relies on early diagnosis, incorporation of molecular profiling, and expanding oncologic indications for LT, all on a backbone of multidisciplinary management of these complex pts.

Hirschfield[9], Trine Folseraas[2,3,5], Lei Ling[10], Johannes R. Hov[2,3,5,8], Morten Karsdal[4], Tom Hemming Karlsen[2,3,5,8], Mette Vesterhus[3,6,11], Kristin Kaasen Jørgensen[1,2,3]. *[1]Dept. of Gastroenterology, Akershus University Hospital, Lørenskog, Norway; [2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [3]Norwegian PSC Research Center, Department of Transplantation Medicine, Oslo University Hospital, Oslo, Norway; [4]Nordic Bioscience AS, Herlev, Denmark; [5]Section of Gastroenterology, Department of Transplantation Medicine, Oslo University Hospital, Oslo, Norway; [6]Dept. of Medicine, Haraldsplass Deaconess Hospital, Bergen, Norway; [7]Norwegian PSC Research Center, Department of Transplantation Medicine, Oslo, Norway; [8]Research Institute of Internal Medicine, Division og Surgery and Specialized Medicine, Oslo University Hospital, Oslo, Norway; [9]The Autoimmune and Rare Liver Disease Programme, Division of Gastroenterology and Hepatology, Toronto General Hospital, Toronto, Canada; [10]NGM Biopharmaceuticals, South San Francisco, United States; [11]Department of Clinical Science, Haraldsplass Deaconess Hospital, University of Bergen, Bergen, Norway*
Email: ushanaresh@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) lacks dynamic biomarkers suitable for short-term evaluation of disease activity. Procollagen type III N-terminal (PRO-C3) reflects active fibrogenesis. This study aimed to estimate the biological variability of PRO-C3 in PSC and its association with relevant clinical outcomes.
Method: The biological variability of PRO-C3 in PSC was assessed in the placebo group (n = 20) of a phase II clinical trial with 7 repeated measurements obtained over 16 weeks[1]. The associations between PRO-C3 and hepatic decompensation and liver transplantation-free survival were evaluated in an observational, cross-sectional PSC cohort (n = 235). Competing risk regression and Cox proportional hazard models with a linear spline were used to identify a threshold of PRO-C3 and to estimate the linear association with clinical outcomes. Absolute risk predictions were estimated for 1-, 2- and 4-year horizons.
Results: The intraindividual coefficient of variation of PRO-C3 was 13.8%, with an intraclass correlation of 0.88. In the observational PSC cohort, the median (IQR) follow-up time was 5 (2–12) years, and baseline alkaline phosphatase and PRO-C3 were 221 (126–364) U/L and 55.2 (40.5–79.6) ng/mL, respectively. Patients in the highest PRO-C3 tertile (>69.7 ng/mL, (n = 78)) had increased subdistribution hazard of hepatic decompensation (sHR 4.11 95% CI 1.33–11.4) and

hazard of liver transplantation or death (HR 2.71, 95% CI 1.69–4.36) compared with the lowest tertile (<45.4 ng/mL, (n = 78)). Above an identified threshold value of 42 ng/mL, each doubling of PRO-C3 was associated with a two-fold increase in the hazard of liver transplantation or death (HR 2.07 95% CI 1.62–2.65). SIMEX correction confirmed the robustness of the threshold and the effect estimate. A two-fold increase in PRO-C3 above 42 ng/mL was associated with a 1.92-, 1.88-, and 1.78-fold risk of liver transplantation or death at 1-, 2, and 4- years, respectively. Model discrimination was moderate across all time horizons (AUROC 0.70–0.71).
Conclusion: PRO-C3 has low biological variability over time in people with PSC. Higher PRO-C3 levels is associated with increased risk of hepatic decompensation and liver transplantation or death, with a linear relationship with the latter endpoint among individuals with PRO-C3 > 42 ng/mL. PRO-C3 may serve as a candidate prognostic biomarker and therapeutic trial endpoint in PSC.

Long-term outcome of autoimmune hepatitis: complications, cancer risk and survival in a large nationwide swedish cohort

Richard Thörn[1], Mårten Werner[1], Jonas Wixner[1]. [1]*Umeå University, Department of Public Health and Clinical Medicine, Norrland University Hospital, Umeå, Sweden*
Email: richard.thorn@regionvasterbotten.se

Background and aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease that can lead to end-stage liver disease if untreated. Long-term data on prognosis and risk of AIH-related complications such as hepatic and extrahepatic cancer remain limited. This study aimed to investigate long-term outcome of AIH, focusing on survival, cause of death and cancer risk.
Method: A nationwide cohort of AIH patients linked to all Swedish university hospitals has been established by the national hepatologist collaboration SweHep. Data from this cohort was used in our study and supplemented with data from the Swedish Cause of Death and the National Cancer Registers. Outcomes were compared to a matched Swedish reference population and relative survival (RS) and standardised incidence ratios (SIR) were calculated.
Results: The cohort comprised 1086 patients (24.4% male) with a follow-up time of 18,091 patient-years. Cirrhosis was found in 21.7% at diagnosis and in 35.5% overall by the end of follow-up. The most common causes of death were cancer (29.8%), liver disease (24.4%) and cardiovascular disease (15.4%). Liver disease was a significantly less common cause of death among patients without cirrhosis (8.2%, $p < 0.001$). A slight, yet significant, reduction in RS was observed after 5 years of disease duration. After 12 years, a steeper decline in RS emerged, reaching 50% after 36 years. The SIR for any cancer was 2.60 (95% CI 2.34–2.88), significantly higher in men. Thirty-three patients (3.0%) developed HCC, the vast majority having cirrhosis. The SIR for hepatobiliary cancer among cirrhotic patients was 24.39 (95% CI 16.44–34.57). The annual incidence of HCC in patients with cirrhosis was 0.56%. Among patients who progressed to cirrhosis during follow-up, 12.1% eventually developed HCC (SIR 93.98; 95% CI 57.8–142.79), compared with 5.1% of patients with cirrhosis at AIH diagnosis ($p = 0.013$).
Conclusion: Patients with AIH showed reduced survival, which became more evident after the first decade of disease. Cancer was the most common cause of death and there was an increased overall risk of malignancy, especially in men. The risk of HCC was increased compared to the general population, particularly in patients with cirrhosis, but the risk was notably lower than in other chronic liver diseases. Thus, HCC surveillance might not be cost effective in all patients with AIH cirrhosis, but rather in those with disease progression despite immunosuppressive treatment.

SAT-412

Acute cholangitis in primary sclerosing cholangitis: profile classification of patient-reported symptom burdens predicts recovery from cholangitis episodes

Brian Thorsen[1], Martine Walmsley[2], Mary Vyas[3], Mark Chatterley[2], Stephen Rossi[1]. [1]*PSC Partners Seeking a Cure, Greenwood Village, CO, United States;* [2]*PSC Support, Manchester, United Kingdom;* [3]*PSC Partners Seeking a Cure Canada, Toronto, Canada*
Email: brian@pscpartners.org

Background and aims: Acute cholangitis (AC) is a significant complication in patients living with primary sclerosing cholangitis (PSC). Previous data showed a significant and highly variable symptom burden during AC. We aim to identify patterns in symptom presentation which may link to patient characteristics and post-AC recovery.
Method: A de-identified survey was distributed to adults with PSC and ≥1 AC episode by PSC Partners Patient Registry and PSC Support. Patient characteristics, AC symptom frequency, severity, and change during the latest AC episode, and medical interventions were collected. Symptom profile classes (SPCs) were developed by latent class analysis (LCA) based on severity of AC symptoms, such as liver pain, fatigue, pruritus, fever, nausea, jaundice, anxiety, and depression. SPCs were analyzed for categorical associations with clinical and demographic variables, interventions, and patient-reported recovery after AC.
Results: A total of 564 responses met screening criteria. Clinical characteristics are consistent with other cohorts, except for 45% male. All AC symptoms had >50% prevalence except jaundice (43%) and vomiting (40%), with highest prevalence of fatigue (90%) and liver pain (84%). Three SPCs were identified by LCA and interpretability, labeled as Low, Medium, and High, each containing 25%, 45%, and 30% of patients. Most symptoms had increasing incidence and severity across SPC. The High SPC had the greatest incidence and severity in all symptoms: 100% with moderate/severe fatigue and >75% with moderate/severe liver pain, fever, nausea, anorexia, and insomnia. The Low SPC had mostly lower incidence, including 12% with brain fog vs. 66% and 92% in Medium and High. However, the Low SPC had higher rates of severe liver pain, fever, nausea, and vomiting than the Medium SPC (all $p < 0.05$). Full recovery to baseline health after AC was strongly associated with SPC (Low: 90%, Medium: 76%, High: 52%, $p < 0.001$). Longer recoveries were associated with higher SPC ($p < 0.001$). Antibiotic use was weakly associated with SPC ($p = 0.03$). Women were more likely to be in the High SPC vs. the Low SPC ($p = 0.002$). No other demographics were associated with SPC. The SPC model shows fever and nausea alone during AC indicate a milder or treatable case of AC and a likely full recovery.
Conclusion: There is an overall gradient of symptom burden in AC, and higher burdens have worse recovery. Fatigue, liver pain, fever, nausea, and brain fog are key symptoms to understand the symptom burden of AC.

SAT-413

Natural history of primary biliary cholangitis in Alberta: province-wide registry data on treatment uptake, biochemical response, liver transplantation, and survival

Bryce Tkachuk[1], Aldo J Montano-Loza[2], Abdel-Aziz Shaheen[1]. [1]*University of Calgary, Calgary, Canada;* [2]*University of Alberta, Edmonton, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: Population-based audits have described primary biliary cholangitis (PBC) management and outcomes, but registry-wide Canadian data are limited. We characterized incident PBC in Alberta, including ursodeoxycholic acid (UDCA) use, biochemical response across published criteria, liver transplantation, and survival.
Method: A validated case-finding algorithm identified 3250 adults with a PBC diagnostic code; charts were reviewed to confirm PBC.

Incident cases from 2005 to 2022 were linked to provincial laboratory and administrative datasets. The reference date was the index date. Baseline and 12-month laboratory results (ALP, bilirubin, AST, GGT, albumin, platelets), AMA status, biopsy results, UDCA prescriptions, and biochemical response (Rochester, Barcelona, Paris I/II, Rotterdam, Toronto, Ehime) were extracted. age-sex adjusted Cox models were used to assess survival.

Results: Patients were predominantly women (1291/1470; 88%) with median age 58 years (IQR 50–67). UDCA was prescribed in 1397 (95%), 61 (4.1%) had liver transplantation, and 278 (18.9%) died during follow-up. Median baseline ALP was 202 U/L (IQR 139–330), bilirubin 10 µmol/L (7–16), AST 49 U/L (32–78), and GGT 209 U/L (99–456). AMA was positive in 87.8%, negative in 8.9%, and unavailable in 3.3%. Biopsy was performed in 559 (38%); among AMA-negative biopsied cases, 86/90 (96%) showed histologic findings of PBC. Biochemical response rates after at least one year of UDCA treatment were Rochester 82%, Barcelona 62%, Paris I 91%, Rotterdam 84%, Toronto 75%, Paris II 81%, and Ehime 54%. At 12 months, ALP decreased to 138 U/L (102–201), and bilirubin remained low at 9 µmol/L (7–14). Using the POISE composite score (12-month ALP < 1.67 ×ULN, normal bilirubin, and ≥ 15% ALP reduction), 37% met response criteria. In age-sex adjusted models, Paris I response best predicted liver transplant-free survival in Alberta (aHR 0.19; 95% CI 0.11–0.34), followed by Rotterdam (aHR 0.23; 95% CI 0.15–0.36) and Rochester criteria (aHR 0.33; 95% CI 0.22–0.50).

Conclusion: In this population-based cohort, PBC primarily affected middle-aged women with a high UDCA prescription rate and predominantly with normal bilirubin. Biochemical response differed substantially by criterion; Toronto and Paris I classified most patients as responders. The low POISE response rate underscores unmet need for second-line therapy in PBC. Variation in the criteria used resulted in changes in responder classification, with potential implications on clinical care.

SAT-414-YI

Secretory immunoglobulin A (sIgA): a new prognostic marker for primary sclerosing cholangitis (PSC)

David Tornai[1], Anita Szabo[1], Laura Hanisch[1], Istvan Tornai[1], Tamas Tornai[2], Péter Antal-Szalmás[3], Maria Papp[1]. *[1]University of Debrecen, Faculty of Medicine, Division of Gastroenterology, Department of Internal Medicine, Debrecen, Hungary; [2]Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary; [3]University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary*
Email: tornai.david@med.unideb.hu

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive inflammatory disease of the bile ducts, frequently associated with inflammatory bowel disease (IBD). The gut-liver axis is considered a pivotal factor in PSC pathogenesis. In a previous study, we demonstrated that elevated serum levels of secretory (s)IgA —which is produced in the gut and secreted into the lumen—serve as a marker of gut-barrier damage and a strong predictor of short-term mortality in patients with acute-on-chronic liver failure. In this study, we aimed to evaluate the association of serum sIgA with disease severity, clinical characteristics, and outcomes in PSC.

Method: We conducted a cohort study of PSC patients analyzing data collected during annual follow-up visits. Serum sIgA concentrations were measured from baseline samples. We investigated the association between sIgA and clinical parameters and assessed sIgA's prognostic value for a composite endpoint defined as liver transplantation (LTx) or liver-related mortality over a 10-year period.

Results: The cohort included 135 patients (51.9% male; median age: 36.4 years [IQR: 25.5–48.9]). Co-existing IBD was present in 54.1% of patients, autoimmune hepatitis (AIH) variant syndrome in 19.3%, and established liver cirrhosis in 22.2%. sIgA levels were not associated with the presence of IBD or AIH variant syndrome but were significantly higher in patients with cirrhosis (40.8 [14.0–58.4] vs. 10.7 [5.1–27.8] g/mL; $p < 0.001$). sIgA showed significant positive correlations with disease severity scores (Revised Mayo Risk Score, Amsterdam-Oxford Model, UK-PSC), macrophage activation markers (sCD14, sCD163), liver enzymes (AST, ALT, GGT, ALP), liver function tests (total bilirubin, albumin) (all $p < 0.001$), and CRP ($p = 0.007$). Furthermore, sIgA was a significant predictor of the composite endpoint (AUROC: 0.697; 95% CI: 0.612–0.773). Using an optimal cut-off of > 20.1 µg/mL, elevated sIgA was associated with a nearly 5-fold increased risk of adverse outcomes (HR: 4.975; 95% CI: 2.117–11.695; $p < 0.001$).

Conclusion: Serum sIgA levels correlate with disease severity and predict 10-year transplant-free survival in PSC. Notably, sIgA levels were independent of the presence of co-existing IBD, supporting the hypothesis that gut-barrier dysfunction occurs in PSC even in the absence of manifest intestinal inflammation. The correlation with macrophage activation markers further suggests a link with bacterial translocation.

SAT-415

Prognostic utility of circulating macrophage activation markers in primary sclerosing cholangitis: gadget or magic?

David Tornai[1], Peter Ven[2], Istvan Tornai[1], Tamas Tornai[3], Péter Antal-Szalmás[4], Maria Papp[1]. *[1]University of Debrecen, Faculty of Medicine, Division of Gastroenterology, Department of Internal Medicine, Debrecen, Hungary; [2]University of Pécs, Division of Gastroenterology, First Department of Medicine, Pécs, Hungary; [3]Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary; [4]University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen, Hungary*
Email: tornai.david@med.unideb.hu

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease with a highly variable clinical course. The reliability of current biomarkers in predicting disease activity and progression remains limited. As dysregulated macrophage activity is increasingly recognized as a pivotal driver of PSC pathophysiology, we aimed to evaluate circulating macrophage activation markers as prognostic tools.

Method: We analyzed serum levels of soluble macrophage activation markers (sCD14, sCD163, sCD206/sMR, and suPAR) in a cohort of 93 Hungarian PSC patients. We assessed associations with disease severity (Revised Mayo Risk Score, UK-PSC, and Amsterdam-Oxford Model [AOM]), gut-barrier function (sIgA), a composite endpoint defined as liver transplantation (LTx) or liver-related mortality over a 10-year period.

Results: The cohort (median age 36 years; 57% male) included 46.2% with co-existing IBD and 21.5% with baseline cirrhosis. During follow-up, 24 patients (25.9%) reached the composite endpoint (14 LTx, 10 liver-related deaths). All four markers were significantly elevated in patients with cirrhosis ($p < 0.01$ for all) and those reaching the composite endpoint (AUROC: sCD206: 0.674; sCD163: 0.789; sCD14: 0.736; suPAR: 0.794; $p < 0.01$ for all). sCD163, sCD14, and suPAR correlated positively with clinical risk scores and all markers correlated with sIgA. In univariate Cox regression, log-transformed sCD14, sCD163, and suPAR predicted the composite outcome. notably, sCD14 demonstrated the highest predictive value (HR: 10.43 CI: 3.81–28.8). After adjusting for clinical risk scores, sCD14 remained an independent predictor across all models, whereas suPAR lost significance when adjusted for AOM, and sCD163 lost significance across all scores. A novel composite score combining optimal cut-offs of these three macrophage markers provided superior risk stratification: patients with 0, 1–2, or 3 positive markers had a 0%, 40.7%, and 81.7% event rate, respectively.

Conclusion: Serum level of macrophage activation markers are increased by PSC severity in and predict long-term outcomes. sCD14 bares additional information to clinical scores and the combination of markers representing different aspects of macrophage activation offers robust risk stratification. The correlation with sIgA highlights

the role of the gut-liver axis in macrophage-mediated disease progression.

SAT-416

Metabolic syndrome as a determinant of inadequate biochemical response to ursodeoxycholic acid in primary biliary cholangitis

Christos Triantos[1], Konstantinos Papantoniou[1], Efthymios Tsounis[2,3], Ioanna Aggeletopoulou[2], Maria Bali[2], Nikitas Kimiskidis[2], Odysseas Ampazis[2], Georgia Diamantopoulou[2], Konstantinos Thomopoulos[2]. *[1]Division of Gastroenterology, Department of Internal Medicine, University of Patras, 26504, Patras, Greece, Patras, Greece; [2]Division of Gastroenterology, Department of Internal Medicine, University of Patras, Patras, Greece; [3]Division of Gastroenterology, Department of Internal Medicine, 251 Hellenic Airforce Hospital, Athens, Greece*
Email: chtriantos@hotmail.com

Background and aims: Ursodeoxycholic acid (UDCA) is the first-line therapy for primary biliary cholangitis (PBC), yet many patients fail to achieve an adequate biochemical response. Metabolic syndrome (MetS) may modify treatment response in PBC, beyond the contribution of individual metabolic risk factors. The aim of the current study was to evaluate the association between MetS and biochemical response to UDCA in patients with PBC.
Method: Data from patients with PBC treated with UDCA at a tertiary referral center in Western Greece were collected retrospectively, with prospective follow-up for outcome assessment. Biochemical response at 12 months was defined as alkaline phosphatase (ALP) $\leq 1.67 \times$ ULN and normalization of total bilirubin. MetS was defined as the presence of three or more established metabolic abnormalities at baseline, including obesity defined by body mass index (BMI), dyslipidaemia, hypertension, and impaired glucose regulation. Comparisons were performed using the Mann–Whitney U and Pearson's chi-square tests, while binary logistic regression was used to identify independent predictors of biochemical response.
Results: A total of 95 PBC patients were included (median age 62 years; 91.6% female; 81.1% AMA positive; 47.4% ANA positive; 13.7% baseline cirrhosis; 15.8% current smokers; 7.4% PBC–autoimmune hepatitis overlap). MetS was significantly more frequent among non-responders than responders (42.1% vs 19.3%; $p = 0.021$). Non-responders were older and had higher baseline ALP, higher ALP at 6 months, and higher baseline bilirubin compared with responders ($p = 0.048$, $p = 0.004$, $p < 0.001$, and $p = 0.035$, respectively). In multivariable analysis adjusted for age, baseline bilirubin, and baseline ALP, MetS independently predicted lack of biochemical response (OR = 3.95, 95% CI : 1.06–14.76; $p = 0.041$). When ALP at 6 months was included instead of baseline ALP, lower ALP at 6 months emerged as an independent predictor of response ($p = 0.016$), while the association with MetS was attenuated (OR = 5.81, 95% CI : 0.85–39.84; $p = 0.073$).
Conclusion: MetS is associated with an increased likelihood of inadequate biochemical response to UDCA in patients with PBC. Early biochemical response, as reflected by ALP at 6 months, seems to be a strong determinant of treatment outcome and may partially mediate the effect of metabolic dysfunction. These findings highlight the potential clinical relevance of metabolic risk assessment in PBC.

SAT-417

Presence of myopathy in patients with primary biliary cholangitis

Yiğit Şahin[1], Yasemin Balaban[1], Mete Üçdal[1], Şaziye Apraş Bilgen[2], Gözde Kart Bayram[1], Beyza Atay[1]. *[1]Hacettepe University Faculty of Medicine Hospital, Altındağ, Türkiye; [2]Hacettepe University Faculty of Medicine Hospital, Ankara, Türkiye*
Email: yb.sahin7@gmail.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease frequently associated with extrahepatic manifestations. Although muscle involvement has been described in isolated reports, myopathy remains an under-recognized complication in PBC. This study aimed to systematically evaluate the presence and characteristics of myopathy in patients with PBC.
Method: In this prospective study, 56 adult patients fulfilling EASL diagnostic criteria for PBC were evaluated between December 2024 and December 2025. Clinical symptoms, muscle strength (Medical Research Council, MRC), biochemical markers of muscle injury (creatine kinase [CK], CK-MB, myoglobin, troponin), inflammatory parameters, autoantibodies, and quality-of-life scores (PBC-40 fatigue domain, HAQ) were recorded. Patients with neurological, endocrinopathic, oncological or rheumatologic disorders explaining myopathy were excluded. Patients with elevated muscle enzymes or reduced muscle strength underwent further radiological evaluation. Comparisons were performed using Independent Samples t-test and Mann–Whitney U test.
Results: The cohort was predominantly female (92.9%) with a mean age of 53.7 ± 8.6 years. Muscle-related symptoms were common, including myalgia (39.3%) and muscle weakness (26.8%), despite preserved muscle strength (mean MRC score 4.9 ± 0.3). Two patients (3.6%) exhibited marked CK elevation (>300 U/L). Compared with patients with normal CK levels, those with elevated CK demonstrated significantly higher CK-MB, myoglobin, and troponin levels as expected. Whole-body imaging revealed myositis-like changes or sarcopenia in selected cases.
Conclusion: Myopathy may represent an under-recognized extra-hepatic manifestation of PBC, even in patients without overt muscle weakness. Systematic screening using biochemical markers may facilitate earlier detection of muscle involvement and guide multi-disciplinary evaluation in this population.

SAT-418-YI

Enhanced liver fibrosis test significantly improves the predictive value of the Amsterdam-Oxford model in primary sclerosing cholangitis

Jutta van Crevel[1,2], Tim Middelburg[1,2], Bregje Mol[1,2], Johannes Bogaards[3], Cyriel Ponsioen[1,2]. *[1]Department of Gastroenterology & Hepatology, Amsterdam University Medical Center, Amsterdam, Netherlands; [2]Amsterdam Gastroenterology, Endocrinology & Metabolism, Amsterdam, Netherlands; [3]Department of Epidemiology & Data Science, Amsterdam University Medical Center, Amsterdam, Netherlands*
Email: j.n.vancrevel@amsterdamumc.nl

Background and aims: Reliable individual prognostication in primary sclerosing cholangitis (PSC) remains challenging. The Amsterdam Oxford Model (AOM) predicts transplant-free survival with moderate discrimination (C-statistic 0.67–0.75). The Enhanced Liver Fibrosis (ELF) test has shown promising prognostic value in PSC. This study evaluated whether the predictive value of AOM can be improved by incorporating ELF.
Method: In a prospective Dutch PSC cohort, first available ELF measurements were linked to clinical and laboratory data. Transplant-free survival was defined as time from ELF measurement to PSC-related death or liver transplantation. Cox models assessed AOM, ELF, and their combination, with incremental value evaluated via Wald tests and C-statistics. Next, we applied exploratory LASSO-penalized regression with bootstrap validation on AOM candidate predictors plus ELF. Calibration was assessed by comparing predicted survival with Kaplan-Meier estimates based on risk quartiles.
Results: We included 292 PSC patients (64% male, median age at PSC diagnosis 35 years, 72% inflammatory bowel disease (IBD), 7% features of autoimmune hepatitis (AIH)). Median time from PSC diagnosis to ELF measurement was 5.1 years (IQR 2.6–11.0), with a median follow-up from ELF measurement of 5.6 years (IQR 3.0–13.2). During follow-up, 79 events occurred. AOM and ELF were moderately correlated (Pearson's $r = 0.60$). Prediction by AOM at the time of ELF measurement showed a C-statistic of 0.75 (HR 2.91, 95% CI 2.14–3.96), while prediction by ELF alone showed a C-statistic of 0.78 (HR 2.07,

95% CI 1.77–2.43). Combining AOM and ELF improved the C-statistic to 0.80 (AOM HR: 1.60, 95% CI 1.07–2.38; ELF HR: 1.81, 95% CI 1.50–2.19). Wald tests confirmed that incorporating ELF improved the prediction by AOM ($p < 0.0001$). The LASSO-derived model achieved an optimism-corrected C-statistic of 0.84, and consistently selected ELF (HR 1.55, 95% CI 1.25–1.93) along with PSC subtype, bilirubin, albumin, gamma GT, IBD, sex, AIH and time since PSC diagnosis. Calibration was satisfactory, with good agreement between predicted and observed survival across risk groups.

Conclusion: ELF provided significant incremental prognostic value in addition to AOM alone and was consistently selected in LASSO-penalized modeling. The optimized model demonstrated robust and excellent discriminative performance and good calibration in internal validation, showing promising utility for prognostic assessment in PSC.

SAT-419

Recurrence rate and clinical outcomes for recurrent primary sclerosing cholangitis after liver transplantation: a systematic review with meta-analysis

Lisa van Lierop[1], Qiming Tan[1], Raymond Odsen[1], Janice Kung[1], Aldo J Montano-Loza[1], Abdel Aziz Shaheen[2], Juan Abraldes[1], Frank Hoentjen[1]. *[1]University of Alberta, Edmonton, Canada; [2]University of Calgary, Calgary, Canada*
Email: lvanlier@ualberta.ca

Background and aims: Liver transplant (LT) is a dreaded outcome of end-stage primary sclerosing cholangitis (PSC). PSC recurrence (rPSC) after LT impacts graft survival and patient outcomes, but recurrence rate and clinical outcomes remain unclear. This systematic review with meta-analysis aims to quantify pooled rates of rPSC after LT and to evaluate post-transplant clinical outcomes, including graft and patient survival.

Method: A systematic search of multiple databases was conducted from inception to June 27, 2025, to identify cohort studies reporting rPSC after LT in adults. The primary outcome was the rPSC rate (pooled proportion); secondary outcomes included time to rPSC, rPSC in patients with PSC-IBD or post-colectomy, graft and patient survival, re-transplantation, and all-cause mortality. Pooled rates were estimated via random-effects (DerSimonian and Laird) and generalized linear mixed models (GLMM). Heterogeneity was evaluated using I^2 statistics, and robustness was assessed through leave-one-out sensitivity analyses. Risk of publication bias was assessed using contour-enhanced funnel plots, Egger's test, and trim-and-fill.

Results: Fifty-six articles contributed 59 independent study estimates (7946 LT recipients). The pooled rate of rPSC was 20.4% (95% CI 18.2–22.9%) using a DerSimonian-Laird random-effects model, with a similar estimate obtained using a GLMM approach (19.1%; 95% CI 16.4–22.1%). Heterogeneity was substantial ($I^2 \approx 80\%$), and the 95% prediction interval ranged from 9.5% to 38.6%. Assessment for publication bias demonstrated no significant small-study effects (Egger's $p = 0.38$). The median time to rPSC was 4.1 years. Recurrence occurred in 25.6% of patients with PSC-IBD and 18.8% post-colectomy, with histologic recurrence in 12.0%, re-transplantation in 12.6%, and re-transplantation for rPSC in 30.9%. One-, five-, and ten-year graft survival rates were 80.7%, 70.0%, and 56.4%, respectively; overall patient survival rates were 90.7%, 81.9%, and 73.7%, with a pooled mortality rate of 22.5%.

Conclusion: This meta-analysis provides the most comprehensive estimate to date, demonstrating that rPSC is frequent after LT (about 20%) and carries clinically relevant risks of graft failure, re-transplantation, and death. These findings have important implications for long-term surveillance, patient counseling, and future research objectives.

Background and aims: Primary Biliary Cholangitis (PBC) is a rare progressive chronic liver disease. Prognostic scores are useful for decision making in patients with PBC, but the role of biomarkers is unclear. We studied the association of serum glycomics with disease progression and liver transplant free survival (TFS) in patients with PBC.

Method: In this multicentric international study stored serum samples of 858 PBC patients from 3 European PBC expert centers of the GLOBAL PBC Study Group were included. Serum N-glycomic analysis was performed using DNA sequencer assisted-Fluorophore Assisted Carbohydrate Electrophoresis. A glycomics-based biomarker was developed using uni-and multivariate Cox regression analyses on one time point.

Results: Patients had a mean follow-up of 6.43 years, with an 5- and 10-year (TFS) of 91.6% and 83.1. Poor TFS was associated with an increase of fucosylated glycans (NA2FB, NA3Fbc, NA4Fb) and a decrease of bi-, and tri-antennary glycans (NA2F, NA3), from which the GlycoPBCScore was derived with an area under the curve of 0.82 (95% CI [0.78–0.86], $p < 0.001$). According to a derived cut-off, patients in the 'high risk' group developed more cirrhosis (15.5% vs 6.3%, $p < 0.001$), hepatic decompensation (41.4% vs 15.9%, $p < 0.001$), hepatocellular carcinoma (3.2% vs 0.6%, $p = 0.003$) and had a higher mortality rate (37.4% vs 6.6%, $p < 0.001$), when compared to the 'low risk' group. Hazard ratio (HR) for adverse outcome was 3.36 (95% CI [2.82–4.01], $p < 0.001$) according to this biomarker. In a multivariable Cox proportional hazards model, the association of the GlycoPBCScore with poor TFS was confirmed (HR 2.05, 95% CI [1.66–2.53], $p < 0.001$). Moreover, combining this new glycomics based biomarker with the PBC GLOBE Score increased the prognostic value, leading to a more accurate classification of patients in need of liver transplantation and patients with an uneventful disease course. In particular, a high negative predictive value of 97.3% was observed

using the combination of GLOBE score and GlycoPBCscore, compared to 90% when there was a discordance between the GLOBE score and the biomarker.
Conclusion: The GlycoPBCScore is a new prognostic serum biomarker for liver-transplant free survival in patients with PBC, that provides additional prognostic information if combined with the currently used PBC GLOBE Score. Patients with an uneventful disease course can more accurately be identified.

Background and aims: Elafibranor, a dual peroxisome proliferator-activated receptor agonist, has recently been conditionally approved as second-line treatment for patients with Primary Biliary Cholangitis (PBC) and a suboptimal response to ursodeoxycholic acid (UDCA). In this study, we aimed to evaluate the efficacy and safety of elafibranor 80 mg/day in patients with PBC consecutively enrolled in the Italian Elafibranor Early Access Program and who had discontinued Obeticholic acid (OCA) treatment due to revocation of its marketing authorization.
Method: Patients were recruited into the Italian PBC Registry, a multicentre, observational cohort study that includes more than 60 secondary/tertiary centres managing patients with following PBC across Italy. The primary endpoint was the median change in alkaline phosphatase (ALP) levels from the beginning of elafibranor treatment until most recent follow up, and the secondary endpoints were: rate of patients with ALP <1,67 the upper limit of normal (ULN), rate of normalization of ALP (≤1 × ULN), change in pruritus intensity from baseline as measured on the Worst Itch Numeric Rating Scale (WI-NRS) in those with baseline severe-to-moderate pruritus (WI-NRS ≥4) and the occurrence of Adverse Events (AEs).
Results: We included 80 patients whose median age was 60 years, 87% were female, 16% with cirrhosis, 59% with ALP <1.67 ULN and 17% with ALP ≤1 × ULN. Median duration of OCA before initiation of elafibranor was 17 (4–93) months; median time between last OCA use and elafibranor initiation 3 (0–6) months. During a median treatment duration with elafibranor of 6 months (3–9) median ALP significantly decreased from 170 to 119 U/L (p = 0.013), and 77% and 46% of patients had ALP <1.67 × ULN and 46% ALP ≤1 × ULN, respectively. Among 11 patients who had moderate-to-severe pruritus, 10 improved (91%, median improvement: −4 points). Five patients (6%) prematurely discontinued elafibranor because of gastrointestinal AEs.
Conclusion: This real-world experience on the largest cohort reported to date of patients with PBC previously exposed to OCA and treated with elafibranor, suggests that elafibranor is an effective and safe alternative for such patients as a second-line therapy. Given the relatively short treatment duration of treatment with elafibranor, further evaluation with extended follow-up is warranted.

Faecalibacterium prausnitzii regulates biliary repair via the SCFAs–H3K27ac–ELF3 axis in primary biliary cholangitis

Qi Wang[1], Xi Wang[1], Ronghua Jin[1], Minghui Li[1]. *[1]Beijing Ditan Hospital, Capital Medical University, National Center for Infectious Diseases, Beijing, China*
Email: 18263829683@163.com

Background and aims: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease that primarily affects middle-aged women. Studies suggest that alterations in the gut microbiome are closely associated with the pathogenesis and treatment of PBC, but the underlying mechanisms remain unclear.
Method: This study first conducted gut microbiota analysis of fecal samples from PBC patients and healthy controls using metagenomic sequencing, with LEfSe and other methods employed to identify differential microbial taxa. Subsequently, a bile duct ligation (BDL) mouse model was established and treated with *F. prausnitzii* (1 × 10^9 CFU/day), while ductular reaction and liver fibrosis were evaluated through histopathological staining. For in vitro experiments, a GCDC-induced injury model using human primary biliary epithelial cells (HiBECs) was developed, followed by treatment with varying concentrations of short-chain fatty acids (SCFAs). Furthermore, ChIP assays were performed to detect H3K27ac modification levels, elucidating the specific mechanism by which SCFAs exert their effects through epigenetic regulation of the ELF3/PI3K-Akt pathway. All data were statistically analyzed using two-tailed t-tests/ANOVA with FDR correction ($P < 0.05$ considered statistically significant).
Results: We found that *F. prausnitzii* was significantly reduced in the gut microbiota of PBC patients. Supplementation with *F.prausnitzii* markedly improved BDL-induced biliary injury, including cholangitis, bile duct hyperplasia, and liver fibrosis, while also restoring gut microbial balance and intestinal barrier function. These beneficial effects were linked to SCFAs produced by *F. prausnitzii*. Mechanistic studies revealed that *F. prausnitzii*-derived SCFAs enhanced histone H3K27 acetylation, upregulating the transcription factor ELF3 and subsequently activating the PI3K-Akt signaling pathway to promote bile duct cell repair.
Conclusion: This study demonstrates that *F. prausnitzii* exerts protective effects in PBC. Its depletion in PBC patients and its therapeutic potential in alleviating cholangitis and liver fibrosis,

along with restoring gut function, highlight its promising clinical application for PBC treatment.

Email: g.weijsters@erasmusmc.nl

Background and aims: While aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels during ursodeoxycholic acid (UDCA) are associated with liver-transplant (LT)-free survival and liver-related events in people with primary biliary cholangitis (PBC), this is unclear for the decline in both parameters. The aim of this study was to assess how the percentage reduction of ALT and AST after 1 year UDCA relate to clinical outcome in PBC.

Method: The retrospective Dutch PBC Cohort Study includes every identifiable patient with PBC from 1990 up to last data collection (2019–2023) from all 71 hospitals in the Netherlands. Patients were included if >1 year follow-up after start of UDCA and without autoimmune hepatitis or second-line therapy/immunosuppressants. Where feasible, laboratory values were imputed using joint model multiple imputation. Cox survival analyses were used to study how ΔAST and ΔALT (per 10%) were related to LT-free survival and liver-related events (decompensation, LT, or liver-related death). Continuous variables were fitted as natural cubic spline where needed.

Results: In total, 3139 patients were included. At start of UDCA, median age was 58.0 years (IQR 49.7–67.2), 2745 (87.4%) were female and 203 (6.5%) had cirrhosis. During a median follow-up of 8.0 years (IQR 3.8–13.3), 295 patients developed decompensated cirrhosis, 78 patients underwent LT, and 584 patients died (152 [26%] liver-related; 115 [20%] of unknown cause). Median ΔAST after 1 year was −40% (−59; −15) and median ΔALT was −51% (−69; −25). In multivariable models (including baseline biochemistry), ΔAST (aHR 0.89, 95% CI 0.84–0.93) and ΔALT (aHR 0.94, 95% CI 0.90–0.99) were associated with LT-free survival (both $p < 0.05$). For liver-related events the aHR for ΔAST was 0.90 (95%CI 0.86–0.95) and for ΔALT 0.95 (95%CI 0.91–0.99) (both $p < 0.05$). When combining both ΔAST and ΔALT in one model, ΔAST remained significantly associated with LT-free survival and liver-related events (aHR 0.90, 95%CI 0.86–0.96, $p < 0.001$ and aHR 0.92, 95%CI 0.87–0.98, $p = 0.016$), while ΔALT lost significance. The ΔAST and ΔALT were not related to both outcomes after adjustment for their absolute value at 1 year (aHR~1, $p > 0.4$ for both).

Conclusion: Among people with PBC, the decline in AST during the first year appears to better reflect the clinical benefit of UDCA therapy than the decline in ALT. Yet, to assess prognosis, the decline in the transaminases do not add prognostic value over absolute values of AST and ALT at 1 year.

SAT-427

Early thiopurine metabolite monitoring in autoimmune hepatitis improves biochemical response at 6 months and enables early steroid withdrawal in a prospectively managed cohort

Jan Philipp Weltzsch[1], Moritz Waldmann[2], David Lübbering[1], Ludwig Horst[1], Silja Steinmann[1], Britta Zecher[1], Louisa Lund[1], Stephanie Schulze[1], Thomas Renne[2], Marcial Sebode[1], Christoph Schramm[1], Ansgar W. Lohse[1], Johannes Hartl[1]. *[1]I. Dept. of Medicine, University Medical Centre Hamburg Eppendorf (UKE), Hamburg, Germany; [2]Institute of Clinical Chemistry and Laboratory Medicine, University Medical Centre Hamburg-Eppendorf (UKE), Hamburg, Germany*
Email: j.weltzsch@uke.de

Background and aims: In autoimmune hepatitis (AIH), only 25–55% of patients achieve transaminase normalization after 6 months of standard therapy with azathioprine or mycophenolate mofetil, highlighting the need for improved strategies. We previously showed that, due to poor correlation between weight-adjusted thiopurine doses and metabolite levels of 6-thioguanine/6-methylmercaptopurine (6TGN/6MMP), therapeutic drug monitoring (TDM) improves response rates. Here, we prospectively evaluated whether a dose-adjustment algorithm incorporating early thiopurine metabolite measurements improves treatment responses.

Method: From 06/2022–06/2025, patients with a new diagnosis of AIH treated with thiopurines were prospectively managed according to a published treatment algorithm with early TDM at a median of 2 months and compared with a prospective cohort treated before TDM implementation (02/2017–03/2022). The primary endpoint was biochemical remission (BR), defined as normalization of ALT and AST at 6 months. Secondary endpoints included complete BR (CBR; normalization of ALT, AST and IgG) and steroid-free BR. Multivariable logistic regression assessed associations between TDM and outcomes, adjusting for age, sex, baseline ALT, AST, IgG, bilirubin, INR and fibrosis stage.

Results: A total of 216 patients with AIH were included: 75 were managed using TDM and 141 served as controls. Baseline characteristics (age, sex, ALT/AST levels, IgG, mHAI, INR), were similar between groups, advanced fibrosis tended to be more frequent in controls (23% vs. 12%). In patients with low 6TGN levels lacking BR (34/75, 45%), TDM-guided dose adjustments resulted in improved metabolite profiles (median 6TGN +28% at 6 months vs. baseline measurement; $p < 0.001$). Eight patients (11%) were switched to combination therapy with allopurinol due to shunting toward 6MMP, defined by a 6MMP:6TGN ratio >5. In these patients, the 6MMP:6TGN ratio decreased from 13.3 at baseline to 0.7 at 6 months ($p = 0.016$). Dose escalation based on early TDM achieved BR in 72%, and combination with allopurinol in 63% at month 6. Accordingly, early TDM was overall independently associated with higher rates of BR (72% vs. 52%; OR 2.24; $p = 0.022$), steroid-free BR (41% vs. 17%; OR 3.11; $p = 0.003$), and CBR (71% vs. 46%; OR 2.51; $p = 0.019$) at month 6 compared to controls.

Conclusion: Dose adjustments based on early TDM significantly improved 6-month biochemical response and facilitated early steroid withdrawal, supporting individualized thiopurine dose optimization.

SAT-428-YI

Differentiating acute-onset autoimmune hepatitis from drug-induced autoimmune-like hepatitis: a multicenter study and score development

Haoyu Wen[1,2], Yu Chen[1], Yu-Jie Zhou[1], Tianyu Mao[1], Qi Miao[1], Qiuxiang Lin[3], Zuxiong Huang[3], Yongfeng Yang[4], Xiong Ma[1], Xiao Xiao[1]. [1]*Division of Gastroenterology and Hepatology, Key Laboratory of Gastroenterology and Hepatology, Ministry of Health, State Key Laboratory for Oncogenes and Related Genes, Renji Hospital, School of Medicine, Shanghai Jiao Tong University; Shanghai Institute of Digestive Disease, Shanghai, China;* [2]*Department of Gastroenterology and Hepatology, Guangzhou Key Laboratory of Digestive Diseases, Guangzhou Digestive Disease Center, Guangzhou First People's Hospital, School of Medicine, South China University of Technology, Guangzhou, China;* [3]*Department of Hepatology, Mengchao Hepatobiliary Hospital of Fujian Medical University, Fuzhou, China;* [4]*Department of Infectious Disease and Liver Disease, The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, Nanjing, China*
Email: xxiao_sh@163.com

Background and aims: The incidence of acute-onset autoimmune hepatitis (A-AIH) is rising, but its diagnosis remains challenging, particularly in patients with a history of hepatotoxic drug exposure. The clinical presentations of A-AIH and drug-induced autoimmune-like hepatitis (DI-ALH) at onset are often indistinguishable, complicating their timely diagnosis.
Method: We conducted a three-center retrospective study in China, screening patients with acute liver injury, hepatotoxic drug exposure, and autoimmune features. Patients were definitively classified as DI-ALH if they achieved sustained remission after culprit drug cessation, or as A-AIH if they relapsed. We compared the two groups across baseline demographics, laboratory indices, immunological profiles, and liver histology. After evaluating the performance of established AIH diagnostic criteria, we developed and independently validated a novel multivariable logistic regression model to improve discrimination between A-AIH and DI-ALH.
Results: Of 458 patients screened, 238 met the inclusion criteria and constituted the final cohort: 94 with A-AIH and 144 with DI-ALH. Compared to DI-ALH, A-AIH patients had significantly higher IgG levels, lower platelet counts, and higher autoantibody titers. Histologically, A-AIH exhibited more severe portal inflammation, interface hepatitis, fibrosis, and rosette formation. The discriminatory capacity of both the 2022 and 2008 histological criteria was limited and comparable (AUC 0.62 vs. 0.59, p = 0.616). The novel Dx-AID score —incorporating platelet count, IgG, autoantibodies, and histological features—achieved high diagnostic accuracy in both the derivation cohort (AUC 0.84, 95% CI: 0.77–0.91) and the independent validation cohort (AUC 0.83, 95% CI: 0.72–0.94).
Conclusion: A-AIH and DI-ALH share many clinical similarities, but they differ in immunological and histological profiles. The Dx-AID score effectively integrates these key differences, providing a clinically actionable tool for early differentiation and guiding personalized treatment decisions.

Background and aims: Various biochemical criteria have been proposed to evaluate prognosis with ursodeoxycholic acid (UDCA) in people with Primary Biliary Cholangitis (PBC). Most results, however, are derived from tertiary cohorts. We aimed to assess the relation between the various criteria and clinical outcome in a nationwide cohort of people with PBC.
Method: The retrospective Dutch PBC Cohort Study (DPCS) includes in-depth clinical data of every identifiable individual with PBC in the Netherlands from 1990 up to last data collection (2019–2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Where feasible, imputation was performed using joint model multiple imputation. People were included in case of at least one year of follow-up (FU) after initiating UDCA. Survival analyses were used to evaluate the various biochemical criteria in relation to liver transplantation (LT) or death.
Results: In total, 3566 patients were included with a median age of 57.6y (IQR 49.5–66.9) of whom 3131 (87.8%) were female, 294 (7.2%) had cirrhosis and 3376 (83.0%) were treated in non-academic hospitals. At one year of UDCA, 79.9% met Paris I (ALP $\leq 3 \times$ ULN, AST $\leq 2 \times$ ULN, and Total Bilirubin [TB] $\leq$ ULN), 75.0%, the Rotterdam criteria (normal TB and albumin), 74.5% Toronto (ALP $\leq 1.67 \times$ ULN), 65.2% Barcelona (normal ALP or 40% ALP decrease), 57.4% PARIS II (ALP and AST $\leq 1.5 \times$ ULN with TB $\leq$ ULN), 53.0% POISE (ALP$<1.67 \times$ ULN, ALP decrease $\geq$15% from baseline, and TB $\leq$ ULN), and 25.6% the Global Deep Response (normal ALP and TB $\leq 0.6 \times$ ULN. Median FU was 8.0 years (IQR 3.9–13.3) during which 622 patients died and 95 patients underwent LT. Irrespective of the criteria, those who met these had a favorable LT-free survival as compared to those with did not ($p < 0.001$ for all). Over the various criteria, the cumulative 10-year survival ranged between 85.5% (95%CI 83.9–87.2, Toronto) and 89.2% (95%CI 86.3–92.2, Global Deep Response) among those with a biochemical response. However, among those with an incomplete response, the cumulative 10-year survival ranged between 54.7% (95%CI 49.3–60.7, Rotterdam) and 81.8% (95%CI 79.9–63.7, Global Deep Response).
Conclusion: This large, recent, representative nationwide PBC cohort study, supports that all previously suggested biochemical criteria at one year of UDCA therapy are associated with the LT-free survival. The prognosis was similar between the responders to the various criteria, but varied substantially depending on which of the criteria was not met after one year of UDCA.

Email: e.werner@erasmusmc.nl

Background and aims: Prognostic tools in Primary Biliary Cholangitis (PBC) are mostly derived from tertiary cohorts. The GLOBE score is commonly used to predict the liver transplantation-free survival (LTFS). We aimed to evaluate the prognostic performance of the GLOBE score in a nationwide cohort of people with PBC.
Method: The Dutch PBC Cohort Study is a retrospective study which includes in-depth clinical data from every identifiable individual with PBC in the Netherlands from 1990 up to last data collection (2019–2023) in all 71 Dutch hospitals. Where feasible, imputation was performed using joint model multiple imputation. Inclusion criteria were ursodeoxycholic acid (UDCA) initiation and availability of the GLOBE score parameters alkaline phosphatase (ALP), total bilirubin (TB), platelets and albumin at one year after start of UDCA. Survival analyses were performed to assess the relation between the GLOBE score and LT or death. Discriminative ability of the GLOBE score was assessed with the c-statistic and the accuracy of the predicted probabilities were assessed through calibration plots. The Integrate Brier Score (IBS) summarized prediction error over time.
Results: In total, 2637 patients were included of whom 2056 (78.0%) were treated in non-academic hospitals. At baseline, median age was 57.2 years (IQR 49.3–66.9), 2319 (87.9%) were female and 203 (7.7%) had cirrhosis. At one year of UDCA, ALP was 1.2 × ULN (IQR 0.9–1.7) and TB was 0.5 × ULN (IQR 0.4–0.7). Overall, the median GLOBE score was −0.1 (IQR −0.7–0.6). During a median follow-up (FU) of 7.9 years (IQR 3.9–13.3) years, 74 underwent LT and 491patients died. The GLOBE-score was independently associated with LT or death (adjusted HR 3.05, 95%CI 2.68–3.47, p < .001). The c-statistic was 0.79 (95%CI 0.77–0.82). Calibration showed an IBS of 0.05 over a 10y follow-up. In the 25% of people with highest GLOBE scores (>0.56) the observed 10y LT-free survival probability was 60.3% (95%CI 55.7–65.2) vs a predicted 10y LT-free survival of 59.2%. These were 97.5% (95%CI 96.0–99.0) vs 94.1% for people with a GLOBE score of <−0.66 (lowest 25%) and 90.1% (95%CI 88.0–92.2) vs 85.3% for people with a GLOBE score −0.66 to 0.56 (middle 50%).
Conclusion: In this nationwide cohort of people with PBC, a higher GLOBE score was associated with risk of LT or death with an accurate discriminative ability. Especially for people with PBC at greater risk of LT or death, the GLOBE's projected prognosis was very accurate.

SAT-433

Alkaline phosphatase in relation to clinical outcome according to subgroups of people with primary biliary cholangitis

Email: e.werner@erasmusmc.nl

Background and aims: Alkaline phosphatase (ALP) has been associated with prognosis in people with primary biliary cholangitis (PBC). The strength of this association is likely influenced by specific patient and disease characteristics. We aimed to assess the relation between ALP at one year of ursodeoxycholic acid (UDCA) and clinical outcome in subgroups of people with PBC.
Method: The retrospective Dutch PBC Cohort Study (DPCS) includes every identifiable patient with PBC in the Netherlands from 1990 up to last data collection (2019–2023) in all 71 Dutch hospitals. Clinical data were obtained through medical chart review. Where feasible, imputation was performed using joint model multiple imputation. Patients were included in case of ≥1 year of follow-up after initiating UDCA. Laboratory values are presented as upper limits of normal (ULN). The association between ALP and liver transplant (LT) or death was evaluated using Cox survival analyses. Depending on the subgroup, analyses were adjusted for sex, age, cirrhosis at baseline, total bilirubin (TB), use of immunosuppressives and calendar year.
Results: In total, 3566 patients were included (median age 57.6 years (IQR 49.5–66.9), 3131 (87.8%) were female). At baseline, 2433/3422 (71.1%) had early disease stage (normal TB and albumin) and 989/3422 (28.9%) moderately advanced (abnormal TB or albumin). The median follow-up was 8.0 years (IQR 3.9–13.3) during which 95 patients underwent LT and 622 patients died. At one year after start of

UDCA, median ALP was 1.2 (IQR 0.9–1.6) and median TB was 0.5 (IQR 0.4–0.7). Overall, the aHR of ALP was 1.40 (95%CI 1.28–1.52, p < .001). The aHR of ALP was significant in the assessed subgroups (all p < .05); 1.27 (95%CI 1.10–1.46) in those with an early stage vs 1.31 (95%CI 1.18–1.44) in those with a moderately advanced stage, 1.41 (95%CI 1.07–1.86) in males vs 1.19 (95%CI 1.03–1.38) in females, 1.26 (95%CI 1.06–1.50) in people aged <45y up to 1.30 (95%CI 1.12–1.50) in people >65y and 1.24 (95%CI 1.10–1.39) when UDCA was initiated <2010 vs 1.40 (95%CI 1.22–1.60) ≥2010. The aHR of ALP at one year was 1.58(95%CI 1.16–2.15) in those with a baseline ALP <2 and 1.21 (95%CI 1.05–1.40) in those with a baseline ALP >4. Baseline TB ≤ 0.6 resulted in an aHR for ALP of 1.18 (95%CI 1.01–1.38) vs 1.24 (95%CI 1.01–1.40) for TB > 0.6.
Conclusion: This large nationwide cohort supports that ALP at one year after start of UDCA is a consistent prognostic marker for the population with PBC, across all clinically relevant subgroups.

Utilization of maralixibat, an ileal bile acid transporter inhibitor, for the treatment of intrahepatic cholestasis of pregnancy: a case series

Mogul[8], Jolan Terner-Rosenthal[8], Pamela Vig[8], Catherine Williamson[4]. *[1]King's College Hospital NHS Trust, London, England, United Kingdom; [2]University of Edinburgh, Edinburgh, Scotland, United Kingdom; [3]Barts Health NHS Trust, London, England, United Kingdom; [4]Institute of Reproductive and Developmental Biology, Imperial College London, London, England, United Kingdom; [5]ICP Support, Poole, England, United Kingdom; [6]King's College London, London, England, United Kingdom; [7]Imperial College Healthcare NHS Trust, London, England, United Kingdom; [8]Mirum Pharmaceuticals, Inc., Foster City, California, United States*
Email: catherine.williamson@imperial.ac.uk

Background and aims: Intrahepatic cholestasis of pregnancy (ICP) is characterized by elevated maternal total serum bile acids (TBA) and liver transaminases. Maralixibat (MRX) is an ileal bile acid transporter (IBAT) inhibitor that effectively reduces pruritus and total serum bile acid (TBA) levels in non-gestational cholestasis. This case series reviewed the effectiveness and tolerability of MRX on hypercholanemia and pruritus in recurrent, severe ICP.
Method: Retrospective analysis of four cases of recurrent, severe ICP with marked hypercholanemia and pruritus with insufficient ursodeoxycholic acid response treated with MRX through a compassionate use program was conducted. Key clinical, biochemical, and safety data were collected.
Results: Case 1 was a 37 year old White woman (heterozygous p.[V444A] *ABCB11*), previous stillbirth and miscarriage. She had elevated TBA (118 µmol/L) but no recorded pruritus. She began MRX treatment (70 µg/kg/d, uptitrated to 175 µg/kg/d) at 28 + 0 weeks' gestation. MRX reduced TBA (<40 µmol/L) and the patient delivered a live baby at 35 + 5 gestational weeks. Case 2 was a 36 year old Black woman (homozygous p.[V444A] *ABCB11*), previous live birth at 37 weeks' gestation. She developed pruritus at 17 weeks and elevated TBA (219 µmol/L) at 22 + 4 weeks' gestation. She began MRX treatment (70 µg/kg/d, uptitrated to 210 µg/kg/d) at 28 + 5 weeks' gestation and pruritus and TBA improved (<40 µmol/L). Due to a sudden unexplained increase in TBA, the clinical team induced instead of increasing the MRX dose. A healthy baby was delivered at 34 + 5 weeks of gestation. Case 3 was a 42 year old South Indian woman (ICP-associated genetic variants not detected), previous stillbirth and fetal loss after placental abruption. TBA was elevated (237 µmol/L) and she began MRX treatment (300 µg/kg BID) and saw an improvement in TBA (<40 µmol/L). A healthy baby was delivered at 34 weeks' gestation. Case 4 was a 38 year old White woman (heterozygous, p.[V444A] *ABCB11*) two previous stillbirths. TBA was elevated (148 µmol/L) since nine weeks' gestation. She began MRX treatment (70 µg/kg/d, uptitrated to 300 µg/kg/d) at 18 weeks' gestation. TBA was reduced (52–93 µmol/L), then rose (125 µmol/L) at 31 weeks when a decision was made to expedite delivery. She delivered a live baby at 31 + 2 weeks' gestation. Mild GI events occurred in three patients during MRX treatment but were manageable.
Conclusion: These findings suggest that maralixibat may effectively manage ICP by lowering TBA and improving pruritus.

SAT-435

Early liver stiffness measurement improves the prediction of liver-related events beyond biochemical remission in newly diagnosed autoimmune hepatitis

Mason[1], Mark Swain[15], Bettina Hansen[4], Ellina Lytvyak[1], Aldo J Montano-Loza[1]. *[1]Division of Gastroenterology and Hepatology, University of Alberta, Edmonton, Canada, Edmonton, Canada; [2]Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, Singapore; [3]Woodlands Health Campus, Singapore, Singapore; [4]The Autoimmune and Rare Liver Disease Programme, Division of Gastroenterology and Hepatology, Toronto General Hospital, Toronto, Canada, Toronto, Canada; [5]Division of Gastroenterology, University of British Columbia, Vancouver, Vancouver, Canada; [6]Department of Internal Medicine, Section of Hepatology, University of Manitoba, Manitoba, Canada; [7]Departments of Medicine & Public Health Sciences, Queen's University, Kingston, Ottawa, Canada; [8]Nanaimo Regional Hospital, Nanaimo, Nanaimo, Canada; [9]Department of Medicine, Western University, London, Ontario, Canada; [10]Division of Gastroenterology and Hepatology, College of Medicine, University of Saskatchewan Royal University Hospital, Saskatoon, Canada; [11]Liver Unit of the Centre hospitalier de l'Université de Montréal, Montreal, Canada; [12]University of Ottawa's Faculty of Medicine, Ottawa, Canada; [13]McGill University Health Centre, Royal Victoria Hospital, Montreal, Canada; [14]Department of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada; [15]Division of Gastroenterology and Hepatology, University of Calgary, Calgary, Canada*
Email: wongyujun1985@gmail.com

Background and aims: Biochemical remission (BR) is the primary treatment target in autoimmune hepatitis (AIH), yet it may not fully capture residual fibrosis or long-term risk. The prognostic role of liver stiffness measurement (LSM) in AIH, particularly when performed early after diagnosis and treatment initiation, remains unclear. We evaluate whether *early LSM* provides independent prognostic value for liver-related events (LRE) beyond BR in AIH.
Method: From the Canadian Network for Autoimmune Liver Disease registry, we identified AIH patients (diagnosed 2010–2025) across 13 centres who underwent *early LSM* (<12 months after AIH diagnosis and treatment initiation). A landmark analysis was performed using the first *early* LSM. The primary composite outcome was time to first LRE, defined as hepatic decompensation, liver transplantation, hepatocellular carcinoma, or death. BR was defined as ALT normalization, with sensitivity analysis using complete BR (ALT and IgG normalization) at 6 months.
Results: Among 305 AIH patients (median age: 55 years, 32.1% cirrhosis at diagnosis), median time to *early* LSM was 2.1 months (IQR: 0.5–5.6), and median LSM was 12.6 kPa (IQR:7.5–23.1). ALT normalization was achieved in 57.6% and 72.6% at 6 and 12 months, respectively. Over a median follow-up of 58 months, 29 patients developed LRE, most commonly hepatic decompensation. Despite low absolute event rate typical of treated AIH cohorts, patients with LREs had significantly higher LSM and lower platelet counts at diagnosis (all p < 0.05). LSM ≥15 kPa independently predicted LREs

(HR 4.6, 95%CI: 1.9–11.2, p < 0.0001). Importantly, 52% of patients with LSM ≥15 had already achieved BR at 6 months. The association between LSM ≥15 kPa and LREs remained robust after adjustment for BR status, diabetes, MELD score, and prior decompensation. Cox-adjusted survival analysis demonstrated significantly reduced LRE-free survival in patients with LSM ≥ 15 kPa (aHR: 3.95, 95%CI: 1.44–10.89). Among patients with repeated LSM <6 months, no LRE occurred in patients achieving ≥20% LSM reduction or LSM regression to <15 kPa, whereas all LRE occurred in patients without LSM improvement.
Conclusion: Biochemical remission does *not* fully eliminate long-term risk in AIH. *Early* LSM ≥15 kPa identifies a clinically important high-risk subgroup despite apparent biochemical control. Incorporating early LSM into post-treatment assessment may enable more precise risk stratification and guide surveillance intensity in AIH.

SAT-436
Challenging the paradigm: IBD status does not independently predict hepatic outcomes in a large, long-term PSC cohort
Yu Jun Wong[1,2], Guan Sen Kew[1,3], Ellina Lytvyak[1], Devika Shreekumar[1], Shagani Thisairajah[1], Andrew L. Mason[1], Aldo J Montano-Loza[1]. *[1]Division of Gastroenterology and Hepatology, University of Alberta, Edmonton, Canada, Edmonton, Canada; [2]Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore, Singapore; [3]Woodlands Health Campus, Singapore, Singapore*
Email: wongyujun1985@gmail.com

Background and aims: Inflammatory bowel disease (IBD) is integral for risk stratification, surveillance strategies, and clinical trial design in primary sclerosing cholangitis (PSC). However, whether IBD independently predicts hepatic outcomes beyond established markers of disease severity remains uncertain. We aim to evaluate whether IBD status, subtype, and diagnostic timing independently predict the first occurrence of hepatic decompensation (HD) or hepatobiliary malignancy in PSC.
Method: We analysed 611 patients with PSC (EASL criteria) from a tertiary Canadian cohort (1974–2024). The primary outcome was first HD. Fine–Gray model (competing risks: liver transplantation (LT), death, cholangiocarcinoma, hepatocellular carcinoma, gallbladder adenocarcinoma, and colorectal cancer) evaluated the association of IBD with HD risk in PSC patients. Multivariable Cox and Poisson regression provided complementary analyses, adjusting for established risk factors including *cirrhosis*. Prespecified sensitivity analyses assessed IBD subtype (Ulcerative colitis *vs.* Crohn's disease) and IBD diagnosis timing (before and after PSC diagnosis).
Results: Among 611 PSC patients (mean age 34 ± 16 years, 64% male), 72% had concomitant IBD (71% ulcerative colitis, 29% Crohn's disease), with 26% diagnosed after PSC. PSC patients with IBD were younger, more frequently male, more likely to have small-duct PSC, and had higher platelet counts (all p < 0.05). Over a mean follow-up of 9.4 (±7.7) years, 30% experienced HD, 37.2% underwent LT, and 5% developed hepatobiliary malignancy. In competing risk analysis, IBD was *not* associated with HD (Fine-Gray sHR: 0.83, 95%CI: 0.51–1.27; Poisson adjusted IRR 0.70, 95%CI: 0.46–1.04). Null associations persisted for LT-free survival and hepatobiliary malignancy in Cox-models, and across IBD subtype and diagnostic timings. Instead, *cirrhosis* at diagnosis was the strongest independent predictor of HD across all adjusted models (Fine-Gray sHR: 2.85, p = 0.008; Poisson adjusted IRR: 2.84, p = 0.002).
Conclusion: In this large, long-term PSC cohort, concomitant IBD, regardless of subtype or diagnostic timing, was *not* independently associated with HD, transplant-free survival, or hepatobiliary malignancy in PSC, across competing-risks, Cox, and Poisson regression. Conversely, cirrhosis was an independent predictor of HD. Hepatic risk stratification should prioritize disease severity markers like *cirrhosis* over IBD status, advocating a shift towards risk-based surveillance and trial design.

SAT-441
One in four adults have already developed cirrhosis at the time of primary biliary cholangitis diagnosis among a national cohort of veterans in the United States
Robert Wong[1], Zeyuan Yang[2], Ramsey C. Cheung[1]. *[1]Stanford University School of Medicine, VA Palo Alto Health Care System, Palo Alto, United States; [2]VA Palo Alto Health Care System, Palo Alto, United States*
Email: rwong123@stanford.edu

Background and aims: Primary biliary cholangitis (PBC) is a progressive cholestatic liver disease associated with significant morbidity and mortality. Delays in timely diagnosis and linkage to treatment contributes to continued liver injury and progression to cirrhosis and liver-related mortality. We aim to evaluate the prevalence of cirrhosis at time of PBC diagnosis among a national cohort of U.S. Veterans, which reflects delays in timely diagnosis and linkage to care.
Method: Adults with PBC were identified using National Veterans Affairs data from January 1, 2010 to April 30, 2025. PBC was diagnosed based on established definitions and incorporated the presence of ≥1 inpatient or ≥2 outpatient ICD-9/10 diagnosis codes for PBC. The proportion of patients with cirrhosis at time of PBC diagnosis was identified using validated algorithms based on ICD-9/10 diagnosis codes. Comparisons of cirrhosis proportions at time of PBC diagnosis was stratified by sex, age, and race/ethnicity and compared between groups utilized chi-square methods.
Results: Overall prevalence of PBC was 51.6 per 100,000 persons. Among 2147 adults with PBC (mean age 64.6 years, 79.5% men, 78.4% non-Hispanic white, 11.7% African American, 7.1% Hispanic, 2.2% Asian), 24.9% had concurrent diabetes mellitus, 48.9% dyslipidemia, 59.5% hypertension, and median alkaline phosphatase was 157 U/L (IQR 103–256). Overall, 25.3% (95% CI 23.6–27.0) had evidence of cirrhosis at time of PBC diagnosis, which was similar in men (25.3%, 95% CI 23.4–27.2) and women (25.4%, 95% 21.8–29.0). Proportion with cirrhosis at PBC diagnosis was significantly higher in younger patients age 18–39y (40.0% vs. 28.9% in age 40–59y, p < 0.05). Compared to non-Hispanic whites, proportion with cirrhosis was similar among Asians and Hispanics, but African Americans had significantly lower proportion with cirrhosis at diagnosis (20.5% vs. 26.3%, p = 0.02). When stratified by sex and race/ethnicity, the proportion of patients with cirrhosis at diagnosis was lowest among Asian women (14.3%) and highest among Asian men (28.6%).
Conclusion: Among a national cohort of U.S. Veterans with PBC, more than one in four already had developed cirrhosis at time of PBC diagnosis. This was particularly observed for non-Hispanic whites and Asian men. Greater awareness and vigilance are needed to improve timely diagnosis and treatment of patients with PBC to prevent liver-related morbidity and mortality.

SAT-442
Real-world efficacy and safety of fibrates in patients with primary biliary cholangitis
Ewa Wunsch[1], Karolina Wronka[2], Maciej Janik[2], Beata Kruk[3], Sebastian Jędruszek[1], Kaja Kozłowska[1], Magdalena Jaroszek[2], Jacek Tomczuk[2], Joanna Raszeja-Wyszomirska[2], Piotr Milkiewicz[1,2]. *[1]Division of Gastroenterology, Department of Translational Medicine, Pomeranian Medical University in Szczecin, Szczecin, Poland; [2]Department of Hepatology, Transplantology and Internal Medicine, Medical Universty of Warsaw, Warsaw, Poland; [3]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland*
Email: ewa.wunsch@pum.edu.pl

Background and aims: Fibric acid derivatives are used off-label as second-line therapy in patients with primary biliary cholangitis (PBC) with an inadequate response to ursodeoxycholic acid (UDCA) and are

recommended by EASL for the treatment of cholestatic pruritus. However, real-world data on their effectiveness and safety remain limited. We aimed to assess the real-world clinical use, efficacy and tolerability of fibrates in patients with PBC.
Method: This study included all consecutive patients with PBC treated since 2019 in two Polish tertiary university centers. Patients with decompensated liver cirrhosis, after liver transplantation or lost to follow-up were excluded. Clinical, laboratory and drug regimens data were extracted from medical records and analyzed retrospectively.
Results: Among 396 patients with PBC (361 females, mean age 52 ± 12 years), 145 (37%; 132 females, mean age 56 ± 12 years) received fibrates as add-on therapy to UDCA. The main indications were inadequate biochemical response to UDCA according to Barcelona criteria (68%), cholestatic pruritus (21%) and dyslipidaemia (16%). Fenofibrate was the initial agent in 143 (97%) of cases, while bezafibrate - in two remaining patients. Fibrate therapy was associated with a significant improvement in liver biochemistry (reduction in ALP from 248 ± 12 to 160 ± 8 IU/L, $p < 0.001$; GGT from 185 ± 14 to 120 ± 11 IU/L, $p < 0.001$; and ALT from 57 ± 3 to 47 ± 2 IU/L, $p = 0.002$). No differences were observed in albumin, INR, platelets and creatinine levels. Adverse events were reported in 30 (20%) of patients, most frequently myopathy, gastrointestinal intolerance, renal function deterioration and hypertransaminasemia. Due to lack of efficacy or tolerability, fenofibrate treatment was switched to bezafibrate in 10 patients, with recurrent intolerance observed in half of them. Overall, fibrate therapy was discontinued in 22 patients (15%). Owing to insufficient response, elafibranor was initiated recently in two patients, while linerixibat was introduced in two patients with refractory pruritus.
Conclusion: In real-world clinical practice, more than one-third of patients with PBC require second-line therapy. Fibrates provide significant biochemical improvement in vast majority of these patients; however, adverse events occur in a substantial proportion, leading to the discontinuation of therapy. This finding highlights the need for novel therapeutic alternatives with better tolerability, reinforcing the importance of expanding the treatment landscape in PBC.

SAT-443

Liver transplantation for cholestatic liver diseases: trends in primary biliary cholangitis and primary sclerosing cholangitis in the US and Europe over two decades

Zobair M. Younossi[1], Giacomo Germani[1,2], Robert Wong[1,3], Maria Stepanova[1], Fatema Nader[1], Vincent Karam[1,4], René Adam[1,5], Saleh Alqahtani[1,6], Rohit S. Satoskar[1,7], Linda Henry[1], Patrizia Burra[1,2]. *[1]The Global NASH/MASH Council, Washington DC, United States; [2]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy; [3]Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, United States; [4]The European Society for Organ Transplantation, Paris, France; [5]Hopital Paul Brousse, Villejuif, France; [6]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [7]Georgetown Medical Center, Washington DC, United States*
Email: zobair.younossi@cldq.org

Background and aims: Cholestatic liver diseases [primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC)] are indications for liver transplantation (LT). We assessed demographics, clinical features, and outcomes of LT recipients with PBC and PSC in the US and Europe.
Method: Adult LT recipients with PBC or PSC were identified from the European Liver Transplant Registry (ELTR) and U.S. Scientific Registry of Transplant Recipients (SRTR) (2000–2022).
Results: A total of 22,034 LT recipients were included (PBC n = 8774; PSC n = 13,260). PBC recipients were older (56 ± 10 vs. 46 ± 13 years) and predominantly female (85% vs. 31%) (both $p < 0.0001$). HCC was present in 5.4% of PBC, and cholangiocarcinoma in 2.4% of PSC patients. PBC patients had more ascites (66% vs. 50%) and hepatic encephalopathy (46% vs. 32%) (all $p < 0.0001$), and higher MELD scores (20 ± 9 vs. 19 ± 9, $p < 0.0001$). In the entire dataset, PBC as a proportion of all LTs declined from 6.2% (2000) to 2.9% (2022) ($p < 0.0001$), while PSC remained stable (5.9% to 5.7%, $p > 0.05$). Although the declines in PBC-LTs were observed in both SRTR and ELTR, PSC showed a recent increase in ELTR: 4.9% to 7.3% ($p < 0.05$). Post-transplant survival for PBC: 1-year 90%, 3-year 85%, 5-year 81%, 10-year 68%; for PSC: 1-year 92%, 3-year 86%, 5-year 81%, 10-year 69%. In multivariable survival analyses, post-transplant mortality in PBC was independently associated with earlier calendar year (aHR = (95% CI) = 0.980 (0.970–0.991) per year), older age (1.029 (1.023–1.035) per year), male sex (1.31 (1.16–1.48)), moderate (1.15 (1.02–1.29)) and severe hepatic encephalopathy (1.70 (1.40–2.06)), presence of HCC (1.31 (1.08–1.60)), and higher donor age (1.008 (1.005–1.010) per year) (all $p < 0.05$). In PSC, post-transplant mortality was also associated with earlier calendar year (0.975 (0.967–0.984) per year), older age (1.024 (1.021–1.028) per year), male sex (1.15 (1.05–1.26)), higher MELD score (1.017 (1.012–1.022) per 1 point), presence of cholangiocarcinoma (2.14 (1.74–2.64)), receiving a transplantation in a small transplant center (<15/year, aHR = 1.51 (1.09–2.09)), and older donor's age (1.007 (1.005–1.010) per year) (all $p < 0.05$).
Conclusion: Liver transplantations for PBC have declined, likely reflecting improved medical therapy, while PSC have remained stable, with recent increases in Europe. Three-year post-transplant survival exceeds 85% for both groups and continues to improve.

SAT-444

Fecal microbiota transplantation as an adjunctive therapy for refractory cholestatic liver disease: a prospective single-center exploratory study

Yu Zhang[1], Qi Wang[1], Minghui Li[1], Huichun Xing[1], Yifan Xu[1]. *[1]Beijing ditan hospital, Beijing, China*
Email: rainybaby_2527@126.com

Background and aims: Treatment options for refractory cholestatic liver disease are limited. This study evaluated the efficacy and safety of fecal microbiota transplantation (FMT) in patients with an inadequate response to standard therapy.
Method: Seventy patients with cholestatic liver disease, including those with primary biliary cholangitis and primary sclerosing cholangitis, who exhibited an insufficient biochemical response to at least 12 months of standard therapy (e.g., ursodeoxycholic acid) were enrolled. All patients received three weekly administrations of FMT via colonoscopy-guided enema while continuing their existing treatment regimen. The primary efficacy endpoint was the alkaline phosphatase (ALP) response rate at week 12, defined as a reduction of >40% from baseline or normalization of ALP levels. Secondary endpoints included changes in other liver biochemical parameters (serum total bile acids, γ-glutamyltransferase, total bilirubin), the Visual Analogue Scale for pruritus, the Chronic Liver Disease Questionnaire for quality of life, and the incidence of adverse events.
Results: At week 12, the intention-to-treat analysis yielded an overall ALP response rate of 68.6% (48/70). In the primary biliary cholangitis subgroup (n = 15), the response rate was 53.3% (8/15). Compared to baseline, significant reductions were observed in median levels of serum total bile acids, γ-glutamyltransferase, and total bilirubin (all $P < 0.001$). Pruritus scores and quality of life measures also showed significant improvement ($P < 0.01$). Regarding safety, only two patients (2.9%) experienced mild, transient adverse events (one with self-limiting low-grade fever and one with mild diarrhea). No serious adverse events or procedure-related infections were reported.
Conclusion: This preliminary study suggests that adjunctive FMT may improve biochemical response and alleviate clinical symptoms in patients with cholestatic liver disease refractory to standard therapy, demonstrating a favorable safety and tolerability profile. The

therapeutic effect is potentially mediated through the restoration of gut microbial ecology and subsequent modulation of the entero-hepatic bile acid circulation. These findings support the rationale for conducting larger-scale randomized controlled trials.

SAT-445

Clinical characteristics and predictors of poor biochemical response in patients with primary biliary cholangitis: a single-centre study from Xinjiang, China

Caihua Chang[1], Yilihamu Abulitifu[2], Yongping Zhang[2]. [1]*Xinjiang Uygur Autonomous Region People's Hospital, Uruqmi, China;* [2]*Xinjiang Uygur Autonomous Region People's Hospital, Urumqi, China*
Email: 2468005130@qq.com

Background and aims: The incidence of PBC has increased globally and in China in recent years. A comprehensive understanding of clinical characteristics and predictors of poor biochemical response to ursodeoxycholic acid (UDCA) is essential for early identification and optimized management. Data on PBC patients from Xinjiang are limited. This study aimed to analyze the clinical features and factors associated with poor biochemical response in PBC patients in Xinjiang.
Method: We retrospectively enrolled PBC patients diagnosed between November 2020 and November 2025 who received UDCA-based therapy for ≥12 months. Demographic data, clinical manifestations, laboratory parameters, treatment, and outcomes were collected. According to the Barcelona criteria, patients were classified as biochemical responders or non-responders. Multivariable logistic regression was used to identify predictors of poor response.
Results: A total of 190 PBC patients were included, predominantly female (female-to-male ratio ≈9:1), with a mean age of 55.46 ± 12.71 years. Clinically significant portal hypertension(CSPH) was present in 62 patients(32.63%), cirrhosis in 58(30.53%), and decompensated cirrhosis in 21(11.05%). Pruritus and fatigue were reported in 28.42% and 33.16% of patients, respectively, while jaundice occurred in 23.16%. Concomitant metabolic-associated fatty liver disease and autoimmune hepatitis were each observed in 13.68% of patients. Median APRI and FIB-4 scores were 0.74(0.34–1.88) and 2.13(1.19–4.50), respectively. Median alkaline phosphatase was 132.50 U/L, γ-glutamyl transferase 117.00 U/L, alanine aminotransferase 35.45 U/L, aspartate aminotransferase 47.00 U/L, total bilirubin 13.90 μmol/L, and direct bilirubin 5.18 μmol/L. Antimitochondrial antibody positivity was detected in 63.69% of patients and gp210 antibodies in 18.95%. Most patients(88.42%) received UDCA monotherapy, with a biochemical response rate of 61.75%. Multivariable logistic regression identified baseline CSPH(OR = 9.20, 95% CI 1.34–63.17), IgM positivity (OR = 9.62, 95% CI 3.99–23.18), anti-gp210 positivity(OR = 6.77, 95% CI 1.86–24.65) and CHE(OR = 0.79, 95% CI 0.65–0.96) as independent predictors of poor biochemical response to UDCA ($P < 0.05$).
Conclusion: PBC patients in Xinjiang often present with advanced disease. UDCA monotherapy remains insufficient for a substantial proportion of patients. Baseline CSPH, CHE, IgM and anti-gp210 positivity may facilitate early risk stratification and support timely initiation of combination or second-line therapy.

Liver development and regeneration

A 3D atlas of liver tissue microarchitecture during regeneration reveals how hepatocyte division preserves bile canalicular integrity

Dilan Martinez Torres[1,2], Valeria Candia-Campano[1,2], Cristian Perez Gallardo[1,2], Hernán Morales-Navarrete[3], Fabián Segovia-Miranda[1,2]. [1]*Department of Cell Biology, Faculty of Biological-Sciences, Universidad de Concepción, Concepcion, Chile;* [2]*Grupo de Procesos en Biología del Desarrollo (GDeP), Faculty of Biological Sciences, Universidad de Concepción, Concepcion, Chile;* [3]*Bio-Cheminformatics Research Group, Universidad de Las Américas, Quito, Ecuador*
Email: dilanm954@gmail.com

Background and aims: The liver exhibits a remarkable regenerative capacity, restoring its mass within approximately seven days after 70% partial hepatectomy in mice. Successful regeneration, however, requires more than hepatocyte proliferation, demanding the coordinated reconstruction of a highly organized three-dimensional tissue architecture that supports bile and blood flow. This architecture arises from hepatocyte multipolar polarity, aligning apical membranes to form bile canaliculi while maintaining basal sinusoidal interfaces. During regeneration, hepatocytes divide in a crowded environment while preserving bile canalicular integrity, a critical barrier preventing toxic bile acid leakage. How these architectural and functional constraints are maintained remains poorly understood. Here, we generated a time-resolved 3D atlas of liver tissue architecture and used it to investigate how dividing hepatocytes preserve bile canalicular integrity.
Method: Eight- to ten-week-old C57BL/6J mice were subjected to a 70% partial hepatectomy. Fixation was performed by transcardial perfusion at daily intervals (days 1–7) post hepatectomy, followed by the collection of 200 μm vibratome liver sections. Sections were stained for cell borders (phalloidin), bile canaliculi (CD13), sinusoids (FLK-1), and nuclei (DAPI), and subsequently cleared using the SeeDB protocol. Images were acquired using a multiphoton microscope and were processed, reconstructed in 3D, and analyzed using Fiji and MotionTracking software powered by neural networks.
Results: The 3D atlas provides a comprehensive overview of liver tissue organization throughout regeneration. Analysis of hepatocyte division across metaphase, anaphase, and cytokinesis revealed that the spatial organization of apical membranes preserves bile canalicular continuity and consistently positions apical domains between sister cells to generate a new bile canalicular segment. Apical, basal, and lateral membrane domains were symmetrically inherited by daughter cells.
Conclusion: This 3D atlas provides a quantitative, tissue-scale framework to study liver regeneration. By linking hepatocyte division to the preservation of bile canalicular integrity, our work highlights how functional tissue architecture is maintained during regeneration. Moreover, this dataset establishes a foundation for computational and biophysical modeling of tissue growth, polarity maintenance, and network remodeling.

Graphene oxide nanoparticles mitigate ethanol-induced liver injury by modulating miR21, miR-122 and miR-214–associated autophagy pathways

Hiral Aghara[1], Palash Mandal[1]. [1]*Charotar University of Science and Technology Gate, Petlad, India*
Email: hiralaghara@gmail.com

Background and aims: Alcohol-associated liver disease (ALD) is characterized by hepatic lipid accumulation, inflammation, and impaired autophagy, leading to progressive liver injury. Dysregulation of microRNAs (miRNAs), including miR-21, miR-122, and miR-214, plays a key role in regulating lipid metabolism and inflammatory responses during ethanol-induced liver damage. Graphene oxide nanoparticles (GNPs) have emerged as biologically active nanomaterials with the potential to modulate cellular stress responses. This study aimed to evaluate whether GNPs mitigate ethanol-induced liver injury by restoring autophagy through miRNA modulation.
Method: In vitro studies were performed using HepG2 hepatocyte cells exposed to ethanol, followed by GNP treatment. The protective effects of GNPs were assessed using Oil Red O staining and analysis of

autophagy and inflammation-associated mRNA expression. To assess in vivo relevance, male Wistar rats were fed a liquid diet containing 5% ethanol for 28 days. During the ethanol-feeding period, rats received oral administration of GNPs (10 mg/kg), at 5-day intervals. Hepatic injury was evaluated using serum biochemical parameters, histopathological assessment, and lipid staining. Hepatic mRNA expression of autophagy- and inflammation-related genes, along with miRNA expression profiling (miR-21, miR-122, and miR-214), was performed at the end of the study.
Results: Ethanol exposure induced significant lipid accumulation and suppression of autophagy associated mRNA expression in HepG2 cells, accompanied by increased inflammatory gene expression. GNP treatment markedly reduced intracellular lipid accumulation and restored autophagy-related mRNA expression. In vivo, chronic ethanol feeding resulted in hepatic steatosis, elevated serum biochemical markers of liver injury, and histological evidence of liver damage. GNP administration significantly attenuated these effects, reducing hepatic lipid accumulation and improving liver histology. Ethanol-induced dysregulation of hepatic miRNAs, characterized by decreased miR-122 and increased miR-21 and miR-214 expression, was normalized following GNP treatment. These changes were associated with restoration of autophagy-related mRNA expression and attenuation of inflammatory signalling.
Conclusion: GNPs mitigate ethanol-induced liver injury by modulating miR-21, miR-122, and miR-214–associated autophagy pathways. These findings support GNPs as a protective nanoplatform for limiting disease progression in alcohol-associated liver disease.

Engineered extracellular vesicles derived from mesenchymal stem cells enriched with insulin-like growth factor I restore impaired liver regeneration after partial hepatectomy in fibrotic livers
Mailín Casadei[1,2,2], María José Cantero[1], Bárbara Bueloni[1], Fátima Huamán Ormeño[1], Lucía Perez[1], Lucía Lameroli[1], Brian Martinez Ruiz[1], Catalina Atorrasagasti[1], Juan Bayo Fina[1], Esteban Fiore[1], Guillermo Mazzolini[1]. [1]*Instituto de Investigaciones en Medicina Traslacional CONICET-Universidad Austral, Pilar, Argentina;* [2]*Instituto de Investigaciones en Medicina Traslacional CONICET-Austral, Pilar, Argentina*
Email: mcasadei@austral.edu.ar

Background and aims: The liver exhibits a remarkable regenerative capacity, however, this ability is progressively impaired during chronic liver injury. In this context, mesenchymal stem cell–derived extracellular vesicles (MSC-EV) represent a promising cell-free therapeutic strategy due to their immunomodulatory and pro-regenerative properties. Moreover, EV can be genetically engineered to deliver therapeutic molecules such as insulin-like growth factor I (IGF-I), a well-established hepatoprotective and pro-regenerative factor. The aim of this study is to evaluate whether IGF-I–loaded EV can restore liver regeneration in fibrotic mouse livers using a partial hepatectomy (PHx) model.
Method: EV were isolated from umbilical cord–derived MSC transduced with adenoviruses encoding green fluorescent protein (GFP-EV) or IGF-I (IGF-I-EV). Fibrosis was induced in adult male C57BL/6 mice by intraperitoneal administration of thioacetamide (0.2 mg/g body weight, 3 times/week) for 8 weeks, followed by 66% PHx. One hour later, mice received a single intravenous dose of vehicle, GFP-EV or IGF-EV (0.05 mg/mouse) and were euthanized 3 days later for liver sample collection (n = 6/group). Liver regeneration was assessed by liver index (liver/body weight) and regeneration rate (% of recovered liver mass), PCNA immunohistochemistry and qPCR analysis of Pcna, Hgf and Igf-I genes. Liver injury was evaluated by serum alanine and aspartate aminotransferase and lactate dehydrogenase levels.Fibrosis was analyzed by Sirius Red staining and gene expression of Col1A2 and Acta2, while inflammation was assessed by expression of Tnf-alpha, Il1-beta, iNOS, Il10 and Arg1.
Results: IGF-I-EV enhanced liver regeneration in fibrotic mice after PHx, restoring liver index and liver regeneration rate to levels comparable to non-fibrotic PHx controls. This was associated with increased PCNA-positive hepatocytes and upregulation of regeneration-related genes. This effect was associated with reduced liver injury, as evidenced by lower serum aspartate aminotransferase and lactate dehydrogenase levels. Importantly, IGF-I-EV attenuated fibrosis after resection, as shown by reduced collagen deposition and downregulation of Col1A2 and Acta2. This was accompanied by a dampened inflammatory response, with decreased expression of pro-inflammatory genes such as Tnf-alpha, Il1-beta and iNOS.
Conclusion: Our data support IGF-I–EV as a potential strategy to restore impaired liver regeneration in the context of partial hepatectomy in fibrotic livers.

Macrophages drive spatially specific liver regeneration via arginine metabolism reprogramming: the translational potential of arginine supplementation
Jinwei Chen[1], Min Tang[1], Xiaorong Xu[2]. [1]*Tongji University, Tongji University Affiliated Tongji Hospital, Shanghai Tenth People's Hospital, Shanghai, China;* [2]*Tongji University, Shanghai Tenth People's Hospital, Shanghai, China*
Email: 2411217@tongji.edu.cn

Background and aims: Liver regeneration follows a strict spatiotemporal pattern, typically initiated by periportal hepatocytes. The mechanisms underlying this zonation-specific initiation, particularly how immune cells set the spatiotemporal program by modulating metabolic reprogramming, remain unclear. This study aimed to reveal how myeloid S100A4^{+} macrophage deficiency reshapes the regenerative landscape and elucidates its role in driving arginine metabolic reprogramming via IL-6 signaling to activate the proliferative program in specific hepatocyte zones.
Method: Myeloid-specific S100A4 knockout (S100A4 cKO) mice and a 70% partial hepatectomy model were used. Zonation-specific transcriptional programs in regenerating hepatocytes were analyzed by single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics. High-resolution multiplex immunofluorescence, flow cytometry, metabolomics, and in vivo functional experiments were employed for validation.
Results: In S100A4 cKO mice, the core regenerative region shifted from the periportal zone (zone 1) to the mid-lobular zone (zone 2), with enhanced liver weight restoration and proliferation. Single-cell and spatial analyses showed coordinated activation of IL-6 signaling and arginine anabolic pathways in zone 2 hepatocytes. cKO elevated hepatic IL-6 levels and upregulated hepatocyte IL-6 receptor expression, driving sustained JAK-STAT3 activation. STAT3 directly promoted expression of arginine synthesis enzymes ASS1 and OTC, increasing de novo arginine synthesis. Arginine accumulation activated mTORC1 to drive the cell cycle while its metabolites suppressed ferroptosis, specifically unlocking zone 2 hepatocyte proliferation. Exogenous arginine supplementation effectively recapitulated this spatially specific regeneration enhancement, demonstrating translational potential.
Conclusion: This study identifies myeloid S100A4 as a key regulator of liver regeneration spatial programming. Its deficiency activates the IL-6-arginine metabolic axis, triggering zonation-specific metabolic reprogramming that determines regeneration location and intensity. Arginine supplementation may therefore support liver regeneration, benefiting patients awaiting transplants or recovering from resection.

Cell type-specific role of CD44 in liver regeneration

Tanja Derowski[1], Sophia Bernatik[1], Kohnke-Ertel Birgit[1], Fabian Delugré[1], Franziska Ihli[1], Magdalena Kolmstetter[1], Fabian Geisler[1], Carolin Mogler[2], Roland M. Schmid[1], Ursula Ehmer[1]. *[1]Department for Internal Medicine II, TUM School of Medicine and Health, Technical University of Munich, TUM University Hospital, Munich, Germany; [2]Institute of Pathology, School of Medicine, Technical University of Munich, Comparative Experimental Pathology, School of Medicine, Technical University of Munich, Munich, Germany*
Email: tanja.derowski@gmail.com

Background and aims: CD44 is barely detectable in healthy adult livers but is strongly upregulated during chronic liver injury. Previous data suggest that CD44 promotes proliferation in hepatocytes and cells of the ductular reaction (DR) via injury- and cell type-specific pathways. Here, we aimed to uncover the cell-type dependent molecular mechanisms downstream of CD44.
Method: Hepatocyte injury was induced in *Cd44*$^{-/-}$ and age-matched C57BL/6J control mice by a choline-deficient, ethionine-supplemented diet (CDE). As a model of chronic cholestatic liver injury, *Mdr2*$^{-/-}$; *Cd44*$^{-/-}$ mice and age-matched *Mdr2*$^{-/-}$ control mice were used. Formalin-fixed, paraffin-embedded livers were analyzed by single-nucleus RNA sequencing.
Results: Compared to the healthy liver, *Mdr2*$^{-/-}$ and CDE liver injury models both showed expansion of hepatic stellate cells (HSCs), immune cells, and cells of the DR. CD44 expression was mainly found in DR cells, cholangiocytes, and immune cells. In both models, *Cd44*$^{-/-}$ mice displayed a marked reduction of DR cells, while effects on overall immune cells and HSCs were largely negligible. Pathway analysis indicated differential regulation of several pathways such as MAPK, mTOR, Myc, and Wnt signaling – in part in a cell-type dependent manner.
Conclusion: Our data support the role of CD44 as a key driver of the ductular reaction and proliferation in liver injury with cell-type specific activation of several pro-proliferative downstream pathways as potential targets in the treatment of chronic liver injury.

THU-346

Engineering a fibrotic organoid chip revealing ductular reaction driven by matrix-derived forces

Mengqi Zhu[1,2,3], Yu Du[1,2], Mian Long[1,2]. *[1]Insitute of Mechanics, Chinese Academy of Sciences, Beijing, China; [2]School of Engineering Science, University of Chinese Academy of Sciences, Beijing, China; [3]School of Materials Science and Engineering, East China University of Science and Technology, Shanghai, China*
Email: zmq17i@126.com

Background and aims: Ductular reaction (DR) is a hallmark of chronic liver diseases, characterized by compensatory proliferation of biliary epithelial cells (BECs). Temporal delay between extracellular matrix (ECM) deposition and BEC expansion suggests a critical role of fibrotic niche in DR progression. During fibrosis, ECM undergoes profound biomechanical remodeling, becoming stiffer and generating altered mechanical stresses. However, the mechanism by which these matrix-derived mechanical cues drive DR remains poorly understood, largely due to the absence of in vitro models that recapitulate the dynamic 3D mechanical microenvironment of fibrotic liver. Here, we developed a novel bioengineered fibrotic organoid chip (FOC) that incorporates *in vivo* matrix composition, multicellular architecture, and measurable mechanical cues, dissecting the mechanotransductive pathways of DR.
Method: The FOC was created by seeding BECs and fibroblasts within a collagen/Matrigel matrix into microfabricated arrays of microwells with microcantilevers. Self-organized 3D microtissues were cultured for 6 days. Matrix remodeling was assessed via second harmonic generation (SHG) imaging, tissue stiffness by nanoindentation, and contractile forces in real time through cantilever deflection. Mechanical stresses on organoids were quantified using embedded elastic round microgels (ERMGs), together with numerical simulations.
Results: The FOC supported the well-defined co-culture of biliary organoids and fibroblasts, both maintaining phenotypic markers. The FOC formed fibrotic briding band with aligned collagen fibers, increased stiffness, and progressive contraction over time. Organoids within fibrotic niches showed enhanced growth and morphological deformation under contraction. ERMG-based force mapping revealed a shift from tensile to compressive stress on organoids in fibrotic tissues. Pharmacological inhibition of ROCK or myosin II reduced both tissue contraction and organoid growth. Redistribution of α2 integrin under fibrotic cues and reduced BECs growth under inhibition further indicated mechanosensitive regulation of proliferation.
Conclusion: This study established a biomimetic FOC recapitulating key structural and mechanical features of DR, and demonstrated that matrix-derived contractile forces and stiffness actively promote BEC expansion and deformation through mechanotransductive pathways involving ROCK/myosin and α2 integrin, highlighting the role of biomechanical cues in chronic liver disease progression.

Generation of sinusoidal-like endothelial cells from human induced pluripotent stem cells (hiPSCs) for 3D liver models

Clelia Ferraro[1], Riccardo Perriera[1], Minjie Zhao[2], Martina Morsicato[1], Salvatore Gruttadauria[1], Valentina Agnese[1], Massimo Pinzani[1], Giovanni Zito[1]. *[1]ISMETT - Istituto Mediterraneo per i Trapianti Ismett IRCCS, Palermo, Italy; [2]Department of Hepatobiliary Surgery, Chongqing, China*
Email: cleliaferr93@gmail.com

Background and aims: The liver is a highly complex vascularized organ in which liver sinusoidal endothelial cells (LSECs) play a central role in tissue architecture, metabolic exchange, and paracrine signaling. Advanced three-dimensional (3D) in vitro models are required to recapitulate this complexity. Human induced pluripotent stem cells (hiPSCs) provide a valuable platform to generate defined components of the hepatic microenvironment. This study aimed to generate endothelial cells with sinusoidal potential from hiPSCs and to assess whether a 3D microenvironment promotes maturation toward a sinusoidal phenotype.
Method: hiPSCs were differentiated into endothelial-like cells using four protocols (A–D) applied at defined time points. Cell populations were characterized by morphology and transcriptional analysis of endothelial markers. Selected endothelial cells were then integrated into 3D liver models.
Results: Protocols A and C induced expression of CD36 and STAB2, suggesting metabolic and scavenger activity, but showed weak and variable PECAM, CDH5, and ERG expression, with only transient LYVE1 detection. Protocol B did not promote endothelial commitment. In contrast, Protocol D generated cells with a stable endothelial identity, consistent STAB2 and CD36 expression, and low but reproducible LYVE1 levels, compatible with an immature sinusoidal phenotype. These cells were suitable for incorporation into 3D assembloids, where further maturation is expected.
Conclusion: We identify an optimized strategy to generate LSEC-like cells from hiPSCs, providing a robust platform for 3D liver models to study endothelial maturation and cell–cell interactions in a physiologically relevant microenvironment.

Interleukin-17a induces hepatocyte conversion into hepatic progenitor-like cells with stem cell characteristics

Pei-Chi Huang[1], Ben Higgins[1], Man Chun Wong[1], Gareth Hardisty[1], Jonathan Fallowfield[1,2,2], Wei-Yu Lu[1]. [1]*University of Edinburgh, Institute For Regeneration and Repair, Edinburgh, United Kingdom;* [2]*Centre for Inflammation Research, Institute for Regeneration and Repair, University of Edinburgh, Edinburgh, United Kingdom*
Email: p.huang-15@sms.ed.ac.uk

Background and aims: Liver transplantation is the only treatment for end-stage disease, while the lack of available donor organs makes alternative therapies warranted. Low proliferation of hepatocytes *in vitro* is the main challenge in using hepatocytes for cellular therapy. Proinflammatory signals play important roles in mediating tissue repair, cell proliferation and plasticity. We aim to investigate if proinflammatory cytokines could promote hepatocyte cellular plasticity and expansion *in vitro*, ultimately improving the repopulation capacity of expanded hepatocytes.
Method: RFP+ hepatocytes were isolated from tdTomato^{LSL} transgenic mice. Isolated hepatocytes were cultured with either Tissue Necrosis Factor (TNF)-alpha or Interleukin (IL)-17a *in vitro* on collagen-coated plates. Expanded cells were characterised and transplanted into the mouse with p21 overexpressed hepatocytes.
Results: Expanded Primary Hepatocytes (ExPHs) cultured with either TNF-alpha or IL-17a were reprogrammed towards a progenitor phenotype with the upregulation of *Krt19*, *Sox9,* and *Epcam* and downregulation of hepatic markers (*Hnf4a, Hnf1a* and *Asgr1)*. Both TNF-alpha and IL-17a activated the NFkB pathway and promoted ExPHs proliferation. Interestingly, IL-17a ExPHs had the highest expression of biliary and hepatic genes and maintained a higher epithelial phenotype and hepatocyte functions compared to the TNF-alpha expanded group. Bulk RNA sequencing identified the upregulation of stem cell markers (*Prom1* and *Tnfrsf12a)*, on IL-17a ExPHs. Epithelial-Mesenchymal Transition (EMT) genes were upregulated on TNF-alpha ExPHs with the downregulation of cell adhesion and epithelial markers, revealing the instability of TNF-alpha ExPHs. Functionally, IL-17a ExPHs can be differentiated into cells with hepatocyte or biliary function. On the contrary, TNF-alpha ExPHs failed to secrete albumin and store glycogen. We successfully transplanted IL-17a ExPHs into injured mouse livers, and these RFP+ IL-17a ExPHs engrafted the injured liver, and improved mouse survivability compared to the sham transplanted group.
Conclusion: Pro-inflammatory cytokines improve hepatocyte expandability and promote cellular plasticity *in vitro*, while IL-17a treatment stabilised hepatocytes during long-term culture with epithelial properties and hepatocyte functions. The long-term function and stability of ExPHs *in vivo* remains to be tested.

THU-351

Hepatic-lobule-mimetic spheroids composed of chemically derived hepatic progenitors and endothelial cells enhance liver regeneration via spatial patterning

Hee Ju Kim[1], Elsy Soraya Salas Silva[1], Minji Park[2], Ji Hyun Shin[1], Songwan Jin[2], Dongho Choi[1]. [1]*Department of Surgery, Hanyang University College of Medicine, 222, Wangsimni-ro, Seongdong-gu, Seoul, Korea, Rep. of South;* [2]*Research Institute, T&R Biofab. Co. Ltd., Siheung-si, Gyeonggi-do, Korea, Rep. of South*
Email: crane87@hanyang.ac.kr

Background and aims: Conventional 3D hepatic models often fail to recapitulate the hierarchical vascular architecture and functional maturation of native liver tissue. To address this, we established hepatic-lobule-mimetic spheroids composed of mouse chemically derived hepatic progenitors (mCdHs) and endothelial cells (SVEC4-10). This study aimed to systematically evaluate how spatial patterning influences hepatic development and identify the optimal architecture for liver regeneration.
Method: We utilized a preset extrusion-based microfluidic bioprinting strategy to fabricate three defined architectures: non-structured, core-shell, and segmented. This approach enabled precise control over cellular arrangement. Spheroids were evaluated for morphological stability, hepatic differentiation, and angiogenic potential in vitro. Furthermore, orthotopic transplantation into fumarylacetoacetate hydrolase-deficient (*Fah-/-*) mice was performed to assess in vivo engraftment, biocompatibility, and structural integrity.
Results: Among the three architectures, segmented spheroids maintained a stable tripartite geometry for four days and displayed markedly enhanced hepatic differentiation. By Day 10, the segmented group showed a 1.5–1.8-fold increase in albumin and urea secretion relative to other groups. Immunohistochemical analysis revealed spatially confined SOX9+ progenitors within the central region, indicative of zonal maturation, while Matrigel assays demonstrated organized CD31+ angiogenic sprouting specific to structured architectures. In vivo transplantation confirmed that segmented spheroids achieved superior engraftment and structural retention compared to counterparts, leading to significant functional recovery *in Fah-/-* mice.
Conclusion: Collectively, these findings demonstrate that precise spatial control within spheroids significantly improves hepatic maturation and vascularization. The segmented architecture, confirmed as the most effective model in both in vitro and in vivo settings, offers a scalable and translationally relevant platform for regenerative medicine and liver disease modeling.

Surface-modified MSC exosomes with PEGylation and SE-1 antibody conjugation for enhanced circulation and LSEC-targeted therapy in liver fibrosis

Mi Ra Lee[1,2], Jin Suk Lee[2], HyunJung Chung[1,2], Seul Ki Han[1,2], Soon Koo Baik[1,2], Moon Young Kim[1,2]. [1]*Department of Internal Medicine, Wonju Severance Christian Hospital, Wonju, Korea, Rep. of South;* [2]*Regeneration Medicine Research Center, Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and aims: Liver fibrosis involves the defenestration of liver sinusoidal endothelial cells (LSECs), which disrupts physiological exchange between blood and hepatocytes. While mesenchymal stem cell (MSC)-derived exosomes show anti-fibrotic potential, their clinical use is limited by a lack of liver-targeting specificity. We aimed to develop a targeted delivery system by engineering exosomes to display antibodies against the SE-1 receptor, a specific marker on LSECs, to enhance hepatic accumulation and therapeutic efficacy.
Method: High-purity exosomes were isolated from the conditioned media of human MSCs using a Tangential Flow Filtration (TFF) system. To improve systemic stability and targeting capability, the exosomal surface was modified with polyethylene glycol (PEG) and conjugated with anti-SE-1 antibodies (Exo+SE-1). The physicochemical characteristics of the engineered exosomes were analyzed via nanoparticle tracking analysis (NTA), and cytotoxicity was evaluated using the Cell Counting Kit-8 (CCK-8) assay. Targeting specificity was assessed *in vitro* using primary LSECs. Furthermore, *in vivo* biodistribution and tissue accumulation were examined in a murine model following intravenous administration to verify the liver-homing ability of Exo+SE-1.
Results: The engineered Exo+SE-1 exhibited a uniform size distribution and high stability in physiological buffers due to PEGylation. *In*

vitro binding assays demonstrated that Exo+SE-1 bound significantly and specifically to SE-1-expressing LSECs compared to non-targeted control exosomes. In *in vivo* studies, the surface modification effectively reduced reticuloendothelial system (RES) clearance, resulting in a prolonged circulation half-life. Notably, biodistribution analysis revealed that Exo+SE-1 showed significantly enhanced accumulation in the liver tissue compared to unmodified exosomes, confirming effective active targeting to the hepatic endothelium.
Conclusion: This study establishes that SE-1 antibody-conjugated MSC exosomes can effectively target LSECs, overcoming the biodistribution limitations of native exosomes. By restoring LSEC function and delivering therapeutic cargo directly to the injury site, Exo+SE-1 represents a promising, clinically viable nanotherapeutic platform for the precision treatment of liver fibrosis and regeneration.

Spatio-temporal omics identifies ZEB1-BMP4 in hepatic stellate cells as a key axis for liver regeneration after acute injury
Jun Li[1], Bingqi Li[1], Heng Yao[1], Jing Jiang[1], Jiaojiao Xin[1], Xi Liang[1], Dongyan Shi[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases. The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The liver rapidly restores its structure and function after acute liver injury (ALI). Hepatic stellates cells (HSCs) are promptly activated upon ALI; however, the mechanisms through which HSCs contribute to liver repair remain unclear. This study aims to elucidate how HSCs orchestrate Mlxipl$^+$ hepatocytes to promote liver regeneration.
Method: The ALI mouse model was established via intraperitoneal injection of the anti-CD95 antibody JO2. Liver tissues and blood samples were collected at days 0, 1, 3 and 7 post-injury. Single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics (ST) were performed on liver tissues to explore the mechanism driving self-repair. Transcription factors (TF) and ligand-receptor analysis were conducted between HSCs and Mlxipl$^+$ hepatocytes to identify key signaling pathways involved in liver repair, and then were validated experimentally through functional interventions. Clinical relevance was evaluated using plasma, peripheral blood mononuclear cells and liver tissues derived from patients with acute and acute-on-chronic liver failure.
Results: The ALI mouse model was successfully established, characterized with regional necrosis of liver tissue and elevated liver function makers. A spatiotemporal atlas of liver injury and repair was constructed by integrating scRNA-seq and ST data. Dynamic cell-cell interactions were observed among hepatocytes, endothelial cells and mesenchymal cells. Notably, similarity in cellular communication patterns at days 3 and 7 indicated that the process of liver repair stabilized by day 3. Sub-clustering analysis further revealed strong interactions between HSCs and both classical and Mlxipl$^+$ hepatocytes, mediated through extracellular matrix regulation. TF analysis and ChIP-qPCR confirmed that ZEB1 in HSCs binds to and transcriptionally regulates the BMP4 promoter. The overexpression and knockdown of ZEB1 correspondingly altered BMP4 expression ($p < 0.0001$). Plasma BMP4 levels were significantly higher in liver failure patients than in healthy controls ($p < 0.01$). Exogenous BMP4 supplementation also alleviated injury in primary hepatocytes in vitro.
Conclusion: This study maps the spatiotemporal dynamics of liver repair, highlighting the decline and rebound of HSCs and hepatocytes during injury and recovery. We identify the ZEB1-BMP4 axis in HSCs as a key mechanism promoting Mlxipl$^+$ hepatocyte proliferation and tissue regeneration, offering a novel therapeutic target for ALI.

Email: jassi2param@gmail.com

Background and aims: Partial hepatectomy (PHx) is a well-established model for studying acute liver regeneration; yet, molecular distinctions between successful regeneration and recovery from chronic liver injury remain unclear. Alcohol-related liver disease (ALD) exhibits impaired regeneration and progressive hepatic dysfunction. We investigated protein turnover dynamics during liver regeneration and identified key regenerative proteins disrupted in ALD and the effect of alcohol abstinence.
Method: A deuterium oxide (D_2O) labeling approach was used to measure protein turnover in rats with PHx, ALD, and alcohol abstinence. Animals received a priming intraperitoneal dose of 99.9% D_2O (0.35 mL/g) on Day 0, followed by 8% D_2O in drinking water for 7 days. Liver samples were collected on Days 1, 3, 5, and 7. Turnover and pathway analyses identified key regenerative proteins, which were validated by siRNA knockdown in HepG2 cells.
Results: PHx-induced regeneration showed liver-to-body weight ratio and ALT/AST normalized by Day-7. D_2O-analysis revealed 358 proteins with increased turnover post-PHx, particularly in mitochondrial metabolism, protein synthesis, and oxidative phosphorylation (FC>1.5, $p < 0.05$). ALD showed suppressed turnover of 27 PHx-associated proteins, reflecting impaired regenerative capacity. Abstinence partially restored regenerative responses, with 30 proteins commonly elevated in PHx and Abstinence. Among these, GOT2, ETFA, ETFB, HADH, and RPS19 were top-ranked regenerative markers. Their siRNA-mediated knockdown in HepG2 cells reduced expression by 70–90% ($p < 0.001$), decreased BrdU incorporation (50–60%, $p < 0.001$), reduced PCNA expression (~2-fold, $p < 0.01$), and delayed wound closure ($p < 0.01$), confirming their roles in hepatocyte proliferation. Proteomics revealed that GOT2 and RPS19, which are most compromised regenerative proteins linked to the cell cycle (FC > 1.5, $p < 0.05$), were affected post-knockdown.
Conclusion: Using PHx, we identified core regenerative proteins with increased turnover, indicating active liver regeneration. In ALD, these proteins showed suppressed turnover, reflecting impaired regeneration, while alcohol abstinence partially restored their turnover, suggesting recovery of regenerative programs. Overall, shared mitochondrial and biosynthetic turnover pathways were highlighted as essential for liver repair and as potential therapeutic targets.

THU-355-YI
Lymphangiocrine signal, Wnt7a is a key driver of cholangiocyte proliferation during liver regeneration
Aarti Sharma[1], Pinky Juneja[1], Deepika Jakhar[1], Jayesh Kumar Sevak[1], Ashwini Vasudevan[1], Simran Sharma[1], Impreet Kaur[1], Viniyendra Pamecha[1], Dinesh Mani Tripathi[1], Archana Rastogi[1], Shiv Kumar Sarin[1], Sumeet Singh[2], Savneet Kaur[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India;* [2]*Laboratory of Regeneration and Stress Biology, Institut de Recherche Interdisciplinaire en Biologie Humaine et Moléculaire (IRIBHM-Jacques E. Dumont), Université libre de Bruxelles, Belgium, Department of Life Sciences, School of Natural Sciences, Shiv Nadar Institution of Eminence, India, Bruxelles, Belgium*
Email: savykaur@gmail.com

Background and aims: Liver lymphatic vessels (LVs) and lymphatic endothelial cells (LyECs) were characterized after 70% partial

hepatectomy (PHx) to delineate their unexplored contribution to liver regeneration.
Method: We developed 70% PHx rat models and studied LVs and other hepatic cells at different time points. LC-MS/MS of LyECs was performed to identify specific protein signatures. Wnt7a, an identified secreted protein, was further investigated by *in-vivo* studies using lymphangiogenesis inhibitor in rat PHx models and in Wnt7a-knockout zebrafish. Effects of Wnt7a were evaluated on both primary rodent and human cholangiocyte (chol)-organoids. Serum Wnt7a levels were measured in live donor liver transplant (LDLT) and liver biopsies of post-transplant liver failure (PTLF) and post-hepatectomy liver failure (PHLF) patients.
Results: As compared to sham, increased number of dilated PDPN+ LVs were observed in portal areas at day (D) 2 post-PHx (2.56-fold, $p < 0.0001$). Proteomics of LyECs at D2 post-PHx revealed significant upregulation of a secreted protein, Wnt7a compared to sham. *In-vitro* studies of primary rat liver cells with Wnt7a established it as a potent stimulator of hepatocyte and cholangiocyte proliferation. *In-vivo* lymphangiogenesis inhibition by vegfr3 inhibitor in PHx models and *in-vivo* loss-of-function of Wnt7a in zebrafish resulted in reduction of bile ducts by 30 ± 2.7% and 45 ± 5.2% respectively. Mechanistically, Wnt7a activated downstream frizzled 7 (FZD7) receptor in cholangiocytes, driving their proliferation via planar cell polarity /FZD7-AKT-JAK-STAT pathway. In presence of Wnt7a, human chol-organoid proliferation was significantly increased as compared to untreated controls (1.8-fold, $p = 0.006$). In comparison to pre-operative baseline levels, elevated Wnt7a levels were seen in LDLT donors at D2 post-operatively (2.75-fold, $p = 0.04$). Patients with PTLF and PHLF showed weak expression of PDPN+Wnt7a+ LVs along with severe ductopenia.
Conclusion: Portal lymphangiogenesis constitutes a critical component of the regenerative response following 70% PHx. Specifically, Wnt7a secreted by LVs interacts with its cognate receptor, FZD7, on the cholangiocyte membrane and this novel lymphangiocrine signaling axis serves as a primary driver of biliary cell proliferation in the regenerating liver.

SLC1A5-dependent glutamine transport regulates macrophage senescence and efferocytosis during liver regeneration
Hao Wang[1], Haoran Hu[1], Jian Xu[1], Yuechen Wang[1], Yue Yu[1], Feng Cheng[1], Haoming Zhou[1]. *[1]The First Affiliated Hospital with Nanjing Medical University, Nanjing, China*
Email: hmzhou@njmu.edu.cn

Background and aims: Liver regeneration is an extraordinary process vital for the maintenance of homeostasis, governed by complex metabolic and immune interactions, particularly concerning the function of macrophages. Prior research underscores the significant role of these immune cells in the repair of tissue; nevertheless, the precise mechanisms that govern macrophage phenotypes and their functions throughout liver regeneration are not well understood. This study aims to investigate the role of SLC1A5, a neutral amino acid transporter responsible for glutamine transport, in macrophage senescence and efferocytosis during liver regeneration.
Method: We employed myeloid-specific SLC1A5 knockout mice ($SLC1A5^{fl/fl}Lyz2^{cre}$) in conjunction with a partial hepatectomy model to examine the effects of macrophage SLC1A5 deficiency on liver regeneration. Bone marrow-derived macrophages (BMDMs) were extracted and subjected to RNA sequencing and a range of functional assays to assess macrophage senescence, efferocytosis, and cytokine production levels.
Results: The results indicate that SLC1A5 is essential for thwarting macrophage senescence and maintaining efferocytosis during liver regeneration. Macrophages lacking SLC1A5 showed elevated senescence markers and transitioned towards a pro-inflammatory phenotype, marked by increased levels of TNF-α and IL-6. Significantly, efferocytosis was compromised due to the reduced expression of Gas6, a critical ligand for macrophage efferocytosis. Treatment with L-glutamine and recombinant Gas6 effectively restored macrophage functions and enhanced liver regeneration in vivo.
Conclusion: This investigation demonstrates that SLC1A5 is integral in modulating macrophage functions via glutamine transport during liver regeneration. The enhancement of glutamine availability may offer a new therapeutic strategy to alleviate macrophage senescence and promote liver recovery following injury.

Time-resolved single-cell profiling of liver fibrosis regression identifies monocyte-derived Kupffer cells as central mediators of resolution
Katharina Bonitz[1,2], Thomas Sorz-Nechay[1,2], Henriette Horstmeier[1], Katja Sommer[1,2], Vlad Taru[1], Oleksandr Petrenko[1,2], Benedikt Hofer[1], Benedikt Simbrunner[1], Kerstin Zinober[1], Katharina Regnat[1], Hubert Scharnagl[3], Raphael Bednarsky[1,2], Christoph Bock[1,2], Michael Trauner[1], Stefan Günther Kauschke[4], Peng Sun[4], Eric Simon[4], Philipp Schwabl[1], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Vienna, Austria; [2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [3]University Hospital Graz, Graz, Austria; [4]Boehringer Ingelheim Pharma GmbH & Co.KG, Biberach an der Riss, Germany*
Email: katharina.bonitz@meduniwien.ac.at

Background and aims: After cessation of liver injury fibrosis can spontaneously regress. However, the underlying molecular mechanisms of liver fibrosis regression remain poorly understood. Hepatic macrophages are key drivers of fibrosis progression, and understanding their transcriptomic changes in liver disease regression may uncover therapeutic targets.
Method: Liver fibrosis was induced in two murine models by administration of carbon tetrachloride (CCl_4) or by Choline-Deficient L-Amino Acid-Defined High Fat Diet (MASH) for 12 weeks. Healthy controls received olive oil or CHOW diet for 12 weeks. After disease induction spontaneous regression was allowed for 3, 7 and 14 days in the CCl_4 model, and for 7, 14 and 28 days in the MASH model. Animals were sacrificed at peak of disease and at the indicated timepoints of regression. At each study endpoint we assessed disease severity including collagen proportionate area, portal pressure and transaminases, and performed hepatic scRNA-Seq.
Results: Disease induction led to pronounced fibrosis, portal hypertension and liver injury compared to healthy controls – followed by significant improvements over the course of regression. We generated a single-cell fibrosis regression atlas with 183.000 cells across both models and all timepoints. Transcriptional state changed most in hepatic macrophages with seven distinct macrophage subpopulations. They contained monocyte-derived populations, such as scar-associated macrophages (Trem2+, Cd9+) and Kupffer cell (KC) signatures. While embryonically derived KCs (EmKCs: Clec4f+, Timd4+, Vsig4+) were exclusive to healthy controls, monocyte-derived KCs (MoKC: Clec4f+, Timd4-, Clec1b+) expanded in fibrosis regression in both disease models. Expansion of Clec1b+ MoKCs in regression was confirmed by flow cytometry. Differential gene expression analysis between MoKCs and EmKCs revealed an upregulation of genes encoding Matrix metalloproteinases (MMPs), most notably *Mmp12*, indicating a prominent role of MoKCs in extracellular matrix degradation facilitating liver disease regression.
Conclusion: We show that in two murine models of regressive liver disease, the strongest transcriptomic changes of all cell types occurred in hepatic macrophage populations. We identified an expanding

MoKC cluster, that replenishes the niche depleted EmKCs after liver disease. MoKCs demonstrated high *Mmp* expression – suggesting a key role in resolving liver fibrosis.

Prognostic immuneclassification in intrahepatic biliary tract cancer

Ira Godbole[1], Jannis Heyer[2], Konrad Kurowski[2], Philipp Holzner[3], Robert Thimme[1], Peter Bronsert[2], Bertram Bengsch[1]. [1]*Clinic for Internal Medicine II (Gastroenterology, Hepatology, Endocrinology and Infectious Diseases, Freiburg University Medical Center), Faculty of Medicine, University of Freiburg, Freiburg, Germany;* [2]*Institute of Pathology, Faculty of Medicine, University Hospital Freiburg, Freiburg, Germany;* [3]*Department of General and Visceral Surgery (Center for Surgery, Freiburg University Medical Center), Freiburg, Germany*
Email: ira.godbole@uniklinik-freiburg.de

Background and aims: Intrahepatic cholangiocarcinoma (iCCC), a major subtype of biliary tract cancer (BTC), is a highly aggressive malignancy with poor prognosis. Although immune checkpoint inhibitors are increasingly used in BTC, the spatial organization of the tumor immune microenvironment (TiME) and its relationship to outcome remain incompletely understood. Using spatial immune analysis within this project, we investigated how CD8 T cell infiltration and localization relative to tumor stroma and parenchyma define immunotypes with prognostic relevance, independent of treatment.
Method: Resectable iCCC tissue microarrays from a monocentric cohort of 98 patients, predominantly with grade 2 and grade 3 tumors, were analyzed using immunohistochemistry (IHC; n = 95) and 42-plex imaging mass cytometry (IMC; n = 27). The IMC panel covered tumor, immune, extracellular matrix, and architectural markers, enabling single-cell phenotyping with detailed CD8 T cell characterization. Tumor and stromal masks enabled regional CD8 T cell density quantification. Cut-offs were defined using cutoffR and validated in the IHC cohort using matched CD8 and collagen staining. Immune subclasses were spatially clustered to identify immune neighbourhoods and cell–cell interactions. Overall survival was assessed using Kaplan–Meier analysis of clinically annotated data.
Results: Spatial analysis identified three immune neighbourhoods with distinct compositions: IN1 enriched for cytotoxic and dysfunctional CD8 states, IN2 dominated by myeloid and macrophage populations, and IN3 showing higher frequencies of B cells and CD4 T cell subsets ($p < 0.001$). Based on CD8 T cell density and spatial localization, tumors were classified as depleted (<180 CD8 cells/mm^2; 59/95, 62.1%; mean OS 22.47 months), compartmentalized (tumor-to-stroma CD8 ratio <0.45; 6/95, 6.3%; mean OS 40.33 months), or enriched (ratio >0.45; 30/95, 31.5%; mean OS 60.9 months). Kaplan–Meier analysis showed significantly different survival, with enriched tumors outperforming depleted tumors ($p = 0.00696$) and compartmentalized tumors showing intermediate outcomes. Enriched tumors displayed increased CD8$^+$CD45RO$^+$ memory T cells, whereas depleted tumors showed higher FoxP3$^+$ regulatory T cells and myeloid-dominated neighbourhoods ($p = 0.0001$).
Conclusion: We establish a spatial CD8-based immune classification for iCCC that correlates with survival in immunotherapy-naïve patients and reflects intrinsic TiME biology, providing a robust framework for prognostic stratification.

WED-321-YI

Regulatory T cells polarise to TregTh1 in autoimmune cholangitis, yet cells remain functional, enabling GMP Treg therapy

Ayma Asif[1], Naomi Richardson[1], Grace Wootton[1], Kayani Kayani[1], Ye Htun Oo[1], Amber Bozward[1]. [1]*University of Birmingham, Birmingham, United Kingdom*
Email: a.g.bozward@bham.ac.uk

Background and aims: Primary biliary cholangitis (PBC) is an autoimmune cholestatic liver disease characterised by effector T cell–mediated biliary injury. Regulatory T cells (Tregs) are critical for restoring hepatic immune tolerance, yet their phenotype, functional stability and suitability for cell therapy in PBC remain incompletely defined. FoxP3 mutation in mice present with PBC like pathology in the liver. We investigated the frequency, phenotype, immunometabolic profile, lineage stability and suppressive function of Tregs in PBC, and assessed the feasibility of generating clinical-grade good manufacturing practice (GMP) Tregs for therapeutic application.
Method: Peripheral blood mononuclear cells and liver tissue were obtained from patients with PBC, other liver diseases and controls. Tregs were identified as CD4$^+$CD25$^+$CD127^{low} cells and analysed by flow cytometry for phenotypic, functional and metabolic markers. Suppression and lineage-stability assays were performed under Th1 and Th17 polarising conditions. Cytokines were quantified in serum and liver supernatant using LEGENDplex. GMP-grade Tregs were isolated, expanded and phenotyped under GMP conditions.
Results: The frequency of circulating Tregs was comparable between PBC (n = 13) and controls (n = 21). PBC Tregs expressed functional markers CD39, CTLA-4, and FoxP3, with the CD39^{high} subset exhibiting the highest CTLA-4 and FoxP3 expression ($p < 0.0001$). Naïve Tregs (CD45RA$^+$CCR7$^+$) were significantly reduced in PBC compared with AIH, ALD, and healthy donors ($p = 0.0350$, $p = 0.0132$, and $p = 0.0405$), with a reciprocal increase in effector memory Tregs versus ALD and HFE ($p < 0.0001$ and $p = 0.0045$). PBC Tregs remained metabolically competent, with no differences in mitochondrial mass or membrane potential. Under Th1-polarising conditions, PBC Tregs showed reduced FoxP3 stability compared with HFE ($p < 0.05$) without increased IFN-γ or TNF-α production, and suppressive function was preserved. PBC livers were enriched for IL-6 and IFN-γ compared with donor and MASH/ALD samples (all $p < 0.005$). Clinically relevant numbers of GMP-grade Tregs were successfully expanded from PBC patients while retaining phenotype and suppressive capacity.
Conclusion: Tregs in PBC retain suppressive capacity and metabolic competence despite phenotypic plasticity within an inflamed cytokine rich milieu. GMP-grade Treg therapy in PBC is feasible, applying CD39^{high} Tregs and preconditioning strategies targeting IL-12/Th1 pathways may enhance lineage stability and therapeutic efficacy.

WED-322

In silico prediction of microrna-t cell receptor constant region interactions: novel insights into autoimmune liver disease pathogenesis

Kiandokht Bashiri[1]. [1]*Georgetwon University/MedStar Washington Hospital Center, Washington DC, United States*
Email: kiandokht.bsh@gmail.com

Background and aims: Autoimmune liver diseases (ALDs), including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC), are marked by dysregulated T cell responses causing hepatic inflammation. T cell receptor (TCR) constant regions (TRAC for alpha; TRBC1/TRBC2 for beta) ensure TCR stability and signaling. MicroRNAs (miRNAs) regulate immune genes post-transcriptionally, with altered profiles in ALD. This novel in silico study predicted miRNA targeting of TCR constants, cross-referenced with ALD miRNAs, and performed functional enrichment to uncover pathogenic roles.
Method: Human mRNA sequences (TRAC: 4631 nt, ENSG00000277734; TRBC1: 1448 nt; TRBC2: 1489 nt) were analyzed via miRDB (scores ≥ 50), cross-validated with TargetScan. Predictions overlapped with ALD-associated miRNAs from PubMed and GEO datasets. Functional enrichment used miEAA for pathways (KEGG) and tissue specificity.
Results: MiRDB predicted 158 miRNAs for TRAC, 44 for TRBC1, and 39 for TRBC2. Twelve miRNAs were shared between TRBC1 and TRBC2, including hsa-miR-4455. A key disease-associated candidate, hsa-miR-4725-3p, targeted both TRAC (score 64) and TRBC2 (score 84)

and is reported to be upregulated in untreated AIH (fold change >2; $p < 0.05$). Enrichment analysis revealed strong over-representation of T-cell receptor signaling among TRAC-targeting miRNAs ($p = 3.60 \times 10^{-10}$), along with significant enrichment in RIG-I–like receptor signaling ($p = 3.60 \times 10^{-10}$), indicating alpha-chain–specific immune regulation. TRBC1-associated miRNAs were enriched in ECM–receptor interaction pathways ($p = 2.61 \times 10^{-5}$), while TRBC2-associated miRNAs were enriched in blood-specific tissues ($p = 2.57 \times 10^{-4}$) and platelet activation ($p = 1.51 \times 10^{-4}$), suggesting hematopoietic context–dependent modulation.
Conclusion: This in silico analysis identifies multiple high-confidence miRNAs targeting TCR constant regions, with TRAC exhibiting the strongest immunologic pathway enrichment, suggesting α-chain–specific vulnerability to miRNA-mediated dysregulation in ALD. hsa-miR-4725-3p emerges as a compelling dual-target regulator associated with AIH activity, providing a mechanistic link between altered miRNA profiles and T-cell hyperactivation. These findings highlight miRNA–TCR interactions as a previously unrecognized layer of immune dysregulation in ALD. In vitro validation is warranted.

WED-323
Myeloid progenitor cells are enriched and adopt a pro-inflammatory profile in liver fibrosis

Katharina Bonitz[1,2], Emanuel Pietschmann[1], Sarah Dobner[2], Fanni Toth[2], Thomas Sorz-Nechay[1,2], Henriette Horstmeier[1], Katja Sommer[1,2], Benedikt Hofer[1], Benedikt Simbrunner[1], Vlad Taru[1], Jan Embacher[1], Kerstin Zinober[1], Katharina Regnat[1], Michael Trauner[1], Philipp Schwabl[1], Laura de Rooij[2], Thomas Reiberger[1,2]. [1]*Medical University of Vienna, Vienna, Austria;* [2]*CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria*
Email: katharina.bonitz@meduniwien.ac.at

Background and aims: Liver cirrhosis is associated with an increase in myeloid-derived cells both in the liver and the systemic circulation. However, the role of haemopoietic progenitor cells (HPCs) in cirrhosis remains poorly investigated.
Method: Peripheral blood mononuclear cells were isolated from patients with liver cirrhosis (LC) and healthy controls (HC) by gradient centrifugation. Samples were either used for flow cytometry (HC n = 10, LC n = 25) or scRNA-Seq (HC n = 3, LC n = 6). For flow cytometry cells were stained with an 8-color panel to distinguish HPC populations. For scRNA-Seq with ParseBio, samples were sorted for $CD45^{dim}$, excluding mature immune cells. The scRNA-Seq analysis was performed with Seurat, yielding 10265 cells after quality control.
Results: In LC patients the HPC compartment shifted compared to HC. We found a decrease in CD34+CD38+ progenitor cells (LC: 3.37% vs. HC: 7.25%; $p = 0.005$). However, within the progenitor population LC patients had an increase in CD34+CD38+CD45RA-CD123+ common myeloid progenitor cells (CMPs: LC 0.66% vs. HC 0.07%; $p = 0.003$). ScRNA-Seq analysis confirmed a trend towards higher relative abundance of CMPs in LC (28.79% vs HC: 11.00%; $p = 0.282$). To understand if CMPs are functionally different in LC vs HC conditions, we performed differential gene expression analysis and found *CD36*, *LILRB1* and *KCNG2* as the three top upregulated and *WDR49*, *ABTB3*and *CDS1* as the three major downregulated genes in CMPs of LC patients compared to HC. Gene set enrichment analysis revealed that CMPs in LC had a pro-inflammatory phenotype and showed an upregulation of metabolic pathways and oxidative phosphorylation. Monocyte-primed progenitors, which expressed more mature markers, than CMPs, retained a similar enrichment of inflammatory and metabolic pathways in LC, suggesting early shifts in myeloid progenitors persist during differentiation.
Conclusion: LC patients present an increase in CMPs within their hematopoietic progenitor compartment. This CMP population exhibits a pro-inflammatory phenotype that is retained during differentiation – suggesting an early priming towards a potentially disease-driving myeloid lineage.

WED-324-YI
Human liver spatial transcriptomics reveals macrophage-driven antiviral responses distinguishing seronegative fulminant hepatitis from autoimmune hepatitis

Amber Bozward[1], Mahboobeh Behruznia[1], John Cole[2], Scott Davies[1], Kylie Savoye[1], Chiranjit Das[1], Matthew Pugh[1], Grace Wootton[1], Fabian Spill[1], Owen Cain[3], Alan McNally[1], Ye Htun Oo[1]. [1]*University of Birmingham, Birmingham, United Kingdom;* [2]*University of Glagow, Glasgow, United Kingdom;* [3]*University Hospitals Birmingham, Birmingham, United Kingdom*
Email: a.g.bozward@bham.ac.uk

Background and aims: Autoimmune hepatitis (AIH) and seronegative fulminant hepatitis (SNH) share overlapping clinical and histological features, yet their causative factors and underlying immune mechanisms remain poorly understood resulting in liver transplantation. Spatial transcriptomics offers an opportunity to resolve cell-type-specific and tissue-contextual differences across both diseases to explore discovery pathways for diagnostic and translational therapeutic avenues.
Method: We profiled explant human liver from AIH (n = 3), SNH (n = 3), and donor (n = 3) controls using CosMx™ high-plex spatial transcriptomics, complemented by Visium transcriptome-wide spatial profiling (AIH (n = 5), SN (n = 6)), immunohistochemistry, confocal microscopy and metatranscriptomics. The same patient samples were analysed across all platforms. Cell types were annotated using Seurat, SingleR, and spatial context validation. Cell–cell communication was assessed with CellChat.
Results: SNH exhibited a macrophage-dominated antiviral transcriptional signature, characterised by enrichment of interferon-stimulated genes (e.g., MX1, ISG15), consistent with a heightened antiviral response. Metatranscriptomics analysis confirmed viral sequences in SNH samples. Spatial mapping identified CD63 as a significantly upregulated marker in SNH patients, confirmed with immunohistochemistry, implicating vesicle trafficking and exosome-associated pathways in antiviral immunity and highlighting CD63 as a potential diagnostic marker. In contrast, AIH samples demonstrated increased B cell–T cell proximity with reduced TNFSF14 (LIGHT)-HVEM pathway activity, indicating disrupted costimulatory signalling.
Conclusion: Our study provides the first multi-platform spatial transcriptomic analysis of AIH and SNH, revealing macrophage-driven antiviral immunity as a key immunopathological feature of SNH, distinct from the adaptive immune-dominant profile in AIH. The identification of CD63 as an upregulated marker in SNH and reduced LIGHT pathways activity in AIH could be future diagnostic markers for these diseases, demonstrating the power of spatially resolved multi-platform analysis to uncover disease-specific immune architectures, informing future diagnostic strategies and targeted therapeutic approaches for patients.

Email: psarobe@unav.es

Background and aims: Immunotherapy based on immune checkpoint inhibitors (ICI) has become first-line treatment for patients with advanced hepatocellular carcinoma (HCC). However, only 25–35% of treated patients respond to these therapies. Recently, ex vivo culture systems of tumor fragments have been used to study the response of tumor-infiltrating lymphocytes to different immunotherapies and potentially predict treatment outcomes. Our aim was to

establish an ex vivo culture system for HCC to analyze the characteristics of tumors showing responses to ICIs approved for HCC.
Method: One mm^3 fragments were generated from tumors obtained from mice or patients with early HCC, frozen and kept for future experiments. Thawed fragments were cultured in a collagen/Matrigel matrix with different ICI combinations (Roelofsen LM, et al. STAR Protoc. 2023) and IFN-gamma released to the supernatants was measured by ELISA. Tumor lymphocytic infiltrate was characterized by flow cytometry.
Results: In vivo, subcutaneous tumors generated with the HCC cell line PM299L showed partial responses when treated with the ICIs approved for HCC based on PD-L1+CTLA-4 or PD-L1+VEGFR blockade ($p < 0.05$). Ex vivo, treatment with anti-PD-L1 + anti-CTLA-4 antibodies of fragments generated from these tumors showed IFN-gamma production with a remarkable inter- and intra-tumoral heterogeneity. IFN-gamma production was associated with different signals of immune infiltration: responding tumors had higher proportions of leukocytes ($CD45^+$ cells) ($p = 0.007$), T lymphocytes ($p = 0.03$) and CD8 T cells ($p = 0.009$). Overall, tumors that showed positive responses induced by PD-L1+CTLA-4 blockade also responded to PD-L1+VEGFR. No responses to ICI were detected when using fragments of the immune-desert NM53 HCC tumor. Interestingly, cultures of orthotopic tumors with lymphocyte levels equivalent to those found in subcutaneous responding tumors did not show any response, suggesting the presence of additional control mechanisms. Preliminary results using tumor fragments from a cohort of 13 patients with early HCC showed that ex vivo treatment with durvalumab + tremelimumab or atezolizumab + bevacizumab combination immunotherapies induced responses in some patients: according to the response definition criteria, responses ranged from 8 to 24% for PD-L1+CTLA-4 blockade and reached a 38% for PD-L1 +VEGF.
Conclusion: These results suggest that this system could be useful to identify responding patients and to characterize mechanisms associated with response to ICI.

Email: s.p.davies.1@bham.ac.uk

Background and aims: Primary Sclerosing Cholangitis (PSC) is an immune-mediated biliary disease that occurs in close associate with inflammatory bowel disease (IBD). Recently, T cells which are MHC-II restricted, innate-like, commensal-reactive (T_{MIC}) and cytokine-responsive with polyfunctional effector properties were reported in IBD patients and associated mouse model. T_{MIC} cells had a reported phenotype of $CD161^{hi}$, $Va7.2^{negative}$ $PLZF^+$. We aimed to assess their presence and function in the blood and liver of PSC patients.
Method: The abundance and phenotype of T_{MIC} cells were assessed in PSC patients by flow cytometry staining of peripheral blood mononuclear cells (PBMCs) and multiplex immunofluorescence staining of FFPE liver tissue. T_{MIC} function was tested by overnight treatment of liver-infiltrating mononuclear cells (LIMCs) with cytokine cocktails. TCR Va7.2 staining was used to exclude MAIT cells. Stability and suppression capacity of PSC-derived Tregs was assessed in presence of Th1/Th17 polarising cytokine conditions or bile acids. Treg phenotype in blood and liver of PSC and control donors was assessed by flow cytometry.
Results: Immunofluorescence staining of liver tissues showed the presence of T_{MIC}-like cells in PSC with a higher frequency in PSC patients compared to donors (66% vs 25%). These cells were observed in proximity to bile ducts and $FoxP3^+$ $CD4^+$ cells in PSC livers. Flow cytometry phenotyping of PSC PBMCs demonstrated T_{MIC} frequency of (46% ± 7%; n = 7), 36% higher than non-diseased controls (10% ± 5%; n = 4). T_{MIC}-like cells expressed IL-18R (46% ± 8%), IL-7R (CD127;85% ± 2%), and IL-12R (6% ± 1%). Treatment of LIMCs with IL-18 and IL-12 caused increased IFN-γ expression by T_{MIC} (20% ± 7% vs 4% ± 2%, n = 4. PSC liver-derived Tregs maintained functional markers CTLA-4 (72% ± 10%) and FoxP3 (96% ± 2; n = 12). IFN-γ and IL-12 treatment of PSC-derived Tregs resulted in lineage plasticity towards Treg-Th1 phenotype (Tbet; 14% ± 8%, IFN-γ; 56% ± 18%; n = 3) and reduced capacity to suppress proliferation of effector T cells by 24% compared to control suppression (40% ± 8% vs.16% ± 2%). Lithocholic acid treatment of Treg reduced CD25 expression (37% ± 19%).
Conclusion: Liver associated invariant T cells (LAIT), which share the T_{MIC} phenotype, are present in PSC patients. LAIT cells respond to IL-12 and IL-18 and secrete IFN-γ. IFN-γ and IL-12, as well as lithocholic acid, reduced Treg suppressive capacity. These factors may perpetuate chronic cholangiopathy in PSC.

WED-331-YI
Impact of alcohol consumption on the immune architecture in hepatocellular carcinoma

Margaux Delaporte[1,2], Marine Roux[3], Maëlle Guillout[4], Nicolas Gallez[1], Julien Chaigneau[3], Anthony Sébillot[4], Jerome Boursier[3], Michel Samson[1], Céline Raguénès-Nicol[1].

Email: margaux.delaporte.1@univ-rennes.fr

Background and aims: Hepatocellular carcinoma (HCC) remains a major cause of cancer-related mortality and personalized-medicine such as immunotherapy has highly variable efficacy so far. This is partly due to heterogeneity in the tumor immune microenvironment, classified as "hot" or "cold" based on immune cell infiltration. Although chronic alcohol consumption is known to induce oxidative stress and sustain a pro-inflammatory state, the combined effects of metabolic dysfunction-associated liver disease (MASLD) and alcohol misuse, on the HCC immune microenvironment remain poorly understood. We aimed to determine whether alcohol consumption shapes the HCC immune architecture and modulates its "hot" or "cold" status, clues to understanding immunotherapy responsiveness.
Method: We developed a 24-marker multiplex Immunofluorescence panel to characterize immune cell populations in HCC biopsies stratified by alcohol consumption. Biopsies of tumors and non-tumors from 53 patients were processed to identify and localize 20 populations of cells in lymphoid, myeloid and stromal subsets. Cellular quantification, spatial analysis, and unsupervised clustering allow us to describe the heterogeneity among patients. Alcohol weekly consumption was also incorporated as a key stratification variable to determine its influence on the immune landscape.
Results: Tumors with a higher number of infiltrating immune cells were particularly enriched in specific subsets of lymphocytes as well as dendritic cells and neutrophils, consistent with an inflamed and immunologically active microenvironment. Using principal component analysis, we identified a cellular profile captured by PC2 that discriminates immune-high from immune-low tumor phenotypes ($p = 0.022$), and this profile was significantly associated with alcohol consumption ($p < 0.001$). Spatial analyses further revealed denser CTL and T-helper cell clusters within hot tumors, indicating a higher degree of local immune organization and coordinated immune activity.

Conclusion: These findings demonstrate that alcohol consumption is significantly associated with a specific immune microenvironment of HCC, with immune-high phenotype. This immune signature may partly explain immunotherapy responsiveness and support improved patient stratification and tailored therapeutic strategies that integrate alcohol-related immune alterations.

Hepatitis B virus specific T cell immunity to guide discontinuation of nucleoside analogue therapy in hepatitis B e antigen negative chronic hepatitis B

Raquel Encijo Heredia[1,2], Julia Peña Asensio[1], Rocío López[1,3], Joaquín Míquel[1,4], Marta Vila[5], Maria Francesca Cortese[5,6], Ariadna Rando-Segura[5,6], Miguel Torralba[1,2,7], Juan Ramón Larrubia[1,2,4], Henar Calvo Sánchez[1,2,4]. *[1]Translational Research Group on Cellular Immunology (GITIC), Instituto de Investigación Sanitaria de Castilla La Mancha (IDISCAM), Guadalajara, Spain; [2]Department of Medicine and Medical Specialties, University of Alcalá, Alcalá de Henares, Spain; [3]Service of Immunology, University Hospital of Guadalajara, Guadalajara, Spain; [4]Service of Gastroenterology, University Hospital of Guadalajara, Guadalajara, Spain; [5]Department of Microbiology, Liver Unit, Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; [6]Carlos III Health Institute, Network Center For Biomedical Research in Hepatic and Digestive Diseases (CIBERehd), Madrid, Spain; [7]Service of Internal Medicine, University Hospital of Guadalajara, Guadalajara, Spain*
Email: raquelencijo45@gmail.com

Background and aims: Criteria for safely discontinuing nucleoside analogue (NUC) therapy in hepatitis B e antigen negative chronic hepatitis B (CHBe(-)) remain poorly defined. Although treatment withdrawal can lead to functional cure in a subset of patients, reliable immunological predictors of durable viral control are lacking. We aimed to prospectively evaluate whether quantitative and functional hepatitis B virus specific T cell responses can predict relapse-free survival after treatment discontinuation.
Method: Twenty-eight CHBe(-) patients who elected to discontinue long-term NUC therapy were prospectively followed for a median of 5 years. Patients were classified as functional cure, inactive carrier, grey zone, late relapser or early relapser according to virological and biochemical outcomes. Baseline hepatitis B surface antigen (HBsAg) and hepatitis B core related antigen (HBcrAg) levels were quantified. Hepatitis B virus specific T cell immunity was assessed after ten-day antigen specific expansion using interferon gamma enzyme linked immunospot assays with multiple viral peptide pools and multi-parametric flow cytometry to quantify functional CD8 T cell degranulation and cytokine production. Relapse-free survival was analysed using Kaplan–Meier methods according to T cell functionality.
Results: Patients achieving functional cure showed very low antigen burden, defined as HBsAg below 100 IU/mL and HBcrAg below 2 log, together with low interferon gamma spot forming cell responses. In contrast, inactive carriers displayed the strongest multispecific T cell responses, followed by grey zone, late relapsers and early relapsers. Late relapsers exhibited high cytokine intensity, consistent with transient hyperactivation of functionally impaired T cells, whereas early relapsers showed minimal enzyme linked immunospot and CD8 T cell activity. Importantly, patients with two or more functional enzyme linked immunospot responses had no relapse during follow-up, while more than 60% of patients with one or no responses experienced relapse. Relapse-free survival differed significantly between these groups.
Conclusion: Very low antigen levels identify patients who can safely discontinue NUC therapy. Among patients with higher antigen burden, multispecific hepatitis B virus specific T cell responses strongly predict durable viral control, whereas weak responses identify individuals at high risk of relapse. Immune profiling may enable personalised, immune guided treatment discontinuation in CHBe(-).

WED-333-YI

Understanding the impact of the liver microenvironment on the fate of regulatory T cells

Maegen Fleming[1], Elena Perpinan[1], Ada Sera Kurt[1], Elisavet Kodela[1], Marwa Elgosbi[1], Roberto Savoldelli[1], Leonard Bellersheim[1], Nicolas Sompairac[2], Alberto Sanchez-Fueyo[1], Niloufar Safinia[1]. *[1]Roger William's Institute of Liver Studies, School of Immunology and Microbial Sciences, King's College London, SE5 9NU, London, United Kingdom; [2]School of Cancer & Pharmaceutical Sciences, Comprehensive Cancer Centre, King's College London, SE1 1UL, London, United Kingdom*
Email: maegen.fleming@kcl.ac.uk

Background and aims: Regulatory T cell therapies (Tregs) possess considerable therapeutic potential for autoimmune liver disease and liver transplantation. However, fundamental questions remain regarding how Tregs interact with the hepatic microenvironment, potentially limiting their therapeutic efficacy. In previous work we have shown that Tregs exist at a lower frequency in healthy liver tissue, compared to other non-lymphoid organs, and enrich in the tumour tissue of hepatocellular carcinoma (HCC). Additionally, intrahepatic Tregs are more apoptotic than circulating and intratumoral Tregs. This suggests the liver poses a hostile environment to these essential immunosuppressive cells. To generate effective liver-specific Treg-based therapeutics, capable of both trafficking to and surviving within the liver tissue, an understanding of the factors controlling Treg stability and function is crucial.
Method: We obtained surgically resected liver tissue specimens and performed single-cell RNA sequencing (scRNAseq) on purified Tregs and conventional CD4+ T cells from histologically intact liver tissue, matched peripheral blood, alongside paired non-tumoral/tumour tissue from HCC patients. To study the effects of distinct hepatic microenvironments on Tregs, healthy blood-derived Tregs were treated in vitro with secretomes derived from both liver and tumoral tissues.
Results: Transcriptomic analysis displayed marked differences in Tregs isolated from intrahepatic tissue compared to their circulatory and tumoral counterparts. Gene set enrichment analysis (GSEA) revealed augmentation of inflammatory-associated and apoptotic pathways in intrahepatic Tregs relative to circulatory Tregs. Enhanced cytokine signalling, mTOR pathway activation, and metabolic reprogramming was shown in intrahepatic Tregs compared to intratumoral Tregs. Following in-vitro secretome co-cultures, Tregs treated with healthy liver secretomes were shown to be reduced in number and more apoptotic than those cultured in tumour secretomes.
Conclusion: Tregs adapt by transcriptomic, signalling, and metabolic changes in response to environmental exposure. In vitro co-culture experiments, with liver-derived secretomes, mirrored the reduced frequency and viability of Tregs observed in patient samples. These results indicate that tissue factors play critical roles in determining the survival and efficacy of Tregs. Identifying afflicted pathways will crucially inform the development of future strategies for liver-targeted immunotherapies.

Proteomics-driven immune landscape profiling in acute decompensation identifies suppressive monocytes as key determinants of disease progression and mortality

Pratibha Garg[1], Nipun Verma[1], Parminder Kaur[1], Sunil Taneja[1], Ajay Kumar Duseja[1]. *[1]Department of Hepatology, Postgraduate Institute of Medical education and Research, Chandigarh, India*
Email: pgargbhawan@gmail.com

Background and aims: Acute decompensation (AD) in cirrhosis is a paradoxical immune state of systemic inflammation coupled immunoparalysis. Although dysregulated myeloid responses are known,

the relative contribution of distinct immunoregulatory cell phenotypes in shaping disease progression and mortality remains poorly defined.

Method: We performed untargeted LC-MS/MS plasma proteomics in 100 patients with AD (21 AD no-ACLF, 79 ACLF) at admission. Identified proteins were annotated to immune cell–specific signatures using CellMarker2.0, and immune cell enrichment was quantified using single-sample gene set enrichment analysis (ssGSEA). Enrichment profiles were compared across disease state (AD vs ACLF), baseline severity (grade 0–1 vs 2–3), disease course over 30 days (non-severe vs severe trajectory), and 30-day mortality. Predictive performance of immune phenotypes was evaluated using ROC analysis.

Results: At presentation, ACLF was distinguished from AD by early amplification of myeloid immune subsets, predominantly suppressive monocytes (SMs), which were 3.36-fold higher in ACLF ($p = 0.004$), alongside attenuated $CD8^+$ T-cytotoxic immunity (fold change 0.42, $p = 0.013$). Patients presenting with severe disease at baseline (grade 2–3) demonstrated similar enrichment of SMs ($p = 0.023$) alongside early contraction of naïve and cytotoxic T-cell pools. Baseline immune landscape guided disease trajectory. Patients following severe disease course over 30 days exhibited 6.26-fold enrichment of SMs ($p < 0.001$), alongside enrichment of DCs, non-classical monocytes, and M2 macrophages, and progressive depletion of $CD8^+$ cytotoxic and naïve T cells; mortality reflected persistence of this immune state with 7.4 folds-higher SMs and further reduction of CD8+ T-cells (FC: 0.38, $p = 0.018$). SMs, annotated as MO-MDSC like cells ($CD33^{++}CD11b^{++}CD11c^{+}CD14^{+}CD16^{-/+}$HLA-DR-$CD15^{-}CD66b^{-}CD123^{-}$), emerged as the most discriminative phenotype demonstrating robust prediction of severe disease course and 30-day mortality (AUC 0.87–0.89), with performance improving to AUC to 0.906 when combined with baseline CLIF-C OF score.

Conclusion: Untargeted immune landscape mapping in AD identifies MO-MDSC-like suppressive monocytes as central drivers of disease severity, and mortality, supporting disease progression is governed by immunoregulatory myeloid reprogramming, rather than hyperinflammation alone, and highlighting them as clinically informative biomarkers and potential targets for immune-modulatory strategies.

WED-336

Dual TIGIT and PD-1 blockade reverses CD8+ T cell dysfunction in acute-on-chronic liver failure

Yidi Jia[1], Yao Zhang[1], Xueyun Zhang[1], Yan Wang[2], Yuqi Liu[1], Xiaoting Zhao[1], Mengqi Zhu[1], Yuxian Huang[1], Jiming Zhang[1].
[1]Department of Infectious Diseases, Shanghai Key Laboratory of Infectious Diseases and Biosafety Emergency Response, National Medical Center for Infectious Diseases, Huashan Hospital, Fudan University, Shanghai, China, Shanghai, China; [2]Department of Geriatrics, Huashan Hospital, Fudan University, Shanghai 200040, China, Shanghai, China
Email: seven_jyd@163.com

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by the rapid hepatic decompensation and multiorgan failure, with a 90-day mortality rate approaching 60%. Overwhelming bacterial infections, driven by anti-bacterial immunity deficiency, are a leading precipitating factor triggering 35% of ACLF cases. Although dual blockade of immune checkpoints TIGIT/PD-1 has demonstrated activity in oncology, its potential to promote anti-bacterial immunity in ACLF remains unexplored. The aim of this study was to evaluate whether TIGIT and PD-1 are co-upregulated on T cells in ACLF and whether dual checkpoint blockade could improve their function.

Method: Patients with ACLF ($n = 77$) were enrolled within 24 hours of hospitalization, alongside healthy controls (HC, $n = 38$) and patients with cirrhosis patients (LC, $n = 52$). $CD8^+$T cells were isolated from peripheral blood mononuclear cells (PBMCs) for flow cytometric phenotyping and functional assays. T cell responses were assessed following CD3/CD28 stimulation, with or without ex vivo blockade using anti-TIGIT and/or anti-PD-1 antibodies.

Results: TIGIT expression was significantly increased on $CD8^+$ T cells from patients with ACLF (median 35.0%, IQR 28.7–47.3%) compared to HCs (median 15.7%, IQR 9.8–21.2%) and LC patients (median 29.4%, IQR 20.9–40.2%), with upregulation of PD-1 co-expression ($PD\text{-}1^+$ $TIGIT^+$ $CD8^+$T cells: median 60.2%, IQR 36.9–68.5%; $PD\text{-}1^+$ $TIGIT^-$ $CD8^+$T cells: median 29.5%, IQR 15.7–42.1%; $p < 0.0001$). Increased frequencies of $TIGIT^+$ $CD8^+$T cells correlated with ACLF severity (EASL CLIF grade 1: median 23.3%, IQR 16.2–32.5%; grade 2: median 34.5%, IQR 30.1–40.7%; grade 3: median 41.25%, IQR 29.7%-56.8%; $p < 0.05$, respectively) and evidence of bacterial translocation (without bacterial infection: median 33.85%, IQR 23.8–41.1%; with bacterial infection: median 34.7%, IQR 28.5–56.0%; $p = 0.0363$). Ex vivo TIGIT blockade alone restored the proliferative capacity (CD25, CD69) and cytokine production (IFN-gamma, IL-2, TNF-alpha) of $CD8^+$ T cells from ACLF patients. Notably, combined TIGIT and PD-1 blockade resulted in significantly greater enhancement of proliferation and cytokine release compared to single-agent TIGIT inhibition.
Conclusion: Dual TIGIT/PD-1 blockade potently enhances the ex vivo functionality of $CD8^+$ T cells in ACLF. These findings support further investigation into co-blockade of TIGIT and PD-1 as a promising immunotherapeutic strategy for ACLF.

WED-337-YI
Retinoids reprogram TREM2$^+$ monocyte-derived macrophages toward a restorative phenotype via redox control to attenuate liver fibrosis

Kyurae Kim[1], Jang Su Jeon[2], Sung Eun Choi[1], Jihyo Byun[1], Kwangwoo Lee[1], Sang Kyum Kim[2], Won-il Jeong[1]. [1]*Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Rep. of South;* [2]*Chungnam National University, Daejeon, Korea, Rep. of South*
Email: wijeong@kaist.ac.kr

Background and aims: Hepatic macrophages regulate the progression and regression of liver fibrosis by interacting with hepatic stellate cells (HSCs). Among the heterogeneous macrophages, $TREM2^+$ monocyte-derived macrophages (MDMs) emerge in injured livers. Recent studies highlight restorative roles of these cells, the regulation of which remains poorly understood. Here, we aimed to investigate how HSC-derived retinoids program MDMs toward a restorative phenotype during liver fibrosis.
Method: Liver fibrosis was induced in mice by CCl_4 injection. Hepatic macrophages were isolated and analyzed by single-cell RNA sequencing (scRNA-Seq) using the 10X Genomics platform. Macrophage frequency, cellular ROS, and nitric oxide levels were assessed by flow cytometry. HSC-mediated regulation of MDMs was evaluated by *in vitro* co-culturing and retinoid supplementation.
Results: scRNA-Seq identified $TREM2^+$ MDMs, which differentiate from infiltrating monocytes in fibrotic liver, and revealed a restorative subset expressing anti-inflammatory and tissue-remodeling genes. In this subset, KEGG pathway analysis of differentially expressed genes found retinoid metabolism to be highly enriched, along with selective expression of retinoid-responsive genes such as transcription factors, receptors, and metabolizing enzymes. Immunofluorescence staining of fibrotic liver tissue showed that MDMs were localized within fibrotic septa, where activated HSCs release retinoids. *In vitro*, inducible MDMs co-cultured with HSCs or treated with retinoids showed upregulated retinoid-responsive genes (*Rara*, *Stra6l*, *Rbp4*) and anti-inflammatory macrophage markers (*Arg1*, *Il10*), while reducing inflammatory cytokine expression. In addition, retinoids increased NRF2 levels, a master regulator of antioxidant responses, and lowered cellular ROS levels. Interestingly, retinoids induced robust ARG1 expression, driving a metabolic switch in arginine metabolism from nitric oxide production toward polyamine synthesis, thereby conferring restorative macrophage properties. Importantly, retinoid supplementation in mice attenuated liver fibrosis by reprogramming phenotypes of hepatic MDMs toward a restorative state.
Conclusion: This study demonstrates that HSC-derived retinoids act as key regulators, endowing $TREM2^+$ MDMs with restorative functions through redox control mediated by NRF2 upregulation and reprogramming of arginine metabolism in liver fibrosis. Taken together, we propose that modulating MDM properties could be a target for antifibrotic strategies.

WED-338
A TNF-producing neutrophil subset drives age-dependent hepatotoxicity

Jin Lee[1], Gen-Sheng Feng[1]. [1]*University of California San Diego, La Jolla, United States*
Email: jil327@ucsd.edu

Background and aims: Cancer therapy in the elderly is particularly challenging due to heightened treatment-associated detrimental effects, which often lead to treatment discontinuation and increased mortality. The mechanisms by which aging contributes to the detrimental effect of cancer therapy remain poorly understood.
Method: To identify age-associated pathogenic factors in an unbiased manner, we performed single-cell RNA sequencing (scRNA-seq) and bulk RNA sequencing on non-parenchymal cells (NPCs) isolated from young (5-month-old) and aged (20-month-old) livers. Immune cell profiling and functional analyses were conducted using flow cytometry, multiplexed antibodies staining, and Luminex cytokine/chemokine assays. Fundamental biochemical assays, as well as gene deletion and cell depletion models were performed *in vivo* and *ex vivo* to investigate underlying mechanisms.
Results: We recently found that a synthetic double-stranded RNA (dsRNA), poly-inosinic:cytidylic acid (polyIC) that induces interferons (IFNs) and inflammatory response, effectively suppressed liver cancer in multiple murine models when administered to young mice, especially in combination with anti-PD-L1 antibody. Given that the majority of liver cancer patients are over 60 years of age, we evaluated the anti-tumor effect of polyIC in aged mice. Surprisingly, old mice, with or without liver tumors, died suddenly with massive liver necrosis following polyIC administration at doses well tolerated by young mice. We found no evidence implicating IFNs in mediating this toxic effect. However, single-cell and functional analyses unearthed a $CD14^+$ neutrophil subset featured by robust TNFα induction by polyIC exclusively in the aged liver. Impaired NR3C1 expression and elevated NF-κB and AP-1 signaling drive a skewing toward Tnf^+over $Saa1^+$ neutrophils in the aged liver. TNF neutralization rescued polyIC-induced mortality, while also enhancing its antitumor effect in aged mice. Bioinformatic analysis revealed significant association of a Tnf^+Saa1^- neutrophil gene signature with reduced survival in liver cancer patients over 60.
Conclusion: This study uncovers a previously unknown detrimental mechanism in the aged liver, which is undetectable under basal conditions. We provide a new strategy to improve therapeutic outcomes in elderly patients by mitigating treatment-associated toxicity.

WED-339
Lactate triggers HBV-Specific CD8+ T cell exhaustion through mitophagy suppression-mediated mitochondrial dysfunction

Zhipeng Liu[1], Yuhao Wang[1], Xiaoyi Liu[1], Libo Tang[1], Yongyin Li[1]. [1]*Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Key Laboratory of Infectious Diseases Research in South China (Southern Medical University), State Key Laboratory of Multi-organ Injury Prevention and Treatment, GuangZhou, China*
Email: yongyinli@foxmail.com

Background and aims: Hepatitis B virus (HBV) -specific T cells exhibit an exhausted phenotype associated with glycolytic metabolic disruption and perturbation of mitochondrial homeostasis. However, their relationship and underlying mechanisms remain elusive. Since lactate, a key glycolytic metabolite that can modulate immune

response, we investigated its role in HBV-specific T cell dysfunction during chronic HBV infection.
Method: We recruited 242 patients with chronic HBV infection and 78 health controls. The metabolic characteristics of peripheral blood mononuclear cells (PBMC) were comprehensively analyzed using RNA-seq, metabonomics and scRNA-seq. Additionally, we systematically evaluated the glucose uptake, mitochondrial function, autophagy flux, and mitophagy activity of HBV-specific $CD8^+$ T cells using flow cytometry from both PBMC and liver mononuclear cells (LMC). To investigate lactate-mediated T cell exhaustion, we performed exogenous stimulations with Bay-876, lactate, Oligomycin, and Midivi-1, and assessed through multiparametric cytokine profiling and functional assays.
Results: The glucose metabolic status in PBMC was significantly activated during HBV infection, accompanied by the accumulation of lactate. Specifically, HBV-specific $CD8^+$ T cells exhibited more dramatically increased Glut1 expression and 2-NBDG uptake than global T cells, especially in intrahepatic HBV-specific $CD8^+$ T cells. Restraining glucose uptake via Bay-876 improved HBV-specific T cell function, while lactate accelerated their dysfunction. Mechanistically, lactate elicited aberrant mtROS production and mitochondrial membrane potential via suppressing mitophagy dysfunction. Meanwhile, reversing mitochondrial dysfunction by MitoQ and MitoTempo restored the HBV-specific T cells function. However, aggravating mitophagy impairment by Midivi-1blunted the production of IFN-γ and TNF-α in HBV-specific T cell. Concurrently, dysfunctional autophagy also significantly contributed to HBV-specific T cells dysfunction, but this effect was independent of the lactate-mediated exhaustion pathway.
Conclusion: Lactate drives HBV-specific T cell exhaustion by disrupting mitochondrial function via restraining mitophagy. These results highlight lactate metabolism as a potential therapeutic target for chronic HBV infection.

WED-340-YI
Hepatocyte senescence controls RORγt+ cell populations in the liver and is sensitive to metabolic zonation

Yuxin Li[1], Jake Sherrick[1], Soumyajit Saha[2], Kevin Yiyu Fan[1], Hanan Almakhayitah[1], Nadiya Boyar[1], Kulvinder Gill[1], Daniel Kearns[1], Aekkachai Tuekprakhon[1], Zania Stamataki[1]. *[1]Centre for Liver and Gastrointestinal Research, School of Infection and Immunology, University of Birmingham, Birmingham, United Kingdom, National Institute for Health and Care Research (NIHR), Birmingham Biomedical Research Centre (BRC), BIRMINGHAM, United Kingdom; [2]London School of Hygiene and Tropical Medicine, Keppel Street, London, United Kingdom, Norwich Medical School, University of East Anglia, Norwich, United Kingdom, London, United Kingdom*
Email: yxl1800@student.bham.ac.uk

Background and aims: Hepatocyte senescence is a hallmark of chronic liver disease and ageing, contributing to inflammation, fibrosis and impaired regeneration through alterations of the hepatic microenvironment. Senescence-associated secretory phenotypes (SASPs), including IL-1β, IL-6 and TGF-β, promote differentiation of $ROR\gamma t^+$ T cells which drive liver inflammation, fibrosis and tissue repair. We recently discovered that live $ROR\gamma t^+$ cells were engulfed by enclysis in human livers. We hypothesised that senescence-associated inflammatory mediators enhance enclysis to control pathogenic $ROR\gamma t^+$ cell populations in liver disease, and explored the role of hepatic lipids.
Method: Hepatocyte senescence was induced in Huh-7 cells using doxorubicin, with cell cycle arrest confirmed by p21 immunofluorescence. Enclysis was quantified by high-content imaging (n = 6). Intracellular lipid and cholesterol accumulation were assessed by BODIPY and filipin staining. The effects of SASP cytokines (IL-1β, IL-6, IL-8 and TGF-β) and cholesterol on enclysis were tested in vitro. Cholesterol synthesis was inhibited using atorvastatin. Enclysis of $ROR\gamma t^+$ cells was analysed in non-cirrhotic and cirrhotic human liver tissues (n = 60) using digital histopathology and spatial QuPath algorithms to define metabolically distinct liver zones.
Results: Senescent $p21^+$ hepatocytes showed increased enclysis and secreted factors that also influenced neighbouring $p21^-$ cells. SASPs IL1-β and IL-8 increased enclysis, but IL-6 and TGF-β did not. Senescent hepatocytes accumulated intracellular lipids and cholesterol, as demonstrated by increased BODIPY and filipin staining. Cholesterol loading enhanced enclysis, while atorvastatin reversed the senescence-associated, cholesterol-dependent increase in enclysis and reduced T-cell engulfment. Enclysis of $ROR\gamma t^+$ cells was increased in autoimmune, viral and metabolic liver disease compared with healthy liver, and was spatially enriched in the mid-lobular zone associated with regeneration.
Conclusion: Hepatocyte senescence drives enclysis through IL-1β/IL-8 signalling and cholesterol accumulation, linking metabolic rewiring to immune regulation in the diseased liver. Spatially enriched enclysis within the mid-lobular zone limits $ROR\gamma t^+$ cell expansion and may restrain inflammation while preserving regenerative capacity. These findings highlight cholesterol-dependent enclysis as a novel therapeutic axis for senotherapeutic and lipid-targeting strategies in chronic liver disease.

WED-341
Decoupling of monocyte subset expansion and immune competence in hepatitis B–related acute-on-chronic liver failure

Xiaoqin Liu[1], Jingmao Yang[2], Yunyun Wang[1], Ruicong Chen[1], Mingqin Lu[1]. *[1]Department of Infectious Diseases, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [2]Department of Gastroenterology, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China*
Email: lizwondering@sina.com

Background and aims: Hepatitis B–related acute-on-chronic liver failure (HBV-ACLF) is characterized by intense systemic inflammation and high susceptibility to bacterial infection, suggesting profound immune dysfunction. Monocytes are central to antigen presentation and innate pathogen sensing, yet how monocyte subset remodeling relates to immune competence in HBV-ACLF remains unclear. We aimed to characterize global and subset-specific monocyte functional alterations and to determine whether changes in monocyte composition are coupled or decoupled from immune function.
Method: Peripheral blood monocytes from patients with HBV-ACLF (n = 67), chronic hepatitis B, and healthy controls were analyzed by multiparameter flow cytometry. Monocyte subsets were defined by CD14 and CD16 expression. Antigen presentation and pathogen sensing were assessed using human leukocyte antigen–DR (HLA-DR) and Toll-like receptor 4 (TLR4) as primary markers, together with additional immunoregulatory markers including triggering receptor expressed on myeloid cells 2 (TREM2). Analyses were performed according to bacterial infection status and longitudinal disease trajectories based on the Model for End-Stage Liver Disease (MELD) score changes.
Results: HBV-ACLF was associated with marked monocyte functional remodeling. Expression of HLA-DR and TLR4 was progressively reduced from controls to chronic hepatitis B and further to HBV-ACLF, indicating impaired antigen presentation and pathogen sensing (all $p < 0.0001$). In contrast, immunoregulatory markers, including TREM2, were significantly increased ($p < 0.0001$). Intermediate monocytes were markedly expanded in HBV-ACLF ($p < 0.0001$). Regulatory and repair-associated markers tracked with subset expansion, whereas host-defense functions showed an inverse relationship. Despite numerical expansion, HLA-DR and TLR4 expression remained markedly reduced in specific subsets ($p < 0.01$), demonstrating a decoupling between monocyte composition and immune competence. Bacterial infection and disease deterioration further amplified this decoupling, while partial recovery was observed in patients with improving disease course.

Conclusion: HBV-ACLF is characterized by structured and dynamic monocyte immune remodeling, in which subset expansion selectively reinforces immunoregulatory programs while essential host-defense functions are functionally exhausted. This composition–function decoupling provides a mechanistic framework for immune imbalance and susceptibility to infection in HBV-ACLF.

PD-1+ follicular helper T cells as the key discriminator: a combined model with plasmablasts for distinguishing autoimmune hepatitis from drug-induced liver injury

Zikun Ma[1], Yuhong Suo[1], Yao Meng[1], Yubo Zhong[1], Tiantian Guo[1], Mengmeng Zhang[1], Min Li[1], Xu Fan[1], Xinyan Zhao[1]. [1]*Liver Research Center, Beijing Friendship Hospital, Capital Medical University, State Key Laboratory of Digestive Health, National Clinical Research Center of Digestive Disease, Beijing, China*
Email: mazikun0114@163.com

Background and aims: Non-invasive differentiation of autoimmune hepatitis (AIH) from drug-induced liver injury (DILI) remains clinically challenging. We aimed to identify specific circulating T/B-cell subsets for distinguishing AIH from DILI.
Method: This prospective case-control study (Beijing Friendship Hospital, 2024–2025) focused on treatment-naive AIH and DILI patients. Diagnostic gold standard was based on clinicopathological data, and treatment response. Fresh peripheral blood was collected for flow cytometric analysis of T/B lymphocyte subsets. Least absolute shrinkage and selection operator (LASSO) and multivariate logistic regression selected predictors for final models. Diagnostic performance was assessed via area under the curve (AUC), calibration curves, decision curves, bootstrapping, and DeLong's test. SHapley Additive exPlanations (SHAP) values quantified each predictors' contribution.
Results: A total of 158 patients (86 with AIH and 72 with DILI), as well as 41 healthy controls (HC), were included, matched for age and sex. Most patients were women (121, 77%), median age 52 (42–61) years. AIH and DILI differed significantly (all $P < 0.001$) in serum transaminases, bilirubin, and immunological G levels. Circulating programmed death (PD)-1^+ follicular helper T (Tfh) cells [7% (5–8) vs. 3% (3–3) vs. 4% (4–4)] and plasmablasts [14% (5–29) vs. 2% (1–4) vs. 2% (1–4)] were significantly elevated in AIH vs. DILI and HC (all $P <$ 0.001). LASSO and multivariate logistic regression selected PD-1^+Tfh cells [odds ratio (OR) 7×10^{42}, *95%* confidence interval (CI) 2×10^{16}–3×10^{69}, $P = 0.002$] and plasmablasts (OR 1×10^{8}, *95%* CI 2–9×10^{15}, $P = 0.044$) for the final model. This combined model, distinguishing AIH from DILI, achieved an AUC of 0.957 (*95%* CI: 0.929–0.985) with internal validation at 0.956 (*95%* CI: 0.949–0.958), showing good calibration and net benefit. It significantly outperforming PD-1^+ Tfh cells or plasmablasts alone (AUCs 0.957 vs. 0.921vs. 0.859, DeLong's $P < 0.05$). SHAP analysis identified PD-1^+Tfh cells (SHAP: 0.273) as the most influential contributor, outweighing plasmablasts (SHAP: 0.150).
Conclusion: Combining the PD-1^+ Tfh cells with plasmablasts in a logistic regression model provides an accurate, clinically applicable, minimally invasive tool to distinguish AIH from DILI. SHAP values highlighted the importance of PD-1^+ Tfh cells as the strongest positive discriminator for AIH vs. DILI.

Email: s.mantovani@smatteo.pv.it

Background and aims: Liver cancer is a leading cause of cancer death, and its incidence is expected to rise over the next 20 years. Hepatocellular carcinoma (HCC), comprising 85–90% of primary liver cancers, has a poor prognosis. While viral-associated HCC is declining, metabolic dysfunction-associated steatotic liver disease (MASLD)-related HCC is increasing, and the role of NK cells in this context remains poorly understood.
Method: Surgically resected non-MASLD-HCC (n = 7) and MASLD-HCC (n = 6) and matched non-tumor liver tissues were collected from treatment-naïve patients. CD45$^+$ cells were profiled by single-cell RNA sequencing using BD Rhapsody™, and 46,979 high-quality cells were analyzed for differential expression, pathway enrichment, and cell–cell communication.
Results: Unsupervised clustering and marker gene expression analysis revealed 24 distinct immune cell populations, including three NK cell subsets: one circulating (cC4) and two tissue-resident (trC2, trC14). Total NK cells were reduced in tumors compared to liver-infiltrating cells, with the greatest decrease observed in trC2 cells, independent of HCC etiology. Tumor-infiltrating NK-cell subset transcriptional profiles differed between MASLD- and non–MASLD-HCC. In MASLD-HCC, cC4 cells displayed altered immune regulatory pathways and upregulation of lipid-related metabolic pathways, suggesting adaptation to a lipid-rich microenvironment. In the same context, TrC2 and trC14 cells showed downregulation of pathways related to NK activation, cytotoxicity, neutrophil activation, and T cell signaling, alongside enrichment of inflammatory and metabolic pathways. CellChat analysis revealed altered cell–cell interactions in MASLD-HCC, with cC4 showing the strongest reduction in incoming and outgoing signaling, while trC2 displayed high communication activity. TrC2 displayed increased interactions with macrophages, CD8$^+$ T cells, and proliferating cells, reduced interactions with MAIT and mast cells, and enhanced signaling through FASLG, CADM, ICAM, and TRAIL pathways.
Conclusion: All tumor NK cell subsets derived from MASLD-HCC upregulated lipid-related pathways, whereas only tissue-resident NK cells downregulated pathways associated with neutrophil activation and NK cell cytotoxicity. These findings indicate that all three NK cell subsets in MASLD-HCC exhibit metabolic and functional alterations, though the specific changes differ among the clusters, collectively contributing to a less cytotoxic phenotype and potentially impaired anti-tumor immunity.

WED-347

Lessons from single-cell transcriptomics in chronic hepatitis B: refinement without redefinition

Akhilesh Mulay[1], James Cai[1], Jantarika Arora[1], Gerard Hernandez-Mir[1], Patrick Kennedy[1,2], Upkar Gill[1,2]. [1]*Centre for Immunobiology & Infection, The Blizard Institute, Barts and The London Faculty of Medicine & Dentistry, Queen Mary University of London, London, United Kingdom;* [2]*Department of Hepatology, Barts Health NHS Trust, London, United Kingdom*
Email: u.gill@qmul.ac.uk

Background and aims: Single-cell RNA sequencing (scRNA-seq) is increasingly applied to chronic hepatitis B (CHB) cohorts to characterise immune dysfunction and identify pathways relevant to hepatitis B virus (HBV) cure. Although many core aspects of HBV immunopathology were recognised before scRNA-seq, it has enabled higher-resolution characterisation of intrahepatic immune states and interactions; but its incremental translational contribution to cure-directed advances in CHB warrants critical evaluation.
Method: MEDLINE was searched via PubMed using a predefined strategy identifying human studies applying scRNA-seq to CHB. Of 221 records identified, 42 underwent full-text review, with 26 included. Data were extracted using a structured proforma, including sequencing platform, tissue source, immune populations analysed, disease phase, treatment status, and links to HBV cure.

Results: Twenty-six studies applied scRNA-seq to CHB, predominantly using microfluidic droplet-based platforms, with sampling from blood and intrahepatic tissue. Capture of neutrophils and liver parenchymal cells were limited due to dissociation protocols and cell fragility. Although innate populations were studied less frequently than adaptive cells, scRNA-seq verified innate dysfunction contributes to impaired adaptive immunity. Specific macrophage and NK cell subsets, including FCGR3A+ macrophages, were implicated in immunoregulatory and inflammatory pathways, while functional cure was associated with enrichment of immune-active innate populations, including neutrophils, Kupffer cells, and liver-resident NK cells with enhanced effector activity. Adaptive immune findings reinforced existing paradigms of dysfunctional, largely non-HBV-specific liver-resident CD8 T cells, Treg expansion and impaired B-cell maturation. Recovery-associated populations, including IL-2 linked cytotoxic CD4 T cells and attenuated HBV polymerase-specific CD8 T cells, provided mechanistic context for the limited efficacy of checkpoint-based strategies in CHB. Across studies, small sample sizes, heterogeneous cohorts, limited HBV-specific profiling, and infrequent functional validation constrained generalisability.
Conclusion: In CHB, scRNA-seq refines rather than transforms concepts of immune dysfunction, defining liver-resident immune states and cure-associated innate-adaptive networks, enabling dataset reuse. Progress toward functional cure requires strategic, sustainable application of scRNA-seq with longitudinal sampling and validation to aid HBV cure.

WED-348

Impaired vaccine-induced adaptive immunity cross-reactive to emerging influenza viruses in chronic liver diseases

Lisa-Marie Müller[1,2], Wasihun Hailemichael[1,2], David Reeg[1,3], Kevin Ciminski[4], Peter Reuther[4], Martin Schwemmle[4], Robert Thimme[1], Maike Hofmann[1], Hendrik Luxenburger[1].
[1]University Medical Center Freiburg, Department of internal medicine II, Freiburg im Breisgau, Germany; [2]University Freiburg, Faculty of biology, Freiburg im Breisgau, Germany; [3]University Freiburg, Faculty of medicine, Freiburg im Breisgau, Germany; [4]University Medical Center Freiburg, Institute of Virology, Freiburg im Breisgau, Germany
Email: lisa-marie.noll@uniklinik-freiburg.de

Background and aims: Patients with chronic liver disease frequently exhibit immune dysregulation and increased susceptibility to infections, including influenza virus. Vaccination is a key preventive strategy, particularly for influenza A virus due to its seasonal circulation and pandemic potential. The emergence of highly pathogenic avian influenza (HPAI) viruses has raised concerns regarding protection in vulnerable populations. An open question is whether seasonal influenza vaccination induces cross-reactive immunity against emerging strains. This study aimed to assess adaptive cross-reactive immune responses to avian influenza following seasonal influenza vaccination in patients with chronic liver disease compared with healthy individuals.
Method: Patients with liver cirrhosis (n = 6), liver transplant recipients (LTR, n = 13), and healthy controls (< 60 years, n = 10; > 60 years, n = 6) were vaccinated with a seasonal influenza vaccine lacking H5. Peripheral blood mononuclear cells (PBMC) and serum were collected 120–180 days post-vaccination. PBMCs were stimulated with overlapping peptide (OLP) pools spanning the H5 protein of A/Astrakhan/3212/2020. H5-specific $CD4^+$ and $CD8^+$ T cell responses were analyzed by intracellular cytokine staining. Neutralizing antibodies were measured by plaque reduction neutralization test.
Results: H5-specific $CD8^+$ T cell responses were rare and of low magnitude in all cohorts. H5-reactive $CD4^+$ T cell responses were detectable in LTR and cirrhotic patients, but epitope breadth was significantly reduced in LTR compared with age-matched healthy controls ($p = 0.004$). The breadth of polyfunctional IL-2^+TNF$^+$ $CD4^+$ T cell responses was reduced in LTR ($p < 0.001$) and cirrhotic patients ($p = 0.0011$), with reduced magnitude and functionality in selected OLP pools. Neutralizing antibody titers against seasonal H1 and avian H5 were comparable across cohorts, with high H1- and low H5-specific titers.
Conclusion: Seasonal influenza vaccination induces only limited cross-reactive adaptive immunity to avian influenza in patients with chronic liver disease. Although humoral responses were comparable to healthy individuals, low H5-specific antibody titers indicate that cross-reactivity is mainly mediated by $CD4^+$ T cells. However, in LTR and cirrhotic patients, these responses show reduced breadth and functional strength, suggesting limited protection against emerging high-risk influenza strains and emphasizing the need for targeted pandemic preparedness strategies in this vulnerable group.

WED-349

Retinoic acid signaling in hepatic stellate cells orchestrates plasmacytoid dendritic cell recruitment and immune tolerance: implications for cholestatic liver injury

Nobuhiro Nakamoto[1], Yuzo Koda[1], Akihisa Ueno[2], Kentaro Miyamoto[1], Toshiaki Teratani[1], Ryosuke Kasuga[1], Yukie Nakadai[1], Haruka Okada[1], Nobuhito Taniki[1], Keisuke Ojiro[1], Takanori Kanai[1]. *[1]Division of Gastroenterology and Hepatology, Keio University School of Medicine, Tokyo, Japan; [2]Department of Pathology, Keio University School of Medicine, Tokyo, Japan*
Email: nobuhiro.z2@keio.jp

Background and aims: Plasmacytoid dendritic cells (pDCs) are enriched in the steady-state liver and exert immunosuppressive functions beyond their antiviral roles. However, the mechanisms regulating hepatic pDC accumulation remain unclear. Hepatic stellate cells (HSCs) store vitamin A and regulate retinoic acid (RA) metabolism, but upon activation they lose vitamin A–containing lipid droplets and exhibit impaired RA responsiveness. This study aimed to investigate the role of RA signaling in HSCs in hepatic pDC recruitment and liver disease pathogenesis.
Method: pDC dynamics were analyzed in murine models under physiological and pathological conditions. Single-cell RNA sequencing, and immunohistochemistry were used to identify chemokine sources and spatial relationships. Cell-specific CXCL12 knockout mice were generated to define the contribution of HSC-derived CXCL12. Functional relevance was examined using the 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) cholestatic liver injury model. Clinical relevance was assessed by serum vitamin A levels and intrahepatic pDCs in patients with primary sclerosing cholangitis (PSC).
Results: RA signaling was essential for hepatic pDC maintenance; vitamin A deficiency (VAD) or RA receptor inhibition reduced hepatic pDCs, whereas RA administration increased pDC abundance in the liver. Single-cell transcriptomic analyses identified HSCs as the dominant source of CXCL12, which was further enhanced by RA. RA treatment promoted spatial co-localization of Desmin-positive HSCs and pDCs in vivo, and HSC-derived CXCL12 promoted pDC migration via the CXCL12–CXCR4 axis, as confirmed by in vitro chemotaxis assays. HSC-specific CXCL12 depletion abolished both basal and RA-induced pDC accumulation, whereas hepatocyte-specific depletion had a lesser effect. In the DDC model, HSC activation was accompanied by reduced CXCL12 expression and decreased hepatic pDC abundance. RA supplementation partially restored pDCs and ameliorated liver injury, whereas pDC depletion exacerbated disease with reduced regulatory T cells and increased pro-inflammatory immune populations. In human PSC, advanced disease was associated with reduced serum vitamin A levels and loss of portal BDCA-2–positive pDCs.
Conclusion: RA signaling in HSCs induces CXCL12, orchestrating hepatic pDC recruitment and immune tolerance. Disruption of this pathway contributes to cholestatic liver injury, while restoring RA signaling or HSC-derived CXCL12 may offer a therapeutic strategy for chronic cholestatic liver diseases.

WED-350

Soluble liver antigen (SLA)-specific CD4+ T cells phenotypes in the blood of patients with autoimmune hepatitis (AIH) correlate with the clinical situation

Carina Saggau[1], Philipp Hofmann[2], Yang Xu[3], Nicola Gagliani[3], Johannes Herkel[3], Petra Bacher[2], Johannes Hartl[3], Rainer Günther[4], Alexander Scheffold[1]. [1]*Institute of Biotechnology, Technical University Berlin, Berlin, Germany;* [2]*Institute of Medical Immunology, University Hospital Schleswig-Holstein & Christian-Albrechts University Kiel, Kiel, Germany;* [3]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany;* [4]*Division of Hepatology/Transplant Hepatology, UKSH, Campus Kiel, Kiel, Germany*
Email: Carina.Saggau@uksh.de

Background and aims: Anti-SLA autoantibodies represent the only disease-specific autoantibodies in AIH and are associated with reduced overall survival. However, the autoreactive SLA-specific $CD4^+$ T helper (Th) cells that orchestrate autoantibody production and drive the pathogenic immune response remain difficult to detect. Consequently, their functional and molecular characteristics, and their precise role in disease pathogenesis, remain poorly defined.
Method: To address this, we used activation-based antigen-reactive T cell enrichment (ARTE) to characterize *ex vivo* SLA-specific CD4+ Th cells isolated from the blood of patients and healthy controls. We performed multiparameter cytometric characterization, single cell RNA-sequencing and re-expression of autoreactive T cell receptors (TCRs) to confirm specificity and identify peptide/HLA class II recognition. Furthermore, we performed single cell RNA-sequencing of SLA-reactive T cells from the blood and the entire CD4+ T cell compartment from paired liver biopsies enabling tracking of autoantigen-specific T cells in the tissue.
Results: Compared to healthy donors, autoreactive memory Th cells were highly increased in the blood of SLA-antibody-positive AIH patients. These cells exhibited a phenotypically altered, yet heterogenous T cell profile. Exhaustion-associated co-inhibitory receptors were significantly elevated and were co-expressed with variable amounts of FOXP3. The cytokine profile (e.g. expression of IL-21, IFN-g) of SLA-reactive T cells in the blood of AIH patients indicated a TpH phenotype. Thus, T cell responses in AIH patients could be clearly distinguished phenotypically from those of healthy donors, and the heterogeneity within the AIH patient cohort correlated with the individual clinical status (e.g. active disease vs remission, mild disease vs severe course). Paired patient samples were used to track SLA-specific TCRs from the blood and identified by ARTE in scRNA & TCRSeq data from liver tissue-derived memory CD4 T cells. The autoreactive T cells were enriched 10- to 100-fold in tissue versus blood reflecting the respective phenotype of SLA-specific T cells in the blood.
Conclusion: Our data suggest that SLA-specific T cells play a central role in AIH pathogenesis, including the generation of SLA-specific antibodies, and that it is possible to clinically stratify patients based on autoreactive T cell phenotyping. This may help to improve monitoring of treatment response and may define novel autoantigen-specific therapeutic strategies.

WED-351

Using immunohistochemistry to determine the enclysis of T cells in cholestatic and viral liver diseases

Soumyajit Saha[1,2], Yuxin Li[3,4], Kevin Yiyu Fan[3,4], Hanan Almakhayitah[3,4], Aekkachai Tuekprakhon[3,4], Zania Stamataki[3,4]. [1]*London School of Hygiene and Tropical Medicine, London, United Kingdom;* [2]*University of East Anglia, Norwich, United Kingdom;* [3]*Centre for Liver and Gastrointestinal Research, School of Infection and Immunology, University of Birmingham, Birmingham, United Kingdom, Birmingham, United Kingdom;* [4]*National Institute for Health and Care Research (NIHR), Birmingham Biomedical Research Centre (BRC), Birmingham, United Kingdom*
Email: soumyajit2349s@gmail.com

Background and aims: Hepatocytes engulf live $CD4^+$ cells in a process called enclysis. The $CD4^+$ cells can be seen inside hepatocytes. Enclysis has been reported for $Foxp3^+$ cells which are killed inside the hepatocyte and $Tbet^+$ cells which are not killed, but enclysis in $ROR\gamma t^+$ cells has not been investigated, despite their association with pathology. Here, $ROR\gamma t^+$ cells found inside hepatocytes were investigated in primary biliary and primary sclerosing cholangitis, and hepatitis C and B infection. This can improve our understanding of liver disease and may lead to development of better prognostic and therapeutic methods.
Method: RORγt was detected in liver sections by immunohistochemistry. Using QuPath software, the liver tissue was divided into anatomic regions — periportal, midlobular and perifibrous. QuPath's cell detection system was used to distinguish hepatocytes and non-hepatocytes. RORγt was expected to be seen in the latter. Whether a cell was $ROR\gamma t^+$ was determined using the mean optical density of the stain. The number of $ROR\gamma t^+$ cells which were inside and outside hepatocytes was quantified. The proportion of $ROR\gamma t^+$ cells which were inside was compared between anatomic regions of the liver, between disease aetiologies, and between the same anatomic region in different disease aetiologies.
Results: Viral diseases ($n = 22$) had higher proportions of $ROR\gamma t^+$ cells inside hepatocytes than cholestatic diseases ($n = 19$) with the differences being starkest in the midlobular region ($p < 0.01$). Hepatitis B virus infected livers had the highest proportions of $ROR\gamma t^+$ cells inside hepatocytes while primary sclerosing cholangitis livers had the lowest ($p < 0.05$). The midlobular region also had the highest proportion of engulfed $ROR\gamma t^+$ in all diseases ($p < 0.0001$).
Conclusion: The $ROR\gamma t^+$ cells inside hepatocytes were likely enclysed. Previous research showed no difference between $Foxp3^+$ cell enclysis in immune-mediated conditions compared to viral infection. We found greater $ROR\gamma t^+$ cell engulfment in viral infection than cholestatic diseases. There were large differences in $ROR\gamma t^+$ cell enclysis between anatomic regions of the liver and between diseases. This shows that enclysis is sensitive to anatomic regions and disease aetiology and should be studied separately for different T cell subsets. Combining this with existing data on anatomic differences in inflammation in these diseases suggests that the level of enclysis in the midlobular region reduces inflammation, pointing to potential prognostic and therapeutic avenues.

Collectin-11 of the lectin pathway mediates complement-dependent hepatic ischemia-reperfusion injury in mice

Tatsuro Sugaya[1,2], Manabu Hayashi[2], Yumi Ishida[1], Takeshi Machida[1], Masayuki Sekimata[3], Hiromasa Ohira[2], Hideharu Sekine[1].
[1]*Department of Immunology, Fukushima Medical University School of Medicine, Fukushima, Japan;* [2]*Department of Gastroenterology, Fukushima Medical University School of Medicine, Fukushima, Japan;* [3]*Radioisotope Research Center, Fukushima Medical University, Fukushima, Japan*
Email: tsugaya@fmu.ac.jp

Background and aims: Hepatic ischemia-reperfusion injury (IRI) is associated with post-liver transplant complications, and its pathogenic mechanism needs to be elucidated. The complement system is an innate immune system that maintains biological homeostasis through the recognition and elimination of foreign pathogens and apoptotic cells, and has been reported to be involved in hepatic IRI. Collectin-11 (CL-11) is a pattern recognition molecule that recognizes terminal L-fucose of glycans on targets and initiates activation of the complement lectin pathway (LP). However, contribution of CL-11 in hepatic IRI is unknown. In this study, we aimed to clarify whether CL-11 is involved in hepatic IRI.
Method: CL-11-deficient ($CL\text{-}11^{-/-}$) mice were generated by CRISPR/Cas9 system. IRI in the liver was induced by 60 minutes segmental hepatic ischemia and 6 hours of reperfusion. Liver injury was assessed by measurement of serum transaminase levels and

histological scoring using Suzuki scoring system. Deposition of complement component 3 (C3) in the liver was evaluated by immunohistochemical (IHC) staining. *In vitro* inhibitory effects of adding various sugars, including L-fucose, added to mouse sera on LP activity were evaluated by a C4 deposition assay measuring C4 deposition levels on mannan-coated plates. *In vivo* inhibitory effect of intraperitoneally administered L-fucose on liver injury in a hepatic IRI-induced model was evaluated by measuring serum transaminase levels and liver histological scores.
Results: In the hepatic IRI-induced model, *CL-11*$^{-/-}$ mice showed significantly lower levels of liver injury compared with wild-type (WT) mice, as assessed by serum transaminase levels and histological scores. IHC staining revealed marked C3 deposition in the liver of WT mice, but almost no deposition was observed in the liver of *CL-11*$^{-/-}$ mice underwent hepatic IRI. A significant reduction of C4 deposition on mannan-coated plate was observed only when L-fucose was added in the serum mixture. In a hepatic IRI-induced model, mice administered with L-fucose had significantly reduced serum transaminase levels and histological severity compared with control mice.
Conclusion: Our results showed that CL-11 is involved in hepatic IRI most likely via activation of the LP in mice, and administration of L-fucose can be a promising therapeutic approach for hepatic IRI.

WED-353-YI
Oxysterol-binding protein-related protein 2 drives sterol accumulation and neutrophil dysfunction in sepsis associated with alcohol related cirrhosis

Gaurav Tripathi[1], Vasundhra Bindal[1], Sushmita Pandey[1], Neha Sharma[1], Manisha Yadav[1], Vipul Sharma[1], Nupur Sharma[1], Babu Mathew[1], Sanju Yadav[1], Yash Magar[1], Meenu Bajpai[1], Shvetank Sharma[1], Rakhi Maiwall[1], Shiv Kumar Sarin[1], Jaswinder Maras[1]. [1]*Institute of Liver & Biliary Sciences, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Neutrophil dysfunctionality is a hallmark of sepsis in alcohol related cirrhosis (ARC), characterised by impaired pathogen clearance, yet its underlying mechanisms remain poorly understood.
Method: Untargeted multimomics profiling was performed on neutrophils from healthy controls, non-septic ARC, and septic/septic shock ARC patients. A total of 185 patients were randomized into discovery (n = 150) and validation (n = 35) cohorts. Results were validated using omics, ELISA, neutrophil functionalities, and flow cytometry.
Results: Among 9,115 proteins and 1,414 metabolites identified, 6,488 proteins (FC > 1.5, p < 0.05) and 729 metabolites (FC > 1.5, p < 0.05) were significantly altered in septic ARC patients. Lipid and sterol homeostasis emerged as key dysregulated pathways. Further analysis identified OSBPL2 (FC > 3892, AUC = 0.93) and LDLR (FC > 4.47, AUC = 0.92) as important regulators of neutrophil dysfunction in sepsis. Elevated OSBPL2 expression causes sterol overload with elevated cholesterol (FC > 6), 25-hydroxycholesterol (FC > 500), in sepsis and shock patients, causing them to become foamy in nature. Sterol accumulation induces mitochondrial stress (THEM4 FC > 5, HIF1A FC > 7) with impaired oxidative phosphorylation, ROS elevation, and ER stress (HSPA1A FC > 3, AMFR FC > 189) with disrupted protein folding specifically in sepsis. These neutrophils showed membrane rigidity, impaired vesicular trafficking, leading to defective degranulation via dysregulated KLC1 (FC > 59), STX4 (FC > 15), and ITGB2 (FC > 11, p < 0.05). Increase in oxidative stress and ROS further promoted NETosis, upregulating ALOX5 (FC > 24), PRKCD (FC > 44), and FPR2 (FC > 5). Sterol accumulation also increases expression of anti-apoptotic proteins like BIRC (FC > 15.9, p < 0.01) and decreases expression of proapoptotic proteins like TP53 (FC < –10.3, p < 0.05), thereby increasing the lifespan of these bulky foamy neutrophils. The expression of OSBPL2 was further validated as a predictor of sepsis and foamy neutrophils in an independent cohort, with an AUC > 0.95. Benchamarking against clinical scores such as SOFA, MELD, and others. Validation was conducted using flow cytometry, mass spectrometry, and ELISA.
Conclusion: OSBPL2-positive neutrophils act as lipid reservoirs, causing lipid accumulation and activation of anti-apoptotic signaling, along with increased mitochondrial and ER stress, resulting in a aged foamy neutrophil phenotype in sepsis. This makes OSBPL2 a crucial predictive marker for sepsis and immune exhaustion in neutrophils.

WED-354
Ugonin J suppresses hepatocyte inflammation via GPX2-mediated redox regulation

Li-Yun Wang[1], Chih-Chuang Liaw[2], Yu-Hsuan Tseng[1], Ming-Lun Yeh[3], Ming-Lung Yu[1]. [1]*The Center of Excellence for Metabolic Associated Fatty Liver, National Sun Yat-sen University, Kaohsiung, Taiwan;* [2]*Department of Marine Biotechnology and Resources, National Sun Yat-sen University, Kaohsiung, Taiwan;* [3]*The Center of Excellence for Metabolic Associated Fatty Liver, National Sun Yat-sen University, Kaohsiung Medical University, Kaohsiung, Taiwan*
Email: sindy.wly@gmail.com

Background and aims: Hepatocyte-derived oxidative stress plays a pivotal role in regulating inflammatory signaling and immune crosstalk during metabolic and inflammatory liver diseases. Ugonin J, a bioactive flavonoid, has been reported to exhibit antioxidant properties; however, its role in hepatocyte redox–immune regulation remains unclear. This study aimed to investigate whether Ugonin J modulates hepatocyte inflammatory responses through a GPX2–reactive oxygen species (ROS)–dependent mechanism.
Method: Mouse AML12 hepatocytes and human HepG2 cells were treated with Ugonin J for 24 hours. Cytokine and chemokine profiles were analyzed in conditioned media (AML12) or cell lysates (HepG2) using multiplex immune panels. GPX2 expression and intracellular ROS levels were assessed by qPCR, immunoblotting, and fluorescent ROS assays.
Results: In AML12 hepatocytes, Ugonin J markedly suppressed the secretion of pro-inflammatory cytokines and chemokines, including CCL3, GM-CSF, IL-1β, IL-6, IL-12p40, and TNF-α, indicating a robust anti-inflammatory effect. This was accompanied by induction of GPX2 expression and significant attenuation of intracellular ROS levels. In contrast, HepG2 cell lysates showed increased intracellular levels of several immune-related cytokines following Ugonin J treatment, while the ROS- and NF-κB-dependent chemokine IL-8 was consistently reduced. These findings suggest differential regulation of intracellular immune signaling versus paracrine inflammatory output between normal and transformed hepatocytes.
Conclusion: Ugonin J exerts hepatocyte-protective anti-inflammatory effects by enhancing GPX2-mediated antioxidant capacity and suppressing ROS-driven inflammatory signaling. The distinct responses observed between normal and cancerous hepatocytes highlight a context-dependent redox–immune crosstalk, supporting the therapeutic potential of Ugonin J in inflammation-driven liver diseases.

WED-355
Targeting the STING pathway as a strategy to suppress hepatitis B virus replication

Mingyuan Zhang[1], Xiaomei Wang[1], Hongqin Xu[1], Yanhang Gao[2], Junqi Niu[1]. Email: junqiniu@jlu.edu.cn

Background and aims: Activation of the host immune system is a promising strategy for treating hepatitis B (HBV). The stimulator of interferon genes (STING) signaling pathway acts as an innate immune sensor for viral DNA. We aimed to determine whether STING activation can inhibit HBV replication in the liver.
Method: We evaluated STING expression in peripheral blood mononuclear cells (PBMCs) and liver biopsy specimens from patients with chronic hepatitis B (CHB). We examined the effect of the STING agonist 5,6-dimethylxanthone-4-acetic acid (DMXAA) on HBV replication and the immune response in a mouse model of HBV infection (rAAV8-HBV1.3). Additionally, we depleted macrophages in vivo to assess their role in DMXAA's antiviral effects.
Results: STING expression in CHB patients was higher in the immune-active phase than in the inactive phase or uninfected healthy controls, suggesting an association between elevated STING expression and immune activation. In a mouse model with persistent HBV replication, repeated DMXAA administration produced dose-dependent reductions in serum HBV DNA, HBsAg, and HBeAg levels, accompanied by an enhanced hepatic immune response. DMXAA treatment significantly enhanced macrophage secretion of interferon-beta (IFN-beta) and interleukin-6 (IL-6) in a dose-dependent manner, highlighting a correlation between STING agonist concentration and the production of these immune mediators. Transcriptome sequencing of liver tissues revealed 856 differentially expressed genes (DEGs) involved in immune-related signaling pathways. In Kupffer cell-deficient mice, DMXAA's ability to inhibit HBV replication was significantly attenuated.
Conclusion: STING pathway activation enhances the immune response against HBV by upregulating the expression of immune-related genes. Hepatic Kupffer cells play an important role in STING-mediated inhibition of HBV replication. Targeting the STING pathway in macrophages represents a promising strategy for inhibiting HBV replication and warrants investigation in future studies.

WED-356
VISTA deficiency exacerbates the development of acute-on-chronic liver failure by promoting Tc1 differentiation
Yao Zhang[1], Xueyun Zhang[1], Yidi Jia[1], Jiajia Han[1], Yuxian Huang[1], Richeng Mao[1], Jiming Zhang[1]. *[1]Shanghai Key Laboratory of Infectious Diseases and Biosafety Emergency Response, National Medical Center for Infectious Diseases, Huashan Hospital, Fudan University, SHANGHAI, China*
Email: youxiang08707@163.com

Background and aims: Acute-on-chronic liver failure (ACLF) has a high early mortality, and there is abundant evidence that persistent inflammatory response and immune activation are the core pathogenesis of ACLF. However, the mechanism of immune disorder has not been fully clarified. Previous studies have shown that deficiency of V-type immunoglobulin domain-containing suppressor of T-cell activation (VISTA) exacerbates the progression of inflammatory diseases. Moreover, the immune response mediated by $CD8^+$T cells can directly cause liver damage and is closely related to the dysregulation of inflammatory response in ACLF patients. Our study was designed to investigate the role of VISTA expression on $CD8^+$T cells in the pathogenesis of ACLF.
Method: We assessed the expression and function of VISTA on $CD8^+$ T cells in blood samples from healthy controls, patients with stable cirrhosis, and ACLF patients. Transcriptome sequencing was performed to determine the relevant pathways, which was then verified by Western blot. Inhibitors of relevant signaling pathways were added to the $CD8^+$ T cells to explore the key signal mechanism.
Results: In ACLF patients, the expression of VISTA was significantly reduced in the $CD8^+$ T cells compared with healthy subjects and stable cirrhosis patients, especially in the effector memory and terminally differentiated effector memory cells with high CD45RA expression subsets. The expression of VISTA on $CD8^+$ T cells was associated with disease severity and prognosis. VISTA downregulation contributed to the activation and proliferation of $CD8^+$ T cells, and enhanced the differentiation of type 1 cytotoxic T cells (Tc1), as well as heightened inflammatory cytokine secretion. This effect was mediated through the activation of the extracellular signal-regulated kinase 1 and 2 (Erk1/2) signaling pathway.
Conclusion: Our study reveals that VISTA downregulation drives ACLF progression by amplifying Tc1-mediated inflammation. This insight not only advances the mechanistic understanding of ACLF pathogenesis but also nominates VISTA as a potential candidate for therapeutic intervention.

Liver transplantation and hepatobiliary surgery – Clinical

TOP-503
Medication adherence and liver transplantation survival: a nationwide cohort study
Ilias Kounis[1], Cyrille Feray[1], Bruno Roche[1], Thomas Breard[1], Antoine Martin[2], Isabelle Boytchev[2], Eric Vibert[1], Audrey Coilly[1], Antoine Meyer[2]. *[1]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Service de Gastroentérologie, University Hospital of Bicêtre, Assistance Publique-Hôpitaux de Paris, Kremlin Bicêtre, France*
Email: ilias.kounis@aphp.fr

Background and aims: Although the impact of non-adherence to immunosuppressants is well established after kidney transplantation, national-scale data on liver transplantation (LT) remain limited. We aimed to quantify medication adherence after LT and evaluate its association with graft survival.
Method: Using the French National Health Data System (SNDS), we conducted a nationwide cohort study of first-time LT recipients aged >15 years (2010–2022). Adherence was estimated monthly using a time-dependent medication possession ratio (MPR) over a rolling 12-month period. The primary endpoint was graft survival (death/retransplantation), which was analysed using a time-dependent Cox model adjusted for social deprivation, organic and psychiatric comorbidities, liver disease aetiology, and severity indicators.
Results: Among 10,191 LT recipients (median age 55 years, 73.3% male), the mean MPR remained high (85–90%) up to 13 years post-LT. Over a median 6.8-year follow-up, the incidence of death/retransplantation was 4.6 per 100 personyears, rising from 4.2 (MPR≥90%) to 6.5 (MPR<70%). Compared with MPR ≥90%, the adjusted hazard ratios (aHR) for death/retransplantation were 1.14 (MPR 80–90%), 1.39 (70–80%), and 1.64 (<70%) (p-trend<0.001), demonstrating a clear dose–response relationship. Low adherence (<70%) was strongly associated with death (aHR 1.60), retransplantation (aHR 2.26), and biopsy-proven rejection (aHR 3.71) but not with serious infection or severe chronic kidney disease. The excess risk was most pronounced in recipients ≤40 years (aHR 3.47) and those with a low comorbidity burden.
Conclusion: In this nationwide cohort, adherence to maintenance immunosuppression was a major modifiable determinant of long-term graft and patient survival after LT, with no signal for increased infection or nephrotoxicity at higher adherence levels. Systematic adherence monitoring and targeted interventions, particularly for younger and otherwise healthy recipients, should be integrated into routine post-transplant care.

Waitlist outcomes are better and post-transplant outcomes are similar in alcohol associated hepatitis vs. alcohol associated cirrhosis: a UNOS analysis

Mangesh Pagadala[1], Ashwani K. Singal[2], Winston Dunn[3], Robert Wong[4], Patrizia Burra[5], Yong-Fang Kuo[6], Umang Arora[7], Anil Arora[8], Saleh Alqahtani[9]. *[1]Liver Institute Methodist Dallas, Irving, United States; [2]University of Louisville, Louisville, United States; [3]University of Kansas Medical Center, Westwood, United States; [4]Stanford University, Stanford, United States; [5]University of Padua, Padova, Italy; [6]University of texas medical branch galveston, Galveston, United States; [7]Mayo Clinic, Rochester, United States; [8]Sir Ganga Ram Hospital, New Delhi, India; [9]Weill Cornell Medicine, New York, United States*

Email: mangeshpagadala@mhd.com

Background and aims: Alcohol liver disease, including alcohol cirrhosis (AC) and alcohol hepatitis (AH), is the leading indication for liver transplantation (LT). In our previous study (UNOS database), post-LT outcomes in AH were like LT recipients for AC However, data are limited on long-term post-transplant and on waitlist outcomes comparing AH and AC.

Method: Adult LT listings for ALD in the UNOS database (01/2004–03/2025) were stratified to AH and AC indications using UNOS codes. Living donor LT was excluded. Analyses compared AH vs. AC on a) trends on listings and LT; b) 90-day cumulative waitlist (WL) mortality and receipt of LT using competing risk analysis; and c) 10-yr. post-LT graft and patient survival. Propensity score matching (PSM) was performed to balance baseline demographic, clinical, and disease severity variables at listing. Sub-hazard ratios (SHR) and 95% confidence intervals (95% CI) reported for WL outcomes using Fine and Gray models and HR (95% CI) reported outcomes using cox proportional models.

Results: Of 63,025 listings [4168 (6.6%) AH], listings for AH increased from 3.1% in 2004 to 16.1% in 2025. AH vs. AC candidates were younger (45 vs. 53 yrs.) and females (35 vs. 29%), P < 0.001. AH candidates were likely to be obese, on life support and have better functional status despite higher MELD score. Unadjusted cumulative 90-day WLM was lower in AH (13.9 vs. 24.5%) with HR (95% CI) of 0.88 (0.78–0.98), P = 0.019. The 90-d LT probability was higher in AH (76.9% vs 60.3%), 2.53 (2.43–2.63), P < 0.001. In the PSM cohort after matching for demographics and MELD score, 90-d WL mortality was similar comparing AH vs. AC, 0.916 (0.801–1.046), P = 0.195. However, AH candidates had slightly higher probability of 90-d LT, 1.050 (1.003–1.100), P = 0.037. Other predictors for WLM were age, MELD score, hepatic encephalopathy and being on life support at listing. Of 40,902 LT [3233 (7.9%) AH], LT for AH increased from 2.3% to 16.1% between 2004 and 2025. In the PSM cohort, 10-yr. post-LT outcomes were similar in AH compared to AC on graft [88 vs. 82%, Log Rank P = 0.329, 1.09 (0.96–124), P = 0.177] and patient survival [90 vs. 84%, P = 0.988, 1.01 (0.88–1.16), P = 0.873].

Conclusion: Our study shows candidates with AH compared to AC have lower WL mortality, higher probability of LT, and similar long-term post-LT outcomes. These findings support the ongoing LT for AH, while highlighting a need to evaluate equity in organ access for the broader spectrum of patients with alcohol associated liver disease.

Email: parissa.tabrizian@mountsinai.org

Background and aims: Downstaging selected patients with HCC and PVTT can achieve acceptable post-transplant survival, challenging prior dogma. The impact of immune checkpoint inhibitors (ICI) on transplant outcomes in PVTT remains unclear. This study aims to evaluate post-transplant outcomes in the immunotherapy era, define risk stratification, and guide liver transplant selection in PVTT.

Method: We retrospectively analyzed 57 patients with HCC and PVTT listed for transplantation across 13 international centers. Patients were grouped into ICI + LT (n = 22), LT without prior ICI (n = 23), and ICI without LT (n = 12, including 7 waitlist dropouts). Multivariable Cox regression identified independent predictors of 1- and 3-year survival, which were used for risk stratification. OS and DFS were evaluated using Kaplan–Meier analyses across cohorts and risk-based subgroups.

Results: Compared with LT alone, ICI + LT was associated with higher radiographic response rates (CR/PR: 90.9% vs 69.5%, p = 0.022) and longer waitlist time (7.5 vs 1.5 months, p = 0.005). At transplant, the ICI cohort had more favorable tumor features, including lower total tumor diameter (2.0 vs 3.5 cm, p = 0.01), reduced PVTT burden (Vp3–Vp4: 4.5% vs 39.1%, p = 0.02), and lower AFP (AFP<20 ng/mL: 63.6% vs 30.4%, p = 0.035). Three-year OS was comparable between ICI + LT and LT-alone groups (75.6% vs 65.9%, p = 0.302). On multivariable analysis, combined LRT + ICI (HR 0.42,CI 0.26–0.54, p < 0.001), radiographic response (HR 0.22,CI 0.14–0.55, p < 0.001), AFP reduction ≥ 50% (HR 0.62,CI 0.40–0.85, p = 0.016), and meeting Milan criteria at LT (HR 0.19,CI 0.13–0.58, p < 0.001) improved OS, whereas waitlist time ≤ 3 months and Vp3–Vp4 were associated with worse survival (p < 0.001). High-risk patients (no combined therapy, no radiographic or AFP response, no downstaging, waitlist time ≤ 3 months, Vp3–Vp4) derived benefit from ICI + LT versus LT alone (2-year OS: 58.3% vs 38.1%, p = 0.045; DFS: 60.0% vs 33.3%, p = 0.021). Among ICI-treated recipients, LRT conferred additional benefit (2-year OS: ICI alone 55.6% vs ICI + LRT 85.7%, p = 0.043). Mild rejection occurred in 2/22 patients (9.1%) receiving ICI.

Conclusion: In the largest multi-institutional study, selected patients with HCC and PVTT achieved excellent post-transplant survival. In high-risk PVTT, ICI-based therapy—particularly combined LRT + ICI—significantly improved oncologic outcomes, highlighting tumor biology as a key determinant for candidate selection and immunotherapy use in PVTT transplant pathways.

Rejection-associated transcripts distinguish between different types of rejection after liver transplantation

Alejandro Campos-Murguia[1], Richard Taubert[1], Bastian Engel[1], Sophia Heinrich[1], Björn Hartleben[1], Friederike Dellbrügge[1], Fabian Dranicki[1], Luise Gatzweiler[1], Milad Ghahraman[1], Sinan Yilmaz[1], Heiner Wedemeyer[1]. [1]*Hannover Medical School, Hannover, Germany*
Email: taubert.richard@mh-hannover.de

Background and aims: Long-term outcomes after liver transplantation (LT) are largely determined by the chronic side effects of immunosuppression. Accurate assessment of the graft alloimmune status may enable more individualized immunosuppressive management. Rejection-associated transcripts offer the potential to improve the identification and classification of rejection phenotypes. The relevance of antibody-mediated rejection (AMR) after LT has recently been confirmed by reports on liver cirrhosis progression in 40–50% of AMR cases, despite not relevant liver enzyme elevation and independent from the presence of donor-specific antibodies (DSA). The identification of a unique molecular signature using bulk RNA sequencing confirmed involvement of similar pathways after LT. The aim of this study was to validate a selected gene set using high-throughput quantitative PCR (qPCR) as a targeted and clinically applicable approach to distinguish AMR from other forms of graft injury.
Method: Expression of a 91-gene panel, selected based on previously reported genes uniquely associated with TCMR and AMR, was quantified using high-throughput quantitative PCR. Univariate and multivariate analyses, as well as least absolute shrinkage and selection operator (LASSO) regression, were performed to identify genes discriminating between different types of rejection.
Results: A total of 226 liver biopsies obtained after LT between 2018 and 2022 were included, comprising both surveillance and indication biopsies. Of these, 17 showed clinical TCMR, 31 subclinical TCMR, 21 AMR histology without detectable DSA, and 6 AMR with positive DSA. Additionally, 41 biopsies showed no type of inflammation, and 110 biopsies had other diagnoses not included in the aforementioned categories, 71 of the 91 genes demonstrated statistically significant differential expression across groups. Distinct gene expression signatures discriminating TCMR from AMR were identified in both univariate and multivariate analyses adjusted for age, sex, and time after LT. AMR cases with and without DSA exhibited similar molecular patterns. LASSO analysis identified a subset of 31 genes with high discriminatory power for different rejection phenotypes.
Conclusion: This study validates the presence of a distinct molecular signature characterizing AMR as a separate rejection entity after LT even in the absence of DSA. The prognostic value of these high throughput qPCR transcript set is currently under investigation.

FRI-447

Fenofibrate is associated with improvement in chronic cholangiopathy after liver transplantation: a single-center experience

Fredrik Åberg[1], Johanna Savikko[1], Eija Tukiainen[1], Ville Sallinen[1], Aki Uutela[1], Ines Beilmann-Lehtonen[1], Marko Vannas[1], Tea Kontio[1], Arno Nordin[1]. [1]*Helsinki University Hospital and University of Helsinki, Helsingfors, Finland*
Email: fredrik.aberg@helsinki.fi

Background and aims: Non-anastomotic biliary stricturing (NAS; cholangiopathy) after liver transplantation (LT) is a major complication with limited treatment options. Fenofibrate has shown benefit in early-onset ischemic cholangiopathy related to donation after circulatory death LT. We report our single-center experience using fenofibrate for refractory, long-standing NAS following donation after brain death LT.
Method: In 2023–2025, 18 LT recipients (mean age 53 years, 61% men, 50% PSC, 28% re-LT) with progressive symptomatic NAS despite ERC, UDCA ± antibiotic prophylaxis were started on fenofibrate 145 mg OD (dose reduced in renal dysfunction). This was a retrospective within-subject pre–post study with repeated measures and up to 12-month post-fibrate follow-up. Biochemical response was defined as alkaline phosphatase (ALP) normalization or ≥40% reduction. Clinical response was defined as improvement in patient-reported symptoms (chills, fever attacks, nausea, pruritus, abdominal pain) or reduced cholangitis frequency.
Results: Mean time from LT to NAS onset was 31 months, and mean time from NAS diagnosis to fibrate initiation was 33 months. After fenofibrate initiation, cholestasis improved in all patients, with a median on-treatment ALP reduction of 35% (IQR 22–51) by 1 month, maintained up to the end of the 12-month follow-up. A biochemical response was achieved by 72% of patients and a clinical response by 63%. Among 15 patients treated >90 days, response rates were 80% and 71%, respectively. Overall agreement between biochemical and clinical response criteria was 81%. In a linear mixed-effects model adjusting for time and patient-level variability, ALP levels decreased on average by 163 IU/L (95% CI −233 to −92) during active fenofibrate treatment compared with non-treatment periods ($p < 0.001$). The absence of a significant time trend ($p = 0.23$) suggests the reduction was attributable to fenofibrate rather than natural fluctuation or recovery. Fibrate response rates did not differ significantly by age, sex, pre-treatment ALP, LT indication (PSC vs other), or NAS duration pre-fibrate (all $p > 0.1$). Creatinine increased on average 27% from baseline by 1 month and thereafter remained stable. Five of 18 patients discontinued fenofibrate due to side effects and/or incomplete response. In patients who stopped fenofibrate, ALP increased.
Conclusion: These observed benefits of fibrates in long-standing post-LT NAS warrant further evaluation in prospective trials.

FRI-448

Donor and recipient pharmacogenetic variation at the POR locus is associated with acute rejection and biliary strictures after liver transplantation

Fredrik Åberg[1], Maria Semenova[2], Ville Liukkonen[3], Arno Nordin[1], Jukka Partanen[2], Kati Hyvärinen[2]. [1]*Helsinki University Hospital and University of Helsinki, Helsingfors, Finland;* [2]*Finnish Red Cross Blood Service, Helsinki, Finland;* [3]*North Karelia Central Hospital, Joensuu, Finland*
Email: fredrik.aberg@helsinki.fi

Background and aims: Cytochrome P450 enzymes *CYP3A5* and *CYP3A4*, together with P450 oxidoreductase (*POR*), are key determinants of tacrolimus metabolism and dose requirements. After liver transplantation (LT), drug metabolism is influenced by both donor and recipient genetics, yet the impact of pharmacogenetic variations on clinical outcomes remains unclear. We investigated the effects of donor and recipient pharmacogenetic variation on acute rejections (AR) and biliary strictures (BS) after LT.
Method: Study included consecutive LTs in Finland 2000–2020. Donors and recipients (666 pairs) were genotyped using genome-wide association study arrays with imputation and standardized quality control. Biopsy-verified AR and BS were identified from the national LT registry and medical records. Analyses focused on established variants in *CYP3A5* (rs776746), *CYP3A4* (rs35599367), and *POR* (rs1057868), followed by a systematic assessment of genetic variation in these genes in tacrolimus-treated cases.
Results: For the prespecified candidate variants, minor allele frequencies were 0.07 (*CYP3A5*), 0.04 (*CYP3A4*), and 0.39 (*POR*). In a subset of 108 recipients receiving tacrolimus from LT start, we observed 41 AR episodes, including 11 late AR events (>90 days post-LT), and 9 BS. The established candidate variants in *CYP3A5*, *CYP3A4*, and *POR* were not significantly associated with AR, late AR, or BS. In contrast, systematic analysis identified multiple *POR* single-nucleotide variants in both donors and recipients associated with AR (uncorrected $p < 0.05$). These variants clustered within a narrow genomic region and showed identical significance levels, consistent

with a shared haplotype block. In donor analyses, a representative *POR* variant from the associated haplotype block was associated with a reduced AR risk (odds ratio [OR] 0.44, 95% CI 0.21–0.91, adjusted for genotype-specific age, sex, and the first 1–4 genetic principal components). In recipient analyses, a distinct *POR* haplotype block within the same genomic region was associated with a higher risk of AR (adjusted OR 9.61, 95% CI 1.02–90.54). All recipient *POR* variants associated with AR were also associated with BS. Recipient *CYP3A4* variation was associated with late AR, while variation in CYP3A5 showed no significant associations.
Conclusion: Genetic variation at the POR locus was associated with AR and BS after LT. Associations involved a block distinct from the POR rs1057868 candidate variant and these findings require confirmation in independent cohorts.

FRI-449
Clinical characteristics and outcomes of primary sclerosing cholangitis after liver transplant, with or without inflammatory bowel disease, a national 10 year retrospective study
Afaf Ahmad[1], J. Sheridan[1], G. Doherty[1], G. Cullen[1], ZIta Galvin[2], Ross MacNicholas[2], Julia Sopena Falco[2], Audrey Dillon[2], Masood Iqbal[2], Omar El-Sherif[2]. [1]*Gastroentrology department, St. Vincent's University Hospital., Dublin, Ireland;* [2]*The National Liver Transplant Department, St. Vincent's University Hospital, Dublin, Ireland*
Email: afafawad244@gmail.com

Background and aims: Although a rare disease, PSC accounts for 10%–15% of the liver transplant activity in Europe. This national study focused on all PSC-LT recipients in Ireland in St. Vincent's University Hospital during the period 2016–2025.
Method: A retrospective review of data extracted from the waiting list, national liver transplant registry and chart review, included both IBD-PSC-LT and NON-IBD-PSC-LT cohorts.
Results: From 2016–2025; 350 patients were transplanted-DBD; PSC constituted 22.57% (n = 79) of all LT indications in Ireland during this period. 68.4% had associated IBD; 13% of whom were diagnosed post-LT. Mean age at transplant was 46.26 years ± 13.3SD (males 60%) in the IBD-PSC-LT, vs. NON-IBD PSC-LT 48 years ± 12.2 SD (males 64%). The mean listing MELD score was similar in both cohorts (IBD-PSC-LT 15.4 ± 6.95 SD, NON-IBD-PSC-LT 15.7 ± 5.8 SD). THE IBD-PSC cohort were prescribed more combination immunosuppression (65%) vs. NON-IBD-PSC cohort (24%). 44% of the NON-IBD-PSC-LT had biopsy proven acute cellular rejection vs. 29.6% in IBD-PSC LT. No liver-graft related adverse effects or infections were noted in relation to using combination of LT immunosuppression and a biological agent to treat IBD. These agents were; Vedolizumab (n = 7), anti-TNFs (n = 6), interleukin inhibitors (n = 3). (n = 10) PSC-LT had recurrent PSC (rPSC), 80% were in the IBD-PSC-LT-cohort, however there was no statistically significant relationship between IBD and PSC recurrence (Chi-square 1.56, p-value: 0.210). (n = 11) needed re-transplantation; 81% of whom were in the IBD-PSC-LT cohort. (n = 3) were re-transplanted twice for rPSC. Mortality was higher in the IBD-PSC-LT cohort vs. NON-IBD-PSC-LT-Cohort (3.8% and 1.3% respectively), with an overall post-LT colon cancer related mortality of 1.3%.
Conclusion: In our cohort, PSC-LT rates were higher compared to other European studies. The IBD course was variable, however the use of biologic therapies were safe in our cohort.

FRI-450
Left or right graft? Differential complication risks after ex vivo liver resection and autotransplantation for hepatic alveolar echinococcosis
Tuerganaili Aji[1], Yierfan Yilihaer[1]. [1]*First Affiliated Hospital of Xinjiang Medical University, Urumqi, China*
Email: tuergan78@sina.com

Background and aims: For conventionally unresectable hepatic alveolar echinococcosis (HAE), ex vivo liver resection and autotransplantation (ELRA) enables R0 resection. Left and right lobe grafts present distinct complication risks that guide surgical planning and postoperative management. However, evidence comparing these graft outcomes in HAE remains limited.
Method: We retrospectively analyzed 142 consecutive patients with HAE who underwent ELRA between 2010 and 2023. Patients were categorized into left graft (n = 98) and right graft (n = 44) groups. Propensity score matching generated 42 well-balanced pairs. Postoperative biliary and venous outflow complications were assessed. Predictors were identified using least absolute shrinkage and selection operator (LASSO) regression followed by multivariable logistic regression. Model performance was evaluated by receiver operating characteristic (ROC) curves, calibration plots, and decision curve analysis.
Results: No intraoperative deaths occurred. Pleural effusion was the most common postoperative complication (66.7%). Compared with left graft transplantation, right graft transplantation was associated with longer operative time and greater intraoperative blood transfusion (both $P < 0.05$). Biliary complications occurred more frequently in the right graft group (28.6% vs. 11.9%; $P < 0.05$). Independent predictors of biliary complications included preoperative biliary duct dilation (odds ratio [OR] = 18.82) and right graft type (OR = 6.12). In contrast, venous outflow complications were significantly more common in the left graft group (38.1% vs. 16.7%; $P < 0.05$). Independent predictors of outflow complications included use of artificial vascular reconstruction (OR = 3.42), left graft type (OR = 3.40), and portal hypertension (OR = 3.93). Predictive models demonstrated good discrimination for biliary complications (AUC = 0.83) and venous outflow complications (AUC = 0.80), with favorable calibration and clinical utility confirmed by decision curve analysis.
Conclusion: ELRA for HAE is associated with distinct graft-specific complication patterns. Right grafts predispose to biliary complications, whereas left grafts increase the risk of venous outflow obstruction. The validated predictive models provide a practical tool for individualized graft selection and perioperative risk stratification, potentially improving surgical planning and postoperative management in complex HAE cases.

Email: tarannum.behlim@gmail.com

Background and aims: Sickle cell disease (SCD) is an autosomal recessive haemoglobinopathy that can cause severe hepatobiliary complications, for which liver transplantation (LT) may represent the only lifesaving option. We conducted a systematic review and meta-analysis of post-transplant outcomes in patients with SCD.
Method: We searched Ovid MEDLINE, Ovid EMBASE, the Cochrane databases, and Scopus from inception to 17 July 2025. Our search was limited to human studies published in English.We included case reports, case series, and observational cohorts reporting post LT outcomes in patients with SCD. Two reviewers independently performed study selection, data extraction, and risk of bias assessment. We conducted single arm random effects meta analyses to pool data on patient and graft survival at 1 year and 5 years.
Results: Twenty nine studies were included, comprising 23 case reports, 3 case series, and 3 retrospective cohort studies, with a total of 83 patients. Within 90 days post LT, the most frequently reported complications were infectious (26.5%), renal (18.2%), and vascular (15.7%). Reported long term complications were predominantly haematologic (7.2%) and mainly SCD related. Nine patients (12%) required retransplantation, including one patient who underwent two retransplants within five months of the index LT. Pooled 1 year patient survival was 76% (95% CI 42–89%), with a similar estimate for 1 year graft survival (76%, 95% CI 42–89%); heterogeneity was substantial (I^2 62.6%), reflecting variation in case mix, perioperative management, and reporting quality within primarily case based evidence. Long term outcomes were poorer, with pooled 5 year patient survival of 46% (95% CI 25–68%) and 5 year graft survival of 41% (95% CI 25–57%); heterogeneity was moderate and not statistically significant. Reported causes of graft loss included sickle cell crisis (n = 3), vascular complications (n = 3), primary nonfunction (n = 1), secondary haemochromatosis (n = 1), and multiple intrahepatic biliary strictures without hepatic artery thrombosis (n = 1).
Conclusion: LT can provide meaningful short term survival forcarefully selected patients with SCD. However, long-term patient and graft survival remain significantly impaired. Improved perioperative protocols, structured long term follow up, and more consistent reporting of SCD specific complications are needed to enhance care and outcomes in this complex transplant population.

Email: halima.alshueili@gmail.com

Background and aims: Donor hypernatremia is common in neurologically deceased organ donors and has been proposed as a risk factor for adverse outcomes after liver transplantation, although evidence remains inconsistent. We conducted a systematic review and meta-analysis to evaluate the association between donor hypernatremia and post-transplant graft outcomes and recipient mortality after deceased donor liver transplantation.
Method: Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, we searched MEDLINE, EMBASE, PubMed, Web of Science, Scopus, and the Cochrane Central Register of Controlled Trials from inception to 17 July 2025. Eligible studies reported terminal donor serum sodium levels and post-transplant graft or patient outcomes. Donor hypernatremia was generally defined as serum sodium greater than or equal to 145 milliequivalents per liter. The primary outcome was 30-day recipient mortality. Secondary outcomes included graft dysfunction or loss ≤ 7 days, 30 days, and 1 year, and recipient mortality at 7 days and 1 year. Risk of bias was assessed using the Risk Of Bias In Non-randomized Studies of Interventions (ROBINS-I) tool. Random-effects meta-analyses were performed when appropriate.
Results: From 2,656 screened records, 15 retrospective cohort studies including 7704 patients were identified. Donor hypernatremia was associated with a higher risk of graft dysfunction or loss within 7 days compared with normonatremic donors (relative risk [RR] 1.79, 95% confidence interval [CI] 1.42–2.26; I squared = 70%). At 30 days, the association was less consistent (RR 1.57, 95% CI 0.87– 2.82). At 1 year, donor hypernatremia was associated with increased graft dysfunction or loss (RR 2.11, 95% CI 1.43–3.12; I squared = 80%). Donor hypernatremia was associated with higher 30-day mortality (RR 2.04, 95% CI 1.51–2.76; I squared = 66%) but not with recipient mortality at 7 days or 1 year. Most studies had a moderate to serious risk of bias, mainly due to confounding and incomplete adjustment.
Conclusion: Donor hypernatremia was associated with increased early graft dysfunction, higher 1-year graft loss, and elevated 30-day recipient mortality after liver transplantation, but not with longer-term post-transplant mortality. Given substantial heterogeneity and risk of bias, donor hypernatremia may represent a marker of graft vulnerability, warranting further prospective study.

FRI-458

Post-transplant comorbidities, MASLD development and long-term survival in liver recipients with and without HIV infection

Adriana Cervo[1], Maddalena Albertini[1], Federica Casari[1], Jovana Milic[1], Barbara Catellani[2], Paolo Magistri[2], Gian Piero Guerrini[2], Cristina Mussini[1], Giada Sebastiani[3], Fabrizio Di Benedetto[2], Giovanni Guaraldi[1]. *[1]Infectious Diseases Clinic, University Hospital of Modena, Modena, Italy; [2]Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, University Hospital of Modena, Modena, Italy; [3]Division of Gastroenterology and Hepatology, McGill University Health Centre, Montreal, Canada*
Email: adriana.cervo@gmail.com

Background and aims: Data on long-term outcomes and post-transplant comorbidities in liver transplant (LT) recipients with HIV infection remain limited, particularly regarding metabolic complications and metabolic dysfunction–associated steatotic liver disease (MASLD).
Method: This retrospective, propensity score–matched (1:3) case–control study included 87 LT recipients with HIV and 261 without HIV transplanted at the University Hospital of Modena between 2003 and 2024. Matching variables were age, sex, MELD score, hepatocellular carcinoma (HCC), HBV/HCV coinfection, and donor age. Prevalence at LT and incidence rates (IR) post-LT of hypertension, diabetes, dyslipidemia, cardiovascular events (CVE), MASLD (imaging-based diagnosis), and recurrent HCC were assessed, together with long-term survival.

Results: Of 348 recipients, 17% were females, with age of 53 (IQR 47–58). At LT, active HCV infection was present in 39% of HIV and 31% of non-HIV recipients, and HCC prevalence was similar (49.4% vs 47.5%). At LT, hypertension and dyslipidemia were more prevalent in HIV recipients than non-HIV (38% vs 18% and 26% vs 6%, $p < 0.05$), while diabetes prevalence was comparable (21% vs 18%). Post-LT dyslipidemia occurred more frequently in HIV recipients (58% vs 35%; incidence rate [IR] 1.8 vs 0.5 per 100 PYFU), whereas incidence rates of hypertension and CVE were similar. New-onset diabetes occurred in 15% of HIV and 25% of non-HIV recipients ($p = 0.052$) with IR 2.2 vs 3.3 per 1000 PYFU. Post-LT overweight/obesity developed in 17% of HIV and 32% of non-HIV recipients ($p = 0.053$). Post-LT MASLD was diagnosed in 19.2% of recipients, with similar IR between groups. However, a hepatic steatosis index >36 was more frequent in non-HIV recipients (31% vs 21%, $p = 0.038$). Post-LT IR of recurrent HCC did not differ between groups (1.8 vs 1.4 per 100 person-years of follow-up [PYFU], $p = 0.519$), although time to recurrence tended to be longer in HIV recipients (2.4 vs 0.8 years, $p = 0.06$). MASLD was not associated with increased HCC recurrence. Ten- and fifteen-year survival was 59.6% and 48.9% in HIV recipients versus 66.7% and 53.1% in non-HIV recipients, respectively.
Conclusion: LT in people with HIV achieves long-term survival comparable to non-HIV recipients. Post-LT metabolic comorbidities remain highly prevalent, with dyslipidemia more common in HIV and diabetes in non-HIV recipients. MASLD develops in approximately one-fifth of recipients, highlighting the need for integrated, multidisciplinary metabolic care after LT.

FRI-459
Impact of pre-transplant metabolic syndrome on survival and causes of mortality after liver transplantation: a 20-year cohort study
Carmen Alonso Martin[1], Irene Peñas Herrero[2], Samuel Fernández-Prada[2], Elena Velasco Martinez[2], Natalia Marcos Carrasco[2], Carolina Almohalla Alvarez[2], Félix García Pajares[2], Gloria Sánchez Antolín[2]. *[1]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain; [2]Hospital Universitario Rio Hortega, Valladolid, Spain*
Email: calonsoma@saludcastillayleon.es

Background and aims: Metabolic syndrome is increasingly prevalent among liver transplant candidates, but its impact on long-term survival and cause-specific mortality after transplantation remains uncertain. This study aimed to evaluate the influence of pre-transplant metabolic syndrome on post-transplant survival, causes of death, and vascular and tumour-related morbidity.
Method: We retrospectively analysed 682 adult patients who underwent liver transplantation from January 2002 to December 2022. Metabolic syndrome was defined by the presence of at least two of the following conditions: diabetes mellitus, arterial hypertension, dyslipidaemia, or obesity (body mass index 30 kg per square metre or higher). Survival was analysed using Kaplan–Meier curves and compared with the log-rank test. Causes of death and vascular and tumour-related events were assessed according to metabolic syndrome status.
Results: Metabolic syndrome was present in 23 percent of patients. Median survival was lower in patients with metabolic syndrome compared with those without (92 versus 158 months), although this difference did not reach statistical significance ($p = 0.29$). Early mortality within the first six months after transplantation was similar between groups. However, non-fatal vascular complications during the first year were more frequent in patients with metabolic syndrome (6.9 percent versus 4.0 percent). From the fifth year onwards, cardiovascular mortality was markedly higher in the metabolic syndrome group (13.6 percent versus 1.9 percent). The overall incidence of post-transplant tumours was lower in patients with metabolic syndrome (9.4 percent versus 15.2 percent), while tumour-related mortality was comparable between groups, with a slight numerical increase in patients with metabolic syndrome (11.3 percent versus 9.9 percent).
Conclusion: Pre-transplant metabolic syndrome was not associated with early post-transplant mortality or tumour incidence but was linked to a higher burden of early vascular complications and increased late cardiovascular mortality. These findings underscore the clinical relevance of early identification and strict control of metabolic risk factors in liver transplant candidates to improve long-term outcomes.

FRI-460
Computed tomography–defined sarcopenia as a predictor of mortality in liver transplant candidates: a systematic review and meta-analysis
Sofia Araujo[1], Carlos Eduardo Freitas Dantas[1], Witória Lins[2], Lorena Madureira[2], Maria Clara Silva Dutra de Amorim[1], Ângelo Bonfim[1], Ana Sofia Albuquerque Ponte[3], Iasmin Nogueira[3], Matheus Costa[3], João Filipe Melo[3]. *[1]Faculdade De Ciências Médicas, Recife, Brazil; [2]Universidade Federal De Pernambuco, Recife, Brazil; [3]Uninassau-Recife, Recife, Brazil*
Email: sofia.coriolano@upe.br

Background and aims: Sarcopenia is prevalent in advanced liver disease and has been studied as a prognostic marker in liver transplant (LT) candidates. Computed tomography (CT)–derived skeletal muscle index (SMI) is the reference standard for diagnosis; however, its association with waitlist mortality is inconsistent. This systematic review and meta-analysis evaluated the prognostic impact of CT-defined sarcopenia on mortality in adult LT candidates.
Method: This PRISMA-compliant systematic review searched PubMed, Embase, Scopus, and Web of Science up to December 2025. Eligible studies assessed CT-derived sarcopenia at the L3 level and reported mortality in adult liver transplant candidates. Risk ratios (RR) with 95% confidence intervals (CI) were pooled using common and random effects models. Statistical heterogeneity was quantified using the I^2 statistic, with an $I^2 < 60\%$ prespecified to support the common effect model as the primary analytical approach.
Results: Four observational studies including 869 LT candidates were analyzed (357 with CT-defined sarcopenia and 512 without). Sarcopenia was significantly associated with increased mortality (common effect: RR = 1.33, 95% CI [1.08–1.63], $p = 0.0068$; random effects: RR = 1.30, 95% CI [1.03–1.64], $p = 0.0274$). Individual estimates ranged from a non-significant protective effect to a markedly increased mortality risk. Heterogeneity was low ($I^2 = 23.6\%$), indicating statistical homogeneity, though this apparent consistency warrants caution. All studies were monocentric, had relatively small sample sizes, used heterogeneous sarcopenia cut-offs, and lacked robust control for selection or confounding bias, limiting external validity and generalizability of the pooled results.
Conclusion: CT-defined sarcopenia is associated with increased mortality in LT candidates; however, methodological limitations and limited population diversity require cautious interpretation. Future multicenter studies with standardized diagnostic thresholds and formal bias-reduction strategies are needed, along with comparative assessments of CT versus alternative non-ionizing muscle evaluation methods to define its role as the prognostic reference standard.

Email: becchettichiara@tiscali.it

Background and aims: Weight gain in liver transplant recipients (LTR) is common and increases the risk of major adverse cardiovascular events (MACE). Glucagon-like peptide-1 receptor agonists (GLP-1 RA) may mitigate post-LT obesity and metabolic complications. We evaluated the safety, tolerability, and efficacy of GLP-1 RA in LTR from multiple countries.
Method: All adult LTR treated with GLP-1 RA between 2010 and 2021 in four centers (Canada, USA, Italy, Switzerland), with follow-up through June 2024 were analyzed. Primary outcome was 1-year weight change; secondary outcomes included metabolic parameters, MACE, graft function, immunosuppressive drug exposure, and treatment tolerability. GLP-1 RA users were matched 1:1–1:2 with non-users by age, sex, diabetes status, transplant year, and center. Analyses used mixed models with multiple imputation.
Results: The cohort included 104 GLP-1 RA LTR users, of which 77.9% were male, 68.3% had diabetes and 49% were obese. Metabolic dysfunction-associated liver disease was the main indication for LT (49.0%). GLP-1 RA were initiated a median of 7.0 ± 3.5 years post-LT, most commonly semaglutide (67.3%), and maintained at ≤1 mg weekly. At 1 year, body weight decreased by 3.9% (−3.8 kg, 95%CI 1.9–5.7; $p < 0.001$), BMI by 5.0% (−1.6 kg/m^2, 95%CI 0.9–2.3; $p < 0.001$), and HbA1c by 6.7% (−0.48%, 95%CI 0.19–0.78; $p = 0.002$), with improvements in total cholesterol (−7.36%; $p = 0.001$) and LDL cholesterol (−7.54%; $p = 0.018$). Liver enzymes remained stable, and no treatment discontinuations occurred. In the matched analysis (80 users vs 116 controls), GLP-1 RA users showed significant reductions in weight (delta −3.40; 95%IC −5.93, −0.87; $p = 0.009$), BMI (delta −1.57 kg/m^2; 95%IC −2.63, −0.50; $p = 0.005$) and HbA1c (delta −0.43%, 95%CI −0.83, −0.02, $p = 0.042$), when compared to controls who showed no changes. Immunosuppressive drug exposure showed no relevant differences compared with matched controls. Acute rejection (2.5% vs 1.72%) and MACE (6.25% vs 8.62%) rates were statistically similar between groups.
Conclusion: GLP-1 RA represent a safe therapeutic option for managing metabolic dysfunction in LTR, without adversely affecting graft function or immunological stability. The notably low dosing observed likely attenuate efficacy compared with the general population. Given the safety profile, dose escalation in LTR should be encouraged.

FRI-462
Impact of multimodal prehabilitation in patients with cirrhosis awaiting liver transplantation: a feasibility trial

Amine Benmassaoud[1], Chelsia Gillis[1], Olivia Geraci[1], Myriam Martel[1], Yusuf Afif[1], Larry Lands[1], Jeffrey Barkun[1], Tianyan Chen[1], Giada Sebastiani[1], Franco Carli[1], Amal Bessissow[1]. *[1]Centre universitaire de Santé McGill, Montréal, Canada*
Email: amine.benmassaoud@mcgill.ca

Background and aims: Patients awaiting liver transplantation (LT) are commonly malnourished and frail. Prehabilitation aims to improve physiological reserves before a major surgery. To date, its impact before LT remains unknown. We assessed whether a multimodal prehabilitation program is feasible, safe, and improves exercise fitness, nutrition, and health-related quality of life (HRQoL).
Method: Our prospective single-arm clinical trial recruited adults with cirrhosis awaiting a first LT (NCT05237583). Participants were excluded if they were delisted, had a MELD > 20, were awaiting combined organ transplantation, or deemed unsafe to exercise. All participants enrolled in a structured and supervised multimodal prehabilitation program (exercise training, nutritional optimization, and psychological support). The program was divided into a 4-week induction phase (3 exercise sessions per week) and a 5-month maintenance phase (1 exercise session every 2 weeks). Feasibility objective included recruitment of 25 participants. Exercise fitness, nutritional status, and HRQoL were compared before and after the intervention using non-parametric tests and linear mixed models to evaluate changes over multiple assessments.
Results: Overall, 25 participants received the intervention (age 57.9 ± 9.4 years; 20% women; 48% alcohol-related cirrhosis; 12% hepatocellular carcinoma; 24% prior TIPS; MELD score 11.6 ± 3.8; 8% frail by Liver Frailty Index [LFI]; 32% adequately nourished [RFH-GA]). Overall, 16 (64%) completed the induction phase and 6 (24%) completed the entire program. There were 9 AEs; all mild, and 1 was related to intervention. Reasons for lack of completion included LT (n = 6), consent withdrawal (n = 7), and AE (n = 6). Peak oxygen consumption (VO_2max) was stable after 4 weeks but increased by end of program (pre: 13.0 ± 3.9; end: 25.5 ± 19.1 mL/kg/min); LFI improved significantly after 4 weeks (LFI pre: 3.63 ± 0.48 vs post: 3.39 ± 0.64; $p = 0.03$), and it remained stable thereafter (LFI end: 3.32 ± 0.70) ($p = 0.84$). Nutrition status tended to improve as more patients became adequately nourished (pre: 32% vs end: 83%, $p = 0.08$). Trend toward improved HRQoL was noted (CLDQ pre: 4.95 ± 1.38 vs end: 5.53 ± 1.02). Overall acceptability to the intervention, rated on a 5-point scale, remained high (pre: 4.60 ± 0.50 vs end: 4.67 ± 0.52).
Conclusion: Our feasibility trial shows that our multimodal prehabilitation program is feasible, safe, and seems to improve preoperative fitness. Larger studies are needed to confirm these findings.

FRI-463
Liver transplantation for HBV-related disease in France: NUC type before LT is major determinant of patient survival

Email: isaure.bienvenue@chu-lyon.fr

Background and aims: Liver transplantation (LT) is indicated in the case of liver complications related to hepatitis B virus (HBV) infection:

acute liver failure (ALF), decompensated cirrhosis, and/or hepatocellular carcinoma (HCC). LT for HBV in France accounts for approximately 5% of all liver transplant indications, a figure that has remained fairly stable over the past 20 years. The present study aimed to describe and evaluate post-LT survival for HBV in France during the past 2 decades.

Method: This retrospective multicenter study included all adult patients who underwent a first LT in France with a positive HBsAg (+/– coinfected with HDV), between January 1, 2005, and December 31, 2023, for ALF, or cirrhosis complicated or not by HCC.

Results: A total of 1,083 patients were included, the majority of whom were men (82%) with a median [IQR] age at LT listing of 52.8 [42.5; 59.8] years. The main indication for LT was HCC in 47.0% of cases, decompensated cirrhosis in 41.2%, ALF (9.4%), or HCC without cirrhosis (1.4%). At LT listing, 79.9% of the patients with HCC had an AFP score ≤2. Median follow-up time after LT was 6.0 [2.2; 11.1] years. At the time of LT, 411 patients were on tenofovir (40.9%), 347 were on entecavir (34.6%), 143 were receiving another NUC (14.2%), 76 patients were not receiving antiviral treatment (7.6%) and 27 patients were receiving both tenofovir and entecavir (2.5%). Overall patients' survival at 1, 5, 10, and 15 years was 89.9%, 76.4%, 66.4%, and 54.5%, respectively. The main causes of death were HCC recurrence (27.6%), infection (23.3%), followed by oncological causes excluding HCC (10.0%), and 10.0% of patients died in early post-operative period. There were no deaths related to HBV recurrence. Multivariate analysis disclosed that independent significant risk factors for overall mortality were age at LT (HR: 1.030; 95CI: 1.019–1.042; $p < 0.0001$) and type of pre-LT nucleos(t)ides analogue (NUC): compared to tenofovir, entecavir (HR: 1.735; 95CI: 1.312–2.295; $p < 0.0001$) or another NUC (HR: 1.471; 95CI: 1.059–2.043; $p = 0.021$) were associated with decreased overall patient survival. The indication for LT (ALF, cirrhosis and HCC) had no significant impact on patients' survival. Similarly, HDV co-infection had no significant impact on patients' survival.

Conclusion: Our results suggest that survival of patients who underwent LT for HBV-related disease is significantly dependent on the type of antiviral treatment before LT, tenofovir use being associated with a better survival.

FRI-464

Liver transplantation for HBV in France: study of antiviral prophylaxis and HBV recurrence in 1,083 patients

Email: isaure.bienvenue@chu-lyon.fr

Background and aims: Liver transplantation (LT) can be indicated in the case of acute liver failure (ALF), decompensated cirrhosis, and/or hepatocellular carcinoma (HCC) related to hepatitis B virus (HBV) infection. Post-LT antiviral prophylaxis recommendations have evolved in recent years, with a reduction in the duration of HBIG administration. The present study aimed to describe and evaluate the efficacy of post-LT antiviral prophylaxis in France during the past 2 decades.

Method: This retrospective multicenter study included all adult LT patients who were HBsAg positive (+/- coinfected with HDV) at the time of LT, between January 1, 2005, and December 31, 2023. Post-LT HBV recurrence was defined as the detection of serum HBV DNA.

Results: A total of 1,083 patients were included, most of them were men (81.5%) with a median [IQR] age at LT listing of 52.8 [42.5; 59.8] years. HCC was the primary indication for LT in 47.2% of cases, followed by decompensated cirrhosis (41.2%) and ALF (9.4%). At the time of LT, 411 patients were on tenofovir (40.9%), 347 were on entecavir (34.6%), 143 were receiving another NUC and 27 patients were receiving both tenofovir and entecavir (2.5%). At the time of LT, 75.9% of the patients had an undetectable serum HBV DNA, 4.4% had a detectable but not quantifiable HBV DNA, and 19.7% had a quantifiable HBV DNA. Median follow-up time after LT was 6.0 [2.2; 11.1] years. All patients received HBIG for at least 5 days after LT. Patients treated with HBIG received subcutaneous form in 46.0% of the cases and intravenous form in 54.0%. Among 684 patients initially treated with HBIG + NUC, 206 (30%) discontinued HBIG during follow-up, with a median time to discontinuation from LT of 4.0 [1.9; 7.3] years. At the end of follow-up, 50.0% of the patients were still receiving a combination therapy with HBIG + NUC, 47.0% were receiving NUC alone, and 3.0% were receiving HBIG alone. The main reason for discontinuing HBIG was to follow recommendations. The factor identified in multivariate analysis for maintaining combination prophylaxis was a co-infection with HDV ($p = 0.034$). A total of 22 patients had HBV recurrence after LT with a median delay of 2.6 [0.7–3.2] years. The cumulative incidence of HBV reactivation after LT was therefore 4.1% at 15 years.

Conclusion: Our results strongly confirm that HBV recurrence after LT is now very rare. The antiviral prophylaxis regimen is heterogeneous and differs from current recommendations, with frequent continuation of a combination HBIG/NUC therapy.

FRI-465

Impact of hypothermic oxygenated perfusion on very old liver graft issued from donors after circulatory death (>70 years) livers: insights from a belgian bi-centric experience

Eliano Bonaccorsi-Riani[1], Maxime Foguenne[1], Antoine Dubois[1], Joris Blondeel[2], Lancelot Marique[1], Aniss Channaoui[1], Olga Ciccarelli[1], Laurent Coubeau[1], Géraldine Dahlqvist[1], Kristof Vandevoorde[2], Karlien Degezelle[2], Mauricio Sainz-Barriga[2], Ina Jochmans[2], Jacques Pirenne[2], Diethard Monbaliu[2]. *[1]Cliniques Universitaires Saint-Luc, Brussels, Belgium; [2]UZLeuven, Leuven, Belgium*
Email: eliano.bonaccorsi@saintluc.uclouvain.be

Background and aims: Liver graft recipients from donors after circulatory death (DCD) face an increased risk of complications such as primary non-function (PNF) and non-anastomotic biliary stricture (NAS). This is due to the warm ischemia time, inherent to the DCD procurement. Similarly, liver grafts from very old (>70 years) donors are known to increase these risks, although they represent a valuable option to safely increase the donor pool. Ex-situ end-ischemic hypothermic oxygenated perfusion (HOPE) of DCD-grafts <60 years has been demonstrated to reduce the incidence of complications following liver transplantation (LT). However, results of HOPE in grafts from very Old-DCD (>70 years) remains scarce. Therefore, we aim to study impact of HOPE on these specific grafts.

Method: Data from 95 LT using >70 years DCD-graft, transplanted in 2 Belgian centres between 2015 and 2025 were collected. Of those, 53 were preserved with HOPE (Old-DCD-HOPE), and 42 were preserved

in static cold storage (Old-DCD-SCS). Graft-related complications was defined as the occurrence of PNF, biliary complications, vascular complications, re-laparotomy within 10 days after LT and occurrence of renal replacement therapy after LT.
Results: Recipient characteristics (indication, age, MELD score) and warm ischemia times were comparable between groups. HOPE-liver grafts were perfused for 172 minutes (mean), reducing static cold ischemia time to 216 minutes (mean) (compared to 332 minutes (mean), $p < 0.001$). Donors were older in the Old-DCD-HOPE (76.9 ± 5.7 years old) compared to the Old-DCD-SCS (73.5 ± 2.9 years old) ($p < 0.001$). Old-DCD-HOPE presented a lower rate of graft-related complications (0.57/patient) compared to Old-DCD-SCS (1.14/patient) ($p = 0.003$), including NAS (5.7% *vs* 21.4%, $p = 0.047$), while graft-threatening complications (leading to re-LT or death) were reduced (7.5% *vs* 28.6%, $p = 0.015$). There was no difference in 1-year graft survival (84.0% vs. 76.0%, $p = 0.238$).
Conclusion: These findings support that using of HOPE for DCD-graft >70 years results with fewer graft-related and graft-threatening complications. By enabling the safe transplantation of grafts from very old DCD donors, HOPE contributes to a meaningful expansion of donor availability. Larger prospective studies are required to confirm these encouraging results.

FRI-466
Minimal immunosuppression is still too much: oncological and cardiovascular events impact 20-years survival rates of liver recipients
Eliano Bonaccorsi-Riani[1], Léa Peiffer[1], Maxime Foguenne[1], Lancelot Marique[1], Laurent Coubeau[1], Olga Ciccarelli[1], Géraldine Dahlqvist[1], Jan Lerut[2]. *[1]Cliniques Universitaires Saint-Luc, Brussels, Belgium; [2]Institut de Recherche Expérimentale et Clinique, UCLouvain, Brussels, Belgium*
Email: eliano.bonaccorsi@saintluc.uclouvain.be

Background and aims: Chronic immunosuppression (IS) is necessary to maintain graft survival. Yet, it is associated with severe adverse effects; affecting recipients' long-term survival. Minimal IS (mIS) protocols have been proposed as a strategy to mitigate these consequences. This study assesses 20 years long-term graft and patient outcomes of patients included in a mIS prospective randomised controlled trial (RCT).
Method: Between February 2000 and September 2004, 156 adults were enrolled in a prospective RCT aiming to establish long-term mIS (tacrolimus monotherapy - TacMono). Outcomes were evaluated over a minimum follow-up of 20 years.
Results: Sixty-seven patients (pats) (43%) were alive at 20 years post-LT. From those, IS regimens were known for 52 pats (76%). Thirty pats (58%) were on TacMono therapy with 8 of them were on spacing monotherapy (IS not every day per week). Five pats (10%) achieved the IS-free status. Thirteen pats (25%) were on double and 4 (8%) on triple IS, mainly due to recurrent auto-immune disease (29%), impaired renal function (29%) and poorly tolerated neurological IS side-effects (12%). Neoplasia was the leading cause of death (26%), most of them being de novo malignancies (78%); followed by sepsis (19%), mainly due to biliary-associated infections (67%). Cardiovascular events (14%) represent the third cause of mortality, equally divided between myocardial infarction and stroke. Eighteen patients (12%) required a re-transplantation (reLT), 72% occurring within 5 first years. Disease recurrence was the cause of re-LT in 6 pats (33%), biliary complications in 3 pats (17%) and chronic rejection in another 3 pats (17%). For note, all re-LT because of chronic rejection were due to non-compliance and not to mIS protocols. Clinical data were available for 59 pats, 19 of those (32%) suffered from moderated chronic kidney disease (KDIGO stage 3a and 3b); 7% patients required renal replacement therapy (KDIGO stage 4–5). Diabetes, arterial hypertension and hypercholesterolemia were diagnosed and treated in 41%, 63% and 31% of patients respectively.
Conclusion: mIS (based on tacrolimus monotherapy), including spaced and even no therapy can be reached safely in a majority of patients without compromising long-term outcome. Although, IS-related complications still impact patient survival. This very-long term follow-up study clearly shows that IS should be reduced as much as possible, as it is an important strategy to improve long-term outcome of liver recipients.

FRI-467-YI
Secretin therapy during ex-situ normothermic liver machine perfusion: a critical factor for restoration of bile duct physiology and the protective "bicarbonate umbrella"
Roberto Broere[1], Stefan H. Luijmes[1], Puck C. Groen[1], Jorke Willemse[1], Iris E.M. de Jong[2], Marcel Bijvelds[3], Caroline den Hoed[3], Sarwa Darwish Murad[3], Luc van der Laan[4], Jeroen de Jonge[1], Robert Porte[1]. *[1]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, Netherlands; [2]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Pathology, Rotterdam, Netherlands; [3]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]Erasmus Medical Center Rotterdam, Transplant Institute, Laboratory of Experimental Transplantation and Intestinal Surgery, Rotterdam, Netherlands*
Email: r.broere@erasmusmc.nl

Background and aims: Normothermic machine perfusion (NMP) is increasingly used for assessment of deceased donor livers. Cholangiocytes modify bile composition by secretion of bicarbonate (HCO_3^-), creating alkalotic bile that protects against bile salt toxicity (known as the "bicarbonate umbrella"). Low biliary HCO_3^- during NMP indicates cholangiocellular injury and contributes to additional bile salt-induced injury. Secretin is a hormone that stimulates biliary HCO_3^- secretion in-vivo. The aim of the study is to assess whether 1) administration of secretin during NMP restores biliary physiology and the protective bicarbonate umbrella, and 2) secretin could be a novel test of biliary viability.
Method: The effect of secretin was studied in-vitro using intrahepatic cholangiocyte organoids (ICO). Secretin administration was evaluated in a preclinical study using discarded human livers. Next, a prospective clinical study (IDEAL stage 1–2) with human secretin therapy was performed during sequential hypo- to normothermic perfusion, linked by controlled oxygenated rewarming (DHOPE-COR-NMP). Secretin was added at the start of the COR-phase (1 hour prior to NMP) and at 2.5 hours of NMP. Changes in biliary HCO_3^- and early post-transplant outcomes were compared to a historical cohort.
Results: Secretin resulted in a swelling of in-vitro ICO and increased signal in Ussing chamber experiments, indicating increased ion and water excretion ($p = 0.008$). In the preclinical study, secretin treatment during NMP resulted in increased biliary HCO_3^- in viable livers, but not in non-viable livers, indicating that biliary testing was not camouflaged. This effect was similar during the prospective clinical trial. Biliary HCO_3^- was higher in transplanted livers ($n = 10$) compared to non-viable livers ($n = 5$) (10.1 mmol/L vs. 2.2 mmol/L; $p = 0.04$) or to historic controls (10.1 mmol/L vs. 0.5 mmol/L; $p < 0.01$). Recipient outcomes in the first 90 days were similar to historical controls.
Conclusion: In a first in man IDEAL stage 1–2 clinical trial, secretin therapy during NMP increased biliary secretion of HCO_3^- in livers with viable bile ducts. Secretin appeared to be a missing component of NMP perfusion fluid that is required for restoration of normal biliary physiology and a functioning bicarbonate umbrella. Moreover, response to secretin could serve as novel tool to assess biliary viability during NMP.

FRI-468

Clinical outcomes of sequential hypo- and normothermic machine perfusion versus abdominal normothermic regional perfusion for extended criteria donors in liver transplantation: a single center comparison

Roberto Broere[1], Fenna van der Heijden[1], Puck C. Groen[1], Femke De Goeij[1], Sarwa Darwish Murad[2], Caroline den Hoed[2], Robert Porte[1], Wojciech Polak[1], Jeroen de Jonge[1]. *[1]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, Netherlands; [2]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: r.broere@erasmusmc.nl

Background and aims: To address the donor shortage, extended criteria donors after circulatory death (ECD-DCD), are increasingly used. However, ECD-DCD livers have a higher risk of primary non-function and biliary complications. Two main perfusion techniques exist to asses liver function: in-situ abdominal normothermic regional perfusion (aNRP), and ex-situ normothermic machine perfusion, in our center combined with dual hypothermic oxygenated perfusion and controlled oxygenated rewarming (DHOPE-COR-NMP). This study presents a single center comparison of DHOPE-COR-NMP and aNRP of clinical outcomes of ECD-DCD livers.
Method: Liver grafts from ECD-DCD donors between October 2018 and the end of December 2023 were included, with a minimum follow-up of 1 year post-transplantation. Livers were categorised as ECD based on factors such as elevated donor laboratory values, or age above 61 years. When the donor was located in the local procurement, aNRP was performed, otherwise DHOPE-COR-NMP was performed. The primary outcome was death-censored graft survival. Secondary outcomes included acceptance rate, patient survival and post-transplant biliary complications.
Results: In total, 53 DHOPE-COR-NMP and 51 aNRP procedures were included, which resulted in 40 (75%) and 37 (73%) liver transplantations. No primary non-function was observed. At one year, death-censored graft survival and overall patient survival was 92% and 88% for DHOPE-COR-NMP and 95% and 97% in aNRP (ns). One year cumulative incidence of post-transplant cholangiopathy, and anastomotic strictures (AS) was 8%, and 19% in DHOPE-COR-NMP, and 5% and 22% in aNRP (ns). Bile leaks occurred in 13% of DHOPE-COR-NMP and 5% of aNRP at one year (ns). Complications Clavien-Dindo $\geq$ 3 were observed in 63% of DHOPE-COR-NMP and 60% of aNRP (ns).
Conclusion: Both DHOPE-COR-NMP and aNRP allow for safe transplantation of ECD-DCD livers with excellent death-censored graft survival and patient survival. There was no difference in the risk of post-transplant biliary complications between the groups, with a lower incidence of post-transplant cholangiopathy comparing to historical cohorts without machine perfusion.

FRI-473

The impact of extending preservation time of extended criteria liver grafts through hypothermic oxygenated machine perfusion prior to normothermic machine perfusion on viability assessment and clinical outcomes

Roberto Broere[1], Domiziana Pedini[1], Efrayim Küçükerbil[1], Puck C. Groen[1], Jorke Willemse[1], Caroline den Hoed[2], Sarwa Darwish Murad[2], Wojciech Polak[1], Robert Porte[1], Jeroen de Jonge[1]. *[1]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, Netherlands; [2]Erasmus Medical Center Rotterdam, Transplant Institute, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: r.broere@erasmusmc.nl

Background and aims: Liver machine perfusion is increasingly used to test and select extended criteria donor (ECD)-livers due to declining donor organ quality. Sequential oxygenated hypothermic and normothermic machine perfusion, linked by one hour of controlled oxygenated rewarming (DHOPE-COR-NMP) can be used to resuscitate donor livers and subsequently perform viability assessment. To improve transplant logistics and facilitate daytime transplantation, prolongation of the DHOPE phase has been proposed. This study evaluates the impact and safety of prolonged DHOPE on donor liver utilization and outcomes in ECD-livers, compared with historical standard DHOPE–COR–NMP.
Method: All donation after circulatory death (DCD)-ECD-livers treated with DHOPE-COR-NMP were included until September 2025. DCD livers were classified as ECD based on elevated laboratory values, age $\geq$61 years, or functional warm ischemia time > 30 mins. Prolonged DHOPE was defined as perfusion time $\geq$ 4 hours. The main outcome was acceptance rate after hepatobiliary viability assessment. Secondary outcomes included death-censored graft survival, overall patient survival, as well as post-transplant complications, such as post-transplant cholangiopathy.
Results: A total of 74 DHOPE–COR–NMP procedures were analyzed, including 16 cases with prolonged DHOPE (median 6 h 52 min) and 58 cases following the standard protocol (median 2 h 9 min). Donor and recipient characteristics did not differ significantly between groups. In the prolonged DHOPE group, 8 livers met acceptance criteria (50%), compared with 44 livers (76%) in the standard group ($p = 0.064$). One-year death-censored graft survival was 75% in the prolonged group versus 88% in the standard group ($p = 0.184$). One-year patient survival was 100% and 85%, respectively ($p = 0.442$). Post-transplant complications were comparable, except for two cases of hepatic artery thrombosis in the prolonged group. Intraoperative red blood cell transfusion requirements were higher following prolonged DHOPE ($p = 0.015$).
Conclusion: This study demonstrates that prolonged DHOPE prior to viability assessment through COR-NMP enables safe transplantation of ECD-DCD livers, yielding outcomes comparable to those of our historical standard cohort. Nonetheless, prolongation of DHOPE was associated with a reduced organ acceptance rate, a finding of clinical relevance that warrants careful monitoring to ensure optimal organ utilization.

FRI-474

Incidence risk factors and outcomes of cytomegalovirus infection after liver transplantation

Maximilian Joseph Brol[1], Greta Marie Bösch[1], Frank Erhard Uschner[1], Martin Sebastian McCoy[1], Kai-Henrik Peiffer[1], Philipp Houben[2], Andreas Pascher[2], Tina Schomacher[1], Michael Praktiknjo[1], Florian Rennebaum[1], Jonel Trebicka[1,3]. *[1]Münster University Hospital, Department of Internal Medicine B, Münster, Germany; [2]University of Münster, Department of General, Visceral and Transplant Surgery, Münster, Germany; [3]European Foundation for the Study of Chronic Liver Failure-EF Clif, Barcelona, Spain*
Email: maximilian.brol@ukmuenster.de

Background and aims: Cytomegalovirus (CMV) infection is the most frequent opportunistic infection after liver transplantation (LT) and is associated with relevant morbidity and adverse outcomes. This study aimed to quantify the incidence of CMV infection after liver transplantation, to identify associated risk factors, and to assess its impact on graft and patient outcomes after LT.
Method: This single-center, retrospective cohort study included 200 adult patients undergoing LT between August 2011 and December 2018. CMV infection was assessed within 1 year and within 5 years after LT. Recipient and donor characteristics, CMV serostatus, post-LT complications, and mortality were analyzed.
Results: CMV infection was diagnosed in 40 patients (20.0%) within 1 year and in an additional 13 patients (8.2%) between 1 and 5 years after LT, resulting in a cumulative 5-year incidence of 22.5%. The median time to CMV infection was 3.0 months (95% confidence interval 2.3–3.7). Donor CMV-IgG positivity was the strongest independent risk factor for CMV infection. In univariate logistic regression, receipt of an organ from a CMV-IgG positive donor was

associated with an increased risk of CMV infection within 1 year (OR 2.91, 95% confidence interval 1.36–6.23, p = 0.006) and within 5 years (OR 2.77, 95% confidence interval 1.35–5.67, p = 0.005). Within 1 year, overall mortality was significantly lower in patients with CMV infection compared with those without infection (7.5% vs 21.4%, p = 0.044). In contrast, no significant difference in 5-year-overall mortality was observed between patients with and without CMV infection (20.0% vs 15.8%, p = 0.541).
Conclusion: In this cohort, CMV infection occurred in one fifth of patients within the first year after LT. Donor CMV serostatus was the strongest predictor of infection. In our study, CMV infection post LT did not influence long-term survival. These findings highlight the pivotal role of donor recipient serostatus in risk stratification and support tailored monitoring strategies after LT.

FRI-475
Healthcare practitioners' perceptions of the care and service needs of young adults undergoing liver transplantation: a mixed-methods study
Hattie Charles[1]. [1]*University of Warwick, Coventry, United Kingdom*
Email: h.m.charles@lse.ac.uk

Background and aims: Young adults (18–25) undergoing liver transplantation represent a clinically distinct group whose outcomes depend heavily on engagement, adherence, and self-management. Despite this, UK transplant services remain primarily adult-oriented, with limited developmentally tailored provision. Emerging evidence suggests that psychosocial vulnerability, limited life experience, and unstable social circumstances may influence clinical outcomes in this age group, yet little is known about how practitioners perceive and respond to these needs. This study aimed to explore healthcare practitioners' perceptions of the care, support, and service needs of young adults undergoing liver transplantation, and to identify barriers and facilitators to delivering effective, age-appropriate clinical care.
Method: A mixed-methods design was used. Semi-structured interviews were conducted with specialist liver transplant practitioners (N = 9) across a major UK transplant centre. Interviews explored clinical challenges, engagement, self-management, psychosocial needs, and service delivery. Data were analysed using thematic analysis. An anonymous online survey (N = 31 respondents; 16–20 per item) captured broader perspectives on training, policy, resources, and clinical practice. Quantitative data were summarised descriptively. Findings were integrated to identify convergent themes relevant to clinical care.
Results: Practitioners described a high psychological burden for young adults, compounded by developmental transitions, limited life experience and social isolation. Engagement was a major barrier, affected by precarious housing, financial insecurity and unequal access to transplant services. Integrated, developmentally attuned clinics were viewed as highly beneficial. Survey data confirmed gaps in training, age-specific policy and psychosocial resources.
Conclusion: Young adults undergoing liver transplantation face distinct clinical and psychosocial challenges that influence engagement, adherence, and outcomes. Practitioners identified a need for developmentally tailored, multidisciplinary models of care that address both clinical and structural determinants of health. Strengthening psychological support, improving communication pathways, and embedding age-appropriate service design into routine transplant care may enhance long-term outcomes for this vulnerable group. These findings highlight an important opportunity to optimise clinical practice for young adult transplant recipients.

Email: m.chvatal-medina@umcg.nl

Background and aims: Post-transplant diabetes mellitus (PTDM) is a common complication following liver transplant (LT) and is associated with adverse outcomes. The triglyceride-glucose product (TyG) and the triglyceride-to-high-density lipoprotein (HDL) cholesterol ratio (TG/HDL-c) are indices that can serve as triglyceride-based proxies for insulin resistance. Their relation to PTDM in liver-transplant recipients (LTRs) is unclear.
Method: TyG and TG/HDL-c (nuclear magnetic resonance spectroscopy) were compared between LTRs without diabetes at baseline (TransplantLines cohort study; NCT03272841) with non-diabetic participants from the community-dwelling PREVEND cohort. Among LTRs, associations with incident PTDM were determined using Cox regression analysis and logistic regression analysis with adjustment for relevant variables.
Results: TyG was higher in 246 non-diabetic LTRs (mean age 52.6 years; 53.7% male) compared to 4533 non-diabetic PREVEND participants (mean age 53.1 years; 48.9% male (p < 0.001), and confirmed using propensity score matching (p < 0.001). Over a median follow-up of 7.1 years, 31 LTRs developed PTDM (12.6% cumulative incidence). A higher baseline TyG index was associated with an increased risk of PTDM (HR per 1-SD increase: 1.67, 95% CI 1.28–2.30; highest vs. lowest tertile HR: 1.77, 95% CI 1.14–2.64). The TG/HDL-c ratio followed the same trend (HR per 1-SD increase: 1.56, 95% CI 1.14–2.15; highest vs lowest tertile: HR 3.80, 95% CI 1.73–10.0). Findings remained in adjusted analyses and were directionally similar in logistic regression models.
Conclusion: In LTRs, both the TyG index and the TG/HDL-c ratio are associated with PTDM. These indices could serve as a basis for post-transplant risk stratification in diabetes development.

FRI-477
Triglyceride-rich lipoprotein cholesterol and risk of post-transplant diabetes in liver transplant recipients
Mateo Chvatal-Medina[1], Adrian Post[2], Margery A. Connelly[3], Yakun Li[1], Han Moshage[1], Stephan J.L. Bakker[2], Vincent E. de Meijer[4], Hans Blokzijl[1], Robin Dullaart[5]. Email: m.chvatal-medina@umcg.nl

Background and aims: Post-transplant diabetes mellitus (PTDM) is the most important metabolic complication after liver transplantation. The role of triglyceride-rich lipoprotein cholesterol (TRL-c, remnant cholesterol) in PTDM risk is poorly defined. We characterized TRL-c in liver transplant recipients (LTRs) (Transplantlines cohort) compared with the general population (Prevention of REnal and Vascular ENd-stage Disease (PREVEND) cohort) and evaluated the association between TRL-c and incident PTDM.
Method: We studied 367 adult LTRs with fasting lipid profiling and long-term follow-up for PTDM (until February 2025). TRL-c was calculated from nuclear magnetic resonance spectroscopy-derived total cholesterol, high density lipoprotein cholesterol (HDL-c) and low density lipoprotein cholesterol (LDL-c). Baseline TRL-c and lipid profiles were compared with 4,837 PREVEND participants with and without type 2 diabetes, and additionally using propensity-score matching. Incident PTDM was analyzed using Cox proportional hazards models and associations were examined per 1-SD increase in TRL-c, adjusting for demographic, metabolic, lipid, and immunosuppressive factors.
Results: Compared with PREVEND participants, LTRs had higher triglycerides, TRL-c, and HDL-c but lower total and LDL-c, both in individuals with and without diabetes at baseline. Among LTRs, TRL-c levels were highest in those with preexistent diabetes and lowest in those who remained non-diabetic. During 7.1 years of follow-up 31 LTRS developed diabetes. LTRs in the highest TRL-c tertile had the highest PTDM incidence (p = 0.017). In unadjusted analyses, each 1-SD increase in TRL-c was associated with a 64% higher PTDM risk (HR 1.64, 95% CI 1.25–2.14). This association remained significant after adjustment for age, sex, BMI, statin use, HDL-c, LDL-c, triglycerides, HbA1c, immunosuppressive regimen.
Conclusion: TRL-c is elevated in LTRs, and independently associates with incident PTDM. Conceivably, TRL-c reflects a dyslipidemic phenotype not captured by other lipid metrics and may help refine risk stratification in this population.

FRI-478

Synergism of trimethylamine n-oxide and lipoprotein insulin resistance with post-transplantation diabetes after liver transplant

Mateo Chvatal-Medina[1], Yakun Li[2], Adrian Post[3], Margery A. Connelly[4], Han Moshage[2], Stephan J.L. Bakker[3], Vincent E. de Meijer[5], Hans Blokzijl[2], Robin Dullaart[6]. Email: m.chvatal-medina@umcg.nl

Background and aims: Post-transplant diabetes mellitus (PTDM) is a common complication after liver transplantation. Trimethylamine N-oxide (TMAO), a microbiota-derived metabolite, has been linked to insulin resistance, but epidemiological findings on type 2 diabetes remain inconsistent. The lipoprotein insulin resistance (LP-IR) score is a nuclear magnetic resonance (NMR)-derived marker of insulin resistance, yet its role in PTDM and interaction with TMAO are unknown.
Method: Prospective cohort study (TransplantLines, NCT03272841) at a tertiary care center (Universitair Medisch Centrum Groningen, The Netherlands). Three hundred sixty-seven (367) liver transplant recipients (LTRs) were studied. Baseline TMAO and LP-IR score were quantified by NMR spectroscopy. Incident PTDM was defined by international criteria. Associations were tested using logistic regression with prespecified adjustment. Effect modification was tested with interaction terms.
Results: 31 out of 246 LTRs at risk developed PTDM after a median follow-up of 7.1 years. Higher TMAO (OR 2.14, 95% CI 1.17–4.00, p = 0.015) and LP-IR score (OR 1.66, 95% CI 1.10–2.37, p = 0.015) were associated with increased PTDM risk after adjustment for eGFR and immunosuppressant use. A positive interaction was present (p = 0.029) with risk amplification when both biomarkers were elevated. TMAO's association with PTDM was strongest at high LP-IR (90th percentile; OR 3.20, 95% CI 1.46–7.03, p = 0.005), and LP-IR's association was strongest at high TMAO (90th percentile; OR 2.56, 95% CI 1.41–4.64, p = 0.002).
Conclusion: TMAO and LP-IR were independently and synergistically associated with PTDM in LTRs, suggesting a diabetogenic potential of TMAO that depends on insulin resistance, as captured by lipoprotein variables.

FRI-479

Liver transplant recipients experiencing biliary complications show elevation in quantitative magnetic resonance cholangiopancreatography metrics during monitoring

Tom Davis[1], Anneli Andersson[1], Elizabeth Shumbayawonda[1], Jelte Schaapman[2], Miguel Castelo-Branco[3], Anil Dhawan[4], Hildo Lamb[2], Minneke Coenraad[2]. [1]*Perspectum Ltd., Oxford, United Kingdom;* [2]*Leiden University Medical Center, Leiden, Netherlands;* [3]*Coimbra Institute for Biomedical Imaging and Translational Research, Universidade de Coimbra, Coimbra, Portugal;* [4]*King's College London, London, United Kingdom*
Email: anneli.andersson@perspectum.com

Background and aims: In the first year after liver transplantation (LT), 20–40% of recipients develop biliary complications, increasing the risk of graft failure and re-listing. Current routine biomarkers are not sufficiently specific and robust for assessment of biliary complications. We aim to explore the potential of quantitative magnetic resonance cholangiopancreatography (qMRCP) for robust non-invasive monitoring in LT recipients.
Method: Retrospective analysis was performed on clinical data from a prospective trial, (RADIcAL2), recruiting patients eligible for biopsy following LT at transplant centres in Leiden (the Netherlands), Coimbra (Portugal), and London (UK). qMRCP was generated by MRCP+ (Perspectum Ltd, Oxford). Upper limit of normal (ULN) values for biochemical markers were 40 U/L for aspartate aminotransferase (AST) and alanine aminotransferase (ALT), 147 U/L for alkaline phosphatase (ALP), 48 U/L for gamma-glutamyl transferase (GGT) and 1.2 mg/dL for total bilirubin.
Results: N = 102 patients (n = 89 adults, n = 13 paediatrics); Median age 53 years; 27% females) had qMRCP results and biochemical markers available. There were 20 post-transplant biliary complications. Median time from LT to biliary complication was 1 month (n = 6 recorded at the time of transplant), and from biliary complication to imaging was 13 months. Median MRCP metrics were higher in patients with, compared to without, recorded biliary complications including number of ducts (132 vs 51, p < 0.0004), length of strictures (106 mm vs 60 mm, p < 0.005), length of dilatations (161 mm vs 76 mm, p < 0.003), number of strictures (14 vs 7, p < 0.02), and number of abnormal ducts (24 vs 11, p < 0.002). In patients where the above listed MRCP metrics were elevated above the healthy reference

ranges, 24–27% had post-transplant biliary complications, significantly more than in those within the reference range (3–7%). In those with ALP elevated above ULN, 28% had post-transplant biliary complications (compared to 6% for ALP <ULN; p < 0.005), while no significance was found for elevated ALT, AST, bilirubin, or GGT.
Conclusion: Quantitative MRCP shows potential as a non-invasive test for biliary complications in LT recipients, with higher rates of recorded biliary complications in those with abnormal biliary tree metrics. To confirm the utility of qMRCP in post-transplant monitoring, prospective research should investigate associations with complication type and prediction of graft survival.

FRI-480-YI
From childhood to adulthood: outcomes after pediatric liver transplantation with a median 25-year follow-up
Julia Collot[1], Marie-Eve Chartier[2], Fernando Alvarez[2], Caroline Lemoine[3], Catherine Vincent[1], Marc Bilodeau[1], Denis Marleau[1], Julian Hercun[1]. *[1]Liver unit, Centre Hospitalier de l'Université de Montréal (CHUM), Department of Medicine, Université de Montréal, Montréal, Canada; [2]Division of pediatric gastroenterology, hepatology and nutrition, CHU Sainte-Justine, Montréal, Canada; [3]Division of pediatric surgery and liver transplantation, CHU Sainte-Justine, Montréal, Canada*
Email: julia.collot@gmail.com

Background and aims: Pediatric liver transplantation (pLT) has become a life-saving procedure for children with end-stage liver disease, but data on extended long-term outcomes remains limited. We aimed to evaluate 25-year outcomes after pLT in recipients from Centre hospitalier universitaire Sainte-Justine (CHUSJ) in Montréal who transitioned to adult care at the Centre Hospitalier de l'Université de Montréal (CHUM), and to identify predictors of patient and graft survival.
Method: We conducted a retrospective cohort study including patients who underwent liver transplantation at CHUSJ between 1986 and 2020 and had at least one follow-up at CHUM. Collected data included sex, age at transplantation, transplant indication, rejection episodes, treatment adherence, socio-educational status, and retransplantation. Survival analyses were performed using Kaplan-Meier and Cox regression models.
Results: A total of 124 patients were included. The main indications for pLT were biliary atresia (BA) (33.9%) and metabolic/congenital diseases (32.3%), followed by fulminant hepatitis, pediatric cholestatic diseases, progressive cholestasis of northwestern Quebec (PCNQ), autoimmune hepatitis (AIH) or primary sclerosing cholangitis (PSC), and miscellaneous causes (including hepatoblastoma and viral cirrhosis). Median follow-up time was 25.6 years (IQR: 19.1–31.5). Overall survival rates were 96.4% at 20 years and 85.0% at 30 years post-transplant, while graft survival rates were 84.8% and 77.7% at 20 and 30 years, respectively. Biopsy-confirmed rejection was the only factor associated with poorer graft survival (HR 3.37 95% CI 1.30–8.72, p = 0.012). Compared with other indications, PCNQ was associated with poorer overall survival (HR 5.34, 95% CI 1.52–18.79, p = 0.009) and the highest rate of nonadherence (OR 16.6, 95% CI 3.1–88.1, p < 0.001). Socio-educational integration was associated with improved overall survival (HR 0.12, 95% CI 0.03–0.47, p = 0.003) and graft survival (HR 0.35, 95% CI 0.13–0.96, p = 0.042). Only 6.5% were lost to long-term follow-up after transition. Initial immunosuppressive regimen had no impact on survival.
Conclusion: pLT offers excellent long-term patient and graft survival, but nonadherence, rejection, and psycho-educational issues remain key challenges. Multidisciplinary care and structured transition are essential to maintain or improve these outcomes. Particular attention should be given to PCNQ, which was associated with poorer long-term outcomes.

FRI-481-YI
Impact of recipient aerobic capacity, donor and graft characteristics on survival in patients with cirrhotic liver disease assessed for liver transplantation
Emma Cook[1], Miriam Cortes Cerisuelo[1], Abid Suddle[1], Claire Kelly[1], Varuna Aluvihare[1], William Bernal[1]. *[1]Institute of Liver Studies, Kings College Hospital, London, United Kingdom*
Email: emma.cook40@nhs.net

Background and aims: Chronic liver disease (CLD) is associated with poor aerobic capacity (AC). Cardiopulmonary exercise testing (CPET) comprehensively measures AC: impaired AC has been associated with non-survival with and without liver transplantation (LT). In a very large, single-centre CLD patient cohort, we aimed to definitively investigate the relationship between AC, recipient and donor characteristics, and survival.
Method: This retrospective, observational cohort study included patients with cirrhotic CLD who underwent elective LT assessment, including CPET determined using a cycle ergometer, at a single LT centre from 2000 to 2024. Descriptive statistics are presented with Chi-squared or Kruskal-Wallis tests. Survival analyses included log-rank testing and multivariate Cox regression.
Results: 2624 patients were assessed for LT, 33% with alcohol and 67% with other causes of CLD. 36% were female, median age was 56 years (IQR: 47–62), follow-up after CPET was 857 days (242–2313), and after LT 1527 days (347–2823). At CPET maximum Heart Rate was 138 (121–156) BPM, Peak Workload 91 (69–118) W, and measures of AC included Peak VO_2 of 16.7 (13.1–20.7), percentage predicted VO_2 62.6 (48.7–78.0) % and Anaerobic Threshold (AT) 10.7 (8.8–12.9) mL/kg/minute. 1860 patients (71%) were LT waitlisted, of whom 226 (12%) died before LT. On multivariate analysis AT determined at CPET was independently associated with waitlist survival (HR 0.93 [0.88–0.98], p = 0.008). Of 1493 (57%) transplanted, 67% received a donor after brain death (DBD) graft, and 28% a donor after circulatory death (DCD) graft. 90-day and 1-year post-LT mortality were 1.6% and 3.5% respectively. DCD recipients had poorer 5-year survival than DBD recipients (9.8% vs. 14.5% mortality, HR 1.72, p = 0.001), however on multivariate analysis recipient age (HR 1.02, p = 0.014), metabolic dysfunction-associated steatotic liver disease (MASLD) aetiology (HR 1.63, p = 0.05) and HCC diagnosis (HR 1.73, p = 0.003), but neither AC, DBD/DCD status or other donor factors retained independent association with post-LT survival.
Conclusion: AC closely associates with survival in CLD patients awaiting LT and interventions to improve AC may impact on survival to transplant. However, AC did not impact post-LT survival, even in recipients of DCD grafts or those with other sub-optimal features.

FRI-482
Evolving liver transplant indications and rising pre-transplant metabolic risk burden: a single-center analysis, 2013–2023
Andrew John Cruz[1,2], Paul Paik[1,2,3], Kalpana Gopalkrishnan[4], Niveda Balemurughan[4], Yinan Su[4], Roxanna Sharifi[4], Jeffrey Kahn[1,3,5], Navpreet Kaur[5,6], Derek Samson[5], Howard Lee[7], Liyun Yuan[1,3,5]. *[1]Keck School of Medicine of USC, Department of Medicine, Los Angeles, United States; [2]Los Angeles General Medical Center, Department of Medicine, Los Angeles, United States; [3]Division of Gastroenterology and Liver Diseases, Keck School of Medicine, University of Southern California, Los Angeles, United States; [4]Keck School of Medicine of USC, Los Angeles, United States; [5]Transplant Institute, Keck Medicine of USC, University of Southern California, Los Angeles, United States; [6]Department of Surgery, Keck School of Medicine of the University of Southern California, Los Angeles, United States; [7]Uniformed Services University of Health Sciences, Gastroenterology and Hepatology, Malcolm Grow Medical Clinics and Surgery Center, Andrews Medical Group, Joint Base Andrews, United States*
Email: andrewjohn.cruz@med.usc.edu

Background and aims: Liver transplantation (LT) etiologies have shifted over the past decade, with metabolic dysfunction–associated

steatotic liver disease (MASLD) and alcohol-associated liver disease (ALD) emerging as leading indications in the United States. Metabolic disease burden among recipients across non-metabolic indications appears to be rising. We evaluated temporal trends in LT indications and clustering of metabolic risk factors (RFs) at transplantation.
Method: We retrospectively studied adults (≥18 years) undergoing primary LT at Keck USC (2013–2023), excluding re-transplantations. Indications were categorized as MASLD, ALD, metabolic alcohol-associated liver disease (MetALD), viral hepatitis (HBV/HCV), autoimmune/cholestatic disease (PSC/PBC/AIH), or cryptogenic/other. Metabolic burden was assessed using four RFs at LT (BMI ≥25 kg/m^2, diabetes, hypertension, dyslipidemia) summed to 0–4. Multinomial logistic regression tested temporal shifts in indication distribution; logistic, Poisson, and linear regression modeled annual trends (OR/IRR/β per year).
Results: Among 1,338 recipients, indications changed over time (multinomial likelihood ratio test: LR = 135.33, df = 50, $p = 8.59 \times 10^{-10}$). Viral hepatitis declined 36.2%→5.8% (OR 0.86/year; 95% CI 0.82–0.90; p < 0.0001) while MASLD increased 16.2%→29.9% (OR 1.09/year; 95% CI 1.04–1.13; p < 0.0001). ALD was most prevalent and increased 28.8%→33.6% (OR 1.06/year; 95% CI 1.02–1.10; p = 0.006). Autoimmune/cholestatic increased 5.0%→14.6% (OR 1.06/year; 95% CI 1.00–1.12; p = 0.04). MetALD showed no consistent trend (12.5%→14.6%; OR 0.95/year; 95% CI 0.90–1.00; p = 0.05), and cryptogenic/other was stable (1.2%→1.5%; OR 0.94/year; 95% CI 0.85–1.03; p = 0.17). Mean metabolic RF count increased 1.09→1.64; linear regression β = 0.042/year (95% CI 0.027–0.057; p = 0.0003; R^2 = 0.78) with similar Poisson findings (IRR 1.033/year; 95% CI 1.018–1.049; p < 0.0001). RF distribution differed between 2013 and 2023 (χ^2 = 20.80, df = 4; p = 0.0003), indicating greater prevalence of ≥2 RFs. Non-MASLD/non-MetALD recipients comprised 41.1% (95% CI 36.8–45.5) of all ≥2 RF and 31.8% (95% CI 25.7–38.6) of all ≥3 RF, demonstrating that metabolic burden extends beyond primary metabolic liver disease.
Conclusion: As LT indications evolve, metabolic RFs are increasingly prevalent across all etiologic categories. These findings support universal metabolic risk stratification and targeted interventions during LT evaluation and post-transplant care to mitigate graft-related and cardiovascular complications.

FRI-483
Donor-related ethical issues in living donor liver transplantation: a single-center survey from North Macedonia
Elena Curakova Ristovska[1], Beti Todorovska[1], Fana Licoska-Josifovik[1], Meri Trajkovska[1], Emilija Nikolovska Trpchevska[1]. *[1]University Clinic for Gastroenterohepatology, Skopje, North Macedonia, Ss. Cyril and Methodius University in Skopje, Skopje, North Macedonia, Skopje, Macedonia*
Email: elenacurakova@yahoo.com

Background and aims: While deceased donor liver transplantation remains the standard of care in most Western countries, living donor liver transplantation (LDLT) has become an essential component of transplant programs worldwide. However, despite the advantages, it raises several important and unique ethical issues. This study aimed to assess key donor-related ethical aspects of the LDLT process and to identify areas for future improvement in clinical practice.
Method: All liver donors evaluated at our center between 2007 and 2026 who donated for LDLT abroad were invited to complete an anonymous survey. The questionnaire collected demographic data and included 18 items addressing donor motivation, voluntariness, adequacy of information, autonomy, coercion, and freedom to withdraw, primarily assessed using a 5-point Likert scale. The study was conducted in accordance with the Declaration of Helsinki and approved by the local Ethics Committee.
Results: Twenty-four adult donors (14 men and 10 women, mean age of 41.5 years) responded (82.8%). Most donors were first-degree relatives (5 siblings, 2 parents, 2 children), followed by spouses (6), close relatives or in-laws (5), and distant relatives or close friends (4). The primary motivation for donation was saving the life of a loved one (n = 21; 87.5%). Despite donors' awareness of the legal and ethical prohibition of financial compensation, indirect compensation in one non–genetically related donor could not be definitively excluded. While most donors reported receiving adequate medical information before consent (complete n = 17, sufficient n = 2, partial n = 3), some later acknowledged insufficient understanding of the associated health risks at the time (complete n = 15, sufficient n = 3, partial n = 4, insufficient n = 1). Full autonomy in decision-making and absence of pressure were reported by 22 donors (91.7%). Twenty-one donors (87.5%) reported no regret and stated they would certainly make the same decision again. Perceived implementation of ethical standards varied, ranging from complete to absent (complete 8, substantial 5, partial 5, insufficient 1, absent 1).
Conclusion: LDLT involves complex ethical challenges that require strict adherence to established ethical principles. Future efforts should focus on improving donor information, preventing coercion, and better integrating ethical standards into practice, with particular caution against compensation in directed altruistic donations between non-relatives, especially in low- and middle-income countries.

FRI-484
Prevalence and factors associated with phosphatidylethanol positivity in candidates for liver transplantation : a proof-of-concept study
Margaux Delhomme[1], José Ursic Bedoya[2], Lionel Moulis[3], Mélanie Russello[1], Idir Makhlouf[1], Nicolas Langendorfer[1], Laura Jaubert[1], Georges-Philippe Pageaux[2], Hélène Donnadieu[1]. *[1]Department of Addiction, Regional University Hospital Center of Montpellier, Montpellier, France; [2]Department of Hepatogastroenterology, Regional University Hospital Center of Montpellier, Montpellier, France; [3]Epidemiological and Clinical Research Unit, Regional University Hospital Center of Montpellier, Montpellier, France*
Email: margaux.delhomme@hotmail.fr

Background and aims: Liver transplantation (LT) is the reference treatment for end-stage chronic liver disease and selected liver cancer. Regardless of etiology, severe alcohol relapse after LT markedly increases morbidity and mortality. Although integration of an addiction team reduce relapse rates, the identification and monitoring of patients at risk remain heterogeneous and rely on self-reported data and indirect biomarkers, which may underestimate alcohol consumption. Direct biomarkers such as phosphatidylethanol enable earlier and more objective detection of alcohol consumption. This proof-of-concept study aimed to evaluate the contribution of PEth in detecting excessive alcohol consumption during pre-transplant assessment and its association with known risk factors.
Method: We conducted an interventional, single-center phase II study including patients enrolled in a LT pathway. All patients underwent a pre-LT addiction assessment. Sociodemographic, addiction and psychiatric data were collected using standardised methods. PEth levels were measured every three months during the pre-LT period, with 12-month follow-up. Analyses focused on describing the pre-transplant population, the prevalence of marker positivity, and the clinical and addiction-related characteristics associated with a positive PEth result.
Results: 24 patients were included (75% men, median age 60.5 years). 58.8% of patients had decompensated cirrhosis (29.4% Child B, 29.4% Child C), with a median MELD score of 9. 66.67% met DSM-V criteria for alcohol use disorder (AUD) prior to pre-LT abstinence. At pre-LT consultation, 91.6% were abstinent (median 12 months), 16.7% received addiction treatment. 4 patients (16.6%) had a strongly positive PEth (>200 µg/L), consistent with heavy alcohol consumption, while 3 of them (75%) reported being abstinent. These patients had more severe AUD (≥6 DSM-V criteria: 50% vs. 0%), shorter

abstinence (median 1.5 [0.7–3.0] vs.18 [9.5–57.0] months; p = 0.006), and lower abstinence confidence (7/10 [5.0–7.5] vs. 9/10 [8.0–10.0]; p = 0.33). The proportion of active smokers was higher in this group (50% vs. 35%). No association was found with sociodemographic factors or liver disease severity.
Conclusion: Regular PEth testing during pre-LT assessment detects recent unreported alcohol use. PEth positivity is associated with a more severe addiction profile, independent of liver disease severity and sociodemographic factors, supporting its use as an objective complement to clinical assessment in the pre-LT pathway.

FRI-485
ACLF-Transplant: a national survey comparing hepatologists' and intensivists' views on access to liver transplantation (LT) for ACLF
Vincent Di Martino[1], Florent Artru[2], Thierry Artzner[3], Delphine Weil-Verhoeven[1] and TRANSPLANT-ACLF Group[4]. *[1]CHU Besançon, Université Marie & Louis Pasteur, Besançon, France; [2]CHU Pontchaillou, Rennes, France; [3]CHU Hautepierre, Strasbourg, France; [4]Hepatology and ICU Departments, 28 centers, France*
Email: vdimartino@chu-besancon.fr

Background and aims: Despite its survival benefit in ACLF, access to LT remains limited. This national survey compared hepatologists' and intensivists' perceptions and practices regarding LT eligibility and barriers to access.
Method: A structured questionnaire was sent to French hepatologists and intensivists involved in the management of cirrhosis and ACLF. Responses covered 4 domains: respondent characteristics, LT decision-making and inter-specialty collaboration, clinical and organizational factors influencing LT access, and potential drivers for improvement. Items were rated using 5- or 7-point Likert scales. Comparisons according to medical specialty and center type (transplant vs. non-transplant centers) were performed using chi-2 and Mann–Whitney tests.
Results: 115 responses were analyzed (65 hepatologists, 50 intensivists) from 28 centers (16 transplant). Hepatologists more often considered ICU-admitted ACLF patients as potential LT candidates (78% vs. 56%). LT was considered "often unreasonable" by 22% of intensivists and 31% of hepatologists. Hepatologists more often reported consideration of advance directives (59% vs. 30%) and early addiction specialist assessment (55% vs. 30%). Clinical instability often limited pre-transplant evaluation. Severe comorbidities were the main reported barrier to LT (73%). LT eligibility criteria were more often considered well defined by hepatologists than intensivists (72% vs. 43%), but only 24% reported a formalized ACLF care pathway. In non-transplant centers, hepatologists more often believed in LT listing of ACLF patients than intensivists (55% vs.14%). Multidisciplinary meetings were less frequently reported by intensivists. Hepatologists more frequently perceived reluctance toward LT among intensivists (45% vs. 16%), whereas intensivists more often reported contradictory information being given to families (53% vs. 34%). Failure to reach agreement was reported by 44%. Support for intensivists' legitimacy to initiate LT discussions was higher among intensivists (94% vs. 78%). Conditioning ICU admission on LT listing was rarely supported (18% vs. 6%). Only 55% of respondent found guidelines for LT in ACLF sufficiently clear. Support for prioritizing ACLF patients at national level was limited (31% vs. 36%).
Conclusion: Substantial inter-specialty discrepancies in LT decision-making for ACLF persist, even in transplant centers. Standardized guidelines and structured care pathways appear to be key drivers to improve consistency and equitable access to LT.

FRI-489
Transplant FITness: the role of prehabilitation in expanding the liver transplant (LT) pool
Andres Duarte-Rojo[1], Susanna Miranda[2], Louis Guzman[1], Joshua Sepic[3], Brittany Zelikoff[2], Justin Boike[1], Laura Kulik[1], Saad Saffo[1], Daniel Ganger[1], Sarang Thaker[1], Amanda Cheung[1], Daniel Borja-Cacho[1], Satish Nadig[1], Daniela Ladner[1], Sean Koppe[1], James Sliwa[3]. *[1]Northwestern University, Evanston, United States; [2]Northwestern Memorial Hospital, Chicago, United States; [3]Shirley Ryan Ability Lab, Chicago, United States*
Email: andres.duarte@northwestern.edu

Background and aims: Advanced chronic liver disease (ACLD) is detrimental to physiologic reserve (PhyRes). Frailty affects 15–20% of LT candidates and >50% have a cardiorespiratory fitness below the threshold for independent living. These conditions severely affect LT eligibility and outcomes. To expand the LT pool and facilitate LT, our hospital started a Prehabilitation Program (PP) in May 2024. Herein, we report PhyRes metrics results and outcomes from our PP.
Method: During baseline evaluation, patients with a liver frailty index (LFI) ≥4.2 were referred to our PP. The program focuses on 1) fostering physical literacy, 2) tailored home-based exercise prescription and dietary prescription, 3) behavioral counseling, and 4) monitoring of metric-based adherence. Patients are seen every 2–6 weeks, and both LFI and 6-min walk test (6MWT) are tested at each visit. Virtual exercise classes were available twice a week.
Results: 57 frail patients (64 ± 7 years; 60% male) were referred to PP (47 [82%] during evaluation). There were 175 scheduled visits with a show-up rate of 84% (≥2 visits in 37 [65%] patients. Four (7%) patients did not engage with program and 2 (4%) were lost to follow up. Main etiologies were MASH (38%) and ALD (34%). Mean MELD 3.0 was 18 ± 6 and BMI 28 ± 7. All were decompensated: HE 70%, ascites 90%—refractory 44%. Prior falls were reported by 39% and 40% were on midodrine for hypotension. Regarding outcomes, 29 (53%) were added to waitlist (n = 23) or discharged after ACLD improvement (n = 6), 25 (45%) achieved LT, and 11 (20%) died. At baseline, LFI was higher among patients not (5.11 [4.72–5.63]) vs. those proceeding to LT (4.71 [4.36–5.26]; p = 0.04). Among 53 prehabilitated patients, LFI improved by second visit (−0.21 [−0.40 to −0.23]; p = 0.028) and peaked by fifth (−0.56 [−0.87 to −0.25]; p,0.001), whereas 6MWT improved by third (35 m [11–59]; p = 0.005) but also peaked at fifth (75 m, [41–109]; p < 0.001). Comparing baseline to last available PhyRes metric for each patient, LFI improved by 0.3, whereas 6MWT improved by 36 m, which was more evident among patients with a favorable outcome. Phase angle numerically improved from 4.42 to 4.58 (p = 0.05), with no differences in relation to LT or death status.
Conclusion: Given the PhyRes decline associated with ACLD, newer strategies are needed to ameliorate the negative effects of frailty. Initial analysis showed that our PP improved PhyRes metrics and facilitated favorable LT outcomes, even for candidates who otherwise would have been denied for frailty.

FRI-490
Fitness accountability in liver transplant (LT) candidates: a survey on exercising habits, barriers and facilitators
Louis Guzman[1], Miriam Rafferty[2], Andy Ponce[3], Sheila Morrissey[3], Susanna Miranda[3], Daniela Ladner[1], Andres Duarte-Rojo[1]. *[1]Northwestern University, Evanston, United States; [2]Shirley Ryan Ability Lab, Chicago, United States; [3]Northwestern Memorial Hospital, Chicago, United States*
Email: andres.duarte@northwestern.edu

Background and aims: LT candidates experience dire physical deconditioning gravely jeopardizing their transplant eligibility. Under the "exercise is medicine" banner, our LT center has pioneered various prehabilitation strategies. We provide physical therapy consultation followed by an exercise prescription to all LT candidates on their baseline clinic visit. Given the challenges of lifestyle modification, we aimed to investigate whether the exercise prescription was being followed, and to learn from candidates what their barriers and facilitators were.
Method: A mixed survey was prospectively administered to LT candidates on their follow-up visit, 4 weeks after their exercise prescription. We applied a questionnaire followed by a brief open-ended-questions interview to characterize exercise habits prior to

and after LT evaluation, and to identify exercising preferences. Retrolective data was obtained from the electronic medical record.
Results: 35 patients (56 ± 10 years; 57% male; BMI 27 ± 5) were surveyed. Most common etiology was alcohol, 69% presented with ascites, and 60% had esophageal varices; MELD 3.0 was 16 ± 6. Approximately 50% of patients had hypertension and coronary artery disease. Liver frailty index (LFI) was 4.09 ± 0.75 at baseline and 4.11 ± 0.75 at follow-up; 9 (26%) had an LFI ≥4.5. Twenty-two (63%) reported engaging on exercise prior to LT evaluation. Walking was the most common activity (46%), although housework/job-related activities were accounted for as exercise. Main reasons for not engaging in exercise were health limitations and lack of interest. Only 9 candidates (26%) recalled being given an exercise prescription and they all reported engaging with exercise; their LFI was unchanged from baseline. Self-reported adherence was low with only 2 patients exercising regularly. None accessed a web-based electronic prescription. Home-based exercise, clear guidance and external motivation were deemed facilitators, whereas lack of routine recall, health-related limitations, and low intrinsic motivation were the main barriers reported. Regarding prescription delivery, candidates favored mobile apps (49%) or printed instructions (34%).
Conclusion: We found our exercise prescription to be ineffective, reflecting lack of fitness accountability. Considering our findings, we have revamped our prehabilitation efforts to include physical fitness education, virtual exercise classes, and timely referral to a dedicated program. We are also revamping the EL-FIT app to maximize home-based fitness resources.

FRI-491
The effect of Tenofovir on bone mineral density in liver transplant recipients

Esra Durmazer[1], Ilker Turan[2], Ilgın Yıldırım Şimşir[3], Ferit Çelik[4], Alper Uysal[5], Ali Senkaya[6], Fulya Günsar[2], Zeki Karasu[2], Ulus Akarca[2]. *[1]Ankara University Faculty of Medicine, Department of Gastroenterology and Hepatology, Ankara, Türkiye; [2]Ege University Faculty of Medicine, Department of Gastroenterology, Izmir, Türkiye; [3]Ege University Faculty of Medicine, Department of Endocrinology and Metabolism, Izmir, Türkiye; [4]Medical Point Hospital, Department of Gastroenterology, Izmir, Türkiye; [5]Kanuni Sultan Süleyman Education and Research Hospital, Department of Gastroenterology, Istanbul, Türkiye; [6]Izmir City Hospital, Department of Gastroenterology, Izmir, Türkiye*
Email: dr.esradurmazer@gmail.com

Background and aims: Metabolic bone disease is a common complication after liver transplantation. In hepatitis B virus–related liver transplant recipients, tenofovir disoproxil fumarate (TDF) is widely used for post-transplant prophylaxis, but its effect on bone mineral density (BMD) remains unclear. This study evaluated the impact of TDF on BMD and the predictive performance of the Fracture Risk Assessment Tool (FRAX) in this population.
Method: This single-centre retrospective study included adult hepatitis B–related liver transplant recipients (2010–2021). Patients receiving TDF for ≥12 months were compared with those treated with entecavir or lamivudine. Dual-energy X-ray absorptiometry before and after transplantation, biochemical parameters, and FRAX scores were analysed. Changes in BMD and T-scores were assessed over time. Time to osteoporosis was evaluated using Kaplan–Meier analysis, and FRAX performance using receiver operating characteristic (ROC) analysis.
Results: A total of 73 patients were included in the analysis (49 in the TDF group and 24 in the control group). Baseline demographic characteristics and osteoporosis related risk factors were comparable between the groups. In the TDF group, lumbar spine T-scores decreased significantly during the first post-transplant year compared with the control group (−0.23 ± 0.56 vs −0.01 ± 0.08 p = 0.006), whereas no significant difference was observed at the second-year follow-up. Kaplan–Meier analysis showed that osteoporosis developed earlier in the TDF group than in the control group (mean time to development: 81.03 ± 4.58 months vs 107.47 ± 16.05 months; p = 0.007). In multivariate analysis, TDF use was the only independent factor significantly associated with BMD loss (p = 0.024). ROC analysis demonstrated that the FRAX score showed good discriminatory performance for predicting BMD loss, with area under the curve values of 0.759 for major osteoporotic fracture risk and 0.802 for hip fracture risk (p < 0.05). The optimal cut-off values were 4.35 and 0.65.
Conclusion: In hepatitis B–related liver transplant recipients, TDF use is associated with greater BMD loss than in controls during the early post transplant period and with an earlier onset of BMD loss during long-term follow-up. Although this bone loss does not appear to progress over time, the earlier development of osteoporosis highlights the need for close bone health monitoring. The FRAX score demonstrated moderate to good discriminatory performance for risk stratification in this population.

FRI-492
Determinants of early mortality after living donor liver transplantation for acute-on-chronic liver failure

Vijay Dyavadi[1], Amy Sangam[1], Navneet Tiwari[1], Changze Hong[2], Qun Cai[2], Meiqian Hu[2], Sina Jameie-oskooei[3], Banwari Agarwal[3], Joerg-Matthias Pollok[3], Michael Spiro[3], Rajiv Jalan[4] and LDLTregistry.org Collaborative[5]. *[1]Royal Free Hospital NHS Foundation Trust, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Royal Free Hospital NHS Foundation Trust, University College London, London, United Kingdom; [4]Royal Free Hospital NHS Foundation Trust, University College London, Liver Failure Group, London, United Kingdom; [5]University College London, International Liver Transplant Society, International Living Donor Liver Transplantation Group, London, United Kingdom*
Email: vjtoday123@gmail.com

Background and aims: Although liver transplantation (LT) is increasingly utilised for selected patients with acute-on-chronic liver failure (ACLF), overall post LT mortality is higher than observed in non-ACLF patients. Outcomes, and factors associated with post-LT mortality is unknown in ACLF patients receiving living-donor LT (LDLT). The aims of this study were to evaluate the short-term post-LT morbidity, mortality and associated factors using a global LDLT registry.
Method: We performed a cohort study of patients undergoing LDLT for ACLF from LDLTregistry.org, a global registry comprising prospectively collected, donor and recipient data submitted by transplant centres worldwide since September 2023. Donor; graft; pre, intra, and post-operative variables were collected. Early mortality (EM) was defined as in-hospital death. Associations with EM were examined using univariable logistic regression, followed by a parsimonious multivariable model. Sensitivity analyses using alternative severity markers were performed.
Results: 64 ACLF patients underwent LDLT [Sex: Male - 61%; Age: 48.5y (IQR 40–52), ACLF grade 3: 20; Extrahepatic organ support (EOS): 28%; Donor age 36y (IQR: 27–45); Donor sex – Female (64.1%)]. The incidence of EM within the cohort was 19.4% - significantly higher in ACLF Grade-3 compared with Grades-1/2 (OR 3.98, 95% CI 1.07–14.77). Donor age, sex and graft-to-recipient weight ratio (GRWR) were not associated with EM. EM was strongly associated with pre-operative recipient severity, particularly EOS requirement prior to transplantation. Among intra-operative variables, longer anhepatic time was associated with early mortality. In a multivariable model including EOS requirement and anhepatic time, life support prior to transplantation remained independently associated with EM (adjusted OR 8.10, 95% CI 1.67–39.21), while anhepatic time was no longer statistically significant. Early post-transplant markers of physiological instability and graft dysfunction (i.e. post op day 1 peak lactate) were associated with EM (OR 1.45, 95% CI 1.16–1.81) but reflected downstream clinical course.
Conclusion: In patients undergoing LDLT for ACLF, EM is driven predominantly by recipient severity at the time of transplantation

and intra-operative ischaemic burden may contribute to early risk. These findings support careful recipient selection and optimisation in ACLF-LDLT, while reinforcing the safety of contemporary living donor and graft selection practices.

FRI-493-YI

Outcomes of retransplant for chronic rejection and risk factors for recurrent chronic rejection in liver transplant recipients at a large American academic transplant center

Eric Fox[1], Archna Patel[2], Michele S. Barnhill[3], Carolyn Mead-Harvey[4], Maria Yataco[5], Kymberly Watt[6], David M. H. Chascsa[3]. [1]*Mayo Clinic Alix School of Medicine, Phoenix, AZ, United States;* [2]*Department of Gastroenterology and Hepatology, Mayo Clinic, Phoenix, AZ, United States;* [3]*Department of Gastroenterology and Hepatology, Department of Transplantation, Mayo Clinic, Phoenix, AZ, United States;* [4]*Department of Quantitative Health Science Research, Mayo Clinic, Phoenix, AZ, United States;* [5]*Department of Gastroenterology and Hepatology, Department of Transplantation, Mayo Clinic, Jacksonville, FL, United States;* [6]*Department of Gastroenterology and Hepatology, Department of Transplantation, Mayo Clinic, Rochester, MN, United States*
Email: fox.eric@mayo.edu

Background and aims: Risk factors for chronic liver transplant rejection have been described, but incidence and risk factors for recurrent chronic rejection (RCR) in patients transplanted for chronic rejection are not known. This study aimed to describe outcomes in patients who received a 2nd liver transplant for chronic rejection and identify risk factors for RCR.
Method: We conducted a retrospective study of patients at Mayo Clinic who had undergone 2nd liver transplantation and were diagnosed with chronic rejection of their re-transplanted liver versus patients who did not experience recurrence of chronic rejection. Statistical analysis was performed using SAS with differences tested using Fisher's exact test for categorical risk factors and Wilcoxon signed rank test for continuous and ordinal risk factors.
Results: Chronic rejection occurred in 93 of 10,727 patients (0.86%) transplanted between 1998 and 2025. Of the patients who had undergone 2nd liver transplantation, 29 patients met inclusion criteria. There was 1-year survival in 27 of 29 patients (93.1%) and 5 year-survival in 20 of 22 patients (90.9%) with median survival of 9.91 years. Of patients with RCR, 3 of 4 achieved 1 and 5-year survival with median survival of 9.45 years. Furthermore, 3 of 4 patients with RCR had a viral indication for first transplant compared to 4 of 25 (16.0%) patients without RCR ($p = 0.067$). Similarly, 3 of 4 patients with RCR had negative donor CMV status with the first transplant (1 patient's donor CMV status was unknown) compared to 6 out of 25 (33.3%) of those without RCR ($p = 0.063$). Median number of acute cellular rejection (ACR) events with 2nd transplant for individuals with RCR was larger than those without RCR ($p = 0.059$), reaching near significance. No statistically significant differences were observed between groups with CMV concordance, sex concordance, recipient race, and age.
Conclusion: Chronic rejection is a rare event, and recurrent chronic rejection occurs even less commonly. Re-transplant is a feasible treatment given good survival. Risk factors for recurrent chronic rejection are difficult to discern given the rarity of the event, however, there were numerically more median ACR episodes in patients with recurrent chronic rejection, suggesting that more intensive immunosuppression regimens should be considered. This is the first study to investigate risk factors for RCR, demonstrating the need for further investigation into this topic and larger sample size for sufficient power.

FRI-494

Donor selection and timing in pediatric liver transplantation for genetic liver disorders: a retrospective sibling cohort analysis

Ibrahim Hassan[1], Razan Bader[1], Ahmed Zidan[1], Mohammed Alqahtani[1], Eyad Gadour[1]. [1]*King Fahad Specialist Hospital, Multiorgan Transplant Centre of Excellence, Pediatric Liver Transplantation, Dammam, Saudi Arabia*
Email: ibrahadi981@yahoo.com

Background and aims: Liver transplantation (LT) is the definitive treatment for genetically inherited liver diseases (GILDs) in children. The choice of donor type, living donor liver transplantation (LDLT) versus deceased donor liver transplantation (DDLTx), and the timing of transplantation critically influence outcomes. This study evaluates the impact of donor type, specific familial donor relationships, and recipient age on post-transplant complications and survival in a matched pediatric sibling cohort.
Method: A retrospective single-center cohort study was conducted on 13 sibling pairs (26 patients) undergoing first-time LT for GILDs between 2015 and 2024. Primary outcomes included biliary and vascular complications and graft survival. Statistical analyses used generalized estimating equations (GEE) and mixed-effects models to account for sibling clustering.
Results: Donor type was not significantly associated with biliary complications ($p = 0.92$; 15.0% in living related, 0% in living unrelated, 20.0% in DDLTx) or vascular complications ($p = 0.81$; 10.0% living related, 0% living unrelated, 20.0% DDLTx), nor graft survival ($p = 0.61$; mean survival 6.08 ± 5.16 years living related, 2.00 years living unrelated, 4.00 ± 2.65 years DDLTx). However, specific donor relation significantly correlated with vascular complications ($p = 0.03$), occurring exclusively with brother (100%), aunt (50%), and deceased donors (20%), while no vascular events were observed with mothers, fathers, or uncles. Infants (<1 year) had zero biliary or vascular complications ($p = 0.15$ and $p = 0.22$, respectively) and higher mean graft survival (6.44 ± 5.92 vs. 5.11 ± 4.25 years, $p = 0.52$), yet experienced significantly higher mortality (25% vs. 0%, $p = 0.04$). Cold and warm ischemia times showed no significant correlation with graft survival ($r = 0.34$, $p = 0.58$ and $r = -0.18$, $p = 0.78$). Neurodevelopmental outcomes, assessed via school performance and ADHD diagnosis, were not significantly associated with donor type or age at transplant ($p = 0.64$ and $p = 0.54$).
Conclusion: In this familial cohort, LDLT outcomes were comparable to DDLTx. Specific donor-recipient relationships influence vascular complication risk, necessitating careful donor evaluation beyond living/deceased classification. Despite excellent surgical outcomes, transplantation in infancy carries a substantial survival risk, highlighting the need for individualized patient selection and perioperative management.

FRI-495

Impact of genetic diagnosis on graft survival and post-transplant complications in pediatric liver transplant recipients: a decade of experience

Eyad Gadour[1], Ibrahim Hassan[1], Razan Bader[1], Hadi Kuriry[1], Ahmed Zidan[1], Mohammed Alqahtani[1]. [1]*King Fahad Specialist Hospital, Multiorgan Transplant Centre of Excellence, Pediatric Liver Transplantation, Dammam, Saudi Arabia*
Email: eyadgadour@doctors.org.uk

Background and aims: Pediatric liver transplantation (PLT) for genetically inherited liver diseases (GILDs) presents unique challenges, with long-term graft survival and complication profiles influenced by underlying diagnoses and genetic factors. This single-center retrospective cohort study evaluates a decade of PLT outcomes focusing on graft survival and post-transplant complications in a genetically homogeneous population.
Method: We retrospectively analyzed 26 pediatric patients (13 sibling pairs) who underwent liver transplantation for confirmed GILDs between 2015 and 2025 at a tertiary center. Kaplan-Meier survival analysis and log-rank tests assessed graft survival across diagnoses. Associations between gene mutations and complications were evaluated using Fisher's exact test.
Results: Overall graft survival declined progressively: 1-year survival was 80%, 3-year survival 60%, 5-year survival 30%, and dropped below

20% beyond 10 years. Stratified by diagnosis, PFIC II demonstrated superior outcomes with a 50% 10-year graft survival and was the only group with grafts surviving beyond 15 years. Neonatal sclerosing cholangitis and PFIC III showed the earliest graft failures, with no grafts surviving past early post-transplant periods. Crigler-Najjar syndrome also showed prolonged graft durability up to 15 years. Biliary complications occurred in 4 of 13 mutation groups but showed no significant association with specific gene mutations (p = 0.567). Vascular complications were identified in 2 of 13 mutation groups, also without significant genetic correlation (p = 0.451). Patients with vascular complications had a significantly longer mean hospital stay (64.0 ± 58.0 days) compared to those without (32.0 ± 17.1 days, p = 0.049). No significant differences in cold or warm ischemia times were observed between patients with and without complications, though ischemia data were incomplete for complication groups.
Conclusion: Long-term graft survival in pediatric liver transplantation for genetic liver diseases remains limited and is strongly influenced by the underlying diagnosis. While no statistically significant associations were found between specific gene mutations and post-transplant biliary or vascular complications, vascular complications significantly increase hospitalization duration and morbidity. These findings highlight the importance of disease-specific management and surgical precision, underscoring the need for larger multi-center studies to clarify genetic contributions to complications.

FRI-496
Risk of venous thrombosis and hemorrhage in early post liver transplant patients with anti-platelet and anticoagulant prophylaxis; the 4-year single center experience
Tabetha Garver-Mosher[1], Manuel Beltran del Rio[1], Eric Klein[1], Daniel Rolston[1], Savni Satoskar[1], Elliot Grodstein[1], Matthew Bank[1], Daniel Jafari[1]. [1]*North Shore University Hospital, Great Neck, United States*
Email: tgarvermosher@northwell.edu

Background and aims: Venous thromboembolism (VTE) is a common, severe complication of post-liver transplantation, leading to significant morbidity and mortality, as well as bleeding risk from the need for anticoagulation. Current guidelines offer limited consensus on optimal timing of prophylactic (PPX) anticoagulant use, dosage, or timing, leaving providers without clear direction. This study aims to report our center's experience since inception by analyzing rates of venous thrombosis formation and clinically significant bleeding.
Method: This was a retrospective chart review of all adult liver transplant (LT) patients at a quaternary referral hospital in metropolitan New York area between January 17, 2021, and March 4, 2025. There were no exclusion criteria. Demographic, medications, intraoperative, postoperative, and outcome data were collected up to 30 days post-surgery. PPX administration was analyzed in 12-hour blocks of time from the first administration date. This study was reviewed and approved by the Institutional Review Board.
Results: A total of 318 adult LT patients, with a median age of 58 at the time of transplant, were included. The majority (93.7%, n = 298) received VTE PPX (heparin 84.3%, enoxaparin 3.5%, apixaban 18.6%, argatroban 1.3%). Most patients received aspirin (92.1%, n = 293). The median postop time to start PPX was 3.48 days [IQR] 2.4–5.43 days; the median to onset of VTE occurrence was 7.27 days. A prior history of VTE did not significantly influence post-transplant VTE incidence. Compared to the group who received no PPX, those with at least a single dose of PPX had a lower chance of VTE (33.3% vs 12.8%, p < 0.01). The rates of post operative transfusion of blood products (BT) for all patients was 58.5% (n = 186). The duration of PPX was associated with increased rates of BT. The mean anticoagulant days for patients who required a BT was 0.08, vs. 0.005 for those who didn't (p < 0.001). The mean antiplatelet days for patients who required a BT was 0.06, vs 0.001 for those who didn't (p < 0.001).
Conclusion: The use of VTE PPX is associated with lower rates of VTE in early post LT patients, but higher rates of transfusion of blood products. The duration of PPX is associated with an increased rate of BT. Future studies should focus on individualized, risk stratified approaches for VTE PPX in early post LT patients.

FRI-497
Local validation of the RETREAT score and simulation of risk-adapted imaging surveillance after liver transplantation for hepatocellular carcinoma
Andrea González Rayo[1], Ana Guiberteau Sánchez[1], Maria Isabel Monge Romero[1], Nerea Rodríguez Diez[1], Ana Rodríguez López[1], Lourdes García Linares[1], Isabel Narváez López[2], Juan Antonio Almena Sereno[1], Ana Gómez Collado[1], Ana Calderón Fernández-Salguero[1], Ana Garcia Galera[1], Gerardo Blanco Fernández[1], Isidoro Narváez Rodríguez[1]. [1]*Hospital Universitario de Badajoz, Badajoz, Spain;* [2]*Departamento de matemáticas. Attendis - Badajoz, Badajoz, Spain*
Email: andrea.gonzalezr@salud-juntaex.es

Background and aims: The RETREAT score (Risk Estimation of Tumor REcurrence After Transplant) combines pre-transplant alpha-fetoprotein, microvascular invasion, and viable tumor burden in the explant to estimate the risk of hepatocellular carcinoma (HCC) recurrence after liver transplantation (LT). Although widely validated, its role in tailoring post-transplant imaging surveillance in real-world practice remains unclear. We aimed to validate the prognostic performance of RETREAT in a local cohort and to estimate, through simulation, the impact of risk-adapted surveillance strategies.
Method: This retrospective observational study included adult patients transplanted for HCC between 2015 and 2022. Forty-three patients with complete RETREAT data were analyzed. Tumor recurrence, defined as the first radiological or histological diagnosis, was the primary outcome. Recurrence-free survival was assessed using Kaplan–Meier analysis, prognostic discrimination with Harrell's C-index, and a univariable Cox model. RETREAT was compared with Milan criteria in the explant. The standard surveillance protocol (semi-annual computed tomography for 3 years and annual imaging up to 5 years) was simulated against RETREAT-based de-escalation strategies, estimating avoidable scans and theoretical diagnostic delay.
Results: Four recurrences (9.3%) were observed, all extrahepatic, with a median time to recurrence of 2.27 years. No recurrences occurred in patients with RETREAT 0, whereas recurrence rates were 5.9% in RETREAT 1–2 and 23.1% in RETREAT greater than or equal to 3. RETREAT showed good discrimination (C-index 0.79), outperforming Milan criteria in the explant (0.62). Each one-point increase in RETREAT was associated with a higher risk of recurrence (hazard ratio 2.17; 95% confidence interval 1.08–4.34). Simulated strategies could reduce the number of scheduled computed tomography scans by 19% to 23% without increasing the theoretical diagnostic delay of observed recurrences.
Conclusion: In this single-center cohort, the RETREAT score effectively stratified post-transplant recurrence risk and outperformed Milan criteria in the explant. Risk-adapted imaging surveillance based on RETREAT may substantially reduce imaging burden in low-risk patients. Larger studies with complete follow-up are required to confirm the safety of this approach.

FRI-498
Warming up for success: controlled oxygenated rewarming prior to normothermic liver perfusion
Puck C. Groen[1], Colin Van Surksum[1], Roberto Broere[1], Jorke Willemse[1], Efrayim Küçükerbil[1], Stefan H. Luijmes[1], Bettina E. Hansen[2], Caroline den Hoed[1], Sarwa Darwish Murad[1], Wojciech Polak[1], Robert Porte[1], Jeroen de Jonge[1]. [1]*Erasmus MC Transplant Institute,*

Rotterdam, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands
Email: p.groen@erasmusmc.nl

Background and aims: To alleviate the donor organ shortage, use of extended criteria donor (ECD) livers has increased. These grafts carry an increased risk of post-transplant complications, including post-transplant cholangiopathy (PTC) and primary non-function. Dual Hypothermic Oxygenated Perfusion (DHOPE) has shown to reduce the incidence of PTC, whereas Normothermic Machine Perfusion (NMP) enables viability assessment of the liver graft. To prevent abrupt temperature shifts and mitigate ischemia-reperfusion injury, Controlled Oxygenated Rewarming (COR) is performed between DHOPE and NMP. During COR, the liver is gradually rewarmed in 1 hour from 20°C to 37°C, with increasing pressure sets on the hepatic artery (HA) and portal vein.
We describe our experience, providing insight into metabolic changes of the liver during rewarming.
Method: ECD livers underwent DHOPE-COR-NMP with hepatobiliary assessment. Perfusion flows and perfusate blood gases were recorded. Gas composition and flow were adjusted based on HA oxygen (O_2) and carbon dioxide (CO_2) levels. Sodium bicarbonate ($NaHCO_3$) was added when base excess was below −13 mmol/L. To preserve Na^+/K^+-ATPase function, potassium chloride (KCl) was administered to keep K^+ levels above 3.5 mmol/L. Dynamic changes during COR and differences between transplanted and non-transplanted livers were analyzed with linear-mixed models.
Results: 35 livers underwent DHOPE-COR-NMP, of which 22 passed all viability criteria and were transplanted (63% utilization). As livers became more metabolically active, shown by decreasing O_2 and rising CO_2, increased gas flow and higher O_2 concentration were required to maintain adequate levels. $NaHCO_3$ was required in all cases, but over supplementation should be avoided, as activation of Na^+/K^+-ATPase will increase Na^+ levels. Na^+ levels were higher in transplanted livers at 15–38 min of COR. K^+ decreased over time, and KCl administration at 4–5 mmol/L is required to prevent hypokalemia. Transplanted livers showed a steeper K^+ decrease, with significantly lower levels at 8–45 min. Lactate clearance, a viability marker during NMP, started after 38 min of COR in transplanted livers, compared to 53 min in non-transplanted livers. Higher Na^+ and lower K^+ levels in transplanted livers indicate earlier metabolic recovery, combined with earlier lactate metabolization.
Conclusion: Active perfusion management during COR is required and continuous monitoring of perfusate parameters provides valuable insights into metabolic recovery of the liver.

FRI-499

Incidence of early infections in liver transplant recipients at a tertiary care center in Mexico

Alejandro Gutierrez-Castillo[1], Carla Román-Montes[1], Javier Gutierrez-Castillo[2], Nayelli Flores-García[1]. *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Gastroenterology, Mexico City, Mexico; [2]Private Practice, Mexico City, Mexico*
Email: alexgtz91@gmail.com

Background and aims: Infections are the leading cause of death during the first three years after liver transplantation (LT). Early infections, defined as those occurring within the first month after LT, are usually related to the surgical procedure or the use of invasive devices. This study aimed to determine the incidence and risk factors associated with early infections in LT recipients at a tertiary care center in Mexico City.
Method: This was a retrospective, cross-sectional, and analytical study of LT recipients from 2019 to 2023. Demographic, clinical, and surgical variables related to early infections were analyzed using univariate and multivariate analyses to determine risk factors.
Results: Of the 181 LT performed over a five-year period, 125 met the inclusion criteria. Among these, 55% (n = 69) were female, with a mean age of 53 years (SD 13.1, IQR 21). Metabolic dysfunction–associated steatotic liver disease (MASLD) was the leading indication for LT, accounting for 30% of cases. Overall, the incidence of early infections was 38%, occurring at a mean of 11.6 days after LT (SD 9, IQR 12). The most frequent infections were urinary tract infections (23%), pneumonia (21%), and diarrhea (10%). Microbiological isolation occurred in 64% of cases; 87% were bacterial, and 56% were multidrug-resistant (MDR) organisms, mainly *Escherichia coli* and *Klebsiella pneumoniae*. Significant variables included hemoglobin < 12.5 mg/dL (OR 1.3, 95% CI 1.06–1.67, p = 0.013), bilirubin > 5.99 mg/dL (OR 5.9, 95% CI 1.12–24, p = 0.035), leukocyte count (OR 0.79, 95% CI 0.65–0.98, p = 0.028), and hospital length stay (OR 0.82, 95% CI 0.75–0.91, p < 0.01).
Conclusion: Early infections occurred in 38% of LT recipients and were predominantly hospital-acquired bacterial infections caused by MDR organisms. These infections were associated with clinical and perioperative risk factors. Early recognition of these factors is essential to give preventive measures and optimize timely management.

FRI-500

Liver transplantation for perihilar cholangiocarcinoma: single-centre experience

Tereza Háková[1,2], Tomáš Hucl[1], Jiri Fronek[3], Jana Jarošová[1], Pavel Taimr[1]. *[1]Department of Gastroenterology and Hepatology, Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University, Prague, Czech Republic; [3]Department of Transplantation Surgery, Institute for Clinical and Experimental Medicine, Prague, Czech Republic*
Email: terezahakova99@gmail.com

Background and aims: Perihilar cholangiocarcinoma (pCCA, Klatskin tumor) is a rare and aggressive malignancy with limited curative treatment options. Liver transplantation (LT) has emerged as a potential therapy for a highly selected subset of patients; however, only a minority of referred patients undergo transplantation. We aimed to analyze indications for LT and reasons for exclusion among patients referred for suspected pCCA.
Method: We retrospectively analyzed all patients referred to our centre for suspected or confirmed pCCA between February 2020 and November 2025. Patients were categorized according to diagnostic outcome and reasons for exclusion from LT, including oncological, procedural, and general transplant-related contraindications.
Results: During the study period, 139 patients (81 men, 58 women; mean age 59.2 years, range 18.6–85) were referred for suspected or confirmed pCCA, while 836 LTs were performed at our center for all indications. In 2 patients (1.4% of total 139), malignancy was not confirmed, 6 patients (4.3%) were diagnosed with intrahepatic cholangiocarcinoma, and 7 patients (5.0%) were indicated for surgical resection. Exclusion due to prior transperitoneal biopsy occurred in 7 patients (5.0%), and 5 patients (3.6%) declined LT. The most common reasons for exclusion were oncological, including local infiltration in 32 patients (23.0%), macrovascular invasion in 19 patients (13.7%), and generalized disease in 24 patients (17.3%). Additionally, 6 patients (4.3%) were excluded due to lymph node positivity during exploratory laparoscopy. Non-oncological exclusions included comorbidities in 5 patients (3.6%), death during evaluation in 2 patients (1.4%), and ongoing alcohol abuse in 2 patients (1.4%). Two patients (1.4%) were removed from the waiting list due to disease progression. Ultimately, 13 patients (9.4%) underwent LT, after median waiting time of 86 days, within a modified Mayo indication criteria (tumor ≤3 cm proximal to the cystic duct, neoadjuvant chemoradiotherapy without brachytherapy). At last follow-up, with a median follow-up of 36 months from LT (range 6–69), 10 transplanted patients (76.9%) were alive without tumor recurrence.
Conclusion: Only a small proportion of patients referred with suspected pCCA met criteria for LT, mainly due to advanced disease. However, carefully selected patients achieved favorable oncological outcomes, likely supported by strict adherence to selection criteria and short waiting times.

FRI-501

First validation of the gender-equity model for liver allocation (sodium and artificial intelligence variants) in an American cohort of patients on the liver transplant waiting list

Austin Halupnik[1], Patrick Ten Eyck[2], Manuel L. Rodríguez-Perálvarez[3], Peregrina Peralta[4], Nazia Selzner[4], Antonio Sanchez[5], Marta Tejedor[5]. *[1]University of Iowa Carver college of medicine, Iowa City, United States; [2]University of Iowa institute for clinical and translational science, Iowa City, United States; [3]Hospital universitario Reina Sofía, IMIBIC, CIBDERehd, Córdoba, Spain; [4]Toronto General Hospital, Toronto, Canada; [5]University of Iowa healthcare, Iowa City, United States*
Email: austin-halupnik@uiowa.edu

Background and aims: The most used allocation system for liver transplantation (LT) is the Model for End-Stage Liver Disease (MELD). Women are disadvantaged, having higher drop-out rates and lower transplant rates. The Gender-Equity Model for Liver Allocation (GEMA) model and its variant including natremia (GEMA-Na) improved 90-day mortality prediction in wait-listed patients, with a greater effect in women. A new derivation using artificial intelligence, GEMA-AI, showed an even better discrimination. No head-to-head comparison of MELD-based and GEMA-based models has been performed in North America.
Method: We analyzed data from all adults listed for LT (2016–2023) at University of Iowa Healthcare and Toronto General Hospital. Severity of liver disease was assessed with both the MELD-based scores (MELD, MELD-Na, MELD 3.0) and GEMA-based scores (GEMA, GEMA-Na, GEMA-AI). Data was collected until the time of transplant, exclusion from the WL, or until February 28, 2025. The ROC curves (receiver operating characteristic curves; AUC) were compared at 90 days of listing. Reclassification of patients using MELD 3.0, GEMA-Na, and GEMA-AI against MELD-Na as the reference category was estimated.
Results: The study included 2,227 patients (297 from University of Iowa, 1,930 from Toronto General), 34% female, mean age 55.3 years. 19% of patients had refractory ascites. Mean MELD, MELD-Na, MELD 3.0, GEMA, GEMA-Na and GEMA-AI scores were 17.1, 19.5, 19.3, 19.7, 21.9 and 19.0 respectively. AUCs for females using MELD-Na, MELD 3.0, GEMA-Na, and GEMA-AI were 0.797, 0.804, 0.794, and 0.814, respectively. In females, when compared to MELD-Na, both GEMA-Na and GEMA-AI had statistically significantly higher AUCs ($p = 0.035$ and $p = 0.039$, respectively); MELD 3.0 was not superior to MELD-Na ($p = 0.17$). 301 (14%) patients reclassified with MELD 3.0. Of them, 96 gained points, of which 57 were women. 763 (34%) patients reclassified with GEMA-Na. Of them, 601 gained points, of which 233 were women. 458 (30%) patients reclassified with GEMA-AI. Of them, 360 gained points, of which 114 were women.
Conclusion: This is the first validation study of GEMA-based liver transplant allocation models in North America. Compared to MELD-Na, both GEMA-Na and GEMA-AI were superior in discriminating mortality for waitlisted females at 90 days. Larger multicenter studies with a more diverse patient population are needed to better understand potential differences between these allocation models.

FRI-505

Post liver transplant alcohol relapse rate – a single center experience

Jordan Holliday[1], Sophoclis Alexopoulos[1], Lea Matsuoka[1], Lydia Aye[1], Vikrant Rachakonda[1]. *[1]University of California-Davis, Sacramento, United States*
Email: lydia.aye@gmail.com

Background and aims: Alcohol associated liver disease (ALD) is the most common indication for liver transplant in the United States. Relapse rates for alcohol use post liver transplant (LT) have been reported to be 8–20%. We defined relapse in our patients as any patient that had a positive PETH result. Our aim is to characterize patients who relapsed with alcohol use post-LT and to identify potential risk factors and interventions to help decrease the risk of relapse in post liver transplant patients.
Method: Retrospective chart review of post-LT patients from July 15, 2023 to July 31, 2025 at University of California Davis Medical Center. All patients underwent monthly PETH testing after LT, and alcohol relapse was defined as positive PETH test.
Results: Ninety-four patients underwent liver transplant; 79 patients were transplanted for ALD [alcohol associated cirrhosis (AC) (n = 67, 84.8%), alcohol associated hepatitis (AH) (n = 12, 5.2%)]. Eleven (13.9%) patients relapsed post-LT [9 AC and 2 AH]. There was no difference in rate of relapse between AC and AH patients ($p = 0.528$). Time to relapse from last alcohol use for AC and AH patients was not significantly different [333 (IQR 199–397) days vs 267 (IQR 120–414) days, $p = 0.727$]. Pre-LT SIPAT score did not differ between AC and AH patients ($p = 0.781$). Patients with post-LT relapse had shorter pre-transplant duration of abstinence [144 (IQR 61–265) days vs 312 (179 = 509) days, $p = 0.016$] and higher MELD at LT [35 (IQR 29–39) vs 25 (20–32), $p = 0.009$] than those with post-transplant abstinence. Post-transplant addiction medicine consultation was offered more frequently to post-LT relapsers [10 (90.1%) vs 23 (33.8%), $p < 0.001$].
Conclusion: Our single center experience in post-LT alcohol relapse rate is consistent with prior studies. There have been several studies that have examined factors that influence post-LT relapse. Most of these studies examine risk factors pre-LT. There was no difference in relapse rates and time to relapse from last alcohol use between those transplanted for AC and for AH. Time of sobriety should not be used alone in determining transplant candidacy. Our patients were found to be minimally acceptable candidates by the SIPAT score and there was no significant difference in SIPAT scores between patients who did or did not relapse post-LT. Future studies should focus on early prediction for relapse in our post-LT patients and developing early interventions for these patients.

FRI-506

Impact of external biliary drainage on early post-transplant biliary outcomes: a randomized controlled trial in living donor liver transplantation

Su Young Hong[1]. *[1]Seoul National University Hospital, Seoul, Korea, Rep. of South*
Email: sypurple@gmail.com

Background and aims: Biliary complications continue to be the most frequent problems following adult living donor liver transplantation (LDLT). External biliary drainage (EBD) using a silastic tube has been adopted to reduce anastomotic pressure and facilitate early detection of graft dysfunction. This study aimed to determine whether the application of EBD during duct-to-duct reconstruction reduces biliary complications after LDLT and assess EBD-related adverse events, long-term clinical outcomes, and patient-reported quality of life (QoL).
Method: This single-center trial randomized adult LDLT recipients eligible for duct-to-duct anastomosis to EBD placement or no drainage. Of 124 planned participants, 59 patients who underwent LDLT before trial termination were analyzed. The primary endpoint was the 1-year incidence of biliary complications. Secondary outcomes included 3-year complications, EBD-related adverse events, readmissions, and QoL using the pLTQ at 1 and 3 years.
Results: No bile leaks occurred in the EBD group (0% vs 6.5% in controls). One-year biliary complications were significantly lower with EBD (17.9% vs 41.9%, $p < 0.05$). Three-year rates remained lower (25.0% vs 41.9%), though not statistically significant. However, interim safety review revealed a markedly higher rate of EBD-related complications (39.3%), exceeding the <10% incidence previously reported and surpassing the predefined safety margin. Grade IIIa events occurred in 10.7%, and readmissions were more frequent in the EBD group (25.0% vs 9.7%). Based on these findings, further randomization was deemed to pose unacceptable risk, and the trial was terminated early for safety. At 6 months, EBD-specific QoL

assessment showed that patients reported noticeable discomfort related to the indwelling EBD, reflected by lower mean scores in several symptom-related items. Despite this, overall pLTQ scores at 1 and 3 years were similar between groups, with both maintaining good long-term QoL.
Conclusion: EBD reduced early biliary complications and eliminated bile leaks after LDLT. Nevertheless, the unexpectedly high frequency of EBD-related adverse events—together with patient-reported discomfort during the drainage period—led to early trial discontinuation on safety aspects. These results suggest that while EBD offers potential protective benefit, it also introduces meaningful short-term burden and device-related morbidity. Selective use, guided by individual anatomical and technical risk profiles, may better balance safety and efficacy.

FRI-507-YI
MELD-based prioritization for hepatorenal syndrome and liver transplant waiting list outcomes

Email: iavaroneselene@gmail.com

Background and aims: Liver transplantation (LT) is the only curative treatment for patients with decompensated cirrhosis (DC). Different allocation policies exist worldwide, with MELD score–based prioritization currently applied in Catalonia. Since its implementation, several exceptions have been introduced to balance survival and dropout rates among patients on the waiting list (WL). A specific criterion is applied to patients with hepatorenal syndrome (HRS), whereby the highest MELD score calculated from peak serum creatinine prior to terlipressin initiation is used. In addition, hepatocellular carcinoma (HCC) high risk patients are assigned a MELD score of 19, with one additional point every three months. However, the impact of this allocation strategy on survival and access to LT for patients on the WL remains unclear, particularly among those with kidney dysfunction (KD).
Method: Patients listed for single LT in Catalonia between 2008 and 2022 were included. Patients were classified into four groups: HRS; KD non HRS-related, defined as serum creatinine >1.5 mg/dL at listing or during WL follow-up; DC without kidney impairment; and HCC. Patients were followed for 12 months from the time of listing.
Results: A total of 1,320 patients from the three transplant centers in Catalonia were included in the analysis (128 HRS, 346 DC, 232 KD, and 614 HCC). Overall, 1,053 patients were male (80%), mean age of 58 ± 8 years. The most frequent etiology was alcohol-related liver disease (n = 695, 48%). The mean MELD score at listing for the entire cohort was 21 ± 5, with no significant differences between groups. During the follow-up period, 1,158 patients underwent LT, with a median waiting time of 49 days. LT rates were significantly higher in the HCC and DC groups (91% and 89%, respectively) compared with the HRS (73%) and KD (76%) groups ($p < 0.001$). In addition, 138 patients (10%) died or were delisted due to clinical deterioration (liver-related complications or cancer progression). Mortality and delisting rates were higher among patients with renal impairment (13% in HRS and 19% in KD) compared with the other groups (8% in DC and HCC patients; $p = 0.001$).
Conclusion: Current allocation policies achieve high LT rates among patients on the WL. However, kidney impairment at the time of listing or during WL follow-up reduces access to LT in cirrhosis patients despite the existence of specific tailored policies. Thus, alternative prioritization strategies for this subgroup may improve access to liver transplantation.

FRI-508
Continuous glucose monitoring in liver transplant recipients in the intensive care unit: a randomized clinical trial cohort
Marc Pañero Moreno[1,2,3], Richie Alexander Inge Cox[1,2,4], Enric Tomas Franch[1], Alberto Villamor Ordozgoiti[1,3], Eva Maria Guix Comellas[3], Fatima Aziz[1]. *[1]Hospital Clinic of Barcelona, Barcelona, Spain; [2]Fundació de Recerca Biomedica Clinic – Institut D'investigació Biomédic August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain; [3]Department of Fundamental and Clinical Nursing, University of Barcelona, Barcelona, Spain; [4]European Foundation for the Study of Chronic Liver Failure (EF CLIF), Barcelona, Spain*
Email: panero@clinic.cat

Background and aims: Postoperative hyperglycemia affects over 90% of Liver Transplant (LT) recipients in the Intensive Care Unit (ICU) due to metabolic and surgical stress, corticosteroids, and immunosuppressive therapy, predisposing to infection and prolonged hospital stays. Continuous Glucose Monitoring (CGM) has demonstrated improved accuracy and glycemic stability in ambulatory settings but remains unvalidated in critically ill patients, and current guidelines do not recommend its inpatient use. This trial aimed to determine whether CGM-guided insulin therapy improves postoperative glycemic control compared with Point-of-Care Glucose (POC-G) testing in LT recipients in the ICU.
Method: A single-blind randomized clinical trial was conducted at the Hospital Clinic of Barcelona (CGM-UCI23 project) and a cohort of LT receptors was extracted. A CGM sensor was placed on the upper arm, and participants were randomly assigned to an experimental group, in which glycemic management was guided by CGM in real time with active alerts included glucose thresholds of 220 mg/dL and 80 mg/dL, trend arrows, a predicted low alert indicating imminent hypoglycemia (<55 mg/dL within the next 20 minutes), and a low glucose alarm for readings below 55 mg/dL. In the control group, glucose was managed using POC-G while CGM remained blinded.
Results: The total number of LT performed between February 2025 until November 2025 was 50. From this population, 38 patients were included. The CGM group achieved significantly higher Time-in-Range (TIR) (54.6 ± 20.9% vs 34.5 ± 22.4%, $p = 0.006$) and lower Time-Above-Range (TAR) (45.0 ± 21.0% vs 64.0 ± 22.6%, $p = 0.007$) compared to control. Mean blood glucose trended lower with CGM (186 ± 28.8 vs 207 ± 38.3 mg/dL, $p = 0.068$). CGM-guided management reduced

daily POC-G measurements (3.17 ± 2.15 vs 6.37 ± 1.78, p < 0.001). Adverse events were significantly lower in the CGM group (26.31% vs 63.15%, p = 0.022). CGM also trended toward shorter ICU stays (7.4 vs 12.1 days, p = 0.99) with significantly reduced pain scores (ESCID 0.07 vs 0.38, p = 0.04; NRS 0.42 vs 0.66, p = 0.04).
Conclusion: CGM-guided insulin therapy significantly improves TIR and reduces hyperglycemia in LT recipients in the ICU while also decreasing POC-G measurements and adverse events. These results support CGM as a feasible and effective alternative to POC-G monitoring, warranting validation in larger multicenter trials.

FRI-509
Differences in immunosuppressive strategies for primary sclerosing cholangitis after liver transplantation
August Tronstad Juliebø[1], Trine Folseraas[1], Tom Hemming Karlsen[1], Kirsten Muri Boberg[1]. [1]*Norwegian PSC Research Center, Department of Transplantation Medicine, Clinic of Surgery and Specialized medicine, Oslo University Hospital, Oslo, Norway, Institute of Clinical Medicine, University of Oslo, Oslo, Norway, Research Institute of Internal Medicine, Institute of Clinical Medicine, University of Oslo, Oslo, Norway, Oslo, Norway*
Email: augusttj@uio.no

Background and aims: In primary sclerosing cholangitis (PSC), liver transplantation (LT) remains the only definite treatment option. Individuals with PSC have an increased risk of rejection and disease recurrence after LT, which can affect graft survival and long-term outcomes. No standardized recommendations exist for immunosuppression in PSC after LT, and it is unclear how strategies vary across centers. We therefore conducted an international survey to characterize current practice.
Method: A web-based questionnaire was distributed internationally to liver transplant centers affiliated with the International PSC Study Group (IPSCSG). The survey collected information on immunosuppressive regimens at predefined time points after LT (after LT (1, 3, 6, and 12 months, and long-term >1 year).
Results: Thirty-one centers completed the questionnaire (Europe n = 21; the US n = 7; one each from Japan, South Africa and Israel), including 11 high-volume centers performing ≥ 15 PSC LTs in 2021–2022. Overall, 42% (13/31) reported using more intensive immunosuppression for PSC than other LT recipients. Triple therapy was standard during the first postoperative month, followed by tapering with prednisolone discontinued by 9 centers at month 3, 20 centers at month 6, and a total of 22 centers at 1 year. For long-term immunosuppression, being defined as standard regimen beyond one year after LT, 23% (7/31) used tacrolimus monotherapy, 52% (16/31) used dual therapy, most commonly with tacrolimus and mycophenolate mofetil, and 26% (8/31) maintained triple therapy. Drug concentrations and dosing were comparable across groups, indicating that maintaining a second or third agent did not lead to a reduction in tacrolimus or mycophenolate exposure. Conversely, centers using fewer long-term agents tended to prescribe lower early postoperative doses. Several centers emphasized individualized dosing based on clinical history and tolerance.
Conclusion: This international survey demonstrates substantial variation in immunosuppressive regimens and treatment intensity for PSC after LT, reflecting the absence of standardized guidelines and evidence-based practice. Differences in both early and long-term management result in marked variation in cumulative immunosuppression exposure across centers. These findings provide a foundation for further studies evaluating how immunosuppressive strategies influence graft survival, recurrence, re-transplantation, and long-term complications.

FRI-510
The LiverRisk score predicts perioperative outcomes in patients undergoing liver transplantation
Shih Hsun Kao[1], Pei Shan Wu[2], Tien En Chang[2], Fang Cheng Kuo[3], Hao-Jan Lei[4], Niang Cheng Lin[3], Kuei-Chuan Lee[1], Hsin Lin Tsai[5], Chinsu Liu[3]. [1]*Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Department of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan;* [2]*Endoscopy Center for Diagnosis and Treatment, Taipei Veterans General Hospital, Department of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan;* [3]*Division of Transplantation Surgery, Department of Surgery, Taipei Veterans General Hospital, Department of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan;* [4]*Division of General Surgery, Department of Surgery, Taipei Veterans General Hospital, Department of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan;* [5]*Division of pediatric surgery, Taipei Veterans General Hospital, Department of Medicine, National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan*
Email: tommy90279@gmail.com

Background and aims: The LiverRisk score has been proposed as a novel tool for predicting future liver-related outcomes; however, its prognostic performance in liver transplant recipients remains unclear. Aim: To evaluate the prognostic value of the LiverRisk score for predicting perioperative outcomes in patients undergoing liver transplantation.
Method: This single-center, retrospective cohort study enrolled adult patients who underwent liver transplantation at Taipei Veterans General Hospital between August 2017 and January 2024. Patients younger than 18 years were excluded. The prognostic performance of the LiverRisk score was compared with that of the Model for End-Stage Liver Disease (MELD) score and the Child–Pugh score for perioperative complications.
Results: A total of 240 patients were enrolled. The median MELD score was 20 (IQR, 13–34), the median Child–Pugh score was 10 (IQR, 8–12), the median LiverRisk score was 8.46 (IQR, 7.42–10.00), and the median graft-to-recipient weight ratio (GRWR) was 1.07 (IQR, 0.87–1.24). In univariate analyses, a higher LiverRisk score was associated with increased risks of overall complications (odds ratio [OR], 1.135; 95% confidence interval [CI], 1.013–1.271; p = 0.029) and biliary events (OR, 1.235; 95% CI, 1.054–1.447; p = 0.010). These associations remained significant in multivariate analyses for overall complications (OR, 1.129; 95% CI, 1.001–1.274; p = 0.048) and biliary events (OR, 1.235; 95% CI, 1.048–1.456; p = 0.012). Receiver operating characteristic (ROC) analysis demonstrated superior prognostic performance of the LiverRisk score for overall complications (area under the curve [AUC], 0.615) compared with the MELD (AUC, 0.526) and Child–Pugh scores (AUC, 0.495). For biliary events, the LiverRisk score showed better discrimination (AUC, 0.649) than GRWR (AUC, 0.504), whereas GRWR showed superior performance for predicting graft failure (AUC, 0.746).
Conclusion: The LiverRisk score demonstrated superior prognostic performance compared with the MELD and Child–Pugh scores for predicting postoperative complications and biliary events after liver transplantation. It may serve as a useful adjunct to preoperative risk assessment.

Email: ali.canbay@rub.de

Background and aims: Creatinine concentrations measured using Jaffe-based assays are known to be systematically higher than those obtained with enzymatic methods. This difference has been shown to influence MELD scores and may have important clinical implications. In this study, we examined the impact of Jaffe-based creatinine assays on MELD-based allocation, with a focus on sex-based disparities.
Method: A serum-free matrix with varying creatinine (0–5 mg/dL) and bilirubin (0–35 mg/dL) concentrations was used to compare Jaffe and enzymatic creatinine assays and to construct a three-dimensional reference model estimating true creatinine values. Data from the Scientific Registry of Transplant Recipients (SRTR) were used to obtain MELD scores, relevant laboratory parameters, and waitlist outcomes for adult liver transplant candidates at selected centers. MELD, MELD-Na, ReMELD-Na, and MELD 3.0 scores were recalculated and sex-specific differences were evaluated. Cumulative incidence functions and Fine–Gray subdistribution hazard models were applied to estimate sex-specific hazards for transplantation and waitlist mortality.
Results: Overall men had consistently higher transplant probability than women at comparable true disease severity, with subdistribution hazard ratios for transplant around 1.15 across MELD variants. Among non-deceased patients for MELD and MELD-Na scores, the proportion of females with $\Delta = -1$ change was consistently lower than that of males. In contrast, among deceased patients, no significant sex difference was observed ($\Delta = \pm 0$ vs. $\Delta = -1$), indicating that fewer females were affected by the correction. Women who receive Jaffe-related MELD upgrades showed the highest cumulative incidence of death on the waiting list (13.0% at 1 year), despite increased transplant probability (51.1% at 1 year), indicating a particularly vulnerable subgroup. Jaffe specific creatinine bias was associated with a small fraction of this disparity (≈0–2% of the log hazard difference), and within MELD classes the effect direction is inconsistent.
Conclusion: Correcting Jaffe-related bias minimally affects sex differences in transplant access, explaining only a small portion of the disparity. Jaffe-related reclassification appears to identify a subgroup with advanced multisystem failure rather than causing the excess mortality itself. While creatinine standardization improves comparability, equity in allocation will likely require sex- and body size–adjusted MELD or additional renal biomarkers.

FRI-512
From retrospective review to guideline creation: establishing CMV management protocols at the Irish national liver transplant centre

Sarah Kenny[1], Jennifer Dwyer[1], ZIta Galvin[1], Omar El-Sherif[1], Audrey Dillon[1], Sinead McDermott[1]. *[1]St. Vincent's University Hospital, Dublin, Ireland*
Email: sarahkenny491@gmail.com

Background and aims: International guidelines for the prevention of cytomegalovirus (CMV) infection in at-risk solid organ transplant (SOT) recipients recommend either universal prophylaxis or pre-emptive therapy. The standard prophylactic dose of valganciclovir (VGCV) is 900 mg once daily; however, some centres advocate for a reduced 450 mg once daily regimen to minimise adverse drug reactions (ADRs), particularly in intermediate-risk patients. Evidence supporting this approach in orthotopic liver transplant (OLT) recipients remains limited. (1) We conducted a five-year retrospective analysis to evaluate the efficacy and safety of low-dose VGCV and to inform a formal CMV management guideline for the National Liver Transplant Centre in Ireland.
Method: A retrospective review was performed of adult OLT recipients (2018–2022) at the National Liver Unit, St. Vincent's University Hospital. Patients at risk for CMV infection (D+/R+, D+/R–, D–/R+) received VGCV 450 mg once daily for three months post-transplant. Data collected included demographics, transplant characteristics, CMV PCR results, clinical CMV disease, and adverse events.
Results: Among 245 OLTs, CMV disease occurred in 3.7% (n = 9) of patients, predominantly in high-risk D+/R– recipients (n = 8, 89%), comparing favourably to reported incidences of 5–22% with standard dose prophylaxis. (2–4) Seven of the nine cases occurred outside the prophylaxis period. Asymptomatic CMV viraemia (range 704–42,042 IU/mL) was identified in a further 23 patients (70% D+/R–, n = 16). No significant ADRs attributed to VGCV were reported.
Conclusion: Low-dose valganciclovir (450 mg OD for 3 months) was effective and well tolerated for CMV prophylaxis in OLT recipients, across all CMV risk groups, with incidence of CMV disease comparing favourably to that seen with standard dose prophylaxis. (2–4) The results of this five-year review support the continued use of low-dose VGCV for the prevention of CMV infection in OLT recipients, including those in the high-risk D+/R– category,enabling a consistent, evidence-based, and safe national approach to CMV prevention post-OLT.

FRI-513
Effect of a centre-specific prophylaxis protocol update on infectious outcomes after liver transplantation

Buse Ketenoğlu[1], Damla Verendağ[1], Aytaç Erdem[1], Oğuz Reşat Sipahi[1], Tansu Yamazhan[1]. *[1]Department of Infectious Diseases, Ege University Faculty of Medicine, İzmir, Türkiye*
Email: busekknoglu@gmail.com

Background and aims: Prophylaxis protocols following liver transplantation can vary across centers and may evolve over time, yet comparative outcome data remain limited. This study assessed the clinical impact of updated antibacterial, antiviral, and antifungal prophylaxis at a tertiary transplant center.
Method: Adult liver transplant recipients transplanted between 3 January 2018 and 30 April 2024 were retrospectively reviewed (n = 224). Prior to the protocol update, ceftriaxone was administered for antibacterial prophylaxis and acyclovir for antiviral prophylaxis. After the update, piperacillin-tazobactam and valganciclovir were implemented. Before the update, antifungal prophylaxis with fluconazole was not routinely administered, but it was introduced as routine prophylaxis for all recipients thereafter. Outcomes assessed included bacterial infection and mortality within 30 days, intensive care unit and total hospital length of stay, total antibiotic exposure days, incidence of cytomegalovirus syndromes during follow-up, and fungal infections within one year after transplantation.
Results: Thirty-day bacterial infection and mortality rates were similar between the piperacillin-tazobactam and ceftriaxone prophylaxis groups. However, piperacillin-tazobactam was associated with reduced intensive care unit and overall hospital stay, as well as fewer total antibiotic exposure days. Surgical site infection rates decreased following the protocol update, with an absolute reduction of 2.6 percentage points. After switching to valganciclovir, incidence of cytomegalovirus syndrome decreased from 10 cases under acyclovir prophylaxis to 1 case under valganciclovir prophylaxis, and no late-

onset cytomegalovirus disease was observed. Overall, fungal infection occurred in 21 of 224 patients (9.4%); 91% presented within six months after transplantation, with *Candida* species being the most common pathogens. Despite a higher baseline risk in the fluconazole prophylaxis group, fungal infection rates did not differ significantly between groups.
Conclusion: In this single-centre cohort, updating prophylaxis protocols was associated with reduced hospitalisation and fewer antibiotic exposure days with piperacillin–tazobactam, as well as a lower incidence of cytomegalovirus syndromes after valganciclovir. Stable fungal infection rates despite increased risk factors suggest a potential protective role of fluconazole. Risk-adapted, local epidemiology–guided prophylaxis strategies may improve outcomes after liver transplantation.

FRI-514
Early bacterial infections after liver transplantation: incidence and independent risk factors
Buse Ketenoğlu[1], Alper Uğuz[2], Tufan Gümüş[2], Elvan Işık[3], Damla Verendağ[1], Funda Yılmaz Barbet[4], Şöhret Aydemir[5], Rüçhan Sertöz[5], Tansu Yamazhan[1]. *[1]Department of Infectious Diseases, Ege University Faculty of Medicine, İzmir, Türkiye; [2]Department of General Surgery, Ege University Faculty of Medicine, İzmir, Türkiye; [3]Department of Gastroenterology, Internal Medicine, Ege University Faculty of Medicine, İzmir, Türkiye; [4]Department of Pathology, Ege University Faculty of Medicine, İzmir, Türkiye; [5]Department of Medical Microbiology, Ege University Faculty of Medicine, İzmir, Türkiye*
Email: buseknnoglu@gmail.com

Background and aims: Infections are major determinants of early morbidity and mortality after liver transplantation. This study evaluated the incidence of bacterial infections occurring within 30 days following transplantation and identified associated risk factors.
Method: Adult recipients who underwent liver transplantation between 3 January 2018 and 30 April 2024 at Ege University Organ Transplantation Center were retrospectively reviewed (n = 224). The primary outcome was the occurrence of bacterial infection within 30 days after transplantation. Independent predictors were assessed using multivariable logistic regression.
Results: Bacterial infection occurred in 84 of 224 recipients (37.5%). The most common infection sites were surgical site infection (35.7%) and pneumonia (35.7%), followed by catheter-related bloodstream infection (16.6%), urinary tract infection (15.4%) and primary bloodstream infection (9.5%). The most frequently isolated pathogens were *Acinetobacter baumannii* (25.0%), *Enterococcus faecium* (25.0%) and *Klebsiella pneumoniae* (21.4%). Multivariable analysis indicated that female sex was protective (odds ratio 0.40; 95% confidence interval 0.21–0.77). Bacterial infection was independently associated with hepatic encephalopathy (odds ratio 1.88), deceased donor transplantation (odds ratio 2.01), Model for End-stage Liver Disease score greater than 15 (odds ratio 1.95), postoperative biliary complications (odds ratio 6.87), and perioperative red blood cell transfusion (odds ratio 2.73). Recipients who developed bacterial infection had higher one-year mortality (odds ratio 4.55), longer stays in the intensive care unit (median 7 vs. 5 days; $p < 0.001$), and longer hospital stays overall (22 vs. 15 days; $p < 0.001$).
Conclusion: Bacterial infections occurred in more than one-third of recipients within 30 days and were associated with longer hospitalisation and higher one-year mortality. It appears that prioritizing enterococci in perioperative prophylaxis and in the management of early postoperative infections may be important in liver transplant recipients. High-risk recipients may benefit from targeted surveillance and preventive measures based on pre- and perioperative risk stratification.

Email: d.tripathi@bham.ac.uk

Background and aims: Transjugular intrahepatic portosystemic shunt (TIPS) is an established treatment for portal hypertension complications. Development of portal hypertension in liver transplant recipients is not uncommon; however, the utility of TIPS in this population remains poorly documented due to small sample sizes, heterogeneity, and single-centre retrospective designs. We aimed to describe the efficacy and safety of TIPS in liver transplant recipients and identify predictive factors for outcomes.
Method: We analysed prospectively and retrospectively collected data from the EASL-endorsed EuroTIPS registry of liver transplant recipients undergoing TIPS for portal hypertension complications. Univariate and multivariate Cox regression analyses were performed to identify variables predicting 1-year survival, including MELD, MELD-Na, Child-Pugh Score, disease aetiology, patient demographics, and TIPS technical factors.
Results: Fifty-one patients from 10 European centres were included. Mean age 55.8 ± 11.1 years; 60.7% male. Baseline: MELD 14.1 ± 4.9, MELD-Na 16.0 ± 6.5, Child-Pugh 7.7 ± 1.3. Median follow-up 33 months (range 1–326). Original disease was cirrhosis in 68%. Aetiology of allograft portal hypertension: recurrent index disease 31.4% (68.7% viral hepatitis), vascular complications 19.6%, PSVD 11.8%, other 23.5%. Indication for TIPS: refractory ascites 56.9%, portal hypertensive bleeding 17.6%, portal vein thrombosis 7.8%, others 17.7%. Indications for TIPS: refractory ascites 56.9%, portal hypertensive bleeding 17.6%, portal vein thrombosis 7.8%, others 17.7%. Median time from transplant to TIPS 33.4 months (2.1–256.1). Covered stents were used in 96.1% of patients. Portosystemic pressure gradient decreased from 17.6 ± 5.9 to 8. ± 3.5 mmHg. TIPS revision was required in 39.2% of cases, achieving 100% secondary patency. Complications included hepatic encephalopathy (29.4%), heart failure responding to TIPS reduction (n = 1), and graft ischaemia requiring re-transplantation (n = 1) within 30-day. Clinical success was 88.2%. Overall mortality during follow-up was 23.5% (66.6% liver-related). Survival at 1, 3, and 5 years was 82%, 75%, and 75%, respectively. No baseline

variables significantly predicted 1-year survival. Graft survival was 86.2%.
Conclusion: TIPS in liver transplant recipients achieves good clinical outcomes despite high intervention rates. Future analyses within the EuroTIPS cohort will focus on developing predictive models with larger sample sizes to address this unmet clinical need.

FRI-516
Liver transplant outcomes and clinical burden in patients with alpha-1 antitrypsin deficiency-associated liver disease in Canada
May Hagiwara[1], Chitra Karki[1], Tami Nussbaum[1], Suna Park[1], Kaili Ren[1], Rahima A. Bhanji[2], Mamatha Bhat[3], Marc Deschenes[4], Julian Hercun[5], Mohommad Qasim Khan[6,7], Julie Zhu[8], Sarah O'Brien[9], Anat Fisher[9], Paul Keown[9]. Email: may.hagiwara@takeda.com

Background and aims: Alpha-1 antitrypsin deficiency (AATD)-associated liver disease (AATD-LD) is caused by misfolded hepatic alpha-1 antitrypsin (AAT) aggregates in patients (pts) with the protease inhibitor (Pi)*ZZ genotype. No approved pharmacological therapies for AATD-LD exist; orthotopic liver transplantation (OLT) is recommended in pts with end-stage liver disease. We assessed clinical burden and liver-related outcomes in pts with AATD-LD assessed for OLT in Canada.
Method: Adults with AATD (physician-diagnosed, presence of an ICD-10-CM E88.01 code for AATD or serum AAT level < 120 mg/dL) were assessed for OLT at 6 regional centres in Canada (2005–2023). Data were obtained from electronic medical records/registries at each centre. Index date was defined as the date of physician assessment for OLT. Liver-related clinical events before index date, time from first liver-related clinical event to index date, time from index date to OLT and liver/OLT-related mortality were assessed.
Results: Among 341 pts (median [IQR] age at index: 57 [51, 64] years; 69% male), 184 (54%) underwent OLT. Genotype was assessed in 54/341 pts (16%) before (34/54, 63%) or after OLT (11/54, 20%); data was missing in 9 pts. Of those, 22/54 pts (41%) had a Pi*ZZ genotype. Median (IQR) time from the first liver-related clinical event (n = 203) to index date was 2 (0, 11) months. Ascites was the most common event (205/341, 60%), with events increasing in frequency closer to index date. Median (IQR) wait time from liver-related clinical event to index date was shortest in pts with hepatic encephalopathy (n = 56; 0 [0, 4] months) and longest in pts with oesophageal varices (n = 52; 9 [2, 23]). Median (95% CI) time to OLT after index date was 9 (6, 11) months (mortality adjusted). At 6 months post-index, the probability of OLT (mortality adjusted) was 40% and the risk of death was 20%. After OLT, 4% had liver-related mortality and 4% had OLT-related complications (liver-related hospitalization; excluding mortality) by Month 6.
Conclusion: This is the first natural history study of pts with AATD-LD assessed for OLT. In this study, few pts had available genotype data before OLT (34/341 pts [10%]) and median time from first liver-related clinical event to index date was short (2 months). These data highlight the need for improved disease awareness to diagnose AATD-LD early in the disease trajectory and prevent progression to end-stage liver disease in pts with AATD-LD.

FRI-517-YI
Redefining futility in the machine perfusion era: insights based on the UK-DCD risk score in 362 DCD liver transplantations
Efrayim Küçükerbil[1], Femke De Goeij[1], Puck C. Groen[1], Lina Gruncell[1], Roberto Broere[1], Sarwa Darwish Murad[1], Caroline den Hoed[1], Robert Porte[1], Wojciech Polak[1], Jeroen de Jonge[1]. [1]*Erasmus University Medical Center, Rotterdam, Netherlands*
Email: e.kucukerbil@erasmusmc.nl

Background and aims: The scarcity of suitable donor grafts and the increased risks associated with donation after circulatory death liver transplantation (DCD-LT) highlights the importance of donor–recipient matching to optimize outcomes and graft utility. The UK-DCD risk score categorizes DCD-LTs as low-risk, high-risk, or futile based on donor and recipient characteristics. In the era of machine perfusion, DCD grafts undergo additional hypothermic or normothermic machine perfusion to resuscitate and evaluate the graft before transplantation. This study compares graft survival in DCD-LT after static cold storage (SCS), hypothermic machine perfusion (HMP), and normothermic machine perfusion (NMP), stratified by UK-DCD risk categories.
Method: In this single-center, retrospective cohort study, 362 DCD-LTs (November 2002-July 2024) were grouped by preservation method: SCS (n = 176), HMP (n = 105), and NMP (n = 81). Baseline donor and recipient characteristics were collected for the UK-DCD risk score. The primary outcome was 2-year graft survival, censored for patient death with a functional graft. Graft loss due to primary non-function (PNF) and post-transplant cholangiopathy (PTC) were also compared.
Results: Low-risk DCD-LTs were highest after SCS (64%), followed by HMP (43%) and NMP (30%). In contrast, futile DCD LTs occurred in 5% of the SCS group, 8% of the HMP group, and 27% of the NMP group. Graft loss due to PNF occurred in 4 cases (2%) in SCS, 2 cases (2%) in HMP, and none in NMP ($p = 0.404$). Graft loss due to PTC was observed in 14 cases (8%) in SCS, none in HMP, and 2 cases (2%) in NMP ($p = 0.005$). Two-year graft survival was significantly higher in HMP and NMP compared to SCS, with survival rates of 93% and 90%, respectively, versus 81% ($p = 0.015$). This improvement was most pronounced in the high-risk group, where survival rates were 83% in SCS, compared to 100% and 97% in HMP and NMP, respectively ($p = 0.002$).
Conclusion: Despite more high-risk and futile transplantations, hypothermic and normothermic machine perfusion significantly reduced graft loss due to PTC, improving 2-year graft survival rate in DCD-LT up to 93%. This solidifies the role of machine perfusion in DCD-LT and highlights the need for a new risk model to better predict graft utility and long-term outcomes.

FRI-521
Comparative outcome of machine perfusion strategies in liver transplantation: a network meta-analysis
Suprabhat Giri[1], Kshitij Kumar[1], Dr Babu Lal Meena[2]. [1]*Kalinga Institute of Medical Sciences, Bhubaneswar, India;* [2]*Post Graduate Institute of Medical Education and Research, Chandigarh, India*
Email: supg19167@gmail.com

Background and aims: Ischemia–reperfusion injury (IRI) remains a major determinant of early graft dysfunction and adverse outcomes following liver transplantation (LT), particularly with the increasing use of extended-criteria and donation after circulatory death grafts. Machine perfusion strategies, including normothermic machine perfusion (NMP) and hypothermic oxygenated perfusion (HOPE), have been developed to mitigate IRI; however, their comparative efficacy and safety remain uncertain. We performed a network meta-analysis (NMA) of randomized controlled trials (RCTs) to compare static cold storage (SCS), NMP, and HOPE across clinically relevant post-transplant outcomes.
Method: A systematic search of MEDLINE, Embase, and Scopus from inception to March 2025 identified RCTs comparing NMP or HOPE

with SCS in adult LT recipients. The primary outcome was early allograft dysfunction (EAD). Secondary outcomes included post-reperfusion syndrome, serious adverse events (Clavien–Dindo ≥IIIb), duration of hospitalization, vascular and biliary complications, and graft loss. The risk of bias was assessed using the RoB 2. A Bayesian random-effects NMA was conducted, with treatment ranking estimated using surface under the cumulative ranking curve (SUCRA) values.
Results: Eleven RCTs encompassing 1,329 patients were included. Compared with SCS, both NMP (risk ratio [RR] 0.47, 95% confidence interval [CI] 0.27–0.80) and HOPE (RR 0.52, 95% CI 0.34–0.77) significantly reduced EAD, with NMP ranking highest (SUCRA 80.8). NMP was also associated with a markedly lower risk of overall biliary complications (RR 0.29, 95% CI 0.12–0.69). In contrast, HOPE significantly reduced non-anastomotic biliary strictures and graft loss (RR, 0.44; 95% CI, 0.18–0.90), ranking highest in terms of graft survival (SUCRA 96.3). Both NMP and HOPE reduced the incidence of serious adverse events compared with SCS, while no significant differences were observed for hepatic artery thrombosis or post-reperfusion syndrome. Most trials were at low risk of bias.
Conclusion: Both NMP and HOPE provide clinically meaningful advantages over static cold storage in liver transplantation, though their benefits differ by outcome. NMP appears superior for the prevention of early graft dysfunction and biliary complications, whereas HOPE offers greater protection against graft loss and severe complications. These findings support a tailored, risk-adapted approach to graft preservation and highlight the need for direct comparative trials between NMP and HOPE.

FRI-522

Histologic recurrence and progression of metabolic dysfunction–associated steatohepatitis after liver transplantation: a 35-year single-center biopsy cohort

Sobia Laique[1], Muhammad Ahmad Nadeem[1], Chase Wehrle[1], Antonio Giuseppucci[1], Puneet Bansal[1], Beren Berber[1], Awwab Hammad[1], Mohamed El Hag[1], Jacob Sweeney, [1], Xuefeng Zhang[1], Alejandro Pita[1], Mazhar Khalil[1], Masato Fujiki[1], Choon Hyuck David Kwon[1], Jaekeun Kim[1], Koji Hashimoto[1], Andrea Schlegel[1], Jamak Modaresi Esfeh[1], Daniela Allende[1].
[1]Cleveland Clinic Foundation, Cleveland, United States
Email: laiques2@ccf.org

Background and aims: Metabolic dysfunction–associated steatohepatitis (MASH) is an increasingly recognized cause of late graft injury after liver transplantation (LT), yet its histologic natural history post-LT is incompletely defined. Studies are limited by non-central pathology review and reliance on surrogate markers. We aimed to determine the incidence, timing, and histologic progression of recurrent and de novo MASH using centrally re-reviewed liver biopsies.
Method: Adult LT recipients at Cleveland Clinic (1984–2020) were included. All available biopsy slides were centrally re-reviewed by expert hepatopathologists according to NASH-CRN criteria. Post-transplant MASLD/MASH was classified as recurrent (MASH as the indication for LT) or de novo (other etiologies). Outcomes included incidence of MASLD/MASH, time from LT to the first biopsy demonstrating MASH, and histologic fibrosis progression. Fibrosis progression was defined as a ≥1-stage increase in fibrosis from the index biopsy and development of advanced fibrosis (≥F3) or cirrhosis (F4), and was assessed in a predefined subcohort with longitudinal histology.
Results: We identified 2,567 adult LT recipients with post-LT liver biopsies, (35% female, 17.3% with MASH indication). Post-LT, 13.9% developed recurrent MASLD, including 6.3% with recurrent histologic MASH. Among patients transplanted for non-MASH, 13.1% developed de novo MASLD and 4.2% de novo MASH. Recurrent MASH and MASLD were both more frequent than de novo disease (log-rank $p < 0.001$ respectively). The development of MASH in the transplant graft was associated with a reduction in overall survival independent of MELD, donor risk, or recipient age ($p < 0.001$). Overall, 118 patients developed post-transplant histologic MASH. The median time from LT to the first biopsy demonstrating MASH was 1.8 years (IQR 0.7–4.2). Fibrosis progression of 1 stage occurred in 27/54 (50%) patients over a median follow-up of 3.0 years, with development of advanced fibrosis (F3) in 16/54 (30%) and cirrhosis (F4) in 3/54 (5.5%). Median annualized fibrosis progression was 0.54 stages/year (IQR 0.3–0.9), corresponding to approximately 1.85 years per one-stage increase.
Conclusion: This long-term, histology-based assessment is the first assessing histologic steatotic liver diseases after transplant. MASLD and MASH are significant issues in transplanted liver grafts, with recurrent disease occurring more commonly than *de novo*. Fibrosis progresses 1 stage every 2 years and is associated with reduced survival.

FRI-523

Refining prognosis after liver transplantation: contribution of artificial intelligence to predict early graft dysfunction

Thomas Levi Strauss[1], Christophe Desterke[1], Astrid Laurent Bellue[2], Eric Vibert[1], Cyrille Feray[1], Audrey Coilly[1], Ilias Kounis[1]. *[1]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Service d'anatomie et cytologie pathologiques, hôpital Bicêtre, AP-HP, université Paris-Saclay, Kremlin Bicêtre, France*
Email: ilias.kounis@aphp.fr

Background and aims: Early allograft dysfunction (EAD) and primary non-function (PNF) remain major determinants of outcome after liver transplantation (LT). Our aim was to evaluate whether machine-learning models incorporating reperfusion biopsy data could improve prediction of early graft dysfunction.
Method: We performed a single-centre retrospective study including all adult LTs from 2017–2023. Retransplantations, living-donor, auxiliary, domino and combined thoracic–hepatic grafts were excluded; combined liver–kidney transplants were retained. For each case, 93 pre- and peri-operative variables were collected from donor, recipient, surgery and reperfusion biopsy. The primary composite endpoint at day 7 (PNF/EAD) combined PNF requiring urgent retransplantation or leading to death, or Olthoff EAD criteria for EAD (bilirubin ≥171 µmol/L or INR ≥1.6 at day 7, or transaminases ≥2000 U/L during the first week). A stricter endpoint of PNF/EAD was used secondly and excluded isolated transaminase elevation. Neural networks after selecting features by random forrest,and multi-variable modelling using LASSO, Ridge and Elasticnet were tested.
Results: Among 908 eligible LTs, 199 patients (21.9%) developed PNF/EAD and 87 (9.6%) met the strict definition. PNF/EAD was associated with reduced overall survival (subdistribution HR 1.61, 95% CI 1.16–2.22); the strict endpoint showed an even stronger association (HR 1.75, 95% CI 1.11–2.71). In univariate analyses, markers of recipient severity (MELD, ICU status, vasopressors, mechanical ventilation), operative complexity (cold ischaemia time, operative duration, transfusions) and reperfusion-biopsy steatosis (micro- and macro-vesicular) were significantly associated with early graft dysfunction. A neural network including 16 donor, recipient, surgical and histological variables achieved an AUC of 0.72 for predicting PNF/EAD. For the strict endpoint, an Elastic Net model based on four variables—pre-transplant bilirubin, pre-transplant platelet count, operative time and quantitative microvesicular steatosis—yielded an AUC of 0.73 and an accuracy of 89.8%, comparable to more complex machine-learning approaches while remaining interpretable.
Conclusion: Machine learning models can predict EAD after LT with acceptable accuracy. However, they did not clearly outperform penalized regression. Reperfusion biopsy steatosis—particularly microvesicular steatosis—emerged as a key histological determinant of early dysfunction.

FRI-524

Basiliximab preserves renal function after liver transplantation without increasing rejection or graft loss

Dorothy Liu[1], Andrew Chan[2], Katrina Tan[3], Alan Wigg[4], Avik Majumdar[1], Marie Sinclair[1], Adam Testro[5]. [1]*Victorian Liver Transplant Unit, Austin Health, Australian Centre for Transplantation Excellence and Research (ACTER), Austin Health, Department of Medicine (Austin Precinct), The University of Melbourne, Melbourne, Australia;* [2]*Victorian Liver Transplant Unit, Austin Health, Melbourne, Australia;* [3]*Victorian Liver Transplant Unit, Austin Health, Australian Centre for Transplantation Excellence and Research (ACTER), Austin Health, Hepatology and Liver Transplantation Medicine Unit, Flinders Medical Centre, Melbourne, Australia;* [4]*Hepatology and Liver Transplantation Medicine Unit, Flinders Medical Centre, Adelaide, Australia;* [5]*Victorian Liver Transplant Unit, Austin Health, Australian Centre for Transplantation Excellence and Research (ACTER), Austin Health, Department of Surgery (Austin Precinct), The University of Melbourne, Melbourne, Australia*
Email: dorothyliu22@gmail.com

Background and aims: Renal dysfunction is common after liver transplantation (LT). Basiliximab is used in recipients with pre-LT renal impairment at risk of post-LT acute kidney injury (AKI) and subsequent progressive renal failure. By allowing for delayed calcineurin inhibitor initiation, basiliximab may mitigate further renal injury. However, data on long-term renal outcomes in high-risk recipients remain limited. We compared longitudinal renal functional trajectories in a real-world, multicentre cohort of LT recipients stratified by basiliximab induction use.
Method: This was a retrospective cohort study of adult patients who underwent initial deceased donor LT at two Australian transplant centres (January 2018 to October 2022). Consecutive eligible patients were grouped based on basiliximab administration. Retransplantation and multivisceral transplants were excluded. Basiliximab was given at clinician discretion, informed by pre-LT renal function and anticipated AKI risk. Renal outcomes were assessed using linear mixed effects modelling of change in serum creatinine (sCr) from baseline to predefined timepoints (day 1 peak and 3, 6, 12 and 24 months), with adjusted pairwise contrasts used to compare groups. Secondary outcomes included renal dysfunction resolution, post-LT renal replacement therapy (RRT), biopsy-proven acute cellular rejection (BPAR), graft survival and patient survival.
Results: Of 405 patients, 232 (57%) received basiliximab. Compared with non-basiliximab recipients, basiliximab patients had significantly higher baseline sCr and MELD, and a greater prevalence of pre-LT hepatorenal syndrome, RRT, terlipressin use and vasopressor support. Despite this, basiliximab recipients had early and sustained reductions in adjusted sCr from 3 months onwards, independent of covariates. By 12 and 24 months, adjusted sCr in basiliximab recipients had returned to or fallen below baseline (adjusted mean sCr change from baseline −17 µmol/L [95% CI −31 to −4] and −21 µmol/L [95% CI −34 to −7], respectively). Basiliximab use was independently associated with renal dysfunction resolution at 12 months (adjusted OR 2.62, $p < 0.001$) and 24 months (adjusted OR 1.71, $p = 0.02$). Adjusted sCr in the non-basiliximab group remained unchanged from baseline. No between-group differences were observed in post-LT RRT, BPAR, graft survival or patient survival.
Conclusion: Basiliximab induction therapy was associated with early and sustained renal recovery in high-risk LT recipients without increasing rejection or graft loss.

FRI-525

Time-adjusted analysis of cumulative immunosuppression and hepatocellular carcinoma recurrence risk after liver transplantation

Dorothy Liu[1], Darren Wong[2], Adam Testro[3], Avik Majumdar[1], Marie Sinclair[1]. [1]*Victorian Liver Transplant Unit, Austin Health, Australian Centre for Transplantation Excellence and Research (ACTER), Austin Health, Department of Medicine (Austin Precinct), The University of Melbourne, Melbourne, Australia;* [2]*Department of Gastroenterology, Austin Health, Department of Medicine (Austin Precinct), The University of Melbourne, Melbourne, Australia;* [3]*Victorian Liver Transplant Unit, Austin Health, Australian Centre for Transplantation Excellence and Research (ACTER), Austin Health, Department of Surgery (Austin Precinct), The University of Melbourne, Melbourne, Australia*
Email: dorothyliu22@gmail.com

Background and aims: Immunosuppression following liver transplantation (LT) for hepatocellular carcinoma (HCC) requires a careful balance between preventing allograft rejection and minimising HCC recurrence, with the assumption that immunosuppression increases cancer risk. We present the first analysis of cumulative immunosuppression exposure by individual agents on HCC recurrence after LT, adjusted for time, transplantation era and concurrent therapy.
Method: Consecutive patients who underwent initial deceased donor LT at a single-centre between 2016 and 2020 were retrospectively evaluated. Immunosuppression regimens from LT until HCC recurrence or last follow-up (death or final review in patients without recurrence) were collected. Cumulative calcineurin inhibitor exposure was calculated as the area under the curve derived from drug levels over time. Mycophenolic acid (MPA) and everolimus exposures were analysed as categorical variables to prevent model instability. A time-varying Cox proportional hazards model was used to assess the association between agent-specific cumulative immunosuppression exposure and HCC recurrence risk.
Results: Among 225 LT recipients, 34 (15%) patients developed HCC recurrence over a median of 70 (43–116) months. Patients with recurrence had significantly higher RETREAT scores, higher pre-LT alpha-fetoprotein, more microvascular invasion, a greater number of viable tumours, and a larger maximum tumour diameter. The rate of treated biopsy-proven acute cellular rejection was comparable between groups. After adjusting for time, transplantation era and concurrent immunosuppressive agents, cumulative tacrolimus exposure (HR 0.90, 95% CI 0.82–0.98, $p = 0.02$) and RETREAT score (HR 1.35, 95% CI 1.06–1.72, $p = 0.02$) were independently associated with HCC recurrence. Cumulative tacrolimus exposure did not differ between patients with HCC recurrence when stratified by RETREAT score < 4 versus ≥ 4. Cumulative MPA exposure was also protective (HR 0.87, 95% 0.85–0.88, $p < 0.001$), whereas cumulative cyclosporine (HR 1.00, $p = 0.17$) and everolimus (HR 0.53, $p = 0.31$) exposure were not associated with HCC recurrence.
Conclusion: We found an association between higher immunosuppression exposure and reduced HCC recurrence, converse to the common assumption. The relationship between cumulative immunosuppression exposure and post-LT HCC recurrence remains incompletely understood, reflecting the complex interplay of tumour biology, recipient characteristics and immunosuppression therapy.

FRI-526

Multidisciplinary follow-up after liver transplantation: diagnostic yield and impact on cancer and cardiovascular outcomes

Erica Nicola Lynch[1], Armando Curto[1], Michele Tanturli[1], Rocco Iamello[1], Giulia Lubian[1], Tommaso Mello[1], Tommaso Innocenti[1], Gabriele Dragoni[1], Stefano Gitto[2], Andrea Galli[1]. [1]*University of Florence, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Florence, Italy, Florence, Italy;* [2]*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, Florence, Italy*
Email: ericanicola.lynch@unifi.it

Background and aims: With improving survival after liver transplantation (LT), de novo malignancies and cardiovascular (CV) disease are major late causes of morbidity/mortality, but evidence for standardized multidisciplinary follow-up is limited. We aim To describe the diagnostic yield and outcomes of a structured post-LT

multidisciplinary follow-up in a hospital without an on-site transplant program.
Method: Retrospective cohort of LT recipients followed 1995–2024. Scheduled assessments: dermatology, cardiology, chest X-ray, Pap/HPV, mammography/breast ultrasound. Diagnoses during scheduled visits in asymptomatic patients were considered screen-detected.
Results: The cohort included 226 patients (72.6% male); median follow-up 10 years. ≥1 malignancy occurred in 32.7% (112 cancers); 52.7% were screen-detected, mainly via dermatology (88.1% of screen-detected cancers). Median time to first malignancy was 7.0 years; malignancy was the main known cause of death (~51%). Dermatologic neoplasms included basal cell carcinoma 12.5%, squamous cell carcinoma 2.7%, melanoma 0.6%; median time to first dermatologic diagnosis 5.6 years. Women (n = 62): Pap/HPV tests (n = 154) were positive in 22.6% (median 6.0 years); mammography/ultrasound (n = 276) 8.7% positive (median 6.6 years). Chest X-rays (n = 847) yielded 152 mainly non-neoplastic findings; 1 cancer (mesothelioma). CV events occurred in 21.7% (63), 14.3% screen-detected; median time to first CV event 5 years; arrhythmias/AF ~24%, ischemic heart disease ~18%, cerebrovascular events ~16%, pulmonary embolism ~11%; one fatal. During cardiology follow-up, 80.1% of prescriptions were antihypertensive or lipid-lowering; elective interventions were only for valvulopathies. All-cause mortality was 19.5% (median LT-to-death 6.5 years).
Conclusion: Structured multidisciplinary follow-up enabled screening detection of over half of malignancies, driven by dermatologic surveillance (most within 10 years post-LT). Cardiology supported CV risk-factor management, whereas routine chest X-rays had negligible impact on early lung cancer detection.

FRI-527
The coexistence of sarcopenia and myosteatosis is associated with adverse clinical outcomes following liver transplantation
Ellina Lytvyak[1,2], Yu Jun Wong[1], Shagani Thisairajah[1], Glenda Meeberg[3], Devika Shreekumar[1], Maryam Motamedrad[1], Alessandro Parente[3,4], Norman Kneteman[3], Khaled Dajani[3], Blaire Anderson[3], David Bigam[3], James Shapiro[3], Aldo J Montano-Loza[1]. *[1]Division of Gastroenterology and Liver Unit, University of Alberta, Edmonton, Canada; [2]Division of Preventive Medicine, University of Alberta, Edmonton, Canada; [3]Division of Transplantation Surgery, Department of Surgery, University of Alberta, Edmonton, Canada; [4]Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: montanol@ualberta.ca

Background and aims: Sarcopenia and myosteatosis are individually associated with adverse outcomes in chronic liver disease, however their combined impact of this "double-muscle defect" on postliver transplantation (LT) survival remains unclear. We hypothesized that the co-existence of sarcopenia and myosteatosis defines a distinct, high-risk muscle phenotype associated with poorer post-LT outcomes beyond conventional risk markers.
Method: We conducted a prospective cohort study that included 400 adult patients undergoing LT. Skeletal muscle index and radiodensity were measured from pre-LT computed tomography (CT) scan three months before their LT to define sarcopenia and myosteatosis, using established cut-offs. The primary outcome was post-LT mortality; secondary outcomes were ICU and total hospital length of stay (LOS). Multivariable Cox-regression adjusted for age, sex, and MELD score at LT.
Results: The cohort was 70% male Caucasians (76.5%), with median age 53.5 years [IQR 44.2–60.5] and median BMI 25.9 kg/m^2 [IQR 23–30.2]. Sarcopenia was present in 54.5%, myosteatosis in 47.3%, and both in 29.8% patients. LT recipients with simultaneous sarcopenia and myosteatosis had longer post-LT ICU stay (4 [2–11] vs. 3 [2–6] days, p = 0.01), and longer post-LT hospital LOS (27 [16–50] vs. 21 [14–34] days, p = 0.004). Importantly, simultaneous sarcopenia and myosteatosis was independently associated with a higher risk of mortality (adjusted HR 1.57 [1.05–1.91], p = 0.029), after adjustment by sex, age at transplant, cirrhosis etiology, presence of acute-on-chronic liver failure, and pre-LT MELD score. The 5-year post-LT survival (72% vs. 82%, p = 0.015) was significantly worse for patients with simultaneous sarcopenia and myosteatosis. This effect was magnified in patients > 60 year-old (62% vs. 72%, p = 0.015), and those requiring ICU admission pre-LT (66% vs. 87%, p = 0.014).
Conclusion: Simultaneous sarcopenia and myosteatosis is a clinically meaningful, independent predictor of post-LT mortality and morbidity, especially in older and critically ill patients. Incorporation of dual muscle assessment into pre-LT evaluation may provide a more objective means to enhance risk stratification, guide candidate selection, and reduce futile transplantation—particularly in older and critically ill patients.

FRI-528
Outcomes of everolimus-based immunosuppression after liver transplantation for hepatocellular carcinoma with or without steroid induction
Bianca Magro[1], Ciro Celsa[2], Michela Triolo[3], Antonio Galante[1], Giuseppe Cabibbo[2], Leonardi Filippo[3], Luisa Pasulo[3], Salvatore Gruttadauria[4], Calogero Cammà[2], Domenico Pinelli[5], Stefano Fagiuoli[3]. *[1]UPMC Italy, Palermo, Italy, Hepatology Section, IRCCS ISMETT, Palermo, Italy, Palermo, Italy; [2]UPMC ISMETT, Palermo, Italy; [3]Gastroenterology, Hepatology and Transplantation Unit, ASST Papa Giovanni XXIII, Bergamo, Italy, Bergamo, Italy; [4]Department of Surgery and Medical and Surgical Specialties, University of Catania, 95124 Catania, Italy, Palermo, Italy; [5]Department of Organ Failure and Transplantation, ASST Papa Giovanni XXIII Hospital, Bergamo, Italy, Bergamo, Italy*
Email: bmagro@ismett.edu

Background and aims: Patients undergoing liver transplantation (LT) for hepatocellular carcinoma (HCC) remain at risk for tumor recurrence. Calcineurin inhibitors (CNIs) have been associated with oncogenic effects, whereas mammalian target of rapamycin inhibitors may offer antitumor benefits. Evidence on everolimus-based regimens within steroid-free induction protocols is limited.
Method: We retrospectively analyzed 344 consecutive patients who underwent LT for HCC at ISMETT (Palermo) and HPG23 (Bergamo) between January 2022 and June 2025. Patients at ISMETT received steroid-free induction with basiliximab, while Bergamo patients received steroid induction. Immunosuppressive regimens were assessed; early conversion was defined as within three months. Kaplan–Meier analysis evaluated acute cellular rejection (ACR), HCC recurrence, graft survival, and overall survival. Uni- and multivariate Cox regression analysis was used to identify predictors of outcomes.
Results: The cohort was predominantly male (79.9%) with a mean age of 58.9 ± 10.4 years. Viral cirrhosis was the leading etiology (44.3%), and 41.9% of grafts were marginal. Everolimus-based immunosuppression was used in 123 patients (35.8%), including monotherapy in 65 cases (18.9%). Among everolimus-treated patients, 83 (69.2%) were converted from CNIs at a median of 4.5 months (IQR 1.8–8.0), with 23 (39%) undergoing early conversion. Median follow-up was 22.9 months (IQR 10.9–41.9). Rejection-free survival was comparable between everolimus and CNI-based regimens. In the steroid-free cohort, ACR was significantly more common among everolimus-treated patients (p = 0.042), likely due to higher use of monotherapy. Among everolimus-treated patients, the risk of ACR was similar between steroid-free and steroid cohort. HCC recurrence-free survival and overall survival did not significantly differ between everolimus and CNI-based regimens. Early conversion was associated with increased mortality (HR 7.52, 95%CI 0.95–59.70, p = 0.056), whereas viral etiology was an independent protective factor by multivariate analysis (HR 0.42, 95%CI 0.21–0.88, p = 0.020). Graft survival was significantly better in the everolimus group (HR 0.49, 95%CI 0.26–0.93, p = 0.020).

Conclusion: Everolimus-based immunosuppression is safe after LT for HCC, even within steroid-free induction protocols. However, everolimus monotherapy may increase the risk of ACR. CNI-minimization strategies appear feasible when carefully selected and monitored.

FRI-529-YI

Who drops out? Preoperative prediction of hepatic hypertrophy techniques failure from the IGROWtoH registry

Cecilia Maina[1], Elio Jovine[2], Matteo Serenari[2], Francesca Ratti[1]. [1]*San Raffaele, Milano, Italy;* [2]*Ospedale Maggiore Carlo Alberto Pizzardi, Bologna, Italy*
Email: ratti.francesca@hsr.it

Background and aims: Liver resection feasibility is mainly limited by the volume and function of the future liver remnant (FLR), with posthepatectomy liver failure remaining a major cause of post-operative mortality. Hypertrophy-inducing techniques increase FLR volume and expand resectability but are associated with a relevant risk of treatment drop-out, due to insufficient hypertrophy or disease progression. This study aimed to identify preoperative predictors of drop-out to improve patient selection and outcomes.
Method: Adult patients with malignant liver disease requiring a hypertrophy-inducing strategy for insufficient FLR volume (<40%) and/or impaired function were extracted from the multicenter IGROWtoH registry (2014–2025). Univariate and multivariate analyses were performed to identify independent predictors of drop-out. A points-based clinical score was developed from the multivariable model using the Sullivan–Framingham method and internally validated by bootstrap resampling. Disease-specific predictors were explored through subgroup analyses.
Results: Among 445 eligible patients, 114 (25.6%) experienced drop-out. Prior locoregional treatments (OR 0.33, $p = 0.004$) and the use of portal vein embolization or liver venous deprivation as hypertrophy technique were associated with lower drop-out odds (OR 0.21, $p = 0.002$ and OR 0.25, $p = 0.013$, respectively), whereas preoperative hyperbilirubinemia and secondary liver tumor diagnosis increased them (OR 1.93, $p = 0.028$ and OR 1.95, $p = 0.013$, respectively). The derived drop-out risk score stratified patients into four categories, with drop-out rates rising from 12.2% in the low-risk group to 45.5% in the very high-risk group. Disease-specific predictors included albumin-bilirubin grade ≥ 2 for primary intrahepatic tumors; obesity, prolonged international normalized ratio (INR) and gallbladder cancer for extrahepatic-perihilar tumors; and bilobar disease and elevated carcinoembryonic antigen (CEA) for secondary liver tumors.
Conclusion: Drop-out after hypertrophy-inducing strategies is influenced by both patient- and disease-specific factors. The preoperative risk score effectively stratifies drop-out risk and may support individualized treatment planning. Disease-specific predictors act as clinical "red flags" with an additive effect, amplifying the probability of drop-out.

FRI-530

Medical management of patients undergoing elective, liver-related invasive procedures - a novel collaboration model between hepatologists and hepato-biliary surgeons

Chiara Mangini[1], Federica Giunta[1], Domenico Bassi[2], Riccardo Boetto[2], Carmine Gambino[1], Riccardo Carandina[3], Matteo Ghisa[2], Caterina Soldà[4], Sabrina Cervesato[1], Michele Tessarin[5], Sara Montagnese[1], Umberto Cillo[2]. [1]*Department of Medicine, University of Padova, Padua, Italy;* [2]*Department of Surgical, Oncological and Gastroenterological Sciences, University of Padova, Padova, Italy;* [3]*Department of Integrated Diagnostic Services, Padova University Hospital, Padova, Italy;* [4]*Veneto Institute of Oncology IOV-IRCCS, Padova, Italy, Padova, Italy;* [5]*Medical Management, Padova University Hospital, Padova, Italy*
Email: chiara.manginij@gmail.com

Background and aims: To describe and test a novel, joint management system (surgery/hepatology) of patients undergoing elective procedures for hepato-biliary disorders of varying origin, within the setting of a short medical hospitalisation.
Method: Patients electively admitted under this system to the Internal Medicine Ward 5 - Hepatology (Padova University Hospital) between Feb 2023 and June 2025 were included. Admissions were jointly scheduled/prioritized by designated hepatologists and hepato-biliary surgeons, and managed by a specialist nurse. On admission, clinical and laboratory tests were performed, and patients prepared as appropriate (i.e. hydration, antibiotic prophylaxis etc.), and then monitored after the procedure; any complications were treated as necessary. Outcomes were classified as discharge within 72 hours, longer hospitalization, transfer to other ward, death.
Results: 352 procedures were performed over the testing period: 99 (28%) endoscopic retrograde cholangiopancreatographies (ERCP), 127 (36%) locoregional treatments (LRT) for hepato-biliary malignancies, 71 (20%) percutaneous transhepatic biliary drainages (PTBD), and 55 (16%) other. 264 (75%) were first admissions (76% males, 68 ± 12 years) and 88 (25%) were repeated admissions (i.e. patients undergoing ≥ 2 procedures). Baseline disease were cirrhosis (34%), a history of liver transplantation (22%), and hepato-biliary malignancies (38%). Inpatient stay was 2.4 ± 4.3 days, with 86% of patients being discharged within 72 hours. Complications occurred in 57 patients (16%), with no differences between procedures. While complications were mostly mild, they prolonged the inpatient stay (8.5 ± 8.4 vs 1.2 ± 0.75 days, $p < 0.001$). For ERCP, complications were associated with pre-procedural lower white blood cell counts ($p < 0.05$). For PTBD, complications were associated with lower haemoglobin and elevated AST, ALT, and bilirubin ($p < 0.05$). Elevated pre-procedural AST (HR 1.01, $p < 0.05$) and INR (HR 3.27, $p < 0.05$), and the presence of cirrhosis (HR 1.69, $p < 0.05$) independently predicted the occurrence of complications. In patients undergoing LRT, 30-day CT scans showed complete resolution in 57% of instances.
Conclusion: Integrated hepatological-surgical management of patients undergoing complex hepato-biliary procedures within the setting of an elective medical hospitalization is feasible and effective, ensuring short inpatient stays and low complication rates, at least in a large tertiary referral liver centre.

FRI-531

Coronary revascularization with short-duration dual antiplatelet therapy prior to liver transplantation: an 8-year single-center experience

Chiara Manuli[1], Margherita Saracco[1], Silvia Strona[1], Guglielmo Gallone[2], Federico Conrotto[2], Chiara Stratta[3], Renato Romagnoli[4], Silvia Martini[1]. [1]*SSD Insufficienza Epatica e Trapianto Epatico, AOU Città Della Salute e Della Scienza Di Torino, Turin, Italy;* [2]*Cardiology Unit, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy;* [3]*Anesthesia and Intensive Care Unit 2, AOU Città della Salute e della Scienza di Torino, Turin, Italy;* [4]*General Surgery 2U, Liver Transplantation Center, AOU Città della Salute e della Scienza di Torino, Turin, Italy*
Email: chiara.manuli@gmail.com

Background and aims: Significant coronary artery disease (CAD) is increasing in liver transplant (LT) recipients and its pre-LT treatment can improve LT outcomes. New-generation drug-eluting stents (DES) allow early dual antiplatelet therapy (DAPT) discontinuation, but its optimal duration remains controversial. We aimed to describe pre-LT and early post-LT outcomes of our patients (pts) with CAD who underwent pre-LT revascularization.
Method: All LT pts from 01/2018 to 12/2025 who underwent pre-LT cardiac catheterization (CATH) were included. Significant CAD was defined as stenosis ≥50% in major-vessel or ≥70% in moderate-sized branch vessel.

Results: Among 1608 adult pts transplanted in our Center during study period, 95 (6%) underwent pre-LT CATH due to: a) previous history of obstructive CAD (16%); b) positive/doubtful non-invasive tests (71%) -mostly coronary CT angiography (76%); c) cardiology indication (13%). CATH detected 39 pts (41%) with significant CAD requiring revascularization: 97% male, median age 64 y [IQR 61–68], 64% BMI>25, 38% MetALD, median MELD 12 [9–15], 74% HCC, 69% diabetes, 59% arterial hypertension. 2/39 pts (5%) underwent coronary bypass surgery (CABG) and 37 (95%) percutaneous revascularization (PCI+DES). 5/39 (13%) experienced CATH related complications: 3 anemia, 1 acute kidney injury, 1 intraprocedural myocardial infarction with successful revascularization. After PCI, median DAPT duration was 31 days (d) [30–90]. Median time between DAPT discontinuation, LT listing and LT was 11 d [6–19] and 84 d [22–174], respectively. Median donor age was 64 y [54–76], 18 grafts (46%) underwent machine perfusion. A median of 2 red blood cell units was transfused during LT [0–7]. After a median post-LT follow-up of 13.5 months [1.8–39.9] 87% of the pts are alive. 5/39 pts (13%) experienced post-LT ischemic events: 1 pt at the end of LT due to stent occlusion (pt underwent successful PCI+DES), 1 after 24 d due to CABG occlusion (pt received successful PCI, he died 30 months later due to ischemic heart failure), 1 discrepancy angina 4 months after LT (with negative CATH), and 2 pts with stent occlusion at 4 and 11 months after LT (successfully treated with PCI+DES).
Conclusion: In our real-life cohort of pts with significant CAD, pre-LT DES-PCI and short DAPT was feasible and allowed early LT. A non-negligible incidence of post-LT ischemic events was observed, managed promptly and effectively, underlying the need of high surveillance in this group.

FRI-532
Obesity as a key risk factor for de novo malignancies in liver transplant recipients: a 23-year cohort study
Natalia Marcos Carrasco[1,2,3], Elena Velasco Martinez[1,2], Laura Jiménez[1,2], Alicia San José Crespo[1,2], Samuel Fernández-Prada[1,2], María Jordán de la Fuente[1,2], Carmen Alonso Martin[4], Graciela Salinas Camargo[1,2], Isabel Ruiz Nunez[1,2], Daniela Ortiz Chimbo[1,2], Carlos Maroto Martin[1,2], Félix García Pajares[1,2], Irene Peñas Herrero[1,2,3], Carolina Almohalla Alvarez[1,2], Gloria Sánchez Antolín[1,2,3]. *[1]Hospital Universitario Río Hortega, Valladolid, Spain; [2]IbioVall, Valladolid, Spain; [3]Valladolid University, Valladolid, Spain; [4]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain*
Email: natalia.marcos.carrasco@gmail.com

Background and aims: Advances in the management of liver transplant (LT) recipients have markedly improved long-term survival; however, they have also increased the incidence of de novo malignancies, which represent a major challenge during post-transplant follow-up. Aims: to analyze the overall incidence of cancer in a cohort of adult LT recipients and to identify the main associated risk factors.
Method: Observational, retrospective study based on a prospective cohort, including all adult patients undergoing LT at a Liver Transplant Unit between 2001 and December 2024. Demographic, clinical, and follow-up variables related to the development of malignancies were collected. Hepatocellular carcinoma (HCC) was excluded from the analysis.
Results: 762 patients were analyzed; 78% were male, with a mean age of 56 years at transplantation. Alcohol consumption and tobacco use were reported in 69.5% and 63% of patients, respectively. Mean body mass index was 27.4. Diabetes mellitus, dyslipidemia, and hypertension were present in 27.7%, 10.7%, and 21.6% of patients, respectively. Mean MELD sodium score was 15. The most frequent underlying liver disease was alcohol-related liver disease (49.5%), followed by hepatitis C virus infection (25%). At the time of transplantation, 35.7% of patients had HCC. During follow-up, 119 de novo malignancies were diagnosed. The most frequent were head and neck cancer (25%), lung cancer (18.5%), and hematological malignancies (9.2%), with a median time to diagnosis of 6.8 years after LT. Estimated overall survival was 11.6 years and was significantly lower in patients who developed malignancies (7.9 years; $p < 0.001$). A total of 60 patients (50.4%) died as a direct consequence of cancer. In this cohort, obesity was the only factor significantly associated with the development of de novo malignancies ($p < 0.05$).
Conclusion: De novo malignancies represent a relevant complication after LT, with a negative impact on mortality and quality of life. Prevention strategies and early detection should be prioritized during post-transplant follow-up. In our cohort, obesity was the only factor significantly associated with cancer development after transplantation.

FRI-533
Impact of tumor biology versus imaging on post-transplant outcomes in hepatocellular carcinoma (HCC)
Natalia Marcos Carrasco[1,2,3], Alicia San José Crespo[1,2], María Jordán de la Fuente[1,2], Pedro Enrile Sanchez[1,2], Elena Velasco Martinez[1,2], Samuel Fernández-Prada[1,2], Jorge Lillo Diez[1,2], Cristina Martínez Cuevas[1,2], Irene Peñas Herrero[1,2,3], Carolina Almohalla Alvarez[1,2], Félix García Pajares[1,2,3], Gloria Sánchez Antolín[1,2,3]. *[1]Hospital Universitario Río Hortega, Valladolid, Spain; [2]IbioVall, Valladolid, Spain; [3]Valladolid University, Valladolid, Spain*
Email: natalia.marcos.carrasco@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) accounts for approximately 35% of liver transplantation (LT) indications. Diagnosis relies on radiological criteria, which may underestimate tumor burden. Both radiological underestimation and vascular invasion on explant histopathology are associated with increased post- LT recurrence. Aims: to evaluate the concordance between radiological and explant findings in transplanted HCC patients; to assess their impact on post-LT survival and recurrence.
Method: Single-center, observational, retrospective study based on a prospective database. All patients undergoing LT for HCC between 2001–2024 were included. Radiological findings were compared with explant histopathology. Overall survival, recurrence, and associated risk factors were analyzed.
Results: 266 patients were included; 86.5% were male, with a median age of 60 years (interquartile range 54–64). Alcohol-related liver disease was the most common etiology (47.5%), followed by hepatitis C virus infection (37.7%). Most patients were Child–Pugh class A (63.4%), with a median MELD sodium score of 12. On imaging, 92.4% fulfilled Milan criteria. Radiologically, 56.8% of patients had one nodule, 25.8% had two, 13.3% had three, and 3.4% had four nodules. Median dominant nodule size was 2.5 cm, and median total tumor size was 3.0 cm (2.1–4.4). On explant histopathology, 5.2% had no HCC, while 47.6% had one nodule, 23.2% two, 12.0% three, and 12.0% four or more nodules. Median dominant nodule size was 2.5 cm (1.8–3.5), and median total tumor size was 3.5 cm (2.2–5.0), with 77.2% within Milan criteria. Correlation between radiology and explant was moderate for number of nodules (correlation coefficient 0.48; $p < 0.001$) and tumor size (correlation coefficient 0.41; $p < 0.001$). During follow-up, 50.8% of patients died, with 30% of deaths HCC-related. Estimated overall survival was 10.5 years. Recurrence was associated with significantly lower survival ($p < 0.001$). Predictors of recurrence included total tumor size on imaging, bridging therapy, elevated alpha-fetoprotein levels, dominant nodule size on explant, and adverse histological features.
Conclusion: Pre-transplant radiological assessment remains crucial for optimizing survival and preventing recurrence, particularly regarding tumor size. However, tumor biological characteristics and explant histopathological criteria showed a stronger association with recurrence and post-transplant survival.

FRI-537

Predicting packed red blood cell requirements in patients undergoing orthotopic liver transplant – foundation work for a quality improvement project

Anna Matusiewicz[1], Victoria J. Appleby[1], Richard Parker[1]. [1]*Leeds, United Kingdom*
Email: anna.matusiewicz1@nhs.net

Background and aims: Anaemia is common in patients with liver disease and is often multifactorial. Packed red blood cell (PRBC) transfusion is costly and not without risk, but is frequently required perioperatively in patients undergoing elective orthotopic liver transplantation (OLT). This study aims to identify whether anaemia is a predictor of perioperative PRBC transfusion requirement in patients undergoing elective OLT.
Method: A single-centre retrospective case series was conducted. Data was collected from patients who underwent elective OLT between 2024 and 2025 in St James's University Hospital, Leeds. A dataset was compiled recording patient demographics, liver disease aetiology, transplant assessment blood tests for anaemia, haemoglobin concentration (Hb) at the time of transplant, intra-operative transfusion requirement and total admission transfusion requirement. Statistical analysis was performed using R software.
Results: In total, 120 patients were included: median age was 59 years (IQR 47–66), 71% were male. The most common diagnoses were alcohol-related liver disease (ALD, 55 patients, 46%), biliary disease (24 patients, 20%) and metabolic dysfunction-associated steatotic liver disease (MASLD, 15 patients, 13%). Thirty-two patients had hepatocellular carcinoma (27.4%). Most patients (67, 56%) required PRBC in the perioperative period with a total of 216 units used - based on national UK tariffs for blood products, this is a total cost of £40,286.12 (€ 46252.96), or £335 per patient (€385). Hb at the time of transplantation was independently associated with intraoperative PRBC requirements (HR 0.97, 0.95–0.98, $p < 0.001$) and total perioperative PRBC requirements (HR 0.96, 0.94–0.98, $p < 0.001$). Hb at the time of transplantation was in turn predicted by Hb, folate, ferritin, age and diagnosis at the time of assessment for transplantation, although only Hb remained significant in multivariable analysis (HR 1.88, 1.55–2.27, $p < 0.001$).
Conclusion: We have demonstrated that in patients undergoing OLT, anaemia at the time of transplant predicts PRBC transfusion requirement perioperatively, with lower haemoglobin levels predicting higher PRBC transfusion requirements. Careful attention to the treatment of anaemia may reduce PRBC requirements around the time of transplantation, reducing costs and the risk of complications from transfusion.

FRI-538-YI

Cross-modality validation of 90% pathological response as a predictor of long-term survival in early-stage HCC

Mzamo Mbelle[1,2], Maria Guerra Veloz[1], Yoh Zen[1], David Wallace[3,4], Rosa Miquel[1], Paul Ross[1], Sarah Selemani[1], Dylan Lewis[1], Praveen Peddu[1], Miriam Cortes Cerisuelo[1], Parthi Srinivasan[1], Abdul Hakeem[1], Krishna Menon[1], Kosh Agarwal[1], Varuna Aluvihare[1], Claire Kelly[1], Michael Heneghan[1], Niloufar Safinia[2], Antonio D'Alessio[5], Abid Suddle[1]. [1]*Institute of Liver Studies, King's College Hospital, Denmark Hill, London, United Kingdom;* [2]*Roger Williams Institute of Liver Studies, Kings College London, London, United Kingdom;* [3]*Department of HPB and Liver Transplantation, The Royal Free Hospital, London, United Kingdom;* [4]*Department of Surgical Biotechnology, University College London, London, United Kingdom;* [5]*Division of Cancer, Imperial College London, London, United Kingdom*
Email: mzamo.mbelle@nhs.net

Background and aims: Pathological response, particularly the degree of tumour necrosis, is increasingly recognised as a key predictor of outcomes in hepatocellular carcinoma (HCC) treated with curative modalities such as liver transplantation (LT). 90% tumour regression has been identified as the ideal cutoff for major-pathological response (MPR) after neoadjuvant immunotherapy (ICI) in resectable HCC, however the optimal prognostic threshold remains unclear, particularly after pre-transplant locoregional therapy (LRT).
Method: This retrospective single-centre cohort study included 300 LT recipients enrolled from December 2012 to January 2023, of whom 133 had quantifiable tumour necrosis on explant histopathology. Pathological response was centrally assessed as the proportion of viable tumour relative to necrosis following LRT: Grade 1 (<50% necrosis), Grade 2 (50–90%), Grade 3 (>90%), and Grade 4 (complete pathological response). Overall survival (OS) and recurrence-free survival (RFS) were analysed using Kaplan-Meier method. Optimal necrosis cut-offs for survival prediction were explored using unbiased recursive partitioning and Youden's index derived from ROC analyses.
Results: Overall, 238 patients (78%) underwent LRT, with 57.1% receiving more than one modality; TACE was the most common treatment (84%). After a median follow-up of 69 months (95% CI 65–75), 5-year median overall survival (OS) was 77.5%. Median OS improved form 108.2 months (95% CI 102 – NR) in patients without necrosis to 136.1 months (95% CI 136.7 – NR) in those with necrosis. Stepwise improvement in OS was observed across increasing necrosis grades (log-rank $p = 0.033$), and 5-year RFS was 96.9% (95% CI 92.7–100) in patients with >90% necrosis vs 82.9% (95% CI 77.4–88.7) in those with <90%. Cox proportional hazards modelling demonstrated that Grade 3 necrosis (>90%) was independently associated with improved OS (hazard ratio [HR] 0.12, 95% CI 0.014–0.98, $p = 0.012$). Recursive partitioning and Youden's index both identified Grade 3 (>90%) as the optimal cutoff to predict OS.
Conclusion: Explant necrosis ≥90% is a robust predictor of survival following LT for HCC treated with LRT and supports ≥90% as a potential definition of major pathological response (MPR). This represents, to our knowledge, the first cross-modality validation of a necrosis-based threshold for post-LT outcomes. Multi-centre validation is needed to refine the optimal necrosis cut-off for integration into prognostic models and post-transplant surveillance strategies.

FRI-539

Long-term outcomes of endoscopic therapy for post-transplant biliary anastomotic strictures: a single center experience

Shubham Mehta[1], Abhinav Sengupta[2], Harsh Jain[1], Hitesh Panchal[1], Pawan Rawal[1], Rajesh Puri[1]. [1]*Medanta Hospital, Gurugram, India;* [2]*All India Institute of Medical Sciences, New Delhi, India*
Email: mehta.shubham1493@gmail.com

Background and aims: Biliary complications occur in approximately 14–20% of patients post-orthotopic liver transplantation (post-OLT). Endoscopic retrograde cholangiopancreatography (ERCP) and insertion of plastic stents represent the standard treatment, however, there is limited data on the resolution rate of stricture and bile leak and long-term outcomes in patients with these complications.
Method: We reviewed clinical records of 3590 consecutive patients who underwent OLT between 2011–2023. For the patients who developed anastomotic biliary strictures (ABS) or bile leak (BL), specific data including the demographics, indication of OLT, graft type, configuration of bile ducts, number of biliary anastomosis, number of ERCP sessions required and requirement of per-cutaneous transhepatic biliary drainage (PTBD) were extracted. Primary outcome was to estimate the rate of stricture or bile leak resolution.
Results: Of total 3590 patients who underwent liver transplant, 540 (15%) patients (male = 465, 86.1%; mean age- 49.3 ± 10.6 years) developed biliary complications [ABS – 469 (86.9%) patients; BL – 60 (11.1%) patients; stricture with bile leak – 11 (2%) patients]. The median time to stricture formation after OLT was 6 (IQR: 3–10) months, and the median time from OLT to bile leak was 29.5 (IQR:15–51.5) days. The technical success for ERCP was 89.1% (481/540); 59 (10.9%) patients required a combination of ERCP and PTBD (followed by rendezvous ERCP) for biliary drainage and one patient required surgery. Of 480 patients with ABS, 409 (85.2%) patients achieved

stricture resolution after a median 3 (IQR:2–4) ERCP sessions and median 6 (IQR:4–9) months. Rest required surgery. Stricture recurrence occurred in 20.5% (84/409) patients after median 5 (IQR: 3–12) months of stent free trial; 90% (76/84) patients were subsequently managed by ERCP successfully, and 8 patients required surgery. Of 60 patients with BL, rate of resolution was 95% (57/60) after median 1 (IQR: 1–2) ERCP session and median 3 (IQR: 3–4) months; none of these patients developed recurrence. On multivariate analysis, requirement of more than 3 ERCP sessions (aOR: 1.6, 95% CI: 1.1–1.8; p = 0.004)and multiple duct-to-duct anastomosis (aOR: 1.7, 95% CI: 1.2–2.7; p = 0.02) predicted recurrence of strictures.
Conclusion: ERCP is an effective for post-OLT biliary anastomotic strictures and bile leaks. The number of ERCP procedures and multiple duct-to-duct anastomosis were predictors of stricture recurrence.

FRI-540

Donor PNPLA3 rs738409 genotype is a risk factor of long-term graft survival after liver transplantation

Irena Mikova[1], Milan Jirsa[1], Eva Sticova[1], Jan Mares[1], Pavel Trunecka[1]. [1]*Institut Klinické a Experimentální Medicíny, Praha, Czech Republic*
Email: irena.mikova@ikem.cz

Background and aims: The variants rs738409 c.444C>G (p.I148M) in patatin-like phospholipase domain-containing 3 (PNPLA3) and rs58542926 c.499G>A (p.E167K) in TM6SF2 (transmembrane 6 superfamily member 2) are significant genetic risk factors of development and progression of metabolic dysfunction-associated steatotic liver disease (MASLD). The donor but not the recipient genotypes are crucial for MASLD development after liver transplantation (LT). Increased liver-specific mortality was described in both variants. The aim of the study was to evaluate the impact of the PNPLA3 rs738409 and TM6SF2 rs58542926 genotypes of the donor and the recipient on the long-term patient and graft survival after LT.
Method: We evaluated the patient and graft survival in the cohort of 268 adult LT recipients, in whose PNPLA3 rs738409 and TM6SF2 rs58542926 genotypes of the donor and recipient were available and steatosis/steatohepatitis was evaluated on liver graft biopsy 6–30 months after LT. The median follow-up was 17.0 years. The Kaplan-Meier model was used for the graft and patient survival estimates and the Cox proportional hazard model was used to assess the predictive value of the selected variables.
Results: In the multivariable analysis, recipient age (p < 0.001), male sex (p = 0.001), presence of hepatocellular carcinoma (p = 0.015) and grade of inflammation on the liver biopsy (p = 0.002) negatively influenced long-term patient survival; whereas donor PNPLA3 rs738409 genotype GG/GC vs CC (p = 0.009), male sex (p = 0.009), lower BMI (p < 0.001) and increased stage of fibrosis (p = 0.001) negatively impacted on graft survival. No impact of TM6SF2 rs58542926 genotypes on patient or graft survival was found.
Conclusion: The PNPLA3 c.444G variant of the donor has a negative impact on the long-term liver graft survival.

FRI-541

Validation of the RETREAT score for predicting hepatocellular carcinoma recurrence after liver transplantation: evidence from an Italian multicenter cohort

Leonardo Antonio Natola[1], Veronica Paon[2], Marco Vicardi[1], Aldo Filice[1], Andrea Dalbeni[3], Filippo Cattazzo[1], Lorenzo Canova[4], Eleonora Alimenti[4], Giulia Marini[5], Alex Borin[6], Daniele Dondossola[5], Amedeo Carraro[6], Massimo Iavarone[4], David Sacerdoti[2]. [1]*University of Verona, Department of Medicine, Verona, Italy;* [2]*Liver Unit, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy;* [3]*General Medicine C and Liver Unit, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy;* [4]*Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore, Milano, Italy;* [5]*General and Liver Transplant Surgery Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy;* [6]*Liver Transplant Unit, Azienda Ospedaliera Universitaria di Verona, Verona, Italy*
Email: leosna94@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) recurrence after liver transplantation (LT) remains a major determinant of post-transplant mortality, affecting up to 20% of recipients despite selection within the Milan criteria. The Risk Estimation of Tumor Recurrence After Transplant (RETREAT) score, developed by Mehta et al. (UCSF, USA) has shown excellent predictive performance in international and recent prospective validations but has never been evaluated in Italian transplant centers. This study aimed to validate the RETREAT score in an Italian multicenter cohort and assess its clinical applicability.
Method: We retrospectively analyzed 262 adults transplanted for HCC between 2010–2020 at two Italian centers (Verona and Milan). All patients met Milan criteria at listing. Predictors of recurrence and survival were analyzed using Cox and logistic regression. RETREAT discrimination was assessed using ROC analysis, Harrell's C-index, calibration, and decision curve analysis (DCA).
Results: Over a median follow-up of 83.2 months, 32 patients (12.2%) developed recurrence and 63 (24.0%) died (overall). Median survival after recurrence diagnosis was 23.5 months (IQR: 6.2–43.5). Pre-transplant locoregional therapy was performed in 80.5% of cases: 24 (9.2%) underwent downstaging, 102 (38.9%) bridge, and 85 (32.4%) had previous treatments in the past. Most of them were TACE (37.7%) and RFA (26.5%). Microvascula invasion (MVI) was the strongest recurrence predictor (OR 5.93, 95% CI 2.73–12.87, p < 0.001). RETREAT ≥3 was associated with a 6.7-fold higher recurrence risk (OR 6.72, 95% CI 2.88–15.68, p < 0.001) and remained independently associated in multivariable analysis (OR 3.97, 95% CI 1.23–12.27, p = 0.016). Exceeding Milan criteria on explant histology was not significant (p = 0.239). The score demonstrated excellent discrimination (AUC 0.774, C-index 0.77), good calibration, and positive net benefit on DCA across thresholds of 5–15%. Kaplan-Meier analyses highlighted: (Fig. 1) the strong impact of recurrence on overall survival (p < 0.0001); (Fig. 2) significantly worse RFS for high-risk patients (RETREAT ≥3) compared with low-risk (RETREAT ≤2) (p = 0.012).
Conclusion: This first Italian validation confirms the excellent prognostic accuracy and generalizability of the RETREAT score. RETREAT-based stratification allows effective identification of high-risk patients and supports personalized surveillance strategies across Italian transplant centers.

FRI-542

Quantifying the impact of liver graft dysfunction on kidney outcomes after liver transplantation: a retrospective multicenter longitudinal cohort study using the L-GrAFT risk score

Yu Nie[1], Jinbo Huang[2]. [1]*a General Surgery Center, Department of Hepatobiliary Surgery, Zhujiang Hospital, Southern Medical University, Guangzhou, China;* [2]*Organ Transplant Center, The First Affiliated Hospital, Sun Yat Sen University, Guangzhou, Guangzhou, China*
Email: nieyu19@foxmail.com

Background and aims: The relations between liver graft dysfunction and renal dysfunction is not fully described in liver transplantation (OLT). We performed a quantitative analysis to evaluate the impact of graft dysfunction on clinical trajectories of acute kidney injury (AKI) and long-term renal function using Liver Graft Assessment Following Transplantation (L-GrAFT) risk-score that could stratified graft dysfunction severity.
Method: This retrospective multicenter observational study included 1098 consecutive primary OLT patients from 5 tertiary teaching hospitals between January 2015 and December 2022. L-GrAFT risk-score was used to classify the severity of early graft dysfunction: good function (n = 316), mild dysfunction (n = 542), moderate dysfunction (n = 170) and severe dysfunction (n = 70). AKI was graded using KDIGO criteria. Patients were divided into different groups according to post-OLT renal and graft dysfunction. Perioperative renal-

associated outcomes and long-term survival were compared among different trajectories of AKI and graft dysfunction.
Results: 51.2% (n = 562) recipients developed AKI. 87.9% AKI occurred within 48 hours after OLT, with 40.2% AKI episodes developed during surgery. AKI rates in good, mild, moderate and severe graft dysfunction group were 41.5%, 48.5%, 60.0% and 94.3%. Renal-related outcomes including peak creatinine, AKI duration, AKI severity and rates of persistent AKI, RRT and MAKEs all significantly deteriorated as graft function deteriorated (P < 0.001). Mild (OR: 2.92 and 2.80), moderate (OR: 9.31 and 7.19) and severe (OR: 83.2 and 120.7) graft dysfunction were independent predictors of RRT requirement and MAKEs (P < 0.001). Patients combining both liver and renal dysfunction had significant inferior graft survival and increased MAKEs compared to those with only liver dysfunction (P < 0.001). Synergistic effects of severe graft dysfunction with severe AKI substantially elevated EAF risk, which was associated with the worst renal-related outcomes and one-year graft survival (adjusted HR 24.50, CI: 15.49–38.75, P < 0.001). Severe graft dysfunction with preserved renal function achieve an unexpectedly good prognosis (one-year graft survival 58.3%).
Conclusion: Different severities of graft dysfunction were associated with distinct clinical trajectories of renal dysfunction and survival outcomes. Simultaneous impairment of graft and renal function synergistically exacerbated OLT outcomes while preserved renal function could counteract the adverse effects of severe graft dysfunction.

Rejection rates after liver transplantation are not increased with hormonal contraceptive use
Helen Oberweis-Manion[1], Amy Shui[2], Cynthia Fenton[3], Grace Zhang[1], Monika Sarkar[1]. [1]*University of California San Francisco, Department of Medicine, Division of GI/Hepatology, San Francisco, United States;* [2]*University of California San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States;* [3]*University of California San Francisco, Department of Medicine, San Francisco, United States*
Email: elle.oberweismanion@ucsf.edu

Background and aims: Liver transplantation (LT) among reproductive-aged women is increasing, and fertility rapidly returns post-transplant. Hormonal contraception is highly effective at preventing unplanned pregnancy, though concerns persist regarding potential drug-drug interactions and graft rejection. We therefore aimed to evaluate the association of hormonal contraceptive exposure (CTE) and acute cellular rejection (ACR) after LT.
Method: We conducted a retrospective cohort study of reproductive-aged LT recipients followed at a tertiary transplant center from 1/2013–10/2025 to primarily assess the association ofhormonal contraceptive exposure (CTE) with biopsy-confirmed ACR, and secondarily with incident hypertension (HTN), venous thromboembolism (VTE), and myocardial infarction (MI). CTE was defined as at least 90 days of use, with study outcomes adjudicated to the CTE group if occurred within 90 days of last use. Study outcomes were compared between LT recipients with at least one CTE and LT-controls using Kaplan-Meier rates with log-rank tests or raw event percentages and counts with Fisher's exact tests, as appropriate.
Results: Amongst 416 reproductive-aged LT recipients, 157 (38%) had at least one CTE exposure; of these 157, 73 (46%) with combined hormonal contraception (CHC), 70 (45%) with progestin-only, and 83 (53%) with IUD use (76 hormonal, 7 copper). Median transplant age among CTE exposed and unexposed patients was 23.2 and 33.7 years, with a median follow-up of 14.9 and 10.6 years, respectively. Excluding copper IUDs, ACR but not incident HTN differed significantly by exposure group (log-rank test p = 0.001 for ACR, p = 0.14 for HTN). By 15 years since LT, ACR occurred in 15% vs. 27%, and HTN occurred in 19% vs. 26% of LT recipients in the exposed and unexposed groups, respectively. In LT recipients with vs without CTE, VTE occurred in 0.5% (1) vs 1.2% (3) and MI in 0.5% (1) vs. 0.4% (1) (p ≥ 0.99 for each).
Conclusion: Rates of biopsy-confirmed ACR in reproductive-aged LT recipients was no greater during periods of hormonal contraceptive exposure when compared to no contraceptive exposure. These agents were also not associated with greater risk for incident hypertension or thromboembolic events following LT. Findings support the safety of the breadth of hormonal contraceptive options in LT recipients to best support their reproductive wishes.

Outcomes of patients covertly/overtly consuming alcohol in the transplant assessment/waitlist period: a single centre experience
Helen O'Donovan[1], Francesca D'Arcangelo[1], Adnan Shabbir[1], Nicola Seaward[2], Alex Lawson[1], Charlotte Parker[1], Kerry Webb[1], Andrew King[1], Andrew Holt[1], Neil Rajoriya[1]. [1]*QEHB, Hepatology, Liver Transplant Unit, Birmingham, United Kingdom;* [2]*Dept. of Biochemistry, QEHB, United Kingdom*
Email: helsodon@gmail.com

Background and aims: Measurement of urine ethyl glucuronide (EtG) levels allows monitoring of abstinence in liver transplant (LT) wait listed patients. Testing positive on the wait list usually leads to removal with discharge of care to local physicians & often palliation. There remains limited data on long-term outcomes, including follow-up and potential for LT reassessments. The aim of this study was to assess outcomes for patients testing positive for active alcohol intake during the LT assessment pathway/wait list.
Method: Patients with positive EtG levels attending a quaternary LT centre, 2021–2025, were included. Those not seen by hepatology for potential LT assessment were excluded. Data collected included demographics, indications for referral, point at which turndown (removal from list/assessment process) occurred, follow-up and mortality. Patients may have been seen in a dedicated high intensity alcohol cirrhosis MDT clinic.
Results: 487 patients had positive EtG levels. 64 (13.1%) of those were seen in relation to LT assessment. 26 (40.6%) female, median age 52 (IQR 48–58). The median MELD 16 (IQR 11.5–19.5). 22 (34%) patients were seen in MDT clinic prior to LT assessment. 24 (37.5%) were found to have positive EtG before initiation of LT assessment and thus not considered eligible to proceed. Of the 40 patients who started a transplant assessment, 29 (72.5%) were turned down during the assessment process while 11 (27.5%) were listed for transplant and subsequently de-listed due to positive EtG. 1 patient was found to have positive metabolites on the day of LT. 5 (17.2%) of the 29 patients turned down during the assessment phase were seen for LT reassessment, 3 subsequently listed. 7/11 (63.6%) patients formally de-listed were ultimately referred back to the local team with no re-referrals for LT. 24 (37.5%) patients died.
Conclusion: Sadly, patients with advanced ArLD still covertly drink alcohol during work up for transplant, despite input from a dedicated high intensity alcohol cirrhosis MDT clinic in several cases. None of those with positive metabolites on the wait list were re-referred following discharge to their local teams. However, a small number of those found to have evidence of alcohol intake during the original LT assessment were considered for re-evaluation and LT in our centre. Ongoing alcohol relapse prevention in ArLD patients remains key on the wait list and during assessment. The establishment of a standardised testing pathway/protocol nationally will be of benefit.

FRI-546

Comparative waitlist and early post-transplant outcomes in asian vs. non-asian liver transplant candidates: a propensity-matched UNOS analysis (2014–2024)

Mangesh Pagadala[1], Suvisesh Pothuraju[2], Sajid Jalil[3], Nimish Thakral[4], Chencheng Xie[5], Yong-Fang Kuo[6], Ashwani Singal[2]. [1]*Liver Institute -Methodist Dallas Medical Center, Dallas, United States;* [2]*University of Louisville, Louisville, United States;* [3]*Standford University, Palo Alto, United States;* [4]*University of Lexington, Lexington, United States;* [5]*The University of Iowa, Iowa City, United States;* [6]*University of Texas Medical Branch, Galveston, United States*
Email: mangeshpagadala@mhd.com

Background and aims: Asian individuals represent a growing segment of Liver transplant (LT) candidates in the United States, yet contemporary data evaluating whether they experience differences in waitlist mortality or early post-transplant outcomes remain limited. This study evaluated waitlist mortality and early (1-year) post-transplant outcomes among Asian vs. non-Asian LT candidates using a large national dataset.
Method: Using the UNOS/OPTN database (2014–2024), we identified adult LT candidates and recipients. Pediatric cases and multi-organ transplants were excluded. Propensity score matching (PSM) was performed comparing Asians with Non-Hispanic Whites (NHW), African Americans (AA), Hispanic Whites (HW), and American Indians (AI). Matching variables included demographics, comorbidities, liver disease etiology, MELD components, and listing characteristics. Primary outcomes were waitlist mortality and 1-year post-transplant patient survival.
Results: Among 194,535 adult LT listings, 7,568 (3.9%) were Asian candidates. In unadjusted analyses, Asians had lower waitlist mortality compared with AA (HR 0.80; 95% CI 0.71–0.89), HW (HR 0.81; 95% CI 0.73–0.90), and AI (HR 0.78; 95% CI 0.64–0.94). After PSM, Asians experienced similar waitlist mortality compared with NHW (HR 0.90; 95% CI 0.76–1.05), AA (HR 0.89; 95% CI 0.76–1.05), and HW (HR 0.85; 95% CI 0.73–1.00). However, Asians remained at alower risk of waitlist mortality vs. AI (HR 0.74; 95% CI 0.56–0.97). Post-transplant outcomes showed important contrasts. Compared with AA recipients, Asians demonstrated significantly better 1-year graft (HR 0.83; 95% CI 0.71–0.98) and patient survival (HR 0.80; 95% CI 0.66–0.96). In contrast, Asians had no significant differences in 1-year graft or patient survival when compared with NHW, HW, or AI (all $p > 0.20$). Kaplan Meier analyses revealed no differences in survival across these matched cohorts. Hepatits B was more prevalent among Asian recipients, while MASLD and alcohol-associated liver disease were less common.
Conclusion: In this national UNOS analysis, Asian LT candidates in the US have similar waitlist mortality comparing to most of major racial and ethnic groups, except for lower waiting mortality than American Indian. Post- transplant graft and patient survival were better in Asians as compared to African Americans and similar to NHW, HW, and AI. These findings support overall equity in contemporary transplant outcomes while highlighting population-specific disparities that warrant further investigation.

FRI-547

Accuracy, feasibility, and nursing workload of continuous glucose monitoring in liver transplant recipients in the intensive care unit

Marc Pañero Moreno[1,2,3], Richie Alexander Inge Cox[1,2,4], Enric Tomas Franch[1], Alberto Villamor Ordozgoiti[1,3], Eva Maria Guix Comellas[3], Fatima Aziz[1]. [1]*Hospital Clinic of Barcelona, Barcelona, Spain;* [2]*Fundació de Recerca Biomedica Clinic - Institut d'Investigació Biomédical August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain;* [3]*Departament of Fundamental and Clinical Nursing, University of Barcelona, Barcelona, Spain;* [4]*European Foundation for the Study of Chronic Liver Failure (EF CLIF), Barcelona, Spain*
Email: panero@clinic.cat

Background and aims: Hyperglycemia affects over 90% of liver transplant (LT) recipients in the Intensive Care Unit (ICU) due to metabolic and surgical stress and immunosuppressive therapy. Continuous Glucose Monitoring (CGM) has shown good analytical performance in ambulatory patients with diabetes, but its accuracy and safety remain insufficiently investigated in critically ill LT recipients. Current guidelines do not endorse its routine inpatient use, and a consensus on accuracy is lacking; a Mean Absolute Relative Difference (MARD) below 15% is generally considered acceptable, and compliance with the Diabetes Technology Society (DTS) Error Grid requires at least 98% of values within zones A and B. This study aimed to evaluate the analytical accuracy and bedside feasibility of a CGM compared with nurse-performed Point-of-Care glucose (POC-G) measurements in LT patients in the ICU, and to explore its impact on workflow.
Method: A single-blind randomized clinical trial was conducted at the Hospital Clinic of Barcelona (CGM-UCI23 project). A CGM sensor was placed on the upper arm of LT recipients, and glucose readings were paired with nurse-performed POC-G measurements. Accuracy and safety were evaluated using the DTS Error Grid and MARD, providing comprehensive metrics of accuracy, clinical utility, and safety in the ICU setting. Nursing workload reduction was quantified by measuring the time required to obtain POC-G measurements (based on 20 random determinations) and comparing this with CGM use.
Results: The CGM sensor was worn for a mean of 5 days and remained active for 98.9% of the monitoring period. CGM showed excellent accuracy performance, with a MARD of 12.1% and 99.6% of readings falling within the safe zones of the DTS Error Grid. The CGM group required significant fewer daily POC-G tests (3.17 ± 2.15 vs 6.37 ± 1.78, $p < 0.001$) and fewer fingerstick samples (9.11 ± 26.1 vs 45.2 ± 70.2, $p < 0.001$) than controls. Overall, CGM produced 49,670 glucose readings versus 2,089 POC-G measurements, delivering a much denser glycemic profile while reducing bedside testing burden. On average, 50.68 POC-G tests and an estimated 43.56 minutes of nursing time were saved per patient during the ICU stay, underscoring the impact of CGM on nursing workload.
Conclusion: CGM is accurate, feasible, and significantly reduces nursing workload in LT recipients in the ICU while improving glycemic control. These findings support CGM implementation in ICU with LT recipients admitted to the ICU, to optimize workflow and patient safety.

FRI-548

Evolution of MASLD with and without alcohol consumption and comorbidity profile in liver transplant candidates over two decades

Simona Parisse[1], Erika Coltorti[2], Flaminia Ferri[2], Fabio Melandro[3], Quirino Lai[3], Federica Masciocchi[2], Giulia Bergamin[2], Gianluca Mennini[3], Massimo Rossi[3], Stefano Ginanni Corradini[2]. [1]*Department of Wellbeing, Health and Environmental Sustainability, Sapienza University of Rome, Rieti, Italy;* [2]*Department of translational and precision medicine, Sapienza University of Rome, Rome, Italy;* [3]*General Surgery and Organ Transplantation Unit, Sapienza University of Rome, Rome, Italy*
Email: simona.parisse@gmail.com

Background and aims: The liver transplantation (LT) landscape has substantially evolved over the past decades due to the rising prevalence of metabolic syndrome and the decline of HCV due to direct-acting antivirals (DAAs). Therefore, the complexity of LT candidate evaluation has increased. We aimed to assess the impact of epidemiological shifts on LT waiting list composition over a 20-year period, focusing on disease etiology and extrahepatic comorbidity burden as measured by the Charlson Comorbidity Index (CCI).
Method: All consecutive patients with cirrhosis and non-urgent indications for LT who were listed between 2005 and 2024 at our LT center were retrospectively analyzed and stratified into pre-DAA (2005–2014) and post-DAA (2015–2024) eras. The CCI was calculated, as previously described, based on nine extrahepatic comorbidities.

CCI was analyzed both as a continuous variable and as a categorical variable. Multivariable linear regression was used to identify factors independently associated with CCI.
Results: A total of 491 patients were listed for LT, including 200 (41%) in the post-DAA era and 291 (59%) in the pre-DAA era; of these, 55% and 60%, respectively, underwent transplantation from deceased donors. Over 20 years, pure MASLD etiology increased from 2.4% to 17.4%, and Met-ALD (MASLD and alcohol-related cirrhosis) from 7.1% to 22.4%, with a concomitant reduction in pure alcohol-related cirrhosis (from 20.0% to 8.6%). MASLD and MetALD were not significantly associated with the probability of undergoing LT. Higher CCI categories were more frequent post-DAA (CCI 0: 59% vs 40%; CCI 1–2: 31% vs 40%; CCI >3: 9% vs 20%; p = 0.001). Regarding LT indications, HCC (57% vs 41%, p = 0.001) and other MELD exceptions (10% vs 1%, p < 0.001) were more common in the post-DAA era. On multivariable linear regression, CCI was independently associated with MASLD etiology (B = 1.307, 95% CI 1.085–1.529, p = 0.001), older age (B = 0.022, 95% CI 0.010–0.035, p = 0.002), and male sex (B = 0.344, 95% CI 0.081–0.607, p = 0.009), and inversely associated with HCC (B = –0.338, CI 95% –0.558 – –0.118, p = 0.003).
Conclusion: The LT waiting list has substantially changed; the prevalence of pure MASLD rose seven-fold and MetALD tripled, marking a move toward indications less reliant on MELD. The rising burden of extrahepatic comorbidities, driven by older age and metabolic disease, highlights the need for more comprehensive pre-transplant evaluation, while evolving LT indications may challenge MELD-based prioritization.

FRI-553
Development and external validation of the MEAF ALT/AST continuous model: a universal tool for assessing early allograft dysfunction in liver transplantation
Carmen Payá Llorente[1], Miriam Cortes Cerisuelo[2], Marina Berenguer[3], Guillermo Quintas Soriano[4], Shubhangi Mehta[2], Eugenia Pareja Ibars[1]. *[1]Hospital Universitario Doctor Peset, Valencia, Spain; [2]King's College Hospital, London, United Kingdom; [3]Hospital Universitario y Politécnico La Fe, Valencia, Spain; [4]Leitat Technological Center, Health and Biomedicine, Barcelona, Spain*
Email: carmenpayallorente@gmail.com

Background and aims: To reduce waitlist mortality, expanded donor criteria are used in liver transplantation (LT). This increases the risk of early allograft dysfunction (EAD); however, the lack of a standardized definition for EAD makes comparing its prevalence and evolution difficult. Among the proposed models, the MEAF (Model for Early Allograft Function) stands out. It continuously evaluates graft function during the first post-LT days with a score, based on the International Normalized Ratio (INR), alanine aminotransferase (ALT), and bilirubin levels.
The main objective of this study is to design a continuous model based on the MEAF, calculated daily during the early post-LT period, using either ALT or aspartate aminotransferase (AST) interchangeably alongside INR and bilirubin, making it applicable to the majority of transplant recipients.
Method: A retrospective observational study with consecutive sampling was conducted using a prospective database, an external valitarion were performed. Clinical, surgical, and analytical data from donors and recipients were evaluated. The model, MEAF ALT/AST, was calculated using eight equations between post-LT days 2 and 5, interpolating biochemical values into sigmoidal regressions to obtain scores from 0 to 10, grouped into five grades of function. We analyzed its correlation with the standard MEAF, its applicability in Donation after Circulatory Death (DCD) donors, and its ability to predict graft survival at 10 and up to 90 days.
Results: The study included 1,351 LTs in 1,315 recipients. Results showed a correlation between the standard MEAF and the MEAF ALT/AST, confirming its applicability to DCD donors. The predictive capacity of the model for 10-day survival was excellent (AUC > 0.8), similar to the standard MEAF, and slightly lower at 90 days. External validation performed on 688 LTs (675 recipients) confirmed its utility. As a practical contribution, a web application has been developed to calculate the MEAF ALT/AST and visualize graft function trends in real-time, facilitating its implementation in clinical practice.
Conclusion: The MEAF ALT/AST is a continuous model that allows for the assessment of initial graft function in the first post-LT days, applicable to non-conventional donors and recipients. The ability to use ALT or AST interchangeably increases accessibility and reproducibility, facilitating early therapeutic decision-making and the benchmarking of results between centers.

FRI-554
Dynamic liver stiffness predicts recurrent cirrhosis and mortality after liver transplantation: a longitudinal joint modelling study
Jassin Rashidi-Alavijeh[1], Nargiz Nuruzade[2]. *[1]Department of Gastroenterology and Hepatology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, Department of General, Visceral and Transplantation Surgery, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, Essen, Germany; [2]Department of Gastroenterology and Hepatology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, Essen, Germany*
Email: jassin.rashidi@uk-essen.de

Background and aims: Recurrent graft fibrosis and cirrhosis remain major determinants of long-term outcomes after liver transplantation (LT). Transient elastography–derived liver stiffness measurement (LSM) predicts prognosis in chronic liver disease, but post-LT data are limited and often rely on single time points without accounting for competing risks. We investigated whether longitudinal LSM dynamics independently predict recurrent cirrhosis and mortality after LT using joint modelling.
Method: We performed a retrospective longitudinal cohort study including adult LT recipients with ≥2 reliable LSMs obtained ≥2 years post-LT at University Hospital Essen (2005–2024; follow-up until 2025). Recurrent cirrhosis was defined by graft biopsy; secondary endpoint was all-cause mortality. LSM trajectories were analysed using linear mixed-effects models and linked to time-to-event outcomes via joint models using the current value of log-transformed LSM. Multivariable models were adjusted for diabetes, body mass index, steatosis, sex, age and relapse of primary disease. A competing-risk joint model estimated separate associations for recurrent cirrhosis and death. Discrimination was assessed using time-dependent AUCs.
Results: The cohort comprised 249 LT recipients contributing 2,773 person-years and 1,801 reliable LSMs; median follow-up was 11.2 years. Thirty-nine patients developed biopsy-proven recurrent cirrhosis and 60 died. Higher current log-LSM was strongly associated with recurrent cirrhosis (adjusted association parameter $\alpha = 2.71$, 95% CI 1.81–3.72; p < 0.001). A 20%, 50% and 100% increase in LSM corresponded to hazard ratios (HRs) of 1.61, 2.98 and 6.54, respectively. Model discrimination was good (AUC 0.72 at 5 years; 0.66 at 10 years). Current log-LSM also independently predicted mortality. In competing-risk joint models, a 20% increase in LSM was associated with HRs of 1.38 for recurrent cirrhosis and 1.40 for death. Inclusion of the annual LSM slope did not improve prognostic performance.
Conclusion: Longitudinally modelled current LSM is a strong, independent predictor of both recurrent cirrhosis and mortality after LT. These findings support the integration of serial LSM into

structured post-transplant risk stratification and surveillance strategies.

FRI-555

Etiology-specific patterns of long-term cognitive recovery after liver transplantation: insights from a cross-organ comparison

Joanna Raszeja-Wyszomirska[1], Maciej Miarka[1], Aleksandra Golenia[1], Piotr Olejnik[1], Magdalena Grusiecka-Stańczyk[1], Jolanta Małyszko[1], Marta Zalewska[1]. [1]*Medical University of Warsaw, Warsaw, Poland*
Email: jorasz@gmail.com

Background and aims: Cognitive impairment (CI) is increasingly recognized as a clinically relevant determinant of outcomes after solid organ transplantation. Previous studies have demonstrated cognitive deficits in patients with advanced liver and kidney disease before transplantation and during the early post-liver transplant period, with pronounced impairments in language and executive domains among patients with alcohol-associated liver disease (ALD)[1, 2]. We aimed to characterize organ- and etiology-specific patterns of long-term cognitive recovery after liver transplantation using a cross-organ comparison with kidney transplant recipients.
[1] doi:10.3389/ti.2025.12869 [2] doi:10.1002/brb3.3647.
Method: Adult kidney transplant recipients (KTx; n = 90; median follow-up 100.5 days) and liver transplant recipients (LT; n = 90; median follow-up 1476.0 days) completed Addenbrooke's Cognitive Examination III (ACE-III). LT was stratified into ALD (n = 25) and non-ALD etiologies (n = 65). CI was defined as ACE-III < 85 points. Group differences used Kruskal–Wallis with post-hoc Mann–Whitney U (Holm adjustment). Multivariable models adjusted for age, education and time since transplantation.
Results: Global ACE-III showed a three-group gradient: KTx 90.3 ± 8.7, LT non-ALD 89.3 ± 6.5 and LT ALD 86.9 ± 12.5 points. Overall differences were significant (Kruskal–Wallis p = 0.047). Pairwise comparisons suggested lower ACE-III in LT ALD versus KTx (unadjusted p = 0.039), but no pairwise contrast remained significant after Holm adjustment. CI prevalence (ACE-III < 85) was 16.7% in KTx, 16.9% in LT non-ALD and 24.0% in LT ALD (chi-square p = 0.68). Attention remained high across groups (means 93.0 to 94.5 points). Memory and visuospatial scores were relatively preserved, whereas verbal fluency showed the lowest means (KTx 82.9, LT non-ALD 80.9, LT ALD 78.7 points). In multivariable linear regression, education was positively associated with ACE-III (beta = 0.93 points per education-year, p < 0.001) and age was negatively associated (beta = – 0.12 points per year, p = 0.017); time since transplantation were not independent predictors.
Conclusion: This study fills an evidence gap by characterizing long-term cognition after liver transplantation and benchmarking it against early post kidney transplantation. Global cognition is largely preserved, but ALD recipients show the lowest performance and the highest CI prevalence, supporting structured post-transplant cognitive monitoring and targeted rehabilitation.

FRI-556

Risk factors for T-cell mediate rejections after liver transplantation

Florian Rennebaum[1], Martin McCoy[1], Michael Praktiknjo[1], Philipp Houben[2], Felix Becker[2], Frank Uschner[1], Andreas Pascher[2], Jörn Arne Meier[1], Maximilian Joseph Brol[1], Tina Schomacher[1], Lena Wolters[1], Josune Cabello Calleja[1], Jan Hähner[1], Jonel Trebicka[1,3]. [1]*Universitätsklinikum Muenster, Department of Medicine B, Gastroenterology, Hepatology, Endocrinology and Infectiology, Muenster, Germany;* [2]*Universitätsklinik Münster, Department of General, Visceral and Transplant Surgery, Münster, Germany;* [3]*European Foundation for the Study of Chronic Liver Failure-EF Clif, Barcelona, Spain*
Email: florian.rennebaum@ukmuenster.de

Background and aims: Orthotopic liver transplantation (OLT) is the treatment of choice for complications of liver cirrhosis and hepatocellular carcinoma (HCC). A common complication in the first days to months after OLT is acute T-cell mediated rejection (TCMR), which can occur in up to 10–30% of recipients after OLT. Treatment consists of high-dose prednisolone therapy over 1–3 days. The causes of TCMR are heterogeneous. The aim of the study is the evaluation of possible risk factors for the development of TCMR in order to optimize immunosuppression.
Method: A monocentric retrospective data analysis was performed on patients who underwent OLT between 2020 and 2025. Various parameters (MELD score, presence of acute-on-chronic liver failure (ACLF), HCC, immunosuppression) were evaluated. The primary endpoint was the development of TCMR. Exclusion criteria were follow-up < 4 weeks, combined organ transplants, and immuntherapy (ICI) prior to liver transplantation. A p-value of <0.05 was considered statistically significant.
Results: A total of 273 patients were included. The leading etiology of cirrhosis was alcohol related liver disease (ArLD) (59 patients; 21.7%), followed by autoimmune liver diseases (AILD) including autoimmune hepatitis (AIH), primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) (56 patients; 20.6%). A total of 59 patients (21.7%) had ACLF and 62 patients (22.8%) underwent transplantation due to hepatocellular carcinoma. The median follow-up was 24 months (10–46.5). A total of 46 patients developed TCMR during follow-up (16.9%). In multivariate logistic regression analysis, patients with autoimmune liver disease showed a significantly increased risk of developing rejection (OR 5.44; 95% CI 2.46–12.05; p = 0.001). The presence of HCC was independently associated with a lower probability of rejection (OR 0.32; 95% CI 0.15–0.70; p = 0.002). Normothermic machine perfusion showed a non-significant trend toward a reduced rejection rate in multivariate logistic regression analysis (OR 0.53; 95% CI 0.26–1.07; p = 0.077).
Conclusion: Patients with autoimmune liver diseases appear to have an increased risk of developing TCMR after OLT. Normothermic machine perfusion showed a trend toward lower rejection rates. These patients should be monitored closely for rejection. Further prospective multicenter studies are needed to identify additional risk factors.

FRI-557

Optimising liver transplant candidates through prehabilitation and rehabilitation: preliminary 6-month findings

Jesús Rivera Esteban[1], Victor Valverde[1], Ana Duca[1], Laura Benitez[1], Maria Trapero[1], Ana Arias[1], Natalia Fernandez Puga[1], Enrique Fraga[1], José Luis Calleja Panero[1]. [1]*Hospital Universitario Puerta De Hierro Majadahonda, Majadahonda, Spain*
Email: jesusriveraest@gmail.com

Background and aims: Sarcopenia and frailty are highly prevalent among liver transplantation (LT) candidates and contributed to increased morbidity, mortality, and diminished quality of life. Structured prehabilitation and rehabilitation programmes offer a promising approach to strengthen patients before LT and support a smoother, more effective recovery afterwards. We aim to evaluate the effects of a structured prehabilitation and rehabilitation programme on body composition, frailty and LT-related complications from listing to one year after LT. Results at 6 month follow-up after LT are presented.
Method: We evaluated every LT candidate enlisted at our centre between August 2023 and July 2025 using CT scan, bioelectrical impedance analysis (BIA) and handgrip strength at listing, monthly on WL, at discharge, 3,6 and 12 months post-LT. All patients received nutritional counselling and structured exercise intervention. Sarcopenia was defined as a fat-free mass index <17 kg/m^2 in men or <15 kg/m^2 in women and/or handgrip <27 kg in men or <16 kg in women. A Liver Frailty Index (LFI) >4.5 indicated frailty. Anthropometric changes, sarcopenia, and frailty were analysed using paired Student's t-tests and McNemar's tests.
Results: Mean age for the 25 patients with 6-month post-LT follow-up was 60.4 years, 20% were women, and obesity, hypertension, type 2 diabetes, and dyslipidaemia rates were 64%, 48%, 40%, and 24%,

respectively. Mean MELD score was 15.6, being SLD the most common etiology (64%). No differences in body composition parameters were found in the WL (median WL stay, 94 days). LT surgery and hospitalization resulted in significant declines in lean mass and strength at discharge ($p < 0.001$ for both), with graft-related complications and longer hospital stays associated with ≥10% muscle loss. Compared to discharge, at 6-months post LT muscle mass (47.2 vs 49.4 kg, p0.014), handgrip (26.2 vs 31.5, $p < 0.001$) and LFI (3.98 vs 3.11, p0.004) statistically improved, especially in women. Frailty and sarcopenia rates ranged from 28.6/32% at baseline to 52/52% at discharge and 5.9/35% 6-mo after LT.

Conclusion: Prehabilitation seems to mitigate functional decline before LT. Although LT results in substantial early loss of lean mass and function, especially in the context of complications or prolonged hospitalisation, post-LT rehabilitation delivers rapid and meaningful recovery, resolving frailty. These findings strongly support the systematic implementation of structured pre and post LT rehabilitation strategies.

FRI-558

Excluding ascites from the GEMA-Na score does not impact outcome predictions in liver transplant candidates

Manuel Rodríguez-Perálvarez[1], Antonio M. Gómez-Orellana[2], Avik Majumdar[3], Geoff McCaughan[4], Maria Kalafateli[5], Rhiannon Taylor[6], Gloria de la Rosa[7], Victoria Aguilera Sancho[8], Mikel Gastaca[9], Carmen Cepeda Franco[10], María Luisa Ortiz[11], Jordi Colmenero[12], Alejandra Otero[13], Rocio González-Grande[14], Alba Cachero[15], Esther Molina[16], Mónica Barreales Valbuena[17], Rosa Martin-Mateos[18], Maria Rodriguez Soler[19], Mario Romero[20], Cristina Dopazo[21], Carmen Alonso Martin[22], Elena Oton[23], Maria Luisa Gonzalez Dieguez[24], María Dolores Espinosa Aguilar[25], Ana Arias[26], Gerardo Blanco[27], Sara Lorente Perez[28], Antonio Cuadrado[29], Miguel Sogbe[30], David Guijo-Rubio[2], César Hervás[2], Emmanuel Tsochatzis[31]. *[1]Hospital Universitario Reina Sofía, CORDOBA, Spain; [2]Universidad de Córdoba, Córdoba, Spain; [3]University of Melbourne, Melbourne, Australia; [4]Royal Prince Alfred Hospital, Sydney, Australia; [5]General Hospital of Patras, Patras, Greece; [6]NHS Blood and Transplant, Bristol, United Kingdom; [7]Organización Nacional de Trasplantes, Madrid, Spain; [8]Hospital Universitario La Fe, Valencia, Spain; [9]Hospital Universitario Cruces, Bilbao, Spain; [10]Hospital Virgen del Rocío, Seville, Spain; [11]Hospital Universitario Virgen Arrixaca, Murcia, Spain; [12]Hospital Clínic, Barcelona, Spain; [13]Hospital Universitario A Coruña, A Coruña, Spain; [14]Hospital Regional Universitario de Málaga, Málaga, Spain; [15]Hospital Universitario de Bellvitge, Hospitalet De Llobregat, Spain; [16]Hospital Universitario Santiago de Compostela, Santiago de Compostela, Spain; [17]Hospital 12 de Octubre, Madrid, Spain; [18]Hospital Ramón y Cajal, Madrid, Spain; [19]Hospital General Universitario de Alicante, Alicante, Spain; [20]Hospital General Universitario e Instituto de Investigación biomédica Gregorio Marañón, Madrid, Spain; [21]Vall d'Hebron Hospital Universitari, Barcelona, Spain; [22]Hospital Rio Hortega, Valladolid, Spain; [23]Hospital Virgen de la Candelaria, Tenerife, Spain; [24]Hospital Universitario Central de Asturias, Oviedo, Spain; [25]Hospital Virgen de las Nieves, Granada, Spain; [26]Hospital Universitario Puerta de Hierro, Madrid, Spain; [27]Hospital Universitario de Badajoz, Badajoz, Spain; [28]Hospital Universitario Lozano Blesa, Zaragoza, Spain; [29]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [30]Clinica Universidad de Navarra, Pamplona, Spain; [31]Royal Free Hospital, London, United Kingdom*
Email: ropeml@hotmail.com

Background and aims: Although GEMA-Na outperforms MELD 3.0, concerns about the subjectivity of its ascites component persist. We compared the performance of a GEMA-Na iteration that excludes ascites with other allocation scores to predict waiting list outcomes among liver transplant candidates.

Method: A multinational cohort study was conducted, including adult candidates for elective liver transplantation in the UK (2010–2020), Australia (1998–2020), and Spain (2016–2021). The primary outcome was mortality or delisting due to clinical worsening within the first 90 days. The prognostic impact of ascites was evaluated using multivariable Cox's regression. The discrimination of allocation scores was assessed using Harrell's c-statistics (Hc).

Results: The study included 15,391 patients (28.5% women). The prevalence of the primary outcome was 5.8% in the UK, 5.3% in Australia, and 4.7% in Spain. The presence and severity of ascites was associated with an incremental risk of the primary outcome: 3.3% without ascites, 5.8% with mild ascites, and 7.7% with moderate-severe ascites ($p < 0.001$). Removal of ascites from the GEMA-Na score resulted in a one-point reduction in 18% of patients (52.4% of patients with moderate-severe ascites). No patient showed a difference of two or more score points after removing ascites. GEMA-Na without ascites showed only a marginal decrease in discrimination (Hc = 0.755 vs. Hc = 0.753; $p = 0.007$) but still significantly outperformed MELD 3.0 (Hc = 0.734; $p < 0.001$) and MELD-Na (Hc = 0.737; $p < 0.001$). In women, GEMA-Na with and without ascites demonstrated comparable discrimination (Hc = 0.784 vs. Hc = 0.783; $p = 0.61$), both outperforming MELD 3.0 (Hc = 0.750; $p < 0.001$), and MELD-Na (Hc = 0.749; $p < 0.001$). In the multivariable Cox's regression analysis including each score sequentially, patients with moderate-severe ascites had increased risk of the primary outcome in presence of MELD-Na (HR = 1.166; 95%CI 1.008–1.348; $p = 0.038$) and MELD 3.0 (HR = 1.28; 95%CI 1.092–1.472; $p = 0.002$), but not in presence of GEMA-Na, either with or without ascites (HR = 0.985; 95%CI 0.850–1.141; $p = 0.84$ and HR = 1.073; 95%CI 0.927–1.242; $p = 0.34$, respectively).

Conclusion: Despite the prognostic impact of ascites among liver transplant candidates, GEMA-Na without ascites outperformed other scores in predicting waitlist outcomes and may be used wherever the inclusion of ascites is considered too subjective.

FRI-559

Development and pilot study of a telemedicine model (TXMobile App) to support the after-care of patients after liver transplantation

Angelika Rzepka[1], Kristina Reiter[2], Elisabeth Kletz[3], Sabine Koller[4], Susanna Trummer[4], Moritz Kniepeiss[4], Peter Kastner[2], Günter Schreier[1], Robert Sucher[4,4], Daniela Kniepeiss[4,5]. *[1]AIT Austrian Institute of Technology GmbH, Digital Health Information Systems Center for Health & Bioresources, Graz, Austria; [2]Telbiomed Medizintechnik und IT Service GmbH, Graz, Austria; [3]Medizinische Universität Graz, Department for General, Visceral and Transplant Surgery, Graz, Austria; [4]Medizinische Universität Graz, Graz, Austria; [5]Division for General, Visceral and Transplant Surgery, Graz, Austria*
Email: angelika.rzepka@ait.ac.at

Background and aims: The long-term success of liver transplantation depends on structured and continuous postoperative follow-up care. To support patients in their daily self-management after liver transplantation, we developed the transplant application *TXMobile*.

Method: Results and experiences from a previously conducted study were used as basis for the development of the new app. With participative methods like focus group meetings, questionnaires, and targeted interviews we conducted three different care plans for different stages after transplantation. Items of the different care plans represent the look of the *TXMobile* data management system (DMS) for professional users and the look of the patient's app flexibly, while providing the usability to manage the extent of after-care patients in the outpatient department. Since February 2025, a pilot study has enrolled 60 liver transplant recipients to comprehensively evaluate the app under real-world clinical conditions. In addition to assessing the technical stability and practical feasibility of the defined care plans, particular emphasis was placed on evaluating patients' quality of life and the usability of the application.

Results: The transplant app *TXMobile* comprises an individualized list of medication, a reminder for medication intake, calendar function

for standard visits and reminders for follow-up examinations in the outpatient department as well as in the routine healthcare system. Furthermore, it offers telemonitoring options for e.g. blood pressure. All information attains the DMS in a structured way based on internationals standards (e.g. SNOMED) and can be registered in the national electronic health record ELGA. Feedback of the pilot-study indicated overall good usability of the *TXMobile* app, particularly regarding clarity, intuitiveness, and accessibility for older users. The qualitative and quantitative results obtained during the pilot study provided a basis for targeted refinements and highlight the potential value of the solution for patient-centered, quality-assured post-transplant care.

Conclusion: The *TXMobile* app may support structured post-transplant after-care by facilitating adherence, self-management, and lifestyle optimization. Furthermore, it could reduce outpatient follow-up visits and help manage staff workload amid increasing transplant numbers and longer post-transplant follow-up. Future steps include further app refinement and evaluation for routine clinical implementation.

FRI-560

Post-transplant statin therapy improves long-term survival and lipid trajectories after liver transplantation

Sanjaya Satapathy[1], Mohammad Shadab Siddiqui[2], Mary E. Rinella[3], Danielle Brandman[4], Coleman I. Smith, MD[5], Jason Vanatta[6], Nghiem Ha[7], Amanda Cheung[8], Kymberly Watt[9]. *[1]North Shore University Hospital, Manhasset, United States; [2]University of Virginia, Charlottesville, United States; [3]The University of Chicago Medicine, Chicago, United States; [4]Center For Liver Disease & Transplantation, New York, United States; [5]MedStar Georgetown Transplant Institute, Washington, DC, United States; [6]University of Louisville School of Medicine, Louisville, United States; [7]University of California, San Francisco, United States; [8]Northwestern University Feinberg School of Medicine, Chicago, IL, USA, Chicago, United States; [9]Mayo Clinic, Rochester, MN, USA, Rochester, United States*
Email: ssatapat@northwell.edu

Background and aims: Dyslipidemia is prevalent after liver transplantation (LT), yet the role of statin therapy in managing long-term lipid profiles and survival outcomes remains under-explored. We investigated whether post-transplant statin use is associated with improvements in lipid trajectories and survival over 15 years.

Method: We analyzed 152 adult LT recipients with complete lipid panel data from 6 months to 15 years post-LT. Outliers in lipid changes were excluded using ± 3 × IQR thresholds. Patients were stratified by post-LT statin use. We used generalized linear models (GLMs) to assess 1-year lipid changes and Cox regression for 10- and 15-year survival. Longitudinal mixed models assessed lipid trajectories. Kaplan-Meier (KM) survival curves were generated by statin use.

Results: Post-transplant statin therapy was initiated in 38% of patients. At one year, statin users experienced significantly greater reductions in total cholesterol ($\beta = -30.2$ mg/dL, $p = 0.007$) and triglycerides ($\beta = -97.3$ mg/dL, $p = 0.002$), while changes in LDL ($\beta = -38.7$ mg/dL, $p = 0.17$) and HDL ($\beta = -3.5$ mg/dL, $p = 0.80$) were not statistically significant. Longitudinal mixed-effects modeling demonstrated that statin use significantly modified the trajectory of LDL and total cholesterol over time ($p < 0.01$), contributing to more favorable long-term lipid profiles. Triglyceride levels tended to rise in non-users but stabilized or declined among statin users. Kaplan-Meier survival curves showed improved long-term survival among statin users, although the difference was not statistically significant by the log-rank test ($p = 0.10$). However, in adjusted Cox proportional hazards models, statin use was independently associated with a 4.6-fold reduction in 15-year mortality risk (HR = 0.22; 95% CI: 0.06–0.76; $p = 0.017$). Additionally, lower LDL and higher HDL changes were protective, while increases in total cholesterol were linked to greater mortality risk ($p < 0.05$).

Conclusion: Post-transplant statin therapy is associated with significantly improved lipid profiles and long-term survival following LT. These findings support broader statin use in eligible LT recipients and highlight the utility of longitudinal lipid monitoring.

FRI-561-YI

Hepatic iron overload in explants: associations with underlying liver disease indication and disease severity

Roxanna Sharifi[1], Yinan Su[1], Paul Paik[2], Andrew John Cruz[3], Daanyaal Kumar[3], Kalpana Gopalkrishnan[1], Niveda Balemurughan[1], Derek Samson[4], Jeffrey Kahn[2], Norah Terrault[2], Liyun Yuan[2]. *[1]Keck School of Medicine, University of Southern California, Los Angeles, United States; [2]Division of Gastroenterology and Liver Diseases, University of Southern California Keck School of Medicine, Los Angeles, CA, United States; [3]Department of Medicine, Keck School of Medicine, University of Southern California, Los Angeles, United States; [4]Transplant Institute, Keck Medicine of USC, University of Southern California, Los Angeles, United States*
Email: rsharifi@usc.edu

Background and aims: Hepatic iron deposition is commonly observed in liver transplant explants; however, its clinical determinants and relevance in advanced liver disease, particularly MASLD, remain unclear. We aimed to evaluate the association between hepatic iron deposition, liver disease etiology, and disease severity, and to examine the contribution of metabolic factors in hepatic iron.

Method: We conducted a retrospective analysis of adult liver transplant recipients at a single LT center (2013–2023). Hepatic iron deposition in explant pathology was assessed in relation to pre-transplant Model for End-Stage Liver Disease–Sodium (MELD-Na) score, liver disease etiology, presence of hepatocellular carcinoma (HCC), steatosis (S0 = none/less than 5% steatosis [burnout]; S1 = 5–33%, S2 = 34–66%, S3 ≥ 66%), and diabetes. Associations were evaluated using chi-square testing and multivariable logistic regression adjusted for age, sex, body mass index, diabetes, and race.

Results: Among 1,248 transplant recipients, hepatic iron was present in 50.2% of explants and presence varied significantly by etiology, with the highest prevalence observed in alcohol-associated liver disease (ALD; 60.6%), metabolic dysfunction-associated steatotic liver disease (MASLD; 53.5%), and viral hepatitis (61.1%), and the lowest prevalence in autoimmune and cholestatic liver diseases (26.6%). Iron deposition was more likely in ALD (adjusted odds ratio [aOR] 1.64, 95% CI 1.28–2.12) and less likely in autoimmune and cholestatic liver diseases (aOR 0.31, 95% CI 0.21–0.46). Higher MELD-Na categories (MELD-Na < 20 comparator) were associated with progressively increased odds of iron deposition: 20–24: aOR 1.47; 25–29: aOR 1.85; 30–34: aOR 2.20; ≥ 35: aOR 2.81) (p for trend < 0.001). Older age (aOR 1.01 per year, 95% CI 1.00–1.02) and male sex (aOR 1.30, 95% CI 1.03–1.63) were associated with increased odds of hepatic iron, while HCC (aOR 0.69, 95% CI 0.52–0.90, $p = 0.007$) was associated with lower odds; diabetes was not associated. Among MASLD recipients (N = 239), hepatic iron was not associated with diabetes, burn-out steatosis, steatosis severity, or history of alcohol use. The presence of HCC among MASLD is associated with lower odds of iron deposition (aOR 0.50, 95% CI 0.37–0.65, $p < 0.001$).

Conclusion: Hepatic iron is prevalent in transplant explants and is more closely associated with disease severity than metabolic burden. In MASLD, iron deposition is unrelated to diabetes and steatosis, and is less common in the presence of HCC.

FRI-562

Impact of Glucagon-like peptide-1 receptor agonists on diabetes after liver transplantation - a single-center experience

Chiara Sicuro[1], Paolo Magistri[2], Chiara Giglio[1], Marco Scoppettuolo[1], Martina Montanari[1], Antonio Colecchia[1], Fabrizio Di Benedetto[2], Nicola De Maria[1]. [1]*Chimomo Department, Gastroenterology Unit, University of Modena and Reggio Emilia, Modena, Italy;* [2]*Onco-Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, University of Modena and Reggio Emilia, Modena, Italy*
Email: chiarasicuro44@gmail.com

Background and aims: Metabolic-dysfunction associated steatotic liver disease (MASLD) develops in over 50% of liver transplant recipients (LTR) within one year. Post-transplant diabetes and obesity, affecting up to 30% and 40% of LTR respectively, significantly worsen cardiovascular risk and graft outcomes. Glucagon-like peptide-1 receptor agonists (GLP1-RAs) improve glycemic control, promote weight loss and reduce cardiovascular events in type 2 diabetes, but data in LTR are limited. We aimed to evaluate the efficacy and safety of GLP1-RAs in diabetic LTR.
Method: We retrospectively analyzed diabetic LTR treated with GLP1-RAs (semaglutide, liraglutide, dulaglutide) at our center between 2000 and 2023. Changes in body weight, body mass index (BMI), glycemic parameters, lipid profile, liver stiffness measurement (LSM), Controlled Attenuation Parameter (CAP) and adverse events were assessed. Data are reported as mean ± SD and compared using paired t-test.
Results: Forty-nine LTR (mean age 66 ± 7.9 years) were included. At baseline, mean BMI was 29.7 ± 4.5 kg/m^2 and mean HbA1c was 56.4 ± 15.1 mmol/mol. GLP1-RA therapy significantly reduced HbA1c at 6 months, with a further non-significant decrease at 12 and 18 months. Body weight, BMI and total cholesterol significantly decreased at all time points. CAP values significantly improved at 12 months, whereas LSM remained unchanged. Adverse events occurred in 11 patients, leading to treatment discontinuation in 6 cases. No immunosuppressive therapy adjustments were required.
Conclusion: GLP1-RAs appear safe and effective in diabetic LTR, providing meaningful weight loss and glycemic improvement. Adverse events are relatively frequent and may limit treatment persistence. Larger multicenter studies with longer follow-up are needed to assess long-term graft outcomes and cardiovascular benefits. These findings support the integration of GLP1-RAs into post-transplant metabolic management strategies in selected patients.

FRI-563

Alcohol-related acute-on-chronic liver failure vs alcohol-related cirrhosis: clinical outcomes after liver transplantation - a single center experience

Chiara Sicuro[1], Nicola De Maria[1], Riccardo Cuoghi Costantini[2], Martina Montanari[1], Marco Scoppettuolo[1], Antonio Colecchia[1], Paolo Magistri[3], Fabrizio Di Benedetto[3]. [1]*Chimomo Department, Gastroenterology Unit, University of Modena and Reggio Emilia, Modena, Italy;* [2]*University of Modena and Reggio Emilia, Modena, Italy;* [3]*Onco-Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, University of Modena and Reggio Emilia, Modena, Italy*
Email: chiarasicuro44@gmail.com

Background and aims: Alcohol-associated liver disease (ALD) is a leading indication for liver transplantation (LT). Excessive alcohol use may cause severe alcohol-related hepatitis (sAH) and precipitate acute-on-chronic liver failure (ACLF), which worsens prognosis, increases short-term mortality and reduces response to corticosteroids. Although post-LT survival is comparable between ALD and other etiologies, alcohol relapse (AR) remains a major concern, particularly in patients transplanted for alcohol-induced ACLF (Ai-ACLF). Predictors of post-LT mortality and AR in this population are still poorly defined. This study aimed to compare overall survival (OS) and AR between Ai-ACLF and alcohol-related cirrhosis (AC), and to identify predictors of post-LT mortality and AR.
Method: We retrospectively analyzed all patients transplanted for ALD at our center between January 2020 and December 2023. Patients were stratified into three groups: Ai-ACLF (A), AC with pre-LT abstinence (B), and AC with ongoing alcohol consumption at LT (C). Data are reported as mean ± SD or percentages and analyzed using χ^2/Fisher's exact test, ANOVA or Kruskal–Wallis test. OS and AR were assessed using Kaplan–Meier analysis, and predictors were evaluated by Cox regression.
Results: A total of 161 patients were included (21 A, 117 B, 23 C), with a mean follow-up of 31 ± 16 months. Group A patients were younger, had higher MELD scores, shorter waiting-list time, longer hospitalization and ICU stay, and a higher proportion of women. Rejection and retransplantation rates were higher in Group A. OS did not differ among groups (p = 0.2), with most deaths occurring within the first year. Length of hospitalization (HR 1.03) was the only independent predictor of mortality. AR differed significantly among groups, being highest in Group A and lowest in Group B. Early relapse predominated, and less than half of relapsers developed harmful alcohol consumption. Younger age and rehabilitation program enrollment were associated with AR only in univariate analysis.
Conclusion: LT provides a survival benefit in ACLF, with comparable outcomes between Ai-ACLF and AC, irrespective of pre-LT abstinence. Although abstinence is associated with lower AR risk, it should not represent the sole LT eligibility criterion. Future strategies should focus on identifying high-risk profiles for AR and optimizing targeted post-LT interventions.

FRI-564-YI

Cystatin C is associated with worse survival in patients with cirrhosis awaiting liver transplantation

Miguel Sogbe[1], Amanda Pirola[2], Brittany Bromfield[3], Roberto Tellez[4], Pamela M. Bloomer[4], Christopher B. Hughes[4], Astrid Ruiz Margáin[5], Andres Duarte-Rojo[6]. [1]*Liver Unit, Clinica Universidad de Navarra, Pamplona, Spain, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Pamplona, Spain, Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain, Pamplona, Spain;* [2]*Department of medicine, Northwestern Feinberg school of medicine, Chicago, IL, USA, Pamplona, Spain;* [3]*Department of gastroenterology and hepatology, Brigham and women's hospital, Boston, MA, USA, boston, United States;* [4]*Starzl transplantation institute, university of Pittsburgh, Pittsburgh, PA, USA, PA, United States;* [5]*Division of hepatology, instituto nacional de ciencias medicas y nutricion Salvador Zubirán, México City, México, mexico city, Mexico;* [6]*Division of gastroenterology and hepatology, Northwestern Feinberg school of medicine, Chicago, IL, USA, Chicago, United States*
Email: msogbe@unav.es

Background and aims: Renal dysfunction is a major determinant of morbidity and mortality in patients with cirrhosis. Serum creatinine, despite well-recognized limitations in cirrhosis, remains the primary marker of renal function and a central component of current liver allocation systems, including the Model for End-Stage Liver Disease (MELD) 3.0 and the calculation of the Royal Free Hospital glomerular filtration rate within the Gender-Equity Model for Liver Allocation corrected by sodium (GEMA-Na). Cystatin C (CysC) represents a promising alternative biomarker with improved accuracy and prognostic value in patients undergoing liver transplant (LT) evaluation.
Method: This was a prospective cohort study conducted at a tertiary academic hospital including patients undergoing LT evaluation. At enrollment, participants underwent a standardized evaluation that included measurement of CysC. Associations involving CysC were assessed, and the optimal threshold for predicting mortality was identified using receiver operating characteristic (ROC) curve analysis and the Youden index. Patients were subsequently categorized into two groups according to this cut-off value. The effect of CysC (low vs.

high) on all-cause mortality was evaluated using Fine and Gray competing risks models, considering LT as a competing event. Multivariable analyses were performed with adjustment for MELD 3.0 and GEMA-Na in separate models.
Results: A total of 641 patients underwent CysC assessment. The most common underlying etiology of cirrhosis was alcohol-associated liver disease (37%), followed by metabolic dysfunction–associated steatotic liver disease (35%). At baseline, patients had a mean MELD 3.0 score of 16 ± 8 and a mean GEMA-Na score of 20 ± 6. The optimal CysC cut-off for predicting mortality was ≥1.5 mg/L, yielding an area under the curve of 0.70 (95% CI, 0.64–0.75). After adjustment for MELD 3.0 and GEMA-Na (in separate models), elevated CysC remained independently associated with mortality (adjusted subdistribution hazard ratio [aSHR] 2.58; 95% CI, 1.54–4.29 and aSHR 2.24; 95% CI, 1.35–3.74, respectively). Patients with high CysC had a lower likelihood of undergoing LT compared with those with low CysC levels (SHR 0.70; 95% CI, 0.51–0.96).
Conclusion: Cystatin C represents a promising biomarker to improve prognostic assessment among patients undergoing LT evaluation, given its independent association with mortality beyond established prognostic models such as MELD 3.0 and GEMA-Na.

Using artificial intelligence-based models and radiomics in mri to predict hepatocellular carcinoma after liver transplant
Emma Stevenson[1], Stephanie Harmon[1], Theo Heller[2], Ross Filice[3], Peter Choyke[1], Ismail Turkbey[1], Christine Hsu[2]. *[1]National Cancer Institute, National Institute of Health, Bethesda, United States; [2]National Institute of Diabetes & Digestive & Kidney Diseases, Bethesda, United States; [3]MedStar Georgetown University Hospital, MedStar Medical Group Radiology, Washington, United States*
Email: emma.stevenson@nih.gov

Background and aims: Prediction of hepatocellular carcinoma (HCC) recurrence after liver transplantation (LT) is essential to personalize surveillance regimen and improve survival post-liver transplant. We aim to utilize AI-based MRI radiomics and clinical metrics to predict HCC recurrence and mortality after LT.
Method: A total of 166 patients underwent multi-phase contrast-enhanced T1W MRI scans pre-LT at a tertiary center in this retrospective study. Each focal liver lesion was manually contoured by one radiologist and assigned a Liver Imaging Reporting and Data System (LIRADS) score. Patients were classified based on the presence of LIRADS 4 or 5 lesions on their MRIs. Radiomic features were extracted from liver segmentation obtained from an AI model. Radiomic feature selection was performed using the t-test, Mann-Whitney U test, and the least absolute shrinkage and selection operator. Lesion volume was calculated by summing LIRADS 4 and 5 lesions. Clinical metrics and chosen radiomic features were integrated into univariate (Wilcoxon) and multivariate (Cox proportional hazards) analyses to identify independent predictors of post-LT HCC recurrence and mortality when comparing LIRADS 4 and LIRADS 5 patients.
Results: Out of 166 patients, 21 had HCC recurrence, thus resulting in a cumulative incidence rate of 12.7% and a median time to recurrence of about 34 months (IQR: 11.4, 65.5). Two radiomic features were selected for the LIRADS 5 patients, and eight for the LIRADS 4 patients. Two radiomic features (gldm_GrayLevelNonUniformity and shape_MajorAxisLength) overlapped in terms of significance between both patient groups. The Wilcoxon test revealed that liver volume ($p = 0.03$) was significantly associated with recurrence 12 months post-LT. In the multivariate analysis adjusted for age and gender, two radiomics features (gldm_DependenceNonUniformity and shape_SurfaceArea) were found to be significant for overall recurrence ($p < 0.05$) in LIRADS 5 patients. The same two radiomic features, along with gldm_GrayLevelNonUniformity, were identified as statistically significant ($p < 0.05$) for overall mortality in LIRADS 5 patients as well. An additional multivariate analysis, adjusted for age, gender, and tumor volume, indicated that a decrease in liver volume significantly predicts overall recurrence ($p = 0.02$) and mortality ($p = 0.03$) in LIRADS 5 patients.
Conclusion: Utilizing radiomics alongside clinical factors in prediction models may help predict HCC recurrence in LIRADS 5 patients.

FRI-570
Risk factors and temporal evolution of allograft steatosis following liver transplantation
Yinan Su[1], Roxanna Sharifi[1], Paul Paik[2], Andrew John Cruz[1,3,4], Daanyaal Kumar[1], Kalpana Gopalkrishnan[1], Niveda Balemurughan[1], Derek Samson[5], Jeffrey Kahn[2], Norah Terrault[2], Liyun Yuan[2]. *[1]Keck School of Medicine, University of Southern California, Los Angeles, United States; [2]Division of Gastroenterology and Liver Diseases, University of Southern California, Keck School of Medicine, Los Angeles, United States; [3]Keck School of Medicine of USC, Department of Medicine, Los Angeles, United States; [4]Keck School of Medicine of USC, Department of Medicine, Los Angeles, United States; [5]Transplant Institute, Keck Medicine of USC, University of Southern California, Los Angeles, United States*
Email: yinansu@usc.edu

Background and aims: Hepatic steatosis post-liver transplant occurs as recurrent or de novo metabolic dysfunction–associated steatotic liver disease (MASLD), yet the prevalence, timing, and overlap with rejection remain understudied. We evaluated the prevalence over time and risk factors associated with allograft steatosis in a contemporary liver transplant cohort.
Method: We conducted a retrospective, single-center study of adult liver transplant recipients transplanted 2017–2023 who underwent post-transplant liver biopsy for abnormal liver tests. Hepatic steatosis was defined as ≥5% macrovesicular steatosis and graded as S1–S3 histologically; steatosis was also assessed via imaging studies of MRCP, MRI, ultrasound, and CT. Recurrent vs. de novo steatosis was classified by transplant indication. Acute rejection was assessed histologically. Multivariable logistic regression adjusted for age and sex identified factors associated with allograft steatosis.
Results: Among 347 recipients undergoing post-transplant biopsy, 34.3% (n = 119) had allograft steatosis (31.1% [n = 37] recurrent and 68.9% [n = 82] de novo). Rejection was present in 71.8% (n = 249), with 17.6% (n = 61) showing concurrent rejection and steatosis. Transplantation for MASLD (adjusted odds ratio [aOR] 2.31 [95%CI 1.29–4.14]), obesity at transplant (aOR 1.63 [1.00–2.66]), and donor liver steatosis (aOR 3.19 [1.41–7.22]) were associated with allograft steatosis, but pre-transplant metabolic comorbidities and donor metabolic comorbidities were not associated. The prevalence of steatosis detected via biopsy increased with time post-transplant, from 21.3% at 3 months, 23.0% at 6 months, 28.3% at 1 year, 36.0% at 3 years and 46.2% at 5 years. Among the same population, imaging studies underdetected steatosis (4.8% at 3 months, 13.0% at 6 months, 15.9% at 1 year, 31.4% at 3 years, and 23.1% at 5 years). Rates of concurrent rejection and steatosis persisted across all post-transplant intervals.
Conclusion: Allograft steatosis is common after liver transplantation and increases over time, with underdetection via non-invasive imaging (MRI, MRCP, CT, and ultrasound) compared to histological diagnosis. Recipients transplanted for MASLD, those with obesity at time of transplant, and those who receive steatotic donor livers carry the highest risk for developing allograft steatosis. Longitudinal, multicenter studies are needed to define the impact of allograft steatosis on graft outcomes and inform post-transplant surveillance and intervention strategies.

FRI-571

Beyond survival: long-term growth outcomes in pediatric liver transplant patients with over 20 years of follow-up

Michela Triolo[1], Stefania Camagni[2], Federico Raimondi[3], Luisa Pasulo[1], Leonardi Filippo[1], Francesco Ideo[1], Paola Stroppa[4], Valeria Casotti[4], Domenico Pinelli[2], Lorenzo D'Antiga[4], Stefano Fagiuoli[1]. [1]*Gastroenterology, Hepatology & Transplantation, ASST Papa Giovanni XXIII, Bergamo, Italy;* [2]*Department of Surgery, ASST Papa Giovanni XXIII, Bergamo, Italy;* [3]*Respiratory Unit, Papa Giovanni XXIII Hospital, Bergamo, Italy;* [4]*Department of Pediatric Hepatology, Gastroenterology and Transplantation, ASST Papa Giovanni XXIII, Bergamo, Italy*
Email: mik.triolo@gmail.com

Background and aims: Pediatric liver transplantation (LT) is highly complex, and improved survival has shifted focus toward long-term outcomes. However, data beyond 20 years after LT, particularly on growth, remain limited.

Method: Retrospective data were collected from 152 patients <18 years transplanted at our Center between November 1997–2005. Patients were followed until death or November 1st, 2025. Final height was assessed at the last follow-up, at least 20 years after the first LT. Height was expressed as a standard deviation score (SDS) using the observed height and the corresponding population reference values (mean; standard deviation for age and sex) (1). Target height was computed using Tanner's formula (2). ΔSDS was derived according to Equation (3).

- SDS = (Height observed−mean)/standard deviation (1).
- Target height for boys (cm) = (mother's height (cm) + father's height (cm) + 13)/2.
- Target height for girls (cm) = (mother's height (cm) + father's height (cm)−13)/2 (2).
- $\Delta SDS = SDS - SDST$ (3).

When ΔSDS < −1.5, the patient was classified as not having reached the target height.

Results: The median age at first LT was 1.3 years [0.7–4.2]. During follow-up, 41 patients (27%) underwent retransplantation and 57 (37.5%) died. Among the 95 survivors, 79 (83%) showed adherence to immunosuppression, 5 (5%) required long-term steroid use. At the last follow-up, median height was 1.71 m [1.67–1.77] in males and 1.60 m [1.54–1.63] in females, corresponding to SDS values of −0.48 [−1.37–0.75] and −0.57 [−1.71–−0.14], respectively. Target height was available for 76 patients, of whom 70 (92%) achieved it. The mean height deficit was −1.7 cm in those reaching target height versus −14.8 cm in those who did not ($p < 0.01$). Chronic steroid use and treatment non-compliance were more frequent in the group not reaching the target height (17% vs 1.4%, $p = 0.03$ and 50% vs 18%, $p = 0.05$, respectively). In the multivariable linear regression—using ΔSDS as the dependent variable and sex, age at first LT, retransplantation, Graft-to-Recipient Weight Ratio (GRWR), treatment compliance, and steroid use as covariates -retransplantation was the only factor associated with deviation from target height ($\beta = -0.65$; IC 95% [−1.21 – −0.09]; $p = 0.024$; $R^2 = 0.215$; adjusted $R^2 = 0.144$), indicating poorer growth in retransplanted patients.

Conclusion: Retransplantation was the only factor independently associated with poorer growth, highlighting the long-term impact of complex post-transplant courses.

FRI-572

Favourable real-life outcomes of stereotactic body radiotherapy and magnetic resonance-guided radiotherapy for hepatocellular carcinoma in liver transplant candidates

Email: jose.ursic@yahoo.fr

Background and aims: The optimal bridging or downstaging therapy for hepatocellular carcinoma (HCC) in candidates for liver transplantation (LT) remains uncertain. Stereotactic body radiotherapy (SBRT) is a promising option, but data is limited to small, single-center cohorts. Magnetic resonance-guided radiotherapy (MRgRT), a newer technique allowing delivery of higher equivalent doses, has yet to be evaluated in this setting. We aimed to assess the real-world efficacy and safety of SBRT, including MRgRT, as bridging or downstaging therapy to LT in an intention-to-transplant population across five French academic centers.

Method: Multicenter retrospective cohort, including adult patients listed for LT and receiving SBRT between 2012 and May 2025, followed until December 2025. The primary endpoint was the completion of LT. Secondary endpoints included recurrence risk based on R3-AFP model, post-LT HCC recurrence and safety.

Results: We identified 101 patients with a mean follow-up of 50.4 months. The majority were men (86.1%), with a mean age of 61.6 ± 5.8 years. Median CPT and MELD scores were 5 and 10, respectively. The main underlying liver diseases were alcohol-related liver disease (35%), viral hepatitis (24%), and Met-ALD (24%). SBRT was used as downstaging in 9 patients (8.9%) and as bridging therapy in 92 patients (91.1%). The median SBRT dose was 50 Gy in five fractions, and 29 patients (28.7%) received MRgRT.

Toxicities occurred in 26% of patients, predominantly mild/moderate (no grade >2) events. A decline in liver function was observed in 4.9% of patients. Overall, 77 patients (76.2%) underwent LT at a median of 12.8 months; 32 patients (31.7%) died (20 post-LT). In the downstaging group, 7/9 patients (77.8%) were transplanted, with two dropouts. In the bridging group, 70 of 92 patients (76.1%) underwent LT, with 16 dropouts (17.4%), 4 still on the waitlist, and 2 showing complete, prolonged responses. 8 patients (10.4%) achieved complete histological response. 62 patients (80.5%) had a low or very low recurrence risk (score 0–2) per R3-AFP model. HCC recurrence occurred in 8/77 transplanted patients (10.5%) at a median of 33.1 months. Among MRgRT treated patients, 23 (79.3%) underwent LT, with 87% showing low or very low R3-AFP scores.

Conclusion: This study represents the largest reported cohort of patients treated with SBRT while listed for LT. Our findings suggest that both SBRT and MRgRT are safe and effective in this settiing, with favourable transplantation and recurrence outcomes.

FRI-573

Early barriers to liver transplantation: referral failures in patients admitted for decompensated cirrhosis

Margaux Delhomme[1], Lionel Moulis[1], Faiza Khemissa[2], Ardavan Prost[3], Mohamed Ramdani[4], Saïd Ferroudji[5], Magdalena Meszaros[1], Lucy Meunier[1], Stéphanie Faure[1], Hélène Donnadieu[1], Georges-Philippe Pageaux[1], José Ursic-Bedoya[1]. [1]*Chu Montpellier, Montpellier, France;* [2]*Centre Hospitalier de Perpignan, Perpignan, France;* [3]*Centre Hospitalier Universitaire de Nîmes, Nîmes, France;* [4]*Centre Hospitalier de Béziers, Béziers, France;* [5]*Hôpital de Narbonne, Narbonne, France*
Email: jose.ursic@yahoo.fr

Background and aims: Decompensated cirrhosis is a severe condition for which liver transplantation (LT) remains the only curative treatment. While graft allocation is strictly regulated after listing, the upstream steps leading to LT referral and evaluation are less clearly defined. This study aimed to evaluate the proportion of patients admitted to the emergency department (ED) or intensive care unit (ICU) for acute decompensation who progressed through the key steps toward LT, and to identify factors associated with failure of referral.
Method: We conducted a retrospective multicentre study across five hospitals: one university hospital with an LT program, one university hospital without LT services, and three general hospitals. Patients were identified via Hospital Discharge Database codes over a two-year period. Sociodemographic, clinical, and laboratory data were collected. Primary endpoints included referral to an LT centre, listing for LT, and undergoing transplantation.
Results: Of 1,186 records reviewed, 416 patients were included. The median age was 59.1 years, with a median follow-up of 34.4 months. Most patients were male (77.2%) and had alcohol-related cirrhosis (90%). Acute-on-chronic liver failure (ACLF) was present in 26% of cases (grade 1: 8.9%, grade 2: 9.6%, grade 3: 7.5%). Regarding outcomes, 120 patients (28.8%) were referred to an LT centre, 44 (10.5%) were listed, and 28 (6.7%) underwent transplantation. Among the 296 non-referred patients, 211 (71.2%) died within a median of 7.8 months, with 76.6% of deaths directly attributable to cirrhosis. No reason for non-referral was documented in 46.6% of cases; ongoing alcohol use was cited in 13.2%. In multivariate analysis, factors independently associated with referral included:
- Management in a university hospital (HR 2.7, 95% CI: 1.4–5.5; p = 0.005),
- Admission to a specialized gastrointestinal ICU versus the ED (HR 3.0, 95% CI: 1.4–6.3; p = 0.004),
- Higher MELD score (HR 1.15 per point, 95% CI: 1.1–1.2; p < 0.001),
- Non-alcohol-related cirrhosis (HR 2.1, 95% CI: 1.2–3.6; p = 0.002).

Conclusion: Despite LT being the only curative option for decompensated cirrhosis, fewer than one in three patients admitted to the ED or ICU are referred to a transplant centre. These findings reveal a major loss of opportunity upstream of listing. Standardizing early identification of LT candidates is essential to ensure timely and equitable access to transplantation.

FRI-574
Comparison of four meld-based scores and assessment of gender equity in waiting list outcomes in patients awaiting liver transplantation in The Netherlands

Danny van der Helm[1], Rowan van Golen[2], Wojciech Polak[2], Ian Alwayn[1], Ben Goudsmit[1], Hans Blokzijl[3], Vincent E. de Meijer[3], Marta Fiocco[4], Caroline den Hoed[2], Minneke Coenraad[1]. *[1]Leiden University Medical Center, Transplant Center, Leiden, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands; [3]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [4]Mathematisch instituut, Leiden University, Leiden, Netherlands*
Email: m.j.coenraad@lumc.nl

Background and aims: The Model for End-Stage Liver Disease (MELD) score estimates the 3-month mortality risk on the waitlist and has been the cornerstone of organ allocation for liver transplantation in many organ sharing societies worldwide. Over time, several refinements have been implemented to enhance equity and predictive accuracy, leading from the original MELD to MELD-Na, refitted MELD-Na (reMELD-Na), and MELD 3.0. This study aims to (1) compare the predictive performance of MELD, MELD-Na, reMELD-Na, and MELD 3.0 in adult patients actively listed for liver transplantation in two transplant centers in the Netherlands, and (2) to evaluate potential sex disparities in waiting list mortality and transplantation rates.
Method: Consecutive adult patients who were assigned an active transplantable status ("T-status") on the liver transplantation waitlist between 2007 and 2024 in two Dutch transplant centers were included. Patients listed for acute liver failure or polycystic liver disease, and patients in whom one of the scores could not be calculated due to missing data were excluded. Cause-specific hazard ratio (HRcs) models for death were estimated using competing risk analysis. Competing events were transplantation, waitlist removal for other reasons than transplantation, transition to nontransplantable status, or assignment of exception points. Each model had two risk factors: MELD-based score and sex.
Results: 1867 unique patients were included. The 3-month predictive ability for death on the waitlist of the four scoring systems was comparable for all MELD-based scores: MELD HRCS 1.17 (95%CI 1.15–1.19) and sex HRCS 1.18 (95%CI 0.80–1.74); MELD-Na HRCS 1.19 (95%CI 1.17–1.21) and sex HRCS 1.29 (95%CI 0.87–1.91); reMELD-Na HRCS 1.27 (95%CI 1.23–1.30) and sex HRCS 1.26 (95%CI 0.85–1.86); MELD 3.0 HRCS 1.18 (95%CI 1.16–1.21) and sex HRCS 1.48 (95%CI 1.00–2.18). No significant sex differences were observed in the cumulative incidence of death on the waitlist (p = 0.20) or transplantation (p = 0.49).
Conclusion: In this multicenter Dutch cohort, the predictive performance for waitlist mortality of MELD, MELD-Na, reMELD-Na, and MELD 3.0 was comparable. Moreover, the absence of significant sex-related differences in mortality and transplantation rates supports the fairness of currently used MELD-based scores for organ prioritization and allocation between men and women in the Netherlands.

FRI-575
Natural history and post-transplant outcomes in patients transplanted for autoimmune liver diseases: a comparative analysis of PBC, autoimmune hepatitis and overlap syndromes

Elena Velasco Martínez[1,2], María Jordán de la Fuente[1,2], Laura Jiménez[1,2], Natalia Marcos Carrasco[1,2], Samuel Fernández-Prada[1,2], Irene Peñas Herrero[1,2], Carolina Almohalla Alvarez[1,2], Félix García Pajares[1,2], Gloria Sánchez Antolín[1,2,3]. *[1]Hospital Universitario Río Hortega, Valladolid, Spain; [2]IBioVALL, Valladolid, Spain; [3]Universidad de Valladolid, Valladolid, Spain*
Email: anele_vm@hotmail.com

Background and aims: Autoimmune liver diseases, including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) and overlap syndromes, are a well-established indication for liver transplantation and show marked clinical heterogeneity. We aimed to analyse baseline characteristics, time from diagnosis to transplantation, and post-transplant survival and recurrence, comparing PBC, AIH and overlap syndromes.
Method: Retrospective observational study including 56 patients transplanted for autoimmune liver diseases. Demographic, clinical and outcome variables were analysed. Group comparisons were performed using ANOVA, χ^2 and Tukey post-hoc tests. Multivariable linear regression and Cox proportional hazards models were adjusted for aetiology, sex and age at diagnosis. Survival and recurrence were analysed using Kaplan–Meier and proportional hazards models.
Results: The cohort included 25 PBC, 17 AIH and 14 overlap patients. Overall, 76.8% were women, with a median age at diagnosis of 49 years. At presentation, 72.5% had hypertransaminasaemia, 13.7% decompensated cirrhosis and 13.7% acute hepatitis; 42% had cirrhosis at diagnosis. Autoimmune comorbidities were present in 21%, mainly autoimmune thyroid disease (16%). Mean time from diagnosis to

transplantation was 112.5 ± 88.4 months and was significantly shorter in AIH (54.6 ± 82.2) than in PBC (130.1 ± 71.5) and overlap syndromes (149.8 ± 92.9) (p = 0.018). In multivariable analysis, AIH (β −66.1 months; p = 0.008) and male sex (β −44.7 months; p = 0.042) were independently associated with shorter time to transplantation. Transplant indications were decompensated cirrhosis (72%), fulminant hepatitis (11%), refractory pruritus (11%) and hepatocellular carcinoma (6%). Median follow-up was 61 months (IQR 21–158). Survival was 91.1%, 89.3% and 82.1% at 1, 3 and 5 years, respectively. Recurrence occurred in 11 patients (22%), with a median time of 495 days (IQR 321.5–951). Survival was comparable across groups, whereas recurrence was more frequent and earlier in AIH and overlap syndromes. In adjusted analysis, AIH (HR 2.84; p = 0.028) and overlap syndromes (HR 2.41; p = 0.047) were independently associated with recurrence. Recurrence did not impact survival.
Conclusion: Autoimmune liver diseases differ markedly in pre-transplant course, with faster progression in AIH, but show excellent and comparable post-transplant survival. Although recurrence is more frequent in AIH and overlap syndromes, it does not affect survival.

FRI-576
Non-A1-to-O liver transplantation: should recipient anti-A antibody titers be assessed?
Taylor Viggiano[1], Andres Jaramillo[1,2], Qun Lu[1], Jill Adamski[1], Michele S. Barnhill[1]. [1]*Mayo Clinic Hospital, Phoenix, United States;* [2]*Mayo Clinic, Department of Laboratory Medicine and Pathology, Phoenix, United States*
Email: viggianomed@gmail.com

Background and aims: Historically, ABO compatibility has guided liver transplantation (LT); however, in the last 30 years, non-A1 LT, commonly referred to as A2-to-O LT (AOLT), has become increasingly utilized. This shift follows studies demonstrating comparable graft and patient survival outcomes between AOLT and O-to-O LT (OOLT) which is related to the lower expression of the A antigen and relative lower immunogenicity of non-A1 transplants. The liver is considered an immune-tolerant organ, allowing AOLT to increase the donor pool. However, recent cases of antibody-mediated rejection (AMR) in this cohort at our institution prompted a closer evaluation of outcomes and the potential role of recipient anti-A titers at the time of transplantation. The purpose of this retrospective review was to assess rejection rates and graft outcomes in AOLT and examine the association between rejection and anti-A antibody titers.
Method: We retrospectively reviewed all AOLT performed at our institution from 2001–2025. Rejection type, timing, graft failure, and retransplantation (RT) were recorded. Following an index AMR case in 2020, pre-transplant anti-A antibody titers (AAT) were routinely assessed and retrospectively collected when available.
Results: 46 AOLT were performed. 11 patients had biopsy-proven AMR (n = 3) or acute cellular rejection (n = 8). 7 of 46 (15%) required retransplant (RT) for vascular thrombosis, cholangiopathy, recurrent primary disease, and primary graft failure in the setting of AMR. AAT were available for 22 patients and ranged from 1:16 to 1:65,536. A subset of 8 patients (36%) had high AAT ≥ 1:2048, and 50% of these high-titer patients had AMR, 3 shown by liver allograft biopsy and 1 patient with liver/kidney transplant had presumed liver AMR based on renal biopsy. 2 (25%) patients in this high-titer subgroup required RT due to graft failure. None of the 14 patients with AAT <1:2048 had evidence of AMR and none required RT due to rejection.
Conclusion: AOLT is considered safe and has historically had similar graft and patient survival outcomes as OOLT. However, our retrospective study highlights a strong association between elevated AAT and AMR, which occurred in 50% of our AOLT with AAT > 1:2048, and 25% requiring RT. Therefore, we propose that pre-transplant evaluation should include routine AAT screening and that AOLT should proceed with caution when AAT exceed 1:2048. Larger studies are needed to validate this threshold and standardize patient selection protocols.

FRI-578-YI
Impact of socioeconomic factors on waiting list outcomes and survival after liver transplantation in Germany
Leke Wiering[1], Lola Unger[1], Robert Öllinger[1], Frank Tacke[1], Paul Ritschl[1], Münevver Demir[1]. [1]*Charité, Berlin, Germany*
Email: leke.wiering@charite.de

Background and aims: In liver transplantation socioeconomic disparities have been identified regarding both waiting list outcomes as well as survival after transplantation. However, most evidence originates from the US. The impact of socioeconomic factors in countries with universal healthcare systems, such as Germany, remains unclear. This study aimed to assess the impact of socioeconomic factors on liver transplantation in this setting.
Method: Waiting list outcomes and survival after liver transplantation were retrospectively analyzed in adult candidates listed for liver transplantation at Charité Universitätsmedizin Berlin between 2005 and 2021. Patients listed with high-urgency status were excluded. Socioeconomic variables included citizenship, type of health insurance, and proximity to the transplant centre. For patients residing in Berlin, additional detailed area-level data were assigned based on residential address using governmental data (Gesundheits- und Sozialstrukturatlas, Senatsverwaltung Berlin).
Results: The study includes 1523 candidates on the waiting list, of which 1017 received transplantation. In this cohort waiting list mortality was not significantly influenced by citizenship (German vs. non-German, p = 0.15 for Fine & Gray competing-risks regression) or insurance status (private vs. public, p = 0.26), but waiting list mortality was lower in patients living closer to the transplant centre (p = 0.035, subdistribution hazard ratio (sHR) = 0.78, 95% CI = 0.61–0.98). While the likelihood of receiving liver transplantation was also not influenced by citizenship (p = 0.39), transplantation rates were higher in patients with private insurances (p = 0.009, sHR = 1.28, 95% CI = 1.06–1.54). This was independent of candidates' age and sex (adjusted sHR = 1.22, p = 0.041). In the overall group patient-survival after transplantation did not differ significantly by socioeconomic factors (Cox regression; p = 0.06 for citizenship, p = 0.17 for type of health insurance). Interestingly in the group of male transplant recipients survival was slightly lower in patients with German citizenship (p = 0.048, hazard ratio (HR) = 1.62).
Conclusion: Overall, socioeconomic effects on liver transplantation were less pronounced compared to US findings, but still partially persisted within a universal health care system. While this study cannot provide direct mechanistic explanations, further research should explore potential disparities in waiting list registrations, which may explain our observations.

FRI-579
External validation and comparison of eight risk scores for predicting 3-month early graft failure after liver transplantation: a multicenter study
Wanqing Wu[1], Yu Nie[2], Peihua Cao[1], Kebo Zhong[2], Zhaofeng Lin[1], Lin Feng[1], Manqi Zhuang[1]. [1]*Clinical Research Center, Zhujiang Hospital, Southern Medical University, Guangzhou, China;* [2]*General Surgery Center, Department of Hepatobiliary Surgery II, Zhujiang Hospital, Southern Medical University, Guangzhou, China*
Email: wwq18907507306@smu.edu.cn

Background and aims: Early allograft failure (EAF) seriously affects patient outcomes after liver transplantation (LT). Although numerous risk scores have been developed to predict EAF, their external validation remains limited. This study aimed to externally validate and compare the performance of existing risk scores for predicting 3-month EAF after LT.
Method: This retrospective, multicenter cohort study utilized data from multiple Chinese tertiary hospitals and the Korean INSPIRE dataset. The primary outcome was 3-month EAF, defined as graft failure leading to death or re-LT within 90 days. We evaluated eight scores, including L-GrAFT$_7$, EASE, MEAF, EAD, King-PNF7, Korean ABC,

and Cardoso MELD-Lactate scores. Performance was assessed using the area under the receiver operating characteristic curve (AUC), decision curve analysis (DCA), calibration plots, net classification index (NRI) and integrated discrimination improvement (IDI). Risk stratification was evaluated using the Kaplan-Meier method.
Results: Of the 1263 patients screened, 1156 with available data were included. The median recipient age was 52.0 (IQR, 44.0–59.0) and 81.2% of the recipients were male. The incidence of 3-month EAF was 13.1% (n = 152). The L-GrAFT$_7$ score demonstrated excellent performance (AUC 0.85, 95% CI: 0.80–0.90), which was significantly higher than the MEAF (AUC 0.72, 95% CI: 0.66–0.79), EAD (AUC 0.71, 0.66–0.76), Korean ABC (AUC 0.81, 95% CI: 0.75–0.87), and Cardoso MELD-Lactate (AUC 0.75, 95% CI: 0.70–0.81) scores (all P < 0.05). No significant differences were observed between L-GrAFT$_7$ and either the EASE (AUC 0.84, 95% CI: 0.79–0.88; P = 0.53) or King-PNF7 (AUC 0.82, 95% CI: 0.77–0.88; P = 0.37) scores. The DCA showed a greater net benefit for L-GrAFT$_7$, Korean ABC and King-PNF7 compared to other models. Calibration plots showed good agreement for both the L-GrAFT$_7$ and King-PNF7. Furthermore, L-GrAFT$_7$ exhibited the best capability to identify high-risk patients for graft survival.
Conclusion: The L-GrAFT$_7$ score is a highly accurate and robust tool for individualized risk assessment of 3-month EAF. It demonstrates superior performance to existing risk scores and shows great promise in aiding clinical decision-making for early retransplantation in high-risk patients.

FRI-580

Postoperative peak lactate as a robust predictor for short-term prognosis and development of an updated risk prediction model for early graft failure after liver transplantation

Wanqing Wu[1], Yu Nie[2], Peihua Cao[1], Kebo Zhong[2], Zhaofeng Lin[1], Lin Feng[1], Manqi Zhuang[1]. *[1]Clinical Research Center, Zhujiang hospital of Southern Medical University, Guangzhou, China; [2]Clinical Research Center, Zhujiang Hospital, Southern Medical University, Guangzhou, China*
Email: wwq18907507306@smu.edu.cn

Background and aims: Early identification of recipients at risk for early allograft failure (EAF) following liver transplantation (LT) is critical for improving outcomes. This study aimed to evaluate the prognostic value of postoperative lactate levels and develop novel lactate-enhanced models for predicting early outcomes.
Method: This multicenter, retrospective cohort study utilized data from four Chinese tertiary centers and the South Korean INSPIRE dataset. Patients were divided into a training cohort (n = 706), a Chinese validation cohort (n = 255), and the INSPIRE validation cohort (n = 195). The primary outcome was 3-month EAF. We constructed novel models (L-GrAFT$_7$-Lactate, EASE-Lactate, and MEAF-Lactate) by incorporating lactate into established scoring systems. Model performance was compared using the area under the ROC curve (AUC), net reclassification index (NRI), integrated discrimination improvement (IDI). Risk stratification was assessed with Kaplan Meier survival analysis.
Results: Peak lactate strongly predicted primary non-function (AUC, 0.88), 1-month mortality (AUC, 0.77), and 3-month mortality (AUC, 0.80). The lactate-integrated models significantly improved performance in the training and Chinese validation cohorts (all P < 0.001). For predicting 3-month EAF, L-GrAFT$_7$-Lactate (AUC, 0.91) significantly outperformed MEAF-Lactate (AUC, 0.82) and EAD definition (AUC, 0.71) (all P < 0.001), but showed no significant difference with EASE-Lactate scores (P = 0.82). A simple, easy-to-use EAD-Lactate grading system was developed: Grade 1 (no EAD), Grade 2 (isolated AST/ALT >2000 IU/L within 7 days), Grade 3 (single abnormality among INR ≥1.6 at day 7, bilirubin ≥10 mg/dL at day 7, or peak lactate ≥5 mmol/L), Grade 4 (any two abnormalities), and Grade 5 (all three abnormalities). The EAD-Lactate system provided an excellent discrimination for 3-month EAF (AUC, 0.85), superior to the binary EAD definition and MEAF score, while similar to L-GrAFT$_7$ and EASE (P > 0.05).
Conclusion: Postoperative lactate is a robust predictor of early outcomes after LT. Incorporating lactate into established scoring systems significantly enhances predictive accuracy. EAD-Lactate grading system improves the stratification of graft dysfunction severity, which are valuable for guiding clinical decision-making and early retransplantation strategies.

FRI-581

Liver transplantation (LT) for malignant and benign liver tumors in the United States and Europe: a 20-year perspective

Zobair M. Younossi[1], Giacomo Germani[1,2], Robert Wong[1,3], Maria Stepanova[1], Fatema Nader[1], Vincent Karam[1,4], René Adam[1,5], Rohit S. Satoskar[1,6], Saleh Alqahtani[1,7], Linda Henry[1], Patrizia Burra[1,2]. *[1]The global NASH/MASH council, Washington DC, United States; [2]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy; [3]Division of Gastroenterology and Hepatology, Stanford University School of Medicine, Palo Alto, United States; [4]The European Society for Organ Transplantation, Paris, France; [5]Hopital Paul Brousse, Villejuif, France; [6]Georgetown Medical Center, Washington DC, United States; [7]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*
Email: zobair.younossi@cldq.org

Background and aims: Liver tumors including hepatocellular carcinoma (HCC), other liver malignancies and benign liver tumors are indications for LT. We assessed the characteristics and outcomes of LT recipients with different types of liver tumors using multi-national transplant datasets.
Method: Adult LT recipients with HCC, cholangiocarcinoma (CCA), other primary liver malignancy (PLM), secondary liver cancers (SLCs), or benign liver tumor were identified from the 30-country European Liver Transplant Registry (ELTR) and the U.S. Scientific Registry of Transplant Recipients (SRTR) (2000–2022).
Results: A total of 62,279 LT recipients for all liver tumors were included; 57% from ELTR, 43% from SRTR. HCC was the most common tumor-related LT indication (91%) while benign liver tumors accounted for 4.3% of all tumor-related LTs, followed by CCA (1.9%), other PLM (1.6%), SLCs (1.0%). Over time, the share of HCC among all LTs increased from 10% (2000) to the peak of 32% (2015) and then decreased to 21% (2022). In addition, the share of CCA (in all LTs) increased from 0.3% (2000) to 0.8% (2022) and benign tumors increased from 0.7% (2000) to 1.5% (2015) followed by a decrease to 1.2% (2022) while the prevalence of other PLMs and SLCs remained stable at 0.4% and 0.3%, respectively (trend p > 0.05). The mean MELD scores were similar in all tumor groups (pooled 13.5 ± 7.0) except SLCs (9.7 ± 6.1). Post-LT survival varied substantially across the tumor groups, with 5-year survival ranging from 81% in patients with benign liver tumors to 69% in HCC to 58% in other PLM and SLCs to 50% in CCA. The most common cause of death among liver cancers was malignancy (35–55% of all deaths), and infections for LT benign liver tumors (20%). Over time, LT for HCC related to chronic hepatitis C (CHC) increased from 3.9% of all listings (2000) to the peak of 13.6% (2014) followed by a sharp decrease to 4.2% (2022). Metabolic dysfunction-associated steatohepatitis (MASH)-HCC increased from 0.3% (2000) to 4.0% (2020), 3.9% (2022). Alcohol associated liver disease (ALD)-HCC also increased from 1.2% (2000) to 6.3% (2019), 5.8% (2022) (both trend p < 0.0001), while rates for other etiologies remained stable or decreased.
Conclusion: Among liver tumors, HCC is the dominant indication for LT. Post-LT outcomes vary according to tumor type, with best survival for benign liver tumors and lowest for CCA. Over time, HCC related to MASH and ALD increased, while HCC from CHC declined.

Liver transplantation and hepatobiliary surgery – Experimental and pathophysiology

Hepatic chimerism and partial immune tolerance in an allogeneic mouse liver transplant model

Keiko Iwaisako[1]. [1]*Doshisha University, Kyoto University, Kyoto, Japan*
Email: iwaisako@kuhp.kyoto-u.ac.jp

Background and aims: Although modern immunosuppressive regimens have substantially improved early outcomes after liver transplantation, chronic immune-mediated graft injury remains a major cause of late graft dysfunction. The mechanisms underlying long-term immune accommodation and tissue remodeling remain incompletely defined, partly due to the lack of experimental models permitting prolonged follow-up. We aimed to characterize long-term immune dynamics and cellular remodeling in a fully major histocompatibility complex (MHC)-mismatched mouse liver transplantation model.
Method: Orthotopic liver transplantation with hepatic arterial reconstruction was performed using BALB/c donors and C57BL/6 or CAG-GFP C57BL/6 recipients. No immunosuppressive treatment was administered. Recipients were analyzed at serial time points up to 64 weeks post-transplantation. Histopathology, RNA sequencing, blood biochemistry, and serum immunoglobulin profiling were performed.
Results: Long-term graft survival was achieved in the absence of immunosuppression, except in animals developing technical complications such as thrombosis or cholestasis. Marked immune cell infiltration was evident from one week post-transplantation and progressively attenuated by eight weeks. Low-grade inflammatory infiltrates persisted throughout long-term follow-up. Regulatory T cells were selectively maintained beyond eight weeks. Serum immunoglobulin concentrations increased until four weeks and subsequently declined, but remained above baseline levels. Lineage-tracing analyses demonstrated near-complete replacement of donor Kupffer cells and partial replacement of sinusoidal endothelial cells by recipient-derived cells, indicating progressive hepatic chimerism.
Conclusion: This arterialized MHC-mismatched mouse liver transplantation model demonstrates long-term immune accommodation associated with progressive hepatic chimerism and sustained regulatory T-cell dominance. These findings support a potential role for recipient-derived cellular chimerism in late graft remodeling and provide a translational platform for investigating chronic graft injury and immune tolerance mechanisms. Importantly, these mechanisms must also be validated in human liver allograft tissue.

THU-517-YI

Baseline serum metabolomic signatures predict post- liver transplant early complications

Rosmy Babu[1], Sushmita Pandey[1], Jaswinder Maras[1], Viniyendra Pamecha[1], Chhagan Bihari[1], Gaurav Tripathi[1], Nupur Sharma[1]. [1]*Institute of Liver and Biliary Sciences, Delhi, India*
Email: drcbsharma@gmail.com

Background and aims: Post-transplant early complications significantly increase morbidity following liver transplantation; however reliable pre-transplant biomarkers are limited. We aimed to identify baseline serum metabolomic signatures using LC–MS–based analysis of that help predict post-transplant early complications.
Method: Whole blood samples of cirrhosis recipients aged 18 to 65 with post-transplant early complications (EC), such as graft rejection, biliary complications, and/or infection within 6 months of follow-up (n = 64), and recipients without early complications (NEC), n = 109 were collected. Serum was extracted from blood samples, which was then processed for metabolomic profiling using LC-MS and validated in 48 EC and 52 NEC samples. Peak detection, signal normalisation, and metabolite annotation were performed on the raw data using reference databases. The resulting feature count data was examined for downstream univariate, multivariate, and machine-learning analyses performed in GraphPad Prism v6 and SPSS v20.
Results: Baseline serum metabolomic profiles differed significantly between recipients who developed post-transplant early complications (EC) and those without early complications (NEC), indicating the presence of pre-transplant metabolic differences. Unsupervised hierarchical clustering demonstrated substantial inter-sample variability and no clear segregation by age, sex, disease etiology, MELD score or other clinical parameters; however, it consistently highlighted a subset of metabolites that differed who had EC and NEC. These differences were confirmed by univariate analysis, partial least squares discriminant analysis (PLS-DA), and Random Forest modeling. Five baseline metabolites were significantly elevated in EC recipients compared with NEC recipients (all $p < 0.0001$): acrylamide (2-propenamide), 6-(α-D-glucosaminyl)-1D-myo-inositol, alcophosphamide, glycochenodeoxycholate, and 2-acetylaminofluorene. These metabolites showed strong discriminatory performance (AUC range 0.767–0.975), and their combined baseline metabolomic model achieved near-perfect prediction of early complications (AUC 0.991, 95% CI 0.983–1.000), outperforming MELD-Na. On validation using high-resolution mass spectrometry and machine learning algorithms, the metabolome panel showed >95% accuracy and specificity for prediction of EC.
Conclusion: Baseline serum metabolomics signature identifies recipients at risk for early complications, supporting its use for objective pre-transplant risk stratification.

THU-521

cGAS deficiency alleviate liver ischemia reperfusion injury by blocking macrophage proliferation in the transplanted liver

Ruihan Chen[1], Xiaohan Lin[1], Qi Ling[1]. [1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: 12318397@zju.edu.cn

Background and aims: Liver ischemia reperfusion injury (IRI) is a key risk factor for graft failure post-liver transplantation (LT). cGAS, a DNA sensor, plays critical roles in inflammation responses. This study aims to elucidate the mechanisms of cGAS in liver IRI.
Method: We analyzed cellular cGAS expression profile in liver using western blot, qPCR, and immunofluorescence. Single-cell RNA sequencing from mouse LT model were analyzed to determine the distribution of cGAS and the functional features of $cGAS^{hi}$, macrophage cluster. Subsequently, IRI model was established using wild-type (WT) and $cGAS^{-/-}$ mice, liver injury and macrophage function were evaluated through histopathology, flow cytometry. In vitro, cGAS was knocked down in RAW264.7 cells via lentivirus, and its effects on macrophage polarization and proliferation were assessed by qPCR and flow cytometry. An orthotopic LT model in $cGAS^{-/-}$ mice was used to evaluate cGAS as a potential therapeutic target for mitigating graft reperfusion injury.
Results: In both human and murine livers, cGAS was highly expressed in macrophages but minimally detected in hepatocytes. Its expression in macrophages was upregulated following liver IRI. Analysis of single-cell transcriptomic data from a syngeneic murine LT model revealed that cGAS expression was elevated in the early post-transplant phase and was particularly enriched in a proliferating macrophage subcluster (Top2a_Mac). In a murine IRI model, $cGAS^{-/-}$ mice demonstrated significantly lower serum ALT/AST levels and reduced Suzuki scores compared to wild-type controls. $cGAS^{-/-}$ mice also exhibited attenuated macrophage infiltration and decreased expression of pro-inflammatory cytokines such as IL-6. Furthermore, hepatic macrophages in $cGAS^{-/-}$ mice shifted toward an anti-inflammatory phenotype and showed suppressed proliferation. The functional role of macrophage cGAS was confirmed in a H/R hepatocyte co-culture model, where cGAS knockdown reduced pro-inflammatory cytokine production and induced S-phase cell cycle

arrest in macrophages. Finally, in a syngeneic orthotopic LT model, cGAS deficiency resulted in diminished immune cell infiltration and improved graft survival.
Conclusion: In the liver IRI model, cGAS deficiency in macrophages confers protection by inhibiting their proliferation and impairing the shift toward a pro-inflammatory phenotype, thereby providing a potential therapeutic target for LT.

THU-522
METTL3-mediated m6A modification of ATG12 upregulates autophagy to promote activation and survival of CD8+ T cells during acute rejection after liver transplantation
Xiaolong Chen[1], Wenfeng Zhu[2], Xuejiao Li[3]. [1]*Department of Hepatobiliary Surgery, The First Affiliated Hospital of Jinan University, GuangZhou, China;* [2]*Department of Hepatobiliary Surgery, The Second Affiliated Hospital of Guangzhou Medical University, GuangZhou, China;* [3]*Department of Hepatology Lab, The Third Affiliated Hospital of Sun Yat-sen University, GuangZhou, China*
Email: 15779729700@163.com

Background and aims: Previous studies and ours have demonstrated the critical role of $CD8^+$ T cells in acute rejection (AR) after liver transplantation (LT). N6-methyladenosine (m^6A) modification has been reported to be involved in the regulation of immune cell function and survival recently. However, its role in AR remains to be elucidated.
Method: m^6A modification and related protein levels of $CD8^+$, T in liver grafts from AR patients after LT were assessed first. Rat acute hepatic rejection model and one-way mixed lymphocyte reaction (MLR) model were then established to confirm the methylation levels of $CD8^+$ T cells. Moreover, changes of RNA in murine activated $CD8^+$ T cells were examined and methylated RNA immunoprecipitation (MeRIP) was conducted to identify the specific targets of methyltransferases. Furthermore, underlying mechanisms of m^6A modification in the regulation of function and survival of T cells were explored.
Results: m^6A methylation levels in $CD8^+$, T cells were elevated in both AR patients and rats after LT. Methyltransferase-like 3 (METTL3) was confirmed to mediate methylation of activated $CD8^+$, T cells in vitro, which promoted their activation. RNA sequencing results indicated that the autophagy related signaling plays an important role in allo-antigen triggered activation of $CD8^+$, T cells. Autophagy-related 12 (ATG12) was determined as the direct target of METTL3 through MeRIP. Mechanistically, METTL3 enhances autophagy by up-regulating ATG12 expression through Insulin-like growth factor 2 mRNA-binding protein 2 (IGF2BP2) recognized stabilizing of Atg12 mRNA, resulting in promotion of survival, proliferation and function of T cells.
Conclusion: METTL3-mediated m^6A methylation of ATG12 promotes activation of $CD8^+$ T cells through up-regulating autophagy after LT, offering a theoretical foundation for identifying novel therapeutic targets for the prevention and treatment of AR following LT.

THU-523
Recurrence of primary biliary cholangitis after liver transplantation: predictors and graft and patient outcomes
Paul Domínguez Cardoso[1], Andres Bejarano Cayo[1], Alejandro Gutierrez-Castillo[2,3], Ricardo Gutierrez-Monterrubio[1], Berenice M. Román-Calleja[1], Nayelli Flores-García[1]. [1]*Incmnsz.edu.mx, Ciudad de México, Mexico;* [2]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico;* [3]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Gastroenterology, Mexico City, Mexico*
Email: paulfcodominguez@hotmail.com

Background and aims: Recurrence of primary biliary cholangitis (PBC) after liver transplantation (LT) remains a significant clinical challenge, with reported rates of 20–30%. We aimed to identify predictors of recurrence and to evaluate graft and patient outcomes in a cohort of transplanted patients with PBC, integrating clinical, serological, biochemical, and histopathological variables.
Method: We performed a retrospective cohort study of LT recipients from 2000 to 2024 at a tertiary care center in Mexico. Demographic, clinical and biochemical variables at 3, 6 and 12 months were compared using univariate and multivariate analysis. Prognostic scores (Paris II and GLOBE) were used and recurrence was confirmed histologically.
Results: From a total of 69 patients, 62 (89.9%) were women. Recurrence occurred in 17 patients (24.6%), with a median time of 3 years. In univariate analysis, significant variables included age at LT ($p < 0.001$), AMA positivity ($p = 0.033$), AIH/PBC overlap ($p < 0.001$), tacrolimus levels at the third month ($p < 0.001$) and GGT value at the sixth ($p = 0.045$) and twelve ($p = 0.048$) month. Paris II and GLOBE scores showed similar biochemical response patterns in both groups but neither score predicted recurrence.
In the multivariate analysis relevant variables included age at LT (OR 0.917, $p = 0.44$) and AIH/PBC overlap (OR 0.042, $p = 0.001$).
Conclusion: Post-transplant PBC recurrence is strongly associated with younger age and a more complex immunologic phenotype characterized by a high prevalence of AIH/PBC overlap. Prognostic models developed for non-transplanted PBC (Paris II, GLOBE) do not predict recurrence in the graft. Persistently elevated GGT at 6 and 12 months appears to be an early biochemical marker of recurrence. These findings support closer post-transplant monitoring in patients with overlap syndrome and highlight the need for transplant-specific prognostic tools.

THU-524
Engineering bile ducts with enhanced epithelial maturation and vascularization
Mattia Pasqua[1], Ayesha Rehman[1], Ruben Leone[1], Giovanni Cavalli[1], Maria Giovanna Francipane[1]. [1]*Fondazione Ri.MED, Palermo, Italy*
Email: mgfrancipane@fondazionerimed.com

Background and aims: Injury to the common bile duct (CBD) remains a major clinical challenge due to poor long-term outcomes of current endoscopic and surgical treatments. We previously developed a multiphasic CBD-like scaffold seeded with cholangiocytes, which demonstrated mechanical integrity, leak-proof function, bile acid transport, and favorable immunocompatibility ex vivo. Despite these advances, the engineered biliary tissue remained partially mature and showed limited structural organization. Here, we investigate an advanced cellular seeding strategy in which cholangiocytes are incorporated with supportive stromal and endothelial cells to enhance tissue architecture and promote vascular network formation within this scaffold.
Method: Distinct multicellular aggregates containing cholangiocytes and supportive cell types were generated in suspension culture and seeded into specific layers of the scaffold. Tissue organization, epithelial phenotype, and formation of vascular-like networks were evaluated by immunofluorescence.
Results: Seeding of distinct cell populations enabled the formation of organized epithelial and supportive compartments, recapitulating key features of biliary tissue architecture.
Conclusion: Pre-assembled multicellular aggregates can be effectively integrated into our CBD-like scaffold, supporting tissue organization and vascular network formation. This approach advances the engineering of biomimetic bile duct constructs toward clinical translation.

THU-525
Decellularized bile duct scaffolds facilitate autologous regeneration in a rat model of bile duct defect
Yusuke Hanabata[1], Takamichi Ishii[1], Hidenobu Kojima[1], Fumiaki Munekage[1], Satoshi Ogiso[1], Etsuro Hatano[1]. [1]*Department of Surgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan*
Email: taishii@kuhp.kyoto-u.ac.jp

Background and aims: Bile duct (BD) injury in hepatobiliary surgery can lead to severe biliary complications. Conventional reconstructive procedures often compromise physiological bile flow and are associated with bile leakage, stricture, and recurrent cholangitis, underscoring the need for alternative substitutes. This study investigated the regenerative capacity of a decellularized bile duct (dBD) scaffold as a biological substitute.
Method: A syngeneic dBD scaffold was prepared from Lewis rats using a detergent-based decellularization protocol that preserved extracellular matrix architecture. After resection of a 4-mm segment of the common bile duct, the dBD was orthotopically interposed with an intraluminal stent. Animals were sacrificed at 2, 4, 6, and 12 weeks for macroscopic, biochemical, and histological evaluation. A control group received a stent alone without a biological scaffold. Regeneration was assessed by serial histology and immunostaining for epithelial, stromal, vascular, and inflammatory markers.
Results: The dBD graft maintained luminal patency and preserved liver function without biliary leakage, obstruction, or infection, while eliciting only a minimal inflammatory response. Regeneration progressed through early fibroblast infiltration, angiogenesis, and marked activation of peribiliary glands (PBGs) with high Ki-67 and SOX9 expression, followed by epithelial maturation into $CK19^{+}/SOX9^{-}$ biliary lining. By 12 weeks, the implanted dBD was covered by a continuous epithelium with well-organized collagen and vascular structures. The PBGs transitioned to a quiescent phenotype resembling native BD architecture. Conversely, stent-only controls developed biliary sludge and impaired remodeling.
Conclusion: The dBD enabled autologous regeneration of functional biliary tissue through coordinated epithelial, vascular, and stromal remodeling. This approach offers a promising foundation for next-generation BD substitutes for clinical application.

Macrophage colony stimulating factor (CSF1) induces a proregenerative response in human liver during normothermic machine perfusion

Sahar Keshvari[1], Sarah Schulze[1], Dylan Carter-Cusack[1], Nick Butler[2], Katharine Irvine[1]. [1]*Mater Research - The University of Queensland, Brisbane, Australia;* [2]*Queensland Liver Transplant Service, Brisbane, Australia*
Email: katharine.irvine@uq.edu.au

Background and aims: Macrophages play essential roles in liver homeostasis, regeneration and resolution of injury, but can also contribute to chronic inflammation and liver disease. In the setting of transplantation and surgery, optimal liver macrophage function is essential for resistance to infection and could support tissue regeneration. We previously demonstrated in preclinical models that Macrophage Colony Stimulating Factor (CSF1) therapy promotes liver regeneration after acute and chronic injury and fibrosis resolution in chronic liver disease. To translate these findings we investigated the impact of CSF1 treatment in human livers undergoing ex vivo normothermic machine perfusion (NMP).
Method: A single dose of recombinant CSF1 was administered to six donor livers (3 clinically rejected for transplant and 3 healthy with no suitable recipient) 4–12 h after commencement of NMP on an OrganOx Metra. Perfusate samples and biopsies were taken for measurement of CSF1 by ELISA, histological analysis and bulk RNA Sequencing over a timecourse of up to 24 hours. Meta-analysis of public RNASeq data from livers perfused for 5 h was used to control for changes in gene expression during NMP.
Results: CSF1 was rapidly removed from the perfusate, as it undergoes receptor-mediated endocytosis. Clearance was delayed and reduced in unhealthy livers, likely related to reduced blood flow rate and/or impaired CSF1R+ macrophage function. RNA Sequencing of serial biopsies showed rapid, specific transcriptional responses to CSF1, with highly significant enrichment of binding sites for macrophage transcription factors such as CEBPB, AP1 and MYB in the vicinity of genes induced within 1 h of CSF1 administration. Key pathways implicated in hepatocyte proliferation and liver growth (Hippo/Yap, cell cycle) and regulation of lipid metabolism were also induced within 1 hour and persisted over the perfusion time. Histological analysis demonstrated an increase in staining area of the macrophage marker CD68 during perfusion, consistent with a morphological response to CSF1.
Conclusion: Preclinical studies have demonstrated the therapeutic benefits of CSF1 for ameliorating ischaemic injury, promoting liver regeneration and resolving steatosis and fibrosis. The proregenerative response observed during NMP supports the therapeutic potential of acute CSF1 treatment in the peri surgical setting and more broadly in human liver disease.

Glypican 3-targeted antigen-specific fluorescent imaging enhances real-time intraoperative tumor identification in hepatocellular carcinoma: a translational study

Shuhei Kanda[1], Hiroto Nishino[1], Tomoaki Yoh[1], Yuya Kaneda[1], Kohei Yoshimura[1], Yoshihiko Kurata[1], Motohiko Sato[1], Takahiro Nishio[1], Satoshi Ogiso[1], Keiko Iwaisako[1], Takamichi Ishii[1], Etsuro Hatano[1]. [1]*Graduate School of Medicine, Kyoto University, Kyoto, Japan*
Email: s.kanda.0718@gmail.com

Background and aims: Fluorescence imaging using indocyanine green (ICG) is widely used to support intraoperative navigation in various surgical fields. During hepatectomy for hepatocellular carcinoma (HCC), precise tumor detection and prevention of residual cancer are essential. Glypican-3 (GPC3) is a tumor-associated membrane antigen that is highly expressed in most HCCs but absent in normal liver tissue. The aim of this study was to evaluate the feasibility of GPC3 as a tumor-specific imaging target and to develop a GPC3-targeted fluorescent probe for intraoperative tumor visualization.
Method: In the clinical study, intraoperative tumor identification using ICG fluorescence imaging was assessed in 38 selected patients. Patients were classified into identifiable and non-identifiable groups, and clinicopathological factors were compared between the two groups. The tumor specificity of GPC3 was validated by immunohistochemical staining of resected specimens from both groups. In the experimental study, novel GPC3–targeted fluorescent probe (GPC3-IRDye800) was developed. The probe was administered to human HCC cell line derived orthotopic xenograft models. Tumor-to-background ratio (TBR), fluorescence distribution, margin contrast, and safety profiles were analyzed and compared with ICG and an isotype-control probe.
Results: Intraoperative tumor identification using ICG fluorescence was achieved in 30 patients. Cirrhosis (F4) was significantly more frequent in the non-identifiable group than in the identifiable group. Immunohistochemistry showed GPC3 positivity in 35 cases, with significantly higher expression in tumors than in peritumoral liver ($p < 0.0001$). In the experimental study, GPC3-IRDye800 demonstrated antigen-dependent uptake, yielding higher fluorescence intensity and TBR in GPC3-positive tumors compared with controls ($p < 0.0001$). At 72 hours after administration in both normal- and fibrotic-liver mouse models, GPC3-IRDye800 provided higher fluorescence intensity and clearer tumor margin identification than ICG. No histological organ damage or biochemical toxicity was observed following probe administration.
Conclusion: GPC3-IRDye800 achieved superior tumor visualization, clearer intraoperative margin assessment in mouse models. These findings suggest that GPC3-targeted fluorescence imaging may enhance real-time intraoperative tumor identification in HCC and complement current ICG navigation.

An increase in regulatory B cells contributes to achieve tolerance in liver transplantation patients

Eunju Kim[1], Soon Kyu Lee[2], Jong Young Choi[1,2]. [1]*Chung-Ang University, Gwangmyeong, Korea, Rep. of South;* [2]*The Catholic University of Korea, College of Medicine, Seoul, Korea, Rep. of South*
Email: jychoi@catholic.ac.kr

Background and aims: This study investigates the dynamics of regulatory B cells (Bregs) during immunosuppression (IS) tapering and their contribution to tolerance in liver transplantation (LT) patients.
Method: We prospectively enrolled 15 LT patients who had normal liver function, no history of rejection, and had undergone LT more than five years ago. Patients were followed up every three months, and IS doses were tapered by 25% every 6–9 months. At each visit, blood samples were collected, and the proportions of T cells and B cells were analyzed by flow cytometry. To validate flow cytometry findings, we also compared the infiltration of T and B cell subsets in liver tissue between tolerant (n = 5) and rejection (n = 5) patients using histopathology and confocal microscopy. Additionally, RNA sequencing and *in vitro* analysis were conducted to access Bregs function in tolerance.
Results: Over a median follow-up of 42 months, eight patients successfully discontinued IS without rejection (tolerance group). One patient experienced rejection (rejection group), while the remaining six patients reduced their IS dose to 25% without rejection (minimization group). During IS tapering, Treg cells and the Treg/Th17 ratio increased in the tolerance group but decreased before rejection in the rejection group. Similarly, the tolerance group exhibited an increase in Bregs and the Breg/Th17 ratio, whereas a decrease was observed in the rejection group. Moreover, a negative correlation between Bregs and Th17 cells and a significant positive association between Bregs and plasmablast B cells were identified. In liver tissue, confocal analysis showed a significant increase in Tregs and Bregs in tolerance patients (n = 5) compared to patients with rejection. In vitro analysis demonstrated a reduction in Th17 cells following Breg treatment, and vice versa. Furthermore, treatment with *Faecalibacterium*, enriched in the tolerance group, led to an increase in Bregs and IL-10 levels.
Conclusion: During IS tapering, Bregs increase and contribute to the achievement of tolerance in LT patients. These findings suggest that Bregs may serve as potential biomarkers and therapeutic targets for promoting tolerance in LT.

THU-531

Simvastatin attenuates post-hepatectomy hemodynamic liver injury in fibrotic livers through KLF2-eNOS signaling

Fumiaki Munekage[1], Satoshi Ogiso[1], Yusuke Hanabata[1], Takuma Karasuyama[1], Kentaro Iwaki[1], Hidenobu Kojima[1], Takamichi Ishii[1], Etsuro Hatano[1]. [1]*Kyoto University, Kyoto, Japan*
Email: ogiso@kuhp.kyoto-u.ac.jp

Background and aims: Simvastatin has been reported to reduce portal hypertension in cirrhotic and fibrotic livers, partly through endothelial nitric oxide-dependent mechanisms. However, it remains unclear whether simvastatin can attenuate the acute increase in portal pressure and protect the liver from hemodynamic stress during the early postoperative phase after major hepatectomy in fibrotic livers.
Method: Liver fibrosis was induced in C57BL/6 mice by oral administration of carbon tetrachloride for 12 weeks. Mice were then treated with or without oral simvastatin (30 mg/kg daily for 3 days) and subjected to 70% or 80% partial hepatectomy. Simvastatin-treated and untreated fibrotic mice were compared with respect to postoperative survival, portal venous pressure, biochemical markers of sinusoidal endothelial injury, histological changes, and endothelial-specific molecular signaling.
Results: After 80% hepatectomy, simvastatin-treated fibrotic mice showed significantly higher survival than untreated fibrotic mice (p = 0.022). After 70% hepatectomy, simvastatin-treated fibrotic mice exhibited a significantly smaller necrotic area at 24 hours after surgery (0.2% vs 2.3%, p = 0.030), a trend toward increased remnant liver weight, and significantly lower serum hyaluronic acid levels at 72 hours, while no mortality was observed in either group. Hemodynamic analysis demonstrated that simvastatin-treated fibrotic mice had lower portal venous pressure before hepatectomy and at 4 and 24 hours after surgery, accompanied by increased portal flow volume per liver parenchymal volume at 4 hours and larger sinusoidal areas before hepatectomy and at 4 hours. Western blot analysis further revealed increased expression of the shear stress-responsive transcription factor KLF2 in sinusoidal endothelial cells and higher levels of phosphorylated eNOS in simvastatin-treated fibrotic mice.
Conclusion: In fibrotic livers, acute portal hypertension after major hepatectomy imposes substantial hemodynamic stress on sinusoidal endothelial cells, which is aggravated by impaired sinusoidal dilatory capacity. Our findings suggest that simvastatin attenuates post-hepatectomy hemodynamic liver injury by activating the KLF2–eNOS pathway, thereby promoting sinusoidal dilation, reducing portal pressure, and preserving sinusoidal endothelial integrity in fibrotic livers.

THU-532

Salvianolic acid C alleviates hepatic ischemia-reperfusion injury by activating HSP90α and PI3 K/AKT pathway

Yingmei Shao[1], Alimu Tulahong[2,3], Qiao Tulahong[1]. [1]*The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China;* [2]*The First Affiliated Hospital of Xinjiang Medical University, Department of Hepatobiliary and Echinococcosis Surgery, Urumqi, China;* [3]*Xinjiang Medical University, Urumqi, China*
Email: syingmei1@163.com

Background and aims: Hepatic ischemia-reperfusion injury (HIRI) is a major cause of liver dysfunction following transplantation, yet effective therapeutic interventions remain unavailable. Salvianolic acid C (SaC), a polyphenol derived from Salvia miltiorrhiza, exhibits documented protective effects in cerebral ischemia, but its role in HIRI and the underlying molecular mechanisms are unexplored. This study aimed to investigate the hepatoprotective effects of SaC against HIRI and elucidate its mechanism of action, with a specific focus on heat-shock protein regulation and the PI3 K/AKT pathway. We employed an integrated approach combining bioinformatics analysis of the transcriptomic dataset GSE151648, in vivo murine HIRI models, and molecular biology validation assays.
Method: Transcriptomic profiling identified differentially expressed heat-shock proteins (HSPs), followed by protein-protein interaction (PPI) network construction and pathway enrichment analysis. Murine HIRI models were established with or without SaC pretreatment. Dynamic changes in HSP90α (HSP90AA1) expression, serum pro-inflammatory cytokines (TNF-α, IL-1β, IL-6), apoptosis markers, and histopathological damage were quantified. PI3 K/AKT pathway activation was assessed, and mechanistic validation was performed using the HSP90 inhibitor 17-AAG.
Results: Bioinformatics analysis identified HSP90AA1 as a key hub gene in HIRI and a potential target of S-allyl cysteine (SaC), primarily enriched in the PI3K-Akt signaling pathway. In vivo, HIRI injury peaked at 6 hours of reperfusion, accompanied by an early upregulation of HSP90α. SaC treatment further enhanced HSP90α expression and significantly attenuated hepatic injury, evidenced by

improved liver histology, reduced serum enzymes (ALT, AST, LDH), and suppressed inflammation and apoptosis. Crucially, pharmacological inhibition of HSP90α with 17-AAG exacerbated liver damage and abrogated SaC-mediated protection. Mechanistic studies revealed that SaC activated the PI3 K/Akt pathway, an effect that was reversed by HSP90α inhibition. Collectively, these findings indicate that SaC alleviates HIRI by upregulating HSP90α to activate the PI3 K/Akt signaling cascade.
Conclusion: SaC alleviates HIRI by targeting HSP90α to activate the PI3 K/AKT pathway, thereby reducing inflammation, apoptosis, and tissue injury. This identifies SaC as a novel natural therapeutic strategy against HIRI.

THU-533
Mitochondrial transfer from S100A4+ macrophages triggers hepatocyte GSTP1 lactylation and PANoptosis in ischemic liver injury

Mengxue Sun[1], Min Tang[1]. [1]*Division of Gastroenterology and Hepatology, Institution of Digestive Diseases, Tongji Hospital, Tongji University School of Medicine, Shanghai, China*
Email: ttangmin@sina.com

Background and aims: Hepatic ischemia-reperfusion injury is a common complication in liver transplantation and hepatectomy, which triggers a severe inflammatory response and extensive cell death, potentially leading to acute liver injury or even organ failure. While macrophage polarization and massive hepatocyte death are hallmark features of hepatic ischemia-reperfusion injury, the specific pathways triggering these events and their interrelationship are poorly understood, representing a significant gap in knowledge.
Method: In this study, we established a multi-timepoint mouse model of hepatic ischemia-reperfusion injury. Combined transcriptomic and single-cell RNA sequencing analysis pinpointed macrophage S100A4 as a candidate therapeutic target. To assess the functional contribution of S100A4, a macrophage-specific S100A4 knockout mouse model was subjected to hepatic ischemia-reperfusion injury. Integrated analysis of lactylomics and single-cell RNA sequencing data was performed to investigate the regulatory role of hepatocyte GSTP1 lactylation in mouse hepatic ischemia-reperfusion injury. Furthermore, a macrophage-hepatocyte co-culture system revealed that S100A4-positive macrophages modulate hepatocyte lactylation, leading to alterations in downstream signaling pathways.
Results: This study found that in a mouse model of hepatic ischemia-reperfusion injury, the expression of S100A4 progressively increased with prolonged reperfusion time, peaking at 24 hours. In macrophage-specific S100A4 knockout mice, the inflammatory response, mitochondrial damage, and apoptosis were significantly attenuated following hepatic ischemia-reperfusion injury. Mechanistically, co-culture experiments demonstrated that S100A4-positive macrophages induce this modification by transferring vesicle-encapsulated damaged mitochondria to hepatocytes, induced hepatocyte GSTP1 lactylation. Lactylated GSTP1 in hepatocytes promotes PANoptosis through dual mechanisms: by impairing GSH binding to exacerbate oxidative stress and mtDNA leakage, thereby activating AIM2; and concurrently by disrupting JNK binding to activate the JNK/c-JUN pathway and ZBP1. Promisingly, supplementing healthy mitochondria alleviated this injury cascade.
Conclusion: Macrophage-derived S100A4 promotes hepatocyte injury by vesicular transfer of damaged mitochondria, which induces GSTP1 lactylation, activates the JNK/c-JUN pathway, and causes mtDNA leakage, leading to dual activation of AIM2- and ZBP1-mediated PANoptosis.

Liver tumours – Clinical aspects except therapy

Email: huirex@connect.hku.hk

Background and aims: Image-based deep learning may enhance the diagnostic accuracy of HCC, however current studies are predominantly cross-sectional and lack prospective evaluation.
Method: We prospectively recruited consecutive at-risk liver disease patients (cirrhosis, Asian male hepatitis B patients ≥40 years old, or Asian female hepatitis B patients ≥50 years old) receiving contrast-enhanced CT scans for either new-onset liver nodules on ultrasonography or unexplained elevation of serum alfa-fetoprotein. We evaluated two deep learning models for diagnosing HCC on computed tomography (CT): Spatio-Temporal 3D Convolution Network (ST3DCN) that was developed specifically for multiphasic CT; and a 3D convolutional block attention module (CBAM) designed for opportunistic screening in noncontrast CT. Diagnostic performance was compared with Liver Imaging Reporting & Data System (LI-RADS) as graded by two specialist radiologists. The ground truth diagnosis of liver nodules was validated via a 12-month composite clinical reference standard based on histological or clinicoradiological criteria.
Results: This study included 301 patients with 468 liver lesions (mean age 65.2, 67.1% male, 39.9% cirrhosis, 25.6% steatosis). 93 patients (30.9%) were diagnosed to have HCC. ST3DCN had significantly better diagnostic performance for HCC than LI-RADS at both lesion level (AUC: ST3DCN 0.902 [95%CI 0.874–0.931] vs LI-RADS 0.798 [95% CI 0.740–0.856], $p < 0.001$) & patient level (AUC ST3DCN 0.862 [95%CI 0.821–0.903] vs LI-RADS 0.804 [95%CI 0.743–0.866], $p = 0.032$). ST3DCN was superior to LI-RADS in patients with liver lesion size <20 mm (Patient level AUC: ST3DCN 0.854 [95%CI 0.780–0.928] vs LI-RADS 0.580 [95%CI 0.416–0.744]), cirrhosis (Patient level AUC: ST3DCN 0.906 [95%CI 0.853–0.960] vs LI-RADS 0.761 [95%CI 0.672–0.849]), or steatosis (Patient level AUC: ST3DCN 0.885 [95%CI 0.809–0.961] vs LI-RADS 0.746 [95%CI 0.611–0.880]) (all $p < 0.05$). The noncontrast CBAM model attained AUC of 0.694 (95%CI 0.628–0.759) for diagnosing HCC, limited by a low positive predictive value of 0.514 (95% CI 0.445–0.582).
Conclusion: Our deep learning algorithm on multiphasic CT had superior diagnostic performance over standard-of-care radiologist interpretation for diagnosing HCC, with most prominent advantage in challenging diagnostic scenarios including smaller lesions, presence of cirrhosis, or steatosis. Image-based deep learning can revolutionize the care of at-risk liver disease patients.

Email: wkseto@hku.hk

Background and aims: Hepatocellular carcinoma (HCC) has distinct histological features that are utilized in disease prognostication. Recent advancements in computational pathology, particularly the release of general-purpose foundation models pretrained on large-scale datasets, offer new opportunities for automated diagnosis. We aimed to evaluate the performance of a deep learning framework, which combines a finetuned foundation model with multiple instance learning (MIL) across three HCC histopathological diagnostic tasks: tumor differentiation grading, microvascular invasion (MVI) detection and fibrosis staging.
Method: We used a dataset of digitized whole slide images (WSIs) annotated by clinical experts for the three tasks. Square image patches of size 1024 were extracted and labeled based on their inclusion within tumor, fibrosis, or MVI. We finetuned UNI (a Vision Transformer with 303M parameters, pretrained on > 100,000 WSIs) as a patch feature extractor. Subsequently, we applied TransMIL, a transformer-based MIL feature aggregator, to output slide predictions for each diagnostic task.
Results: The study included 1267 WSIs from 191 patients. For HCC differentiation grading (N = 1,267; Normal: 380, G1: 30, G2: 742, G3: 115), we achieved an Area Under the Curve (AUC) of 0.967 (95%CI: 0.959–0.975), sensitivity of 0.912 (0.904–0.920), specificity of 0.956 (0.955–0.957), positive predictive value (PPV) of 0.781 (0.771–0.791), and negative predictive value (NPV) of 0.949 (0.947–0.951). For MVI prediction (N = 892; Non-MVI: 602, MVI: 290), we achieved an AUC of 0.931 (0.930–0.932), sensitivity of 0.887 (0.884–0.890), specificity of 0.847 (0.845–0.849), PPV of 0.736 (0.732–0.740), and NPV of 0.940 (0.938–0.942). For fibrosis staging (N = 124; F0-F1: 27, F2-F3: 30, F4: 67), we achieved an AUC of 0.971 (0.958–0.984), sensitivity of 0.852 (0.833–0.871), specificity of 0.943 (0.937–0.949), PPV of 0.912 (0.894–0.930), and NPV of 0.952 (0.947–0.957). Overall, the framework consistently achieved AUCs > 0.90, sensitivities > 0.85 and NPVs > 0.93 across all three tasks, demonstrating its robustness in characterizing heterogeneous HCC features.
Conclusion: The integration of foundation models with MIL provides a highly effective and generalizable approach for HCC pathology. Our framework demonstrates superior diagnostic performance across diverse tumor characteristics, including differentiation grading, fibrosis staging, and MVI detection, suggesting significant potential for AI-assisted clinicopathological decision-making.

Background and aims: Liver stiffness measurement (LSM) has been shown to be associated with hepatocellular carcinoma (HCC) risk, yet its role in guiding HCC surveillance remains unclear. We aimed to determine the optimal liver stiffness thresholds for hepatocellular carcinoma surveillance.
Method: We conducted a multicentre longitudinal cohort study across 13 centres comprising 2,568 adults with LSM ≥ 10 kPa. HCC risk was assessed using Cox proportional hazards regression adjusted for age, sex, body mass index and type 2 diabetes mellitus. Absolute 1-year HCC risk was estimated from restricted cubic spline fitted models, and LSM cutoffs corresponding to an annual HCC risk of 0.4% were derived for the overall cohort and etiology-specific subgroups.
Results: Higher liver stiffness measurement (LSM) was associated with an increased risk of HCC in the overall cohort (HR: 1.025 [95% CI: 1.016–1.034]; p < 0.001), with an overall HCC incidence of 2.00 per 100 person-years (95% CI 1.74–2.30). In etiology-specific analyses, LSM was significantly associated with HCC risk in metabolic dysfunction-associated steatotic liver disease (MASLD) (HR: 1.022 [95% CI 1.004–1.041]; p = 0.02) and hepatitis C virus (HCV) (HR: 1.030 [95% CI 1.012–1.047]; p < 0.001), with HCC incidences of 1.38 (95% CI 1.02–1.83) and 3.10 (95% CI 2.47–3.83) per 100 person-years, respectively. No significant association was observed for hepatitis B virus (HBV) (p = 0.50) or alcohol-associated liver disease (ALD) (p = 0.51), although HCC incidence remained substantial (1.98 [95% CI 1.45–2.65]; 2.36 [95% CI 1.32–3.89] per 100 person-years respectively). Using absolute risk–based thresholds, the optimal LSM corresponding to an annual HCC incidence ≥ 0.4% was 16.4 kPa overall, with etiology-specific cutoffs of 12.9 kPa for MASLD, 10.7 kPa for HCV, and 12.2 kPa for ALD. In HBV patients, the predicted 1-year HCC risk exceeded the 0.4% surveillance threshold across the entire observed range of LSM, therefore no discriminative liver stiffness cutoff could be identified.
Conclusion: Liver stiffness-based HCC risk stratification demonstrates substantial heterogeneity across liver disease etiologies. Applying etiology-specific LSM cutoffs aligned with accepted HCC surveillance thresholds may improve precision in identifying patients most likely to benefit from surveillance.

Background and aims: In advanced hepatocellular carcinoma (HCC), neoplastic portal vein thrombosis (nPVT) and metastases could represent distinct manifestations of tumour burden. However, under first-line atezolizumab–bevacizumab (A + B), the relative prognostic weight of these features remains insufficiently explored. This study aimed to assess how nPVT and metastatic involvement influence clinical outcomes, including early decompensating events (EHD), in patients receiving A + B.

Method: Five hundred and six cirrhotic patients with unresectable HCC treated with first-line A + B within the prospective ARTE dataset were included. Patients were evaluated for the presence of nPVT and extrahepatic metastases. EHD was defined as new-onset ascites, encephalopathy, jaundice, or variceal bleeding within 12 weeks of treatment initiation. Primary endpoints were overall survival (OS), progression-free survival (PFS), and radiological progression.

Results: nPVT was present in 331 patients (59.9%) and metastases in 185 (36.5%). EHD occurred in 53 patients (10.5%) and was strongly associated with nPVT (OR 3.1, 95%CI 1.7–6.4), even after adjustments for baseline liver function (Child-Pugh or ALBI grade), whereas metastases showed no association. Patients who developed EHD experienced markedly worse survival (median OS 8.2 vs 19.6 months, $p < 0.001$) and shorter treatment duration (3.5 months, IQR 1.4–9.8 vs 7.3 months, IQR 3.5–15.2). In multivariable Cox analysis for OS, EHD (HR 1.9, 95%CI 1.3–2.7), ALBI grade≥2 (HR 1.5, 95%CI 1.1–1.9), and AFP≥400 ng/mL (HR 1.5, 95% CI 1.1–1.9) were independent predictors, whereas neither nPVT nor metastases retained significance after adjusting for liver function and EHD.

Conversely, extrahepatic metastases were independently associated with radiological progression (HR 1.5, 95%CI 1.2–1.9) and shorter PFS (HR 1.4, 95%CI 1.1–1.6) while nPVT showed no association.

Conclusion: Among patients treated with A+B, nPVT and metastases appear to influence prognosis through different pathways: nPVT primarily by predisposing to EHD, and metastases mainly by accelerating tumour progression. Once EHD occurs, its impact on survival outweighs that of both vascular invasion and metastatic spread, likely due to the shorter treatment duration observed in this group. These findings suggest that assessing early liver deterioration alongside baseline tumour pattern may improve early risk stratification in advanced HCC and help contextualise the prognostic relevance of nPVT and metastases under A+B therapy.

TOP-376

Hepatocellular carcinoma (HCC) in patients with biopsy proven metabolic dysfunction associated steatotic liver disease (MASLD)

Email: zobair.younossi@cldq.org

Background and aims: MASLD is an important cause of HCC. In a large, international, multi-center study of patients with MASLD, we aimed to characterize MASLD patients with HCC.
Method: The Global MASLD (G-MASLD) project included MASLD patients with liver biopsy, laboratory tests, and follow-up data from 41 countries. For this analysis, patients who had HCC at the time of biopsy or developed HCC in the follow-up were selected. A 4:1 sample of MASLD controls without HCC was randomly selected, matched by enrollment site. Regression models evaluated time-to-HCC, overall mortality, and mortality among patients with HCC.
Results: Out of 11,114 subjects in G-MASLD, n = 124 (1.1%) had HCC [20% with HCC at the time of enrollment and 80% developed HCC after a median (IQR) of 5 (3–10) years of follow-up]. The pooled annualized rate of HCC was 0.2% including 1.2% per year in patients with cirrhosis and 0.1% per year in non-cirrhotics. Compared with controls, HCC patients were older (mean age 62 vs. 52 years, $p < 0.0001$), had more components of metabolic syndrome (obesity 71% vs. 58%, type 2 diabetes 69% vs. 46%, hypertension 71% vs. 51%, all $p < 0.01$) with more advanced fibrosis (F3–F4: 81% vs. 30%) and cirrhosis (48% vs. 8%) ($p < 0.0001$). HCC patients also had higher FIB-4 (mean 3.63 vs. 1.61), liver stiffness measurement (23.4 kPa vs. 12.2 kPa), as well as FAST, Agile 3+/Agile 4 scores (all $p < 0.0001$). Adverse outcomes including all-cause mortality (cumulative during median (IQR) 6 (3–11) years of follow-up: 36% vs. 8%), decompensation (37% vs. 2%), and liver transplantation (9% vs. <1%) were more frequent in HCC (all $p < 0.0001$). In multivariate analysis, older age (aHR (95% CI) = 1.041 (1.020–1.063) per year), having at least 3 components of metabolic syndrome [aHR = 2.02 (1.29–3.16)], fibrosis stage 3 [aHR = 3.50 (1.74–7.04)] or cirrhosis [aHR = 10.23 (5.29–19.77)] (all $p < 0.01$) were independently associated with increased risk of HCC in MASLD. On the other hand, diagnosis of histologic MASH did not independently increase the risk of HCC ($p > 0.05$). In turn, HCC was a strong independent predictor of all-cause mortality [aHR = 2.75 (1.57–4.82)], along with older age [aHR = 1.032 (1.009–1.056) per year] and presence of cirrhosis [aHR = 2.34 (1.14–4.80)](all $p < 0.05$).
Conclusion: MASLD-related HCC occurs in both cirrhotic and non-cirrhotic patients, with higher incidence among those with advanced fibrosis or cirrhosis and those with underlying metabolic abnormalities.

THU-216-YI

Evaluating gastrointestinal bleeding risks and esophagogastroduodenoscopy (EGD) requirement in low-risk hepatocellular carcinoma (HCC) patients undergoing atezolizumab and bevacizumab: interim analysis

Laia Aceituno[1], Nadia Rukavina[1], C Lee[2], Ahmed Elsheaita[1,3], Farah Albader[1], Elena Valenzi[1], Ann T Ma[1], Robert Vanner[4], Erica Tsang[4], Robert Grant[4], Roxana Bucur[1], Jennifer Knox[4], Arndt Vogel[1,4]. [1]Toronto General Hospital, Toronto, Canada; [2]Cancercare Manitoba, Westbank, Canada; [3]Yarmouth Regional Hospital, Yarmouth, Canada; [4]Princess Margaret Cancer Centre, Toronto, Canada
Email: laiaaceituno@gmail.com

Background and aims: Atezolizumab–bevacizumab (AB) is considered first-line treatment in hepatocellular carcinoma (HCC). However, concerns about bevacizumab-related variceal bleeding have led to recommendations for routine pre-AB with esophagogastroduodenoscopy (EGD). According to Baveno VII criteria, non-invasive tools can be used to identify patients with cirrhosis at low risk of varices needing treatment, allowing safe avoidance of screening EGD in those with liver stiffness measurement (LSM) <20 kPa and platelets count (Plt) >150 × 10^9/L. This study aimed to evaluate the safety of BAVENO VII criteria to guide pre-treatment endoscopic screening in patients with HCC receiving AB in a real-world setting.
Method: This is an interim analysis of an ongoing prospective interventional study (REB 23–5915). Adult patients scheduled to receive AB for HCC in a single centre were screened and, if consenting, prospectively stratified into two cohorts: low risk (LR) and intermediate/high risk (IHR) based on Baveno VII criteria. Patients classified as IHR undergo EGD prior to initiating AB treatment.
Results: Of 50 patients included, 35 patients (70%) were classified as IHR and 15 (30%) LR. There were no significant differences in demographical data, HCC size or AFP levels between groups. LSM were significantly higher (9 kPa vs. 27 kPa, $p < 0.001$), and platelets significantly lower in the IHR group (160 × 10^9/L vs. 217 × 10^9/L, $p = 0.021$). In the IHR group, esophageal varices were identified in 11/35 (31%) patients, of which 5 had high-risk stigmata; all were managed according to local standard of care. One patient (2%) in the IHR group developed post-AB variceal bleeding. The patient was BCLC B, Child–Pugh A, and ALBI grade 1. Baseline endoscopy showed portal hypertensive gastropathy without esophageal varices. None of the LR patients experienced any bleeding event. Overall, 22 patients (44%) experienced any adverse events (AE), 19 in the IHR group. Median follow-up was 9.7 months (4.2–16.4), AB was discontinued in 7 patients due to AE and 9 due to progression. There were no treatment-related deaths. 15 patients died during the follow-up, 14 due to diseases progression and 1 due to an intracranial bleed while receiving second-line treatment.
Conclusion: Baveno VII–based non-invasive strategy appears safe for identifying variceal bleeding risk in patients receiving AB and may allow omission of routine endoscopic screening in select low-risk patients.

The VETC-associated trabecular subtypes in non-cirrhotic HCC is defined by loss of tumor suppressor and downregulation of ribosomal genes

Khushboo Agrawal[1], Archana Rastogi[1], Varun Suroliya[2], Viniyendra Pamecha[1], Nirupma Trehanpati[1], Shiv Kumar Sarin[1], Gayatri Ramakrishna[1]. [1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Artemis hospital, Gurugram, Haryana, India
Email: drarchana.suri.rastogi@gmail.com

Background and aims: Vessels Encapsulating Tumor Clusters (VETC) are a distinct angiogenic pattern in which tumor nests are surrounded by endothelial-lined vessels and are linked to metastasis and recurrence. This study aimed to define VETC-associated architectural histotypes in non-cirrhotic HCC (NCHCC) and their genetic and transcriptomic profiles.

Method: NC-HCC specimens (N = 53) were assessed for VETC pattern using CD34 immunohistochemistry and classified as VETC+ or VETC – . Patterns were correlated with p53, β-catenin, EpCAM, CK19, MSI markers, and immune features including $CD8^+$ T cells, PD-1, PD-L1, and CTLA-4. Genomic profiling was conducted via targeted NGS (N = 11, 40-gene panel) and RNA-seq (VETC- N = 3 and VETC+ N = 7).
Results: The VETC+ variants was identified in 20.75% (11/53) of the cohort with intense CD34 staining of endothelial cells encompassing the hepatocytes. VETC occupied over 50% of the total tumor area, distributed across microtrabecular (55%) and macrotrabecular (45%) growth patterns. The cryptogenic etiology (36%), was more prevalent while an equal distribution observed in HBV and NASH-related in VETC+ NCHCC (28% each). VETC+ subjects had younger mean age 55.7 (p = 0.08), larger tumor size >10 cm in (90%), elevated AFP (64%) P = 0.052 and universal EpCAM expression (P = 0.027). Clinically, VETC+ tumors demonstrated high recurrence (64%) and poor overall survival compared to VETC-tumors (OS < 2 years in 64% of cases, P < 0.01). VETC+ phenotype was characterized by frequent p53 nuclear positivity, MSI stable status and an "immune-excluded" or "cold" microenvironment with significantly reduced CD8+ infiltration (P = 0.041). Genomic analysis revealed frequent mutations in *TP53* and *RB1* (~60% each) with absence of TERT mutation. Differentially expressed genes between VETC – (n = 3) and VETC+ (n = 7) tumors showed significant downregulation of ribosomal and translational genes (U1, RNU1,RNVU-1, RPL34, RPL37A, EIF1, RMRP), protein targeting and ER processing genes (ITM2B, SELENOP, CLU), cell adhesion and cytoskeletal regulators (COL18A1, VTN, AHNAK), and immune/complement components (C3, C4B, B2M, SERPINA3). Expression of metabolic genes (APOB, APOA2, ADH1B, FTL) were also reduced.
Conclusion: VETC+ identifies a highly aggressive HCC endotype characterized by the functional dominance of lost tumor-suppressive pathways.This phenotype is driven by a profound transcriptional repression of ribosomal biogenesis and protein processing, alongside a metabolic reprogramming and immune-excluded state.

Predicting transcatheter arterial chemoembolization response in hepatocellular carcinoma using a two-stage imaging framework with automated liver segmentation and bidirectional temporal difference modeling

Ting-Feng Hsieh[1], Geng-Hao Bai[2], Cheng-Yu Hsiung[1], Shanq-Jang Ruan[1], Ja-Der Liang[3]. *[1]Department of Electronic and Computer Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan; [2]Department of Internal Medicine, National Taiwan University Hospital, College of Medicine, National Taiwan University, Taipei, Taiwan; [3]Division of Gastroenterology and Hepatology, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan*
Email: m11202131@mail.ntust.edu.tw

Background and aims: Transarterial chemoembolization (TACE) is the standard therapy for patients with intermediate-stage hepatocellular carcinoma (HCC), and early treatment response is a major determinant of prognosis. However, predicting therapeutic response remains challenging because TACE induces complex volumetric, vascular, and textural changes in both the tumor and surrounding liver parenchyma. Existing models typically rely on pre-treatment features or single-time-point post-treatment imaging, limiting their ability to capture the dynamic temporal evolution following TACE. This study aims to develop a robust two-stage deep learning framework that performs automated liver segmentation in the presence of post-procedural artifacts and utilizes bidirectional temporal difference modeling to predict early treatment response after initial TACE.
Method: A total of 104 unresectable HCC patients receiving TACE as initial therapy were retrospectively analyzed. All patients underwent multi-phase contrast-enhanced CT (CECT) before and after TACE. Treatment response was determined using modified RECIST (mRECIST) criteria on follow-up CT within 1 month. In stage one, we designed a refined segmentation pipeline combining a pre-trained deep learning model with morphology-based seed selection and a Seeded Region Growing (SRG) algorithm to mitigate high-intensity Lipiodol artifacts. In stage two, we developed a Bidirectional Temporal Difference Modeling (BiTDM) network that extracts features from paired pre- and post-TACE scans to generate subtraction-based temporal transition maps for response prediction.
Results: The segmentation framework effectively minimized Lipiodol artifacts, providing accurate regions of interest. For treatment response prediction, the BiTDM framework with a ResNet18 backbone achieved the best performance with an AUC-ROC of 0.802, AUC-PR of 0.783, and accuracy of 0.818. Ablation studies showed that incorporating temporal difference maps significantly outperformed single-phase models and standard concatenation methods, underscoring the importance of modeling pre-to-post-treatment transitions.
Conclusion: The proposed framework overcomes the key technical challenges of automated segmentation in TACE-treated livers and improves prognostic performance compared with static imaging methods. By integrating bidirectional temporal difference modeling, it enables reliable early prediction of treatment response following initial TACE in patients with HCC.

THU-219-YI

The IL-7 rs16906115 single nucleotide polymorphism alters the risk for the development of treatment-related AEs in patients with HCC treated with immunotherapy

Lorenz Balcar[1], Hannah Yang[2], Victoria Berger[1], Joao Gorgulho[3], Chan Kim[2], Abelina Kreuter[1], Jung Sun Kim[2], Katharina Pomej[1], Gae Hoon Jo[2], Anton Klotz[1], Ho Young Lim[2], Dahyeon Son[2], Hwasun Yang[2], Michael Trauner[1], Beodeul Kang[2], Johann von Felden[3], Matthias Pinter[1], Hong Jae Chon[2], Bernhard Scheiner[1]. *[1]Medical University of Vienna, Vienna, Austria; [2]CHA University, Seongnam, Korea, Rep. of South; [3]University Medical Center Hamburg-Eppendorf, Hamburg-Eppendorf, Germany*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: The interleukin-7 (IL7) rs16906115 single nucleotide polymorphism (SNP) alters B cell-specific IL7 expression. In immune-checkpoint-inhibitor (ICI) treated patients with melanoma, carriers of the minor allele were at increased risk of treatment-related adverse events (trAEs). The importance of this SNP in patients with hepatocellular carcinoma (HCC) undergoing systemic treatment is unknown.
Method: We included HCC patients treated with systemic therapies at three institutions (Vienna/Austria, Hamburg-Eppendorf/Germany, Seongnam/Republic of Korea). SNP-genotyping was performed using real-time PCR systems following the manufacturer's recommendations.
Results: We included 345 patients (male: n = 283, 82.0%) with a median age of 64.1 (IQR: 56.9–71.9) years mainly undergoing atezolizumab/bevacizumab treatment (95.7%). Observed allele frequencies (wild-type/heterozygous/homozygous variants) were: G/G: 60.0%/G/C: 33.0%/C/C: 7.0%. When applying a time-dependent approach to account for treatment-exposure, we found a stepwise increase of the risk of trAE development linked to IL-7 genotype (C/C or C/G vs G/G, hazard ratio [HR]: 1.33 [95% confidence interval (CI): 1.03–1.72], p = 0.027). In total, 19/24 patients (79%) harbouring two minor alleles (C/C) developed trAEs (% grade 1/2/3: 50%/21%/8%) and treatment was stopped due to trAEs in 8%. Analysis of lymphocyte stability over time (baseline vs. day 21 during treatment) did not reveal significant differences in immune cell counts depending on IL7 genotype. Ultimately, patients harbouring the C/C genotype tended to have a worse median overall survival compared to patients harbouring at least one wild-type allele (10.3 [95%CI: 6.7–18.8] vs 16.2 [95%CI: 12.6–18.8] months; p = 0.241).

Conclusion: The IL-7 rs16906115 genotype may help to predict the risk for trAE development and therefore for the selection of patients appropriate for treatment regimen with a higher or lower risk of trAEs.

Email: lorenz.balcar@meduniwien.ac.at

Background and aims: The diagnostic and prognostic utility of non-invasive tests (NITs) for clinically significant portal hypertension (CSPH) in patients with hepatocellular carcinoma (HCC) remains controversial and robust data on this topic are urgently needed.
Method: We conducted a retrospective Baveno Cooperation-endorsed multicentre European study in patients with HCC who underwent HVPG measurement and NITs (i.e., liver stiffness measurement [LSM] by transient elastography, platelet count [PLT]) from 13 centres. First, the diagnostic performance of CSPH-NITs was evaluated. Second, the prognostic role of NITs for first hepatic decompensation and liver-related death was evaluated by competing risk regression analyses with liver transplantation/non-liver-related death as competing events.
Results: Among 710 patients with compensated advanced chronic liver disease (cACLD, mean age 65 years, 82% male, 31%/44% steatotic/viral), most were BCLC 0/A (75%, B 16%, C 9%). The CSPH prevalence was 41%, the median LSM was 16 kPa (IQR: 11–26), and median HVPG was 8 mmHg (IQR: 6–12). ANTICIPATE ± NASH yielded the highest discriminative ability to detect CSPH (AUC 0.81[95%CI:0.78–0.84]), followed by LSM (AUC 0.77[95%CI:0.74–0.81]), and PLT (AUC 0.76[95% CI:0.72–0.80]). Notably, HCC localisation (right lobe, i.e., potential LSM measurement site involvement, vs. left lobe) did not interfere with CSPH-NITs accuracy. The Baveno VII criteria (LSM<15 kPa & PLT>150 G/L) showed an excellent performance for ruling out CSPH (sensitivity 95.8%, NPV 92.5%), while for ruling in CSPH (>25kPa), performance was modest (specificity 85.7%, PPV 70.4%). ANTICIPATE ± NASH >75% attained a specificity/PPV of 89.3%/74.7%. Additional data on SSM-100 Hz/the NICER model were available in 53 patients (AUC 0.86[95%CI:0.75–0.96]). LSM was independently associated with first decompensation and liver-related death, even after adjusting for relevant baseline characteristics/time-dependent covariables. In time-dependent AUROC analyses, LSM exhibited a numerically higher discriminative ability than HVPG.
Conclusion: ANTICIPATE ± NASH show a good discriminative ability for CSPH in patients with cACLD and HCC. While Baveno VII criteria are capable of ruling-out CSPH, the PPVs of LSM >25 kPa/ANTICIPATE ± NASH >75% were suboptimal, likely owing to the low prevalence of CSPH/pre-test probability in this cohort. LSM is independently associated with liver-related outcomes; its prognostic performance is comparable to HVPG and thus, it may be applied for risk prediction.

THU-221

Blood- and liver stiffness-based noninvasive tests for clinically significant portal hypertension in patients with compensated advanced chronic liver disease and hepatocellular carcinoma

Lorenz Balcar[1], Tina Jasmin Haunold[1], Mathias Jachs[1], Georg Semmler[1], Benedikt Simbrunner[1], Albert Friedrich Stättermayer[1], Christoph Schwarz[1], Stefan Stremitzer[1], Klaus Kaczirek[1], Patrick Starlinger[2], Michael Trauner[1], Bernhard Scheiner[1], Thomas Reiberger[1], Matthias Pinter[1], Mattias Mandorfer[1]. *[1]Medical University of Vienna, Vienna, Austria; [2]Mayo Clinic, Rochester, United States*
Email: lorenz.balcar@meduniwien.ac.at

Background and aims: The applicability of non-invasive tests (NITs) for clinically significant portal hypertension (CSPH) in patients with hepatocellular carcinoma (HCC) is controversial. We performed a head-to-head comparison of the discriminative abilities of various NITs for CSPH and evaluated rule-in/-out criteria in patients with HCC.
Method: We conducted a retrospective study including 283 patients with HCC undergoing HVPG measurement at the Vienna Hepatic Haemodynamic Lab with available data on NITs (i.e., liver stiffness measurement [LSM], platelet count [PLT], von Willebrand factor antigen [VWF:Ag], and the ratio of VWF:Ag and PLT [VITRO]). For the subsequent analysis, we focused on patients with compensated advanced chronic liver disease (cACLD).
Results: Among 164 patients with cACLD (mean age 66 years, 86.0% male, mainly alcohol/viral aetiology), most were BCLC 0/A (50.6%). The CSPH prevalence was 46.3%, the median LSM was 20.0 kPa (IQR: 13.3–37.9), and mean VWF:Ag/VITRO were 266 ± 119%/2.30 ± 1.81. The VITRO score yielded the highest discriminative ability to detect CSPH (AUROC 0.834 [95%CI: 0.772–0.896]), followed by ANTICIPATE ± NASH (AUROC 0.822 [95%CI: 0.756–0.887]), PLT (AUROC 0.803 [95% CI: 0.734–0.871]), LSM (AUROC 0.779 [95%CI: 0.705–0.852]) and VWF:Ag (AUROC 0.707 [95%CI: 0.628–0.785]).
The application of the Baveno VII criterium (LSM<15 kPa & PLT>150 G/L) and the VITRO score (≤1.0) individually showed an excellent performance for ruling out CSPH (sensitivities ≥95%, NPV 100%/87.9%). For ruling in CSPH by individual criteria, the VITRO score provided the highest PPV (≥2.5, specificity/PPV 89.8%/83.0%), followed by the Baveno VII criteria (≥25 kPa; specificity/PPV 81.8%/74.6%). When sequentially applying Baveno VII criteria and VITRO, the grey zone could be significantly reduced to 11% (sensitivity/NPV 94.7%/92.2%; specificity/PPV 73.9%/84.4%), at the cost of reduced PPV/specificity due to the reliance on the Baveno VII rule in criteria. HCC characteristics did not seem to interfere with CSPH-NITs.
Conclusion: The discriminative ability in cACLD patients with HCC was comparable to patients without HCC. However, PPVs of established criteria were <90%, which may be explained by the comparatively low prevalence of CSPH in this context.

Impact of sarcopenic obesity and myosteatosis on postoperative outcomes after hepatectomy in intrahepatic cholangiocarcinoma

Zhiyuan Bo[1], Xinyan Feng[2], Zhengxiao Zhao[3], Fang Wan[1], Fangfang Chen[1], Jingpei Long[1]. [1]*Women's Hospital School of Medicine Zhejiang University, Hangzhou, China;* [2]*Wenzhou Medical University, Wenzhou, China;* [3]*the First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China*
Email: longjp@zju.edu.cn

Background and aims: Muscular abnormality is frequently associated with poor prognosis in intrahepatic cholangiocarcinoma (ICC), but the impact of sarcopenic obesity and myosteatosis on ICC are still unclear. We aimed to perform a retrospective multicenter cohort study to evaluate the impact of sarcopenic obesity and myosteatosis on patients with ICC undergoing hepatectomy.
Method: A total of 506 patients with ICC undergoing hepatectomy at four institutions were retrospectively reviewed. Sarcopenic obesity and myosteatosis were measured by preoperative computed tomography (CT) images. The impact of sarcopenic obesity and myosteatosis on the prognosis was evaluated, and cox regression analyses were performed to identify risk factors. Nomograms were developed to facilitate the risk prediction of survival, and the predictive performance was verified in validation cohort.
Results: 369 patients were included in final analysis, including 265 in training cohort and 104 in validation cohort. Among them, 206 patients (55.8%) had myosteatosis, 104 patients (28.2%) had sarcopenic obesity, and 64 patients (17.3%) had coexistence of sarcopenic obesity and myosteatosis. Patients with sarcopenic obesity or myosteatosis experienced a worse prognosis than patients without muscular abnormality. The overall 1-year survival rate and 90-day mortality rate were 65.9% and 4.61%. Low tumor differentiation ($P = 0.003$), lymphatic metastasis ($P < 0.001$), CA19–9 > 37 U/ml ($P = 0.016$), lower albumin level ($P = 0.006$), sarcopenic obesity ($P < 0.001$) and myosteatosis ($P < 0.001$) were independent risk factors of OS, while low tumor differentiation ($P = 0.015$), TNM stage III–IV ($P < 0.001$), sarcopenic obesity ($P < 0.001$) and myosteatosis ($P = 0.012$) were independent risk factors of RFS. Nomograms were developed to predict survival outcomes in training cohort, with AUCs of 0.718–0.799 and 0.680–0.798 for predicting OS and RFS. The performance was verified in validation cohort, with AUCs of 0.789–0.885 and 0.746–0.895 for predicting OS and RFS.
Conclusion: Sarcopenic obesity and myosteatosis negatively impact the prognosis of ICC, and valuable body composition-based nomograms were developed for clinical usefulness.

Background and aims: Immune checkpoint inhibitors (ICIs) can induce long-term survival and even cure in several cancers, but this has not been formally quantified in advanced hepatocellular carcinoma (HCC). We applied mixture cure models (MCMs) to phase 3 trials and real-world data to estimate the fractions of long-term survivors and cured patients.
Method: Phase 3 first-line ICI trials in advanced HCC with mature follow-up (≥30 months) were identified, and individual patient data were reconstructed from published Kaplan–Meier curves (HIMALAYA, CheckMate-9DW, RATIONALE-301). In parallel, we analysed an international multicentre cohort of 1,581 patients with unresectable HCC treated with atezolizumab–bevacizumab in routine practice. MCMs were fitted separately for each treatment arm for overall survival (OS, long-term survivors) and progression-free survival (PFS, cure), using Weibull latency when appropriate, and were compared with background cirrhosis-related mortality. Prognostic factors for long-term survival and cure were explored.
Results: In HIMALAYA, the long-term survivor fraction was 12.8% (95%CI 8.5–18.6) with durvalumab-tremelimumab versus 5.2% (2.6–10.2) with sorafenib. In CheckMate-9DW, cure modelling suggested higher long-term survival and PFS plateaus with nivolumab-ipilimumab than with sorafenib/lenvatinib, although tail estimates were imprecise. In RATIONALE-301, long-term survival reached 25.2% versus 15.4% and cure 14.7% versus 8.7% with tislelizumab and sorafenib, respectively. In the real-world atezolizumab–bevacizumab cohort including 1581 patients (median follow-up 34.7 months), long-term survival was 12.3% (9.3–16.1) and cure 7.9% (6.3–9.8); in 1,187 patients fulfilling IMbrave150 criteria, these estimates rose to 15.4% and 9.1%. Hazards among long-term survivors approached cirrhosis-related background mortality. ALBI grade and hepatitis C independently predicted both long-term survival and cure.
Conclusion: Across trials and real-world data, ICI-based therapies yield long-term survival in roughly 10–15% of advanced HCC patients and cure in 7–9%. MCMs provide a clinically meaningful framework to quantify durable benefit and highlight the need for biomarkers and optimal cirrhosis management in long-term survivors.

Background and aims: Hepatic decompensation is a major event in patients with unresectable hepatocellular carcinoma (uHCC) treated with systemic therapy. Early identification of high-risk patients is essential. Aim of the study was to develop a simple score to predict decompensation in patients treated with atezolizumab plus bevacizumab (AB).
Method: This study enrolled 453 uHCC patients from the ARTE database (AB first-line, Child-Pugh A). External validation cohort included 292 patients from the AB-real database. Independent predictors derived from Cox regression were combined into a weighted score and operationalized as a point-based algorithm. Patients were then stratified into low, intermediate, and high-risk groups.
Results: In the ARTE database, 74 (16.3%) patients developed hepatic decompensation (median follow-up 14 months). Neoplastic portal vein thrombosis (HR 1.97, 95%CI 1.20–3.23, p = 0.007), elevated bilirubin (HR 2.61, 95%CI 1.52–4.47, p < 0.001), and low platelets (HR 1.82, 95%CI 1.07–3.10, p = 0.026) were independent predictors and they were incorporated into the ARTE-score. Patients were categorized as low (0–1 points, n = 360), intermediate (2 points, n = 49), or high risk (3–4 points, n = 44). Intermediate-risk patients had a 1.96-fold decompensation risk (p = 0.038) and high-risk patients a 4.28-fold risk (p < 0.001), compared to low-risk. Significant separation of decompensation-free survival across groups was observed (p < 0.001), with good discrimination (Harrell's C = 0.7022). Decompensation-free survival at 12 and 24 months was 87% and 83% for low-risk, 79% and 64% for intermediate-risk, and 57% and 56% for high-risk, respectively. The ARTE-score retained prognostic value in the AB-real cohort (HR 1.78, p = 0.009).
Conclusion: The ARTE score is an easy-to-use tool to predict hepatic decompensation in uHCC, aiding clinical decision-making.

THU-228

Liver and spleen MRI changes as predictors of hepatocellular carcinoma in patients with HCV-related cirrhosis and undefined liver nodules after DAA therapy

Luisa Cavalletto[1], Giovanna Lorigiola[1], Camillo Aliberti[2], Chiara Giraudo[3], Riccardo Carandina[4], Umberto Cillo[5], Liliana Chemello[1]. *[1]Dept. of Medicine-DIMED, University-Hospital, Padova, Italy; [2]Pederzoli Hospital, Verona, Italy; [3]Dept. of cardiotoracovascolar sciences and public health, Padova, Italy; [4]Dept DIDAS integrated diagnostic service, Padova, Italy; [5]Dept. of surgical, oncological and gastroenterological sciences - DiSCOG, Padova, Italy*
Email: luisa.cavalletto@unipd.it

Background and aims: Comprehensive data on incidence and significance of HCC development after direct-acting antiviral (DAA) for chronic hepatitis C remain limited. The drastic drop in viremia, resulting in immune system paralysis, could expose dysplastic hepatocytes to the action of endothelial growth factors. Our objectives were to characterize liver remodeling in patients with advanced fibrosis or cirrhosis with undefined/non-malignant liver nodules (ULNs) and to verify if liver and spleen parenchymal changes, using dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI), could be related to the early onset of HCC.
Method: Among 197 consecutively DAA treated, 57 patients (56.6 ± 10.6 years; 56% male) with ULNs, including 9, 11, and 37 with fibrosis stages F3, F4/CPT-A, and F4/CPT-B, were prospectively studied with DCE-MRI at baseline and 6–12 months after discontinuation of therapy. Two blinded radiologists independently analyzed 1710 images using a series of liver parameters (right and left inter lobe in the sagittal, coronal, and transverse planes measures), the porta vein and spleen diameter, and parenchymal homogeneity. All patients also underwent standard serum laboratory tests and liver (LSM) and spleen (SSM) stiffness by vibration-controlled transient elastography (VCTE). All obtained variables were compared using paired t-test and ANOVA for repeated measures.

Results: Seventeen patients (30%) developed HCC during follow-up. In this group, no significant changes were observed in DCE-MRI liver-based parameters, except for a significant increase in spleen size ($p < 0.05$). Conversely, the 40 patients who did not develop HCC showed a significant increase in all liver-based parameters at post-treatment imaging compared with baseline ($p < 0.05$). A reduction in LSM greater than 20% was observed exclusively in patients without HCC ($p < 0.01$). In contrast, patients who developed HCC exhibited increased SSM and a significant loss of parenchymal homogeneity compared with baseline ($p < 0.01$). Post-treatment biochemical profiles in patients with HCC showed significantly higher levels of gamma-globulins, alpha-2 macroglobulin, alpha-fetoprotein, and squamous cell carcinoma antigen (SCCA)-IgM compared with baseline ($p < 0.05$).
Conclusion: Spleen enlargement, increased SSM, and reduced parenchymal homogeneity were associated with HCC development after DAA therapy.These findings suggest a key role of worsening portal hypertension in hepatocarcinogenesis and support tailored MRI surveillance in high-risk patients.

THU-229
A dynamic model incorporating longitudinal alpha-fetoprotein and globulin trajectories to predict early recurrence in early-stage hepatocellular carcinoma

Minghui Zhu[1], Huanhuan Cao[1,2], Yujie Ran[1], Ning Yu[1], Songmei He[2], Jinzhang Chen[1], Huaiyu Chen[1], Dingli Liu[1], Kunyuan Wang[1], Hongyan Liu[1], Yabing Guo[1], Rong Fan[1]. *[1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Infectious Diseases, Dongguan People's Hospital, The Tenth Affiliated Hospital of Southern Medical University, Southern Medical University, Dongguan, China*
Email: rongfansmu@163.com

Background and aims: Hepatocellular carcinoma (HCC) remains a leading contributor to cancer-related mortality worldwide. While ablation and surgery is a mainstay curative treatment for early-stage HCC, high postoperative recurrence rates—particularly early recurrence within 2 years—significantly undermine long-term survival. We aimed to develop and validate a recurrence risk prediction model integrating longitudinal clinical data to optimize postoperative management and improve the prediction of early recurrence.
Method: In this multicenter study, 760 patients with early-stage HCC were enrolled and divided into a training cohort (N = 342), an external ablation validation cohort (N = 132), and a surgical resection validation cohort (N = 286). In the training cohort, latent class mixed models (LCMM) identified longitudinal trajectory patterns of alpha-fetoprotein (AFP) and globulin (GLB). Optimal thresholds, defined as the 95th percentile of longitudinal biomarker levels during follow-up within the low-stable group, were utilized to categorize patients in the validation cohorts. These identified trajectory features were integrated with baseline clinical variables to develop the Trajectory-integrated AFP and GLB-Clinical (TAG-C) model.
Results: Across the training, external ablation, and surgical cohorts, 2-year recurrence rates were 37.7% (129/342), 36.4% (48/132), and 23.1% (66/286), respectively. The majority of patients had hepatitis B virus etiology (ranging from 89.8% to 92.4% across cohorts) and were in Barcelona Clinic Liver Cancer (BCLC) stage 0 or A. The TAG-C model, incorporating AFP trajectory class, tumor size, GLB trajectory class, fibrinogen, and tumor number, demonstrated robust performance. Specifically, 2-year AUCs were 0.775 (95% CI 0.718 to 0.832) in training, 0.784 (95% CI 0.698 to 0.870) in external ablation, and 0.800 (95% CI 0.733 to 0.867) in surgical cohorts. Kaplan-Meier analysis confirmed distinct risk stratification across all cohorts ($p < 0.0001$), with high-risk groups exhibiting significantly increased recurrence risk compared to low-risk groups (Training: HR 7.17, 95% CI 4.78 to 10.75; External ablation: HR 6.11, 95% CI 3.16 to 11.82; Surgical: HR 5.15, 95% CI 3.03 to 8.77).
Conclusion: The TAG-C model, integrating longitudinal AFP and GLB trajectories, reliably predicts early recurrence, facilitating personalized surveillance and management for patients with early-stage HCC after curative treatment.

THU-231
Prognostic impact of geriatric nutritional risk index (GNRI) in patients with BCLC stage 0 hepatocellular carcinoma

Li-Chang Chen[1], Chun-Ting Ho[1], Pei-Chang Lee[1,2], Yi-Hsiang Huang[1,2,3], Ming-Chih Hou[1,2], Jaw-Ching Wu[3], Chien-Wei Su[1,2,3,4]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [3]Institute of Clinical Medicine, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan; [4]Division of General Medicine, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and aims: Nutritional status had been recognized as an increasingly important prognostic factor for hepatocellular carcinoma (HCC), but its significance in very early–stage disease remains unclear. The geriatric nutritional risk index (GNRI), calculated using serum albumin and ideal body weight, is a simple and noninvasive marker of nutritional status. This study evaluated the prognostic impact of malnutrition assessed by GNRI on overall survival (OS) in HCC patients with Barcelona Clinic Liver Cancer (BCLC) stage 0.
Method: This retrospective cohort study included 461 consecutive patients diagnosed with BCLC stage 0 HCC at Taipei Veterans General Hospital between January 2012 and July 2024. GNRI was calculated at diagnosis, and patients were classified into high- and low-GNRI groups using an optimal cutoff value of 103 determined by the Youden index for OS. Baseline characteristics were compared between groups. OS was analyzed using the Kaplan–Meier method with log-rank testing, and Cox proportional hazards regression were utilized to identify independent predictors of OS.
Results: Among the 461 patients, 312 (67.7%) had high GNRI and 149 (32.3%) had low GNRI. Patients with low GNRI were older, more often male, less likely to receive curative treatment, and had worse liver functional reserve, while tumor characteristics and viral etiology were similar between groups. After a median follow-up of 37 months (interquartile range: 19–70), 97 patients died, with a 5-year OS of 73.6%. OS was significantly lower in the low-GNRI group than in the high-GNRI group (61.3% vs. 80.4%, $p < 0.001$). In multivariable analysis, low GNRI (hazard ratio [HR] 1.99, 95% confidence interval [CI] 1.32–2.99, $p = 0.001$), lower platelet count (HR 2.97, 95% CI 1.78–4.94, $p < 0.001$), and elevated serum creatinine (HR 2.62, 95% CI 1.72–3.99, $p < 0.001$) were independently associated with increased mortality, whereas hepatitis B surface antigen positivity was associated with improved survival. Subgroup analyses showed that GNRI had better prognostic value in younger patients aged ≤ 65 years ($p < 0.001$).
Conclusion: Malnutrition, assessed by baseline GNRI, is a strong predictor for OS in patients with very early–stage HCC, particularly among younger individuals, with potential to serve as a practical tool for risk stratification.

THU-232
Diagnostic, screening, and longitudinal performance of des-gamma-carboxy prothrombin as a biomarker for hepatocellular carcinoma

Mateo Chvatal-Medina[1,2], Anneke Muller-Kobold[3], Xinlin Zheng[4], Han Moshage[1,5], Ruben de Kleine[6], Simeon Ruiter[6], Frederike van Vilsteren[1]. *[1]Department of Gastroenterology and Hepatology, University Medical Center Groningen, University of Groningen, P.O. Medellín, Colombia; [3]Department of Laboratory Medicine, University of Groningen, University Medical Center Groningen, Groningen, the Netherlands, Groningen, Netherlands; [4]Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, the Netherlands, Groningen, Netherlands; [5]Grupo Gastrohepatología, Facultad de Medicina, Universidad de Antioquia, UdeA, Calle 70 # 52-21, Medellin 050010, Colombia, Medellín, Colombia; [6]Department of Surgery, Section of Hepatobiliary Surgery and Liver Transplantation, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands
Email: m.chvatal-medina@umcg.nl

Background and aims: Early detection of hepatocellular carcinoma (HCC) is still challenging, as ultrasound has limited sensitivity and alpha-fetoprotein (AFP) has modest discrimination. Des-gamma-carboxy-prothrombin (DCP/PIVKA-II) is a promising biomarker but its incremental value for diagnosis, screening, and longitudinal risk assessment is incompletely defined, particularly in Western populations.
Method: We established a single center cohort from January 2017, consisting of patients who underwent surveillance according to EASL guidelines; as well as patients in whom HCC was suspected. Ultrasound, AFP, and DCP were measured every six months in at-risk patients; CT and/or MRI was used to confirm the diagnosis of HCC. Patients on vitamin K antagonists were excluded. For diagnostic analyses, we used samples within −90 to +45 days relative to the date of HCC-defining imaging; for non-HCC patients, the last available measurement was used.
Results: Among 2,769 patients at risk or suspicion of HCC, 82.8% belonged to the surveillance group and 17.2% to the suspicion group. Mean age was 59.0 ± 15.7 years and 56.4% were male. Among 1830 patients with chronic liver disease (CLD), 75.4% had cirrhosis, and the most frequent etiologies of CLD were metabolic-associated steatotic liver disease (22.9%), viral hepatitis (19.5%), and alcohol-associated liver disease (17.8%). 746 patients were diagnosed with HCC, 377 of them had DCP measurements within −90 to +45 days and were compared with 2,095 non-HCC controls (n = 2,472). AFP alone yielded an AUC of 0.76 (95% CI 0.73–0.79), DCP alone 0.80 (0.77–0.82), and the combined model 0.85 (0.83–0.87; $p < 0.001$ vs AFP). At 90% specificity, sensitivity increased from 47.7% for AFP to 56.9% for the combined model. For screening, 158 HCC patients had DCP measured ≤6 months before diagnosis; the combined model identified 81.9% of future HCC cases, while DCP alone detected 31.0% and AFP 7.7%. Longitudinal analyses in 97 HCC patients with ≥2 pre-diagnostic DCP measurements (median 3; median follow-up 321 days) showed a significant pre-diagnostic increase exceeding biological variation in 26.8%.
Conclusion: In a large real-world cohort reflecting the clinical spectrum in which HCC is considered, DCP provided incremental diagnostic and screening value over AFP, particularly in combined models. Longitudinal analyses further showed important pre-diagnostic increase in DCP, which argues in favor of integrating it with AFP to improve HCC detection.

THU-233
Integrating PIVKA-II into BCLC staging system improves significantly the prognostic stratification of hepatocellular carcinoma

Francesco Damone[1], Gian Paolo Caviglia[2], Francesco Faita[3], Piero Colombatto[1], Filippo Oliveri[1], Marta Guariglia[2], Gabriele Ricco[1], Silvia Gaia[4], Veronica Romagnoli[1], Daniela Cavallone[1], Emanuela Rolle[4], Patrizia Carucci[4], Ferruccio Bonino[3], Maurizia Brunetto[1,3,5]. *[1]Hepatology Unit, Pisa University Hospital, Pisa, Italy; [2]Department of Medical Sciences, University of Turin, Turin, Italy; [3]Institute of Clinical Physiology, Italian National Research Council (IFC-CNR), Pisa, Italy; [4]Gastroenterology Unit, Città della Salute e della Scienza - Molinette Hospital, Turin, Italy; [5]Department of Clinical and Experimental Medicine, Pisa University, Pisa, Italy*
Email: f.damone23@gmail.com

Background and aims: The prognostic stratification of Hepatocellular Carcinoma (HCC) by the Barcelona Clinic Liver Cancer (BCLC) staging system, based on liver function, tumour burden and clinical features does not account for tumour aggressiveness and biological heterogeneity. In a multicentre cohort study we assessed whether integrating BCLC with baseline serum levels of Protein induced by Vitamin K Absence-II (PIVKA-II) might improve prognostic stratification.
Method: PIVKA-II was measured in 605 consecutive HCC patients newly diagnosed at two tertiary Italian centres between 2010 and 2024 and modelled as a continuous variable. Overall survival (OS) was the primary outcome. Two separate Cox proportional hazards regression models were compared, one including BCLC stage alone and the other integrating BCLC stage with baseline PIVKA-II. The prognostic performance of the two models was assessed using time-dependent AUC, Brier score, and C-index at 24, 36, and 60 months, with internal validation based on a 70/30 train–test split.
Results: Eighty-three patients were classified as BCLC-0, 284 BCLC-A, 151 BCLC-B and 87 as BCLC-C. Median OS was 29.0 months, declining across stages from 47.9 to 10.7 months in BCLC-0 and C respectively ($p < 0.001$). The Cox model integrating PIVKA-II with BCLC stage showed significantly improved prognostic discrimination, particularly at mid- and long-term follow-up: at 36 months, the PIVKA-II-integrated model achieved higher time-dependent AUC than BCLC alone (80.8% vs 75.7%, $p = 0.006$), with a significant advantage at 60 months (79.3% vs 73.1%, $p = 0.002$). Calibration showed a limited improvement with PIVKA-II integration, mainly at mid- and longer follow-up, as reflected by lower Brier scores at 36 and 60 months (18.9% vs 19.2% and 19.8% vs 20.1%, respectively), consistent with improved accuracy of predicted survival probabilities. Overall concordance was higher for the PIVKA-II-integrated model than the BCLC model (C-index: 0.71 vs 0.68).
Conclusion: In newly diagnosed HCC patients PIVKA-II serum levels provide useful complementary prognostic information integrating the BCLC staging system with a significantly improved mid- and long-term survival prediction. These findings prompt further prospective studies integrating HCC biomarkers into BCLC to refine the prognostic assessment according to the precision medicine approach.

THU-234
Core diagnostic value of DCP and validation of the novel GADAA nomogram for HBV-related hepatocellular carcinoma

Zihan Liu[1], Juanjuan Shi[1], Wenhao Wang[1], Ling He[1], Shuangsuo Dang[1]. *[1]The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: liuzihan1999@126.com

Background and aims: Hepatocellular carcinoma (HCC) surveillance in patients with chronic hepatitis B (CHB) is often limited by the suboptimal sensitivity of alpha-fetoprotein (AFP), particularly in early-stage disease. This study aimed to evaluate the core diagnostic value of Des-gamma-carboxy prothrombin (DCP) in early-stage and AFP-negative HCC, and to construct and validate a novel, highly sensitive diagnostic model (GADAA) tailored for HBV-infected populations.
Method: A dual-center study involving 652 subjects (212 HCC patients and 440 controls with CHB or cirrhosis) was conducted from January 2023 to October 2025. Subjects were stratified by recruitment center into a training cohort (n = 509) and an independent external validation cohort (n = 143). Random forest algorithms were employed to screen potential predictors from demographic data, liver function tests, and serum biomarkers to construct the GADAA nomogram. Model performance was evaluated using the area under the receiver operating characteristic curve (AUC), calibration curves, and decision curve analysis (DCA). Furthermore, the diagnostic efficacy of GADAA was systematically compared against seven

established models: GALAD, C-GALAD, C-GALAD II, GAP-TALAD, ASAP, GAAP, and aMAP.
Results: DCP demonstrated the highest individual diagnostic accuracy (AUC = 0.862), maintaining robust performance in early-stage (AUC = 0.781) and AFP-negative HCC (AUC = 0.838). Following multistep variable screening, gender, age, DCP, AFP, and albumin were identified as independent predictors and integrated into the GADAA model. The model exhibited exceptional discrimination, achieving an AUC of 0.949 (95% CI: 0.930–0.969) in the training cohort and 0.912 (95% CI: 0.864–0.961) in the validation cohort. In a comparative assessment, GADAA (AUC 0.942) outperformed established models, including GALAD (AUC 0.917), C-GALAD (AUC 0.933), and ASAP (AUC 0.807). Notably, GADAA showed the highest sensitivity (88.7%) among all models, with excellent calibration and significant net clinical benefit.
Conclusion: DCP serves as a pivotal biomarker for early and AFP-negative HCC detection. The GADAA nomogram, incorporating DCP and routine clinical indicators, demonstrates superior diagnostic performance and clinical utility compared to existing models, providing a precise tool for HCC surveillance in HBV-endemic regions.

THU-236
Natural history of indeterminate liver lesions detected by MRI in liver cirrhosis: predicting progression to hepatocellular carcinoma

Thomas Dominicus[1], Jasper van Leengoed[1], Laura Boer[1], Job van der Palen[1], Donald Bouman[1], Maureen Guichelaar[1]. [1]*Medisch Spectrum Twente, Enschede, Netherlands*
Email: maureenguichelaar@yahoo.com

Background and aims: Indeterminate liver nodules in patients with cirrhosis, as classified by the Liver Imaging Reporting and Data System (LI-RADS), have an uncertain risk of progression to hepatocellular carcinoma (HCC), leading to clinical uncertainty and increased frequency of radiologic surveillance. Although LI-RADS provides ancillary features to improve risk assessment, their predictive value remains unclear. This study aims to provide further insight into the risk of HCC development by evaluating changes in indeterminate liver lesions over time.
Method: Our study is a retrospective cohort study concerning patients with liver cirrhosis who underwent annual MRI scanning for HCC surveillance from 2012 through 2024 following local protocol. Liver lesions were evaluated by LI-RADS criteria. LI-RADS ancillary features were assessed by the first researcher and verified by a specialized radiologist. Intralesional and whole-liver fat and iron content were measured using PDFF and T2* mapping.
Results: In the study cohort of 325 patients with liver cirrhosis, 74 patients had at least one indeterminate liver lesion (LR 2-3-4). Patients had a mean age of 61.4 (±11.9) years old, and 41.9% of patients were female. The most common etiologies of cirrhosis were MASLD (39.1%) and ALD (35.1%). A total of 311 liver lesions were studied, including 9 LR2-lesions (3%), 264 LR3-lesions (84%), 28 LR4-lesions (9%)). The median follow-up of these lesions was 3 MRI scans (IQR:2–4), and 15 months (IQR:6.3–30.5). Among 264 LR-3 lesions, 22 (8%) progressed to HCC and 132 (50%) resolved, whereas 6 of 28 LR-4 lesions (21%) progressed to HCC and 11 (39%) resolved during follow-up. Lesion size and the presence of at least one ancillary feature were found to be associated with progression to HCC. A multivariate model based on these variables showed an AUC of 0.80 for HCC development.
Conclusion: Our study demonstrates that LI-RADS 3 and 4 lesions have relatively low rates of progression to hepatocellular carcinoma (HCC), resp. 8% and 21% during the study follow-up. The majority of lesions resolved spontaneously, likely reflecting regenerative noduli. Ancillary imaging features and lesion size were predictive of HCC development, suggesting that models incorporating these factors could enable more individualized follow-up, warranting further studies.

THU-237
Hepatocellular carcinoma risk prediction score: a novel artificial intelligence model for hepatocellular carcinoma risk assessment in hepatitis C patients

Eslam Elmasry[1,2]. [1]*National Committee for control of viral hepatitis, Ministry of Health and Population, Egypt, Cairo, Egypt;* [2]*National Committee for Control of Viral Hepatitis (NCCVH), Ministry of Health and Population, Egypt, Cairo, Egypt*
Email: emji555@gmail.com

Background and aims: HCC remains a major cause of mortality in chronic HCV. Practical non-invasive tools are needed to identify patients at higher likelihood of HCC to support risk-adapted surveillance. We developed and validated a machine-learning HCC Risk Profiling Score (HRPS) using routinely available baseline pre-treatment variables and compared it with FIB-4.
Method: Retrospective NCCVH Egypt HCV cohort enriched to 4% HCC prevalence (N = 133,825; HCC events n = 5,353). Predictors were baseline pre-treatment variables: sex, treatment status, age, ALT, AST, albumin, total bilirubin, WBC, hemoglobin, platelets, INR, and creatinine. To reduce leakage, outcome-related fields and composite fibrosis indices (including FIB-4) were excluded from inputs, while component labs were retained. An XGBoost model with safe engineered features (ratios/log transforms) was trained using a stratified split 70/15/15 (train n = 93,677; validation n = 20,074; test n = 20,074; test HCC n = 803). Discrimination was assessed by AUROC and PR-AUC; calibration by Brier score (model). Clinical utility was assessed using top-k screening policies (top 1%, 5%, 10% predicted risk). FIB-4 was evaluated as a comparator (score-based).
Results: In the held-out test set, HRPS achieved AUROC 0.9129, PR-AUC 0.2934, and Brier 0.0317, outperforming FIB-4 (AUROC 0.8852; PR-AUC 0.2252). For top-k policies, HRPS yielded: top 1% precision 38.8% and recall 9.7% (vs FIB-4 28.9% and 7.2%); top 5% precision 33.4% and recall 41.7% (vs 24.9% and 31.1%); top 10% precision 25.5% and recall 63.8% (vs 22.6% and 56.4%).
Conclusion: HRPS provides a non-invasive baseline model to stratify HCV patients by likelihood of HCC using routine markers, with superior discrimination and high-risk enrichment compared with FIB-4. External validation in independent cohorts and evaluation with time-stamped follow-up are warranted.

THU-238
Anticipated patient responses to reviewing abnormal hepatocellular carcinoma imaging results: a descriptive analysis

Dabel Emebo[1], Laura Salej Duran[1], Beverly Kyalwazi[1,2], John Deng[1,3], Samantha Rangel Silos[1], Mariadelcarmen Yanez[1], Amit Singal[1], Jeremy Louissaint[1]. [1]*University Of Texas Southwestern Medical Center, Dallas, United States;* [2]*UCLA Health, Manhattan Beach, United States;* [3]*Beth Israel Deaconess Medical Center, Boston, United States*
Email: dabel.emebo@utsouthwestern.edu

Background and aims: Patients with cirrhosis are at an increased risk of hepatocellular carcinoma (HCC) and undergo semi-annual abdominal imaging. Since the 21st Century Cures Act, HCC screening results are released immediately to patients via patient portals (portals) and are frequently reviewed before provider communication. Herein, we describe patients' *anticipated* comprehension, emotional responses, communication preferences, and information-seeking behaviors after reviewing a standardized hypothetical abnormal HCC screening result report.

Method: Participants with cirrhosis reviewed a sample abdominal US or MRI result report with an US-3, LR-3, or LR-5 result that they had not previously experienced. Participants then completed a survey assessing *anticipated* outcomes across 4 domains: 1) Comprehension: confusion about the result and need for provider input to improve understanding, 2) Emotional Responses: result-related worry and anxiety (PROMIS Anxiety 7a - population mean of 50), 3) Communication Preferences: expected timing and method of provider communication, and 4) Information-Seeking: whether and how patients would seek result-related information.
Results: We surveyed 39 patients (median age 63 years; 51% Male; 71% non-Hispanic White) who reviewed one of three result samples: 9 US-3, 15 LR-3, and 15 LR-5. Comprehension: 22 (56.4%) found the result somewhat/very confusing and 36 (92.3%) would need provider input to improve understanding. The majority would like the report to include simple language and information about next steps. Emotional Responses: 59% anticipated more or much more worry, and anxiety was elevated (58.4, 56,9, and 62.4 for US-3, LR-3, and LR-5 results, respectively). Communication Preferences: Telephone (56.4%) and Portal Message (30.8%) were the preferred method of result-related provider communication, and communication within 24 hours was expected by 44.4% (US-3), 28.6% (LR-3), and 46.7% (LR-5). Information-Seeking: 87.2% would seek additional information and two-thirds would start with search-engine results.
Conclusion: Patients with cirrhosis anticipated high levels of confusion, worry, and desire for rapid additional result-related information after reviewing a hypothetical abnormal HCC screening result. These findings underscore potential targets for portal-based interventions to improve comprehension and reduce result-related worry and anxiety.

THU-239

Real-world validation of the GAAD algorithm for hepatocellular carcinoma detection across aMAP-defined risk strata in large-scale prospective Chinese cohorts

Rong Fan[1], Haiyan Yang[1], Siru Zhao[1], Hong Ma[2], Junqi Niu[3], Huiying Rao[4], Qing Xie[5], Dong-Ying Xie[6], Jianping Xie[7], Shumei Lin[8], Song Yang[9], Hongbo Gao[10], Jainqi Lian[11], Xiaoguang Dou[12], Jian Sun[1], Jinlin Hou[1]. *[1]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China; [3]Department of Liver, First Hospital of Jilin University, Changchun, China; [4]Peking University Hepatology Institute, Peking University People's Hospital, Beijing, China; [5]Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [6]Department of Infectious Diseases, Sun Yat-Sen University 3rd Affiliated Hospital, Guangzhou, China; [7]Department of Infectious Diseases, Xiangya Hospital, Central South University, Changsha, China; [8]Department of Infectious Diseases, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [9]Beijing Ditan Hospital, Capital Medical University, Beijing, China; [10]8th People's Hospital, Guangzhou, China; [11]Centers of Infectious Diseases, Tangdu Hospital, the Fourth Military Medical University, Xi'an, China; [12]Department of Infectious Diseases, Shengjing Hospital of China Medical University, Shenyang, China*
Email: rongfansmu@163.com

Background and aims: While the GAAD algorithm shows promise for hepatocellular carcinoma (HCC) detection, its performance across diverse clinical settings stratified by HCC risk remains to be validated. We aimed to clinically validate the GAAD algorithm for differentiating HCC in Chinese patients with chronic hepatitis B (CHB) or cirrhosis encompassing all HCC risk strata.

Method: A total of 4,355 participants from two prospective cohorts in China were enrolled, including 1,512 cirrhotic patients from Nanfang Hospital (NCT03588442), predominantly related to hepatitis B virus infection, and 2,843 CHB patients from the nationwide multicentre cohort (NCT02167503). The median follow-up durations were 37.4 (IQR 18.5–60.5) and 60.7 (IQR 48.5–72.8) months, respectively. The GAAD algorithm, calculated from age, gender, AFP, and PIVKA-II, was assessed at HCC diagnosis or last follow-up for non-HCC patients, and HCC risk was stratified by aMAP (cut-off 50) into low- and medium-to-high-risk groups. Performance was evaluated by the area under the receiver operating characteristic curve (AUC), with cutoffs of 2.57, 20 ng/mL, and 28.4 ng/mL for GAAD, AFP, and PIVKA-II, respectively.
Results: The median ages were 51.0 and 47.4 years in the cirrhosis (n = 1512; 97 HCC cases, 1415 controls) and CHB cohorts (n = 2843; 127 HCC cases, 2716 controls), respectively. In the cirrhosis cohort, GAAD demonstrated superior accuracy with AUCs of 0.871 (all-stage) and 0.835 (early-stage), significantly outperforming AFP (all-stage: 0.811, $p = 0.006$; early-stage: 0.758, $p = 0.026$) and PIVKA-II (all-stage: 0.724, $p < 0.001$; early-stage: 0.709, $p = 0.006$). The sensitivity and specificity of GAAD for early-stage HCC detection were 55.6% and 98.2%, respectively. Furthermore, GAAD achieved satisfactory performance in the aMAP low-risk stratum (AUC 0.989), outperforming its moderate accuracy in the aMAP medium-to-high-risk stratum (AUC 0.855). In the CHB cohort, similar findings were observed, with AUCs for early-stage HCC of GAAD, AFP, and PIVKA-II being 0.847, 0.747, and 0.732, respectively. GAAD consistently demonstrated superior performance compared to single biomarkers, yet exhibited better accuracy in the low-risk stratum than in the medium-to-high-risk stratum.
Conclusion: The GAAD algorithm provides a robust and generalizable tool for HCC detection in Chinese patients, although its performance varies across aMAP risk strata. Further prospective validation is warranted to assess the clinical utility.

THU-240

Remaining chronic hepatitis C treatment gaps impact on the care cascade of HCV relatedhepatocellular carcinoma

Joan Flores[1,2], Alexander Thompson[1,3], Thai Hong[1], Stuart Roberts[4], William Kemp[4], Amanda Nicoll[5], Zina Valaydon[6], Gauri Mishra[7], Marie Sinclair[8], Diana Lewis[9], Ammar Majeed[4], Marno Ryan[1], Jessica Howell[1,3]. *[1]Saint Vincent's Hospital Melbourne, Fitzroy, Australia; [2]Canberra Hospital, Garran, Australia; [3]University of Melbourne, Parkville, Australia; [4]Alfred Health, Melbourne CBD, Australia; [5]Eastern Health, Box Hill, Australia; [6]Western Health, Footscray, Australia; [7]Monash Medical Centre Clayton, Clayton, Australia; [8]Austin Hospital, Heidelberg, Australia; [9]Northern Health, Epping, Australia*
Email: ericka@flores.com.au

Background and aims: Direct-acting antivirals (DAAs) for hepatitis C (HCV) became universally available in Australia in 2016, but the impact of HCV cure on the presentation and outcomes of HCV-related hepatocellular carcinoma (HCV-HCC) remains unclear. This study examined the HCV care cascade among people with HCV-HCC and assessed the impact of sustained virological response (SVR) on tumour stage, treatment, and survival.
Method: Incident HCC cases from six Melbourne tertiary hospital networks (2018–2021) were retrospectively identified and followed to October 2023. HCC was diagnosed by histopathology or LIRADS imaging with multidisciplinary team (MDT) consensus. SVR was confirmed by negative HCV RNA or documentation. Statistical analyses included Chi-square, Wilcoxon rank-sum, and Cox regression.

Results: Of 1,013 HCC cases, 35% (n = 348) were HCV-related. HCV-HCC cases were younger (median 61 vs 70 years, p < 0.0001) and more likely to have cirrhosis (95% vs 77%, p < 0.0001) and prior surveillance (45% vs 37%, p = 0.012). Among HCV-HCC cases, 61% achieved SVR, with a median 2.9 years from SVR to HCC diagnosis. Those with SVR had less prior alcohol misuse (27% vs 43%, p = 0.003) and injecting drug use (26% vs 41%, p = 0.003), and were more likely to undergo surveillance (64% vs 18%, p < 0.001), present with early BCLC stage (59% vs 40%, p = 0.001), and receive curative therapy (40% vs 27%, p = 0.015). Mortality was lower in the SVR group (42% vs 59%, p = 0.004) with longer median survival (11.9 vs 6.0 months, p = 0.02). SVR was associated with improved overall survival (HR 0.57, 95% CI 0.41–0.79, p = 0.001), but this was not significant after adjustment for age, liver function, and tumour stage (aHR 0.79, 95% CI 0.54–1.15, p = 0.22).
Conclusion: Despite DAA availability, many people with HCV-HCC remain untreated, undiagnosed with cirrhosis, or unscreened for HCC. Achieving SVR is linked to earlier-stage HCC and better survival, underscoring the need for improved HCV detection, fibrosis assessment, and surveillance to reduce HCV-HCC mortality.

THU-241
Temporal trends of hepatocellular carcinoma and utilization of various abdominal imaging modalities in the United States

Pareen Vora[1], Shweta Shaw[2], Sebastiano Forgia[1], Oisin Butler[1]. [1]*Bayer AG, Berlin, Germany;* [2]*Axtria, Hyderabad, India*
Email: pareen.vora@bayer.com

Background and aims: Use of diagnostic imaging and the incidence of hepatocellular carcinoma (HCC) have both increased in the US over the last two decades. Previous research showed that the incidence of HCC was lowest in whites vs other racial groups. However, a systemic analysis of imaging modality usage in HCC patients, particularly by demographics, is lacking. This study examines temporal trends in the use of diagnostic imaging in HCC patients.
Method: A retrospective cohort study was conducted using Optum Clinformatics DataMart in the US. We identified adults (> = 18 years) who had a diagnosis of HCC and separately adults who underwent at least one abdominal magnetic resonance imaging (MRI), computed tomography (CT), or ultrasound between Jan 2016 and Dec 2024. Further for patients who underwent imaging, we identified diagnosis of HCC within a 12-month window (6 months before or after their imaging). Annual rates per 100,000 patients for HCC and for each imaging modality in HCC patients were calculated and stratified by age, gender, race, and ethnicity.
Results: From 2016–24, the overall rates of HCC increased from 103 to 204 per 100,000, driven by an increase in individuals aged ≥65 years (329 to 470) and males (138 to 260) versus females (68 to 152). Rates in Asians stayed relatively stable (239 to 269), while rates in both White (130 to 285) and Black (131 to 286) populations showed similar increases, as did rates in Hispanic (161 to 262) and non-Hispanic (129 to 280) populations. In HCC patients, MRI, CT, and ultrasound rates increased between 2016 and 2024, from 29 to 83, 38 to 88 and 26 to 56 per 100,000, respectively. The highest rates were in individuals aged ≥65 years, with stable trends in other age groups. Imaging modality usage in HCC patients was higher in males. No racial differences were observed. Although rates were initially higher among Hispanic individuals, this pattern reversed around 2023–2024. Overall rates of diagnostic imaging increased from 2018 onward, coinciding with the LI-RADS update, reflecting its potential impact. This upward trend was interrupted during the COVID-19 pandemic, particularly among individuals aged ≥65 years, across the 2020–22 period.
Conclusion: Incidence of HCC continues to rise, particularly among older adults, with no substantial variation observed across racial or ethnic groups. The use of MRI, CT, and ultrasound in HCC has increased over the last decade, particularly among the elderly and more prevalent in males, reflecting the underlying epidemiology.

THU-242
18F-Fluorodeoxyglucose positron emission tomography is a predictive factor of early response to atezolizumab-bevacizumab in patients with hepatocellular carcinoma

Maria Stella Franzè[1,2], Julia Chalaye[3], Stefano Caruso[2], Hélène Regnault[2,4], Lionel Lerman[3], Sébastien Mulé[2,5], Edouard Reizine[2,5], Alain Luciani[2,5], Vincent Leroy[2,4], Giuliana Amaddeo[2,4]. [1]*Unit of Medicine and Hepatology, University Hospital of Messina, Messina, Italy;* [2]*INSERM U955, Team "Viruses, Hepatology, Cancer", Créteil, France;* [3]*Department of Nuclear Medicine, AP-HP, Henri Mondor University Hospital, Créteil, France;* [4]*Department of Hepatology, AP-HP, Henri Mondor University Hospital, Créteil, France;* [5]*Department of Medical Imaging, AP-HP, Henri Mondor University Hospital, Créteil, France*
Email: mariastellafranze@gmail.com

Background and aims: The role of ^{18}F-fluorodeoxyglucose (FDG) or ^{18}F-fluorocholine (FCH) positron emission tomography (PET)/computed tomography (CT) in assessing immunotherapy (IT) response in hepatocellular carcinoma (HCC) remains unclear. This study evaluated the prognostic role of dual-tracer ^{18}F-FDG and ^{18}F-FCH PET/CT or magnetic resonance imaging (MRI) in predicting early response and overall survival (OS) in HCC patients treated with Atezolizumab/Bevacizumab.
Method: Forty-one patients (37 males; median age 65 years) with unresectable HCC undergoing baseline ^{18}F-FDG and ^{18}F-FCH PET/CT or MRI before IT at Henri Mondor University Hospital (Créteil, France) were analysed. Early response was evaluated after three IT cycles using RECIST 1.1/mRECIST criteria, and defined as disease control rate (DCR), including complete/partial response and stable disease. Metabolic parameters were correlated with DCR, progression-free survival (PFS), and OS.
Results: Thirty-two patients (78%) had BCLC-C stage (41.5% with macrovascular invasion, 43.9% with metastasis). HCC was multinodular in 30 cases (73.2%), with a median largest lesion size of 38 mm (21–86). Early objective response rate was 39%, DCR 66%, and early progression (e-PD) 22%. FDG-PET was performed in 19 patients (46.3%), FCH-PET in 6 (14.6%), and both tracers in 16 (39%). FDG-positive HCC (uptake higher than non-tumoral liver) was observed in 68.6% (median SUVmax 4.8), while extrahepatic FDG uptake in lymph nodes (14.7%; SUVmax 10), portal vein (11.8%; SUVmax 9.1), lungs (11.8%; SUVmax 6.9). FCH-positive uptake was seen in 11 cases (50%; median SUVmax 11.2), and extrahepatic in lymph nodes (22.7%; SUVmax 8.5) and bones (9.1%; SUVmax 24.4). Patients with DCR had fewer FDG-positive HCCs (55% vs 92%, p = 0.05) than ePD. FDG-positive HCC correlated with ePD (p = 0.05) and shorter OS (8.7 vs 31.7 months, p = 0.05). A higher FCH tumour-to-liver ratio (TLR) was associated with death (p = 0.04). In univariate Cox analysis, AFP (p = 0.02), MELD (p = 0.01), ALBI grade >1 (p = 0.02), ECOG ≥1 (p = 0.01), FDG-positive HCC (p = 0.05), and absence of early DCR (p < 0.001) predicted poorer OS. In multivariate analysis, ALBI >1 (HR 5.77, 95%CI 1.69–19.7, p = 0.005) and DCR (HR 0.33, 95%CI 0.14–0.79, p = 0.01) remained independent predictors.
Conclusion: FDG-positive HCC was associated with ePD and shorter OS in patients treated with Atezolizumab/Bevacizumab, suggesting that baseline metabolic phenotype on FDG-PET may reflect tumour aggressiveness and early IT resistance.

THU-245

Anti-HBc positivity is associated with worse tumour features and reduced survival in HBsAg-negative patients with hepatocellular carcinoma

Maria Stella Franzè[1], Arianna Toscano[1,2], Clelia Asero[1,2], Gaia Caccamo[1], Roberto Filomia[1], Concetta Pitrone[1], Irene Cacciola[1,2], Carlo Saitta[1,2]. *[1]Unit of Medicine and Hepatology, University Hospital of Messina, Messina, Italy; [2]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy*
Email: mariastellafranze@gmail.com

Background and aims: Occult HBV infection (OBI) has been identified as a possible co-factor of liver damage in patients with different aetiologies of chronic liver disease (CLD), favouring the progression towards cirrhosis and hepatocellular carcinoma (HCC). This study aimed to evaluate the association between anti-HBc positivity, a surrogate marker of OBI, with clinical features and survival in HBsAg-negative HCC patients.
Method: We retrospectively evaluated all consecutive HBsAg-negative patients with first diagnosis of HCC followed at the Hepatology Unit of the University Hospital of Messina from January 2014 to May 2025. Aetiology and clinical/biochemical data of underlying CLD, tumour features and survival were evaluated. CLD was classified as follows: (1) hepatitis C virus (HCV)-related; (2) chronic alcoholic liver disease (ALD); (3) metabolic dysfunction-associated steatotic liver disease (MASLD)-related; 4) primary biliary cholangitis (PBC)- or autoimmune hepatitis (AIH)-related; 5) cryptogenic in patients without any identifiable aetiology. Overall survival (OS) was defined as the time from HCC diagnosis to death or last follow-up.
Results: A total of 382 patients [75.7% males; median age 70 years; 65 (17%) anti-HBc positive (anti-HBc+)] were analysed. CLD was HCV-related in 125 patients (32.7%, 29 anti-HBc+), MASLD in 110 (28.8%, 17 anti-HBc+), ALD in 72 (18.8%, 7 anti-HBc+), cryptogenic in 67 (17.5%, 11 anti-HBc+), PBC/AIH in 8 (2.1%). During follow-up, 226 patients (59.2%) died [OS 21.4 months (9.3–44.1)]. Among HCV-positives, anti-HBc+ individuals showed higher prevalence of extrahepatic HCC metastases than anti-HBc negative (anti-HBc-) patients (17.2% vs 2.1%, p = 0.009). In the MASLD group, anti-HBc+ patients displayed higher prevalence of multinodular HCC vs anti-HBc- (17.6% vs 1.1%, p = 0.031). In ALD patients, anti-HBc+ was associated with higher prevalence of gastro-oesophageal varices (71.4% vs 58.7% p = 0.008), ascites (57.2% vs 30.2%, p = 0.016), and reduced OS (12.1 vs. 25.3 months, p = 0.037) vs anti-HBc-. Kaplan-Meier analysis confirmed reduced OS (p = 0.018). At multivariate analysis, anti-HBc+ independently predicted reduced OS (HR 5.39, 95%CI 1.8–16.2, p = 0.003), together with higher alpha-fetoprotein levels (p = 0.01), larger tumour size (p = 0.019), and extrahepatic localization (p < 0.001).
Conclusion: Anti-HBc positivity is associated with increased mortality in HBsAg-negative HCC patients with ALD, and with more aggressive tumour features in MASLD- and HCV-related CLD.

THU-246

Machine learning-enhanced serum FTIR spectroscopy analysis for diagnosing hepatocellular carcinoma in cirrhotic patients

Elia Gigante[1], Caden Gunnarson[2], Eng Hock Lee[3], Ali Khammanivong[3], Dan Que Pham[3], Valérie Untereiner[1], Roselyne Garnotel[1], Vanessa Cottet[4], Jean-Pierre Bronowicki[5], Brigitte Beranrd-Chabert[6], François Habersetzer[7], Patrick Hillon[4], Ganesh Sockalingum[1], Gerard Thiefin[1]. *[1]Université de Reims Champagne-Ardenne, CHU Reims, Service d'Hépato-Gastroentérologie et de Cancérologie Digestive, Reims, France; [2]Oncodea, Saint Paul, United States; [3]Oncodea, St Paul, MN, United States; [4]Inserm U1231, Dijon, France; [5]CHU de Nancy, Nancy, France; [6]CHU Reims, Reims, France; [7]Les Hôpitaux Universitaires de Strasbourg, Strasbourg, France*
Email: elia.gigante@hotmail.it

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths worldwide. The identification of novel serum biomarkers is critical to improving screening performance for this malignancy. This study aimed to determine whether serum Fourier transform infrared (FTIR) spectroscopy, combined with machine learning analysis, can generate distinct spectral profiles capable of differentiating cirrhotic patients with HCC from those without.
Method: Serum samples were collected from 2 sets of patients: cirrhotic patients with HCC (n = 280) and without HCC (n = 458). High-throughput FTIR spectra (ten replicates per sample) were acquired in the transmission mode, quality-tested, baseline corrected, converted to second derivative, and vector normalized. The Extreme Gradient Boosting (XGBoost) model and several other supervised machine learning models were trained to predict HCC status. The potential of combining serum AFP and spectral information to improve the diagnostic performance was also explored.
Results: XGBoost model achieved 68% specificity at a fixed sensitivity of 90% (AUROC = 0.86) when tested on the spectral dataset. Diagnostic performance was significantly improved in the non-diabetic subgroup (n = 450, including 151 HCC patients), achieving 84% specificity at 90% sensitivity (AUROC = 0.93). In contrast, performance was suboptimal in the diabetic subgroup (n = 288, including 129 HCC patients) with 42% specificity at 90% sensitivity. Combining the spectral data with serum alpha-fetoprotein (AFP) levels further enhanced diagnostic performance in the non-diabetic patient, resulting in 89% specificity at 90% sensitivity (AUROC = 0.96).
Conclusion: High-throughput serum FTIR spectroscopy combined with machine learning-based analysis represents a promising diagnostic approach for discriminating HCC from non-HCC cirrhotic patients in a non-diabetic population, achieving 84% specificity at 90% sensitivity.

Impact of Hepatocellular Carcinoma on circulating reticulated platelets in patients with and without liver cirrhosis

Pietro Guerra[1], Serena Toffanin[1], Cristiana Bulato[1], Antonio Bonato[1], Silvia Cagnin[1], Caterina Soldà[2], Mario Domenico Rizzato[2], Sara Lonardi[2], Francesca Bergamo[2], Alberto Zanetto[1], Elisa Pinto[1], Marco Senzolo[3], Sara Montagnese[1], Paolo Simioni[1], Elena Campello[1], Andrea Martini[3]. *[1]University of Padova, Padua, Italy; [2]Aziende Sanitarie Padova-Istituto Oncologico Veneto-Irccs, Padova, Italy; [3]Azienda Ospedale-Università di Padova, AOPD, Padova, Italy*
Email: pietro.guerra1@gmail.com

Background and aims: Reticulated platelets (RePLT) are newly released platelets that reflect thrombopoietic activity. Their role in hepatocellular carcinoma (HCC) remains unclear. We assessed RePLT levels and platelet activation patterns in HCC patients with and without liver cirrhosis (LC).
Method: We prospectively enrolled 60 subjects into four groups: healthy controls (CTRL), LC without HCC (LC+ HCC-), HCC on a healthy liver (LC- HCC+), and HCC on cirrhosis (LC+ HCC+). Exclusion criteria were advanced liver disease (Child-Pugh B/C), portal vein thrombosis, and antiplatelet therapy. RePLT were measured by flow cytometry, and their activation was evaluated by phosphatidylserine and P-selectin exposure across different reticulation strata (low/high/very-high). Multivariable linear regression assessed the independent association between HCC and RePLT. Repeated-measures ANOVA tested the effect of reticulation and group interaction.
Results: Sixty subjects were included: CTRL (n = 28), LC+ HCC- (n = 16), LC- HCC+ (n = 5), and LC+ HCC+ (n = 11). RePLT were lower in HCC (median: 4.02% in CTRL, 3.76% in LC+ HCC-, 1.98% in LC- HCC+, and 1.55% in LC+ HCC+; p = 0.004). In a multivariable linear regression, HCC was independently associated with reduced RePLT (coefficient −2.51%; 95% CI −4.55 to −0.46; p = 0.018). Both phosphatidylserine and P-selectin increased significantly with increasing reticulation (p < 0.001 for both). The increase across reticulation strata differed by group for both markers (p < 0.001 for both), showing blunted activation in HCC groups. Specifically, in the three reticulation

strata, Annexin V increased from 1.07%, 8.29%, and 46.0% in CTRL and 0.57%, 11.5%, and 68.6% in LC+ HCC–, with smaller increases in LC– HCC+ (2.54%, 2.83%, and 7.27%) and LC+ HCC+ (4.74%, 7.54% and 20%). Similarly, CD62P rose from 3.02%, 29.6% to 93.7% in CTRL and 3.63%, 45.6% to 96.6% in LC+ HCC–, versus more limited increases in LC– HCC + (1.29%, 2.38% to 15.6%) and LC+ HCC+ (1.59%, 5.01% to 35.3%).
Conclusion: HCC is independently associated with reduced circulating RePLT. The presence of HCC is characterized by lower platelet activation at increasing reticulation levels, supported by significant reticulation-by-group interactions for both Annexin V and CD62P. Further studies should clarify mechanisms and clinical implications.

THU-248
Hepatocellular carcinoma imaging using prostate-specific membrane antigen positron emission tomography - The Hepa-SMART trial

Nicholas Hannah[1,2,3,4,5], Grace Kong[2,5], Kim Taubman[6], Sze Ting Lee[2,7,8,9], Wayland Wang[1,2], Sophia Xie[5], Alex Boussioutas[10,11], Rod Hicks[2,10], Siddharth Sood[2,3]. *[1]The Royal Melbourne Hospital, Parkville, Australia; [2]The University of Melbourne, Parkville, Australia; [3]Northern Health, Epping, Australia; [4]Western Health, Footscray, Australia; [5]Peter Maccallum Cancer Centre, Melbourne CBD, Australia; [6]Saint Vincent's Hospital Melbourne, Carlton, Australia; [7]Austin Hospital, Heidelberg, Australia; [8]Latrobe University Bundoora Melbourne, Bundoora, Australia; [9]RMIT University, Bundoora, Australia; [10]Monash University, Clayton, Australia; [11]The Alfred, Melbourne CBD, Australia*
Email: nicholas.hannah2@mh.org.au

Background and aims: Prostate-specific membrane antigen (PSMA) is a tumour-associated target which can be detected by positron emission tomography (PET). This study aimed to evaluate the diagnostic performance of PSMA PET/CT using [^{18}F]F-DCFPyL radiotracer in detecting hepatocellular carcinoma (HCC).
Method: Hepa-SMART is a multicentre, investigator-initiated, prospective clinical trial (NCT05095519). Two cohorts were recruited: Group 1, radiologically confirmed HCC (LR 5); and Group 2, indeterminate or probable HCC (LR 3–4). Patients were to receive either biopsy or surgical resection to allow histological confirmation and PSMA immunohistochemistry (IHC). Diagnostic performance was assessed using per-patient and per-lesion analyses, with intention-to-treat and per-protocol approaches.
Results: Twenty-five patients were recruited: Group 1 (n = 11) and Group 2 (n = 14) with 36 lesions (HCC confirmed n = 26, benign n = 9, equivocal n = 1). Median lesion size: Cohort 1 18.0 mm (IQR 13.0–31.0), and in Cohort 2 15.0 mm (IQR 11.0–22.5). HCC lesions with positive [^{18}F]F-DCFPyL PET/CT uptake had median SUVmax 5.7 (IQR 4.63–9.15), tumour-background ratio (TBR) 1.13 (IQR 0.97–1.76). [^{18}F]F-DCFPyL PET/CT demonstrated high specificity across cohorts. In LR 5 HCC, sensitivity was 54.5% with a positive predictive value (PPV) of 100%. In indeterminate lesions, per-lesion intention-to-treat analysis demonstrated sensitivity 27.3%, specificity 90%, PPV 75%, and negative predictive value (NPV) 52.9%. Per-protocol analyses yielded similar results. On whole-cohort per-lesion analysis, the area under the receiver operating characteristic curve (AUROC) for a positive scan diagnosing HCC was 0.72 (95% CI 0.60–0.84; p = 0.0012). Quantitative TBR analysis did not improve diagnostic performance. Benign lesions demonstrated exclusively low PSMA expression intensity on IHC, HCC showed significantly high expression intensity (p = 0.005) with a predominant endothelial compartment expression in HCC, with positive correlations between PSMA IHC intensity and PET SUVmax (R = .48, p = 0.019) and TBR (R = 0.42, p = 0.039).
Conclusion: Hepa-SMART is the first prospective multicentre clinical trial evaluating [^{18}F]F-DCFPyL Although sensitivity is modest in early-stage disease, [^{18}F]F-DCFPyL PET/CT demonstrates high specificity and PPV, supporting its clinical utility for confirming HCC and providing tumour-specific information beyond conventional imaging.

THU-249
Would a non-imaging-based strategy be effective for hepatocellular carcinoma surveillance?

Grishma Hirode[1,2], Korosh Khalili[3], Lima Awad El-Karim[3], Hooman Farhang Zangneh[1], Harry L.A. Janssen[1,4], Bettina E. Hansen[5], Morris Sherman[1], Jordan J. Feld[1,2]. *[1]Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, Toronto, Canada; [2]The Viral Hepatitis Care Network Canada (VIRCAN), Toronto, Canada; [3]Joint Department of Medical Imaging, University Health Network, Toronto, Canada; [4]Department of Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands; [5]Department of Epidemiology, Biostatistics, Erasmus MC University Medical Center, Rotterdam, Netherlands*
Email: grishma.hirode@gmail.com

Background and aims: Despite biannual ultrasound (US) for hepatocellular carcinoma (HCC) surveillance, many patients are diagnosed at an advanced stage. US is operator-dependent and adherence is typically poor. Better understanding of existing methods and development of new strategies are needed to improve early-stage HCC detection. We examined whether biomarkers (BMs), alone or in combination with US, and the GALAD score which uses a combination of all 3 BMs – treated as continuous variables – along with age and sex, were as effective as US alone or US + alpha-fetoprotein (AFP); the standard of care.
Method: Prospective study of patients with cirrhosis or high-risk hepatitis B virus (HBV) infection using US + BM for HCC detection. AFP > 100 ng/mL, lectin-reactive fraction of AFP (AFP-L3) > 10%, des-gamma-carboxy prothrombin (DCP) > 2 ng/mL, or US findings triggered further imaging (computed tomography/magnetic resonance imaging) for HCC confirmation. We compared effectiveness of each method using the area under the receiver operating characteristic (AUROC) curve after logistic regression, accounting for patient-level variance.
Results: Among 605 patients (mean age 58 ± 9.9 years, 72% male, 64% cirrhosis), 27 were diagnosed with HCC (22 early, 5 advanced). For US + 3 BMs at study thresholds, AUROC, sensitivity (sens) and specificity (spec) were 0.81, 96% and 65%. For US alone, AUROC, sens and spec were 0.72, 77% and 66%. Without US, the optimal cut-off for AFP was 4.2 ng/mL (AUROC 0.82, sens 84%, spec 80%), AFP-L3 was 1.4% (AUROC 0.73, sens 72%, spec 74%) and DCP was 0.3 ng/mL (AUROC 0.80, sens 85%, spec 75%). Performance of BMs was evaluated using study thresholds and these optimized thresholds, alone or combination with US. US + AFP was comparable to US alone and US + 3 BMs. The optimal cut-off for the GALAD score was −1.8 (AUROC 0.85, sens 89%, spec 81%). The GALAD score at this threshold resulted in higher AUROC, sens, and spec compared with all other examined methods, with or without inclusion of US.
Conclusion: In this study, the GALAD score outperformed all US-based HCC surveillance methods. Thus, a non-imaging-based surveillance strategy may be feasible, and particularly useful when access to US is limited or US is of poor quality. However, a prospective study of such a strategy with validated GALAD score thresholds will be crucial for generalizability and application in practice.

The impact of insulin resistance on hepatic steatosis and outcome for hepatocellular carcinoma patients undergoing surgical resection

Chun-Ting Ho[1,2], Chia-Jung Ho[1], Tsai Shin-Yu[1], Yi-Chen Lin[3], Yi-Hsiang Huang[4], Ming-Chih Hou[5], Jaw-Ching Wu[6], Chien-Wei Su[7]. *[1]Taipei Veterans General Hospital, Department of Medicine, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University Yangming Campus, Ph.D. Program of Interdisciplinary Medicine, Taipei, Taiwan; [3]Linkou Chang Gung Memorial Hospital, Department of Medicine, Taoyuan City, Taiwan; [4]Taipei Veterans General Hospital, Department of Medical Research, Taipei, Taiwan; [5]Taipei Veterans General Hospital, Division of*

Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [6]National Yang Ming Chiao Tung University Yangming Campus, Institute of Clinical Medicine, Taipei, Taiwan; [7]Taipei Veterans General Hospital, Division of General Medicine, Department of Medicine, Taipei, Taiwan
Email: cwsu2@vghtpe.gov.tw

Background and aims: Insulin resistance (IR) significantly influences cardiometabolic status and is a driver for steatotic liver disease (SLD). Triglyceride-glucose index (TyG), calculated using fasting serum triglyceride and glucose levels, is a simple and effective surrogate marker of IR. We aimed to evaluate the impact of IR on the extent of hepatic steatosis and long-term outcome in patients with hepatocellular carcinoma (HCC) undergoing surgical resection.
Method: A total of 744 HCC patients who underwent curative resection at Taipei Veterans General Hospital with available pathological specimens and complete clinical data were included. Patients were divided into high-IR (TyG ≥ 4.5, n = 431) and low-IR (TyG <4.5, n = 313) groups. Hepatic steatosis was histologically assessed using non-tumour liver tissue in the pathology specimen. Pearson correlation and receiver operating characteristic (ROC) analysis were utilized to assess associations between TyG and hepatic steatosis. Cox proportional hazards (COX PH) models and Kaplan-Meier (KM) survival analysis were performed to evaluate the prognostic role of TyG for overall survival (OS). Subgroup analysis was performed in patients with and without diabetes mellitus (DM).
Results: Patients in the high-IR group were older, had lower hepatitis B virus positivity, and a higher prevalence of steatohepatitis. Distinct tumor characteristics, serum biochemical profiles, and cardiometabolic comorbidities were also noted in the high-IR group compared to those in the low-IR group. The TyG index showed a significant positive correlation with the extent of hepatic steatosis and demonstrated good diagnostic performance for SLD (AUROC 0.713, p < 0.001). After a median follow-up of 57.0 months, 161 patients died, with a 5-year OS rate of 72.1%. KM analysis showed no significant difference in OS between high- and low-IR groups (5-year OS: 73.4% vs. 70.1%). COX PH model identified age, stage, prothrombin time international normalized ratio, serum albumin, and alpha-fetoprotein as independent risk factors for poor OS, while IR was not an independent prognostic factor. Subgroup analyses stratified by DM status also revealed no survival differences between high and low-IR groups.
Conclusion: IR was positively associated with the severity of hepatic steatosis and is linked to distinct tumor characteristics, cardiometabolic profiles, and biochemical parameters among HCC patients. However, IR did not independently influence OS after curative resection, irrespective of the presence of DM.

THU-361
Clinical distribution and prognostic implications of the ASAP score in a real-world cohort of hepatocellular carcinoma

Young Mi Hong[1], Hyun Myung Cho[2]. *[1]Department of Internal Medicine, Pusan National University School of Medicine, Pusan National University Yangsan Hospital, Yangsan, Korea, Rep. of South; [2]Pusan National University Yangsan Hospital, Yangsan, Korea, Rep. of South*
Email: 00gurum@hanmail.net

Background and aims: The ASAP score, which incorporates age, sex, alpha-fetoprotein, and protein induced by vitamin K absence-II, was originally developed as a simplified biomarker-based model to enhance early detection of hepatocellular carcinoma (HCC). However, its clinical associations and prognostic relevance in HCC remain unknown. This study aims to evaluate the prognostic and clinical relevance of the ASAP score at the time of diagnosis.
Method: We retrospectively analyzed patients newly diagnosed with HCC. ASAP scores were calculated at diagnosis, and their distribution was assessed. Correlations between ASAP scores and clinical characteristics were evaluated. Overall survival (OS) was evaluated using Kaplan-Meier and Cox proportional hazards models.
Results: Among 1,143 patients, the optimal cutoff value of the ASAP score was 2.9, yielding a sensitivity of 64% and a specificity of 80%, indicating its predictive value for mortality risk stratification. Patients with high ASAP scores had significantly worse OS ($P < 0.001$). In multivariate analysis, the ASAP score was an independent risk factor of OS [hazard ratio (HR) = 2.841, 95% confidence interval (CI) = 2.035–3.966, $P < 0.001$]. Higher ASAP scores were significantly associated with increased Child-Pugh scores ($P = 0.006$), more advanced BCLC stage ($P < 0.001$), and elevated neutrophil to lymphocyte ratio ($P < 0.001$). The mean ASAP scores by BCLC stage were 0.98 in stage A, 3.10 in stage B, 6.47 in stage C and 7.06 in stage D, respectively ($P < 0.001$).
Conclusion: Although originally developed for HCC surveillance, the ASAP score demonstrated a wide distribution and meaningful clinical correlations at the time of diagnosis in a real-world cohort. It also independently predicted OS, suggesting potential utility for risk stratification beyond early detection.

THU-362
mRNA COVID-19 vaccination shortly after PD-1/PD-L1 inhibitor Is associated with better survival in liver cancer: a Mayo Clinic platform study

Chenyu Sun[1], Li Liu[2], Abigail Fickel[3], Elizabeth Lees[1], Yichen Wang[4], Yan Yan[4], Paul Travers[4], Harsh Patel[5], Liu Yang[4], Yuting Huang[4]. *[1]Mayo Clinic Rochester, Rochester, United States; [2]The Second People's Hospital of Hefei, Hefei, China; [3]Mayo Clinic Alix School of Medicine, Rochester, United States; [4]Mayo Clinic Florida, Jacksonville, United States; [5]University of Maryland School of Medicine, Baltimore, United States*
Email: huang.yuting@mayo.edu

Background and aims: Prior research has demonstrated survival benefits of mRNA COVID-19 vaccination in patients with non-small cell lung cancer (NSCLC) and melanoma treated with immune checkpoint inhibitors (ICIs). However, the impact of vaccination on hepatocellular carcinoma (HCC)/liver cancer patients receiving PD-1/PD-L1 inhibitors remains unclear. This study investigates whether mRNA COVID-19 vaccination shortly after PD-1/PD-L1 inhibitor initiation improves overall survival in liver cancer.
Method: A retrospective analysis was conducted using the Mayo Clinic Platform (Full AMC1 dataset) including patients with hepatocellular carcinoma/liver cancer who received at least one dose of PD-1/PD-L1 inhibitors without liver surgery. The intervention group consisted of patients receiving an mRNA COVID-19 vaccine within six weeks of PD-1/PD-L1 inhibitor initiation, while the control group did not receive vaccination within this timeframe. Adjustments were made for BMI <30 and exclusion of patients with diabetes, cardiovascular disease, or heart failure history. The primary outcome was 5-year overall survival assessed via Kaplan-Meier analysis and Cox proportional hazards models. Age differences at diagnosis were assessed using Cohen's D, and sex distribution compared by Chi-square test. All analyses were performed using the Mayo Clinic Platform's tool.
Results: A total of 4,768 patients were included, with 584 in the vaccination group and 4,184 controls. Age and sex distributions were similar between groups (Cohen's D for age = 0.16; χ^2 for sex = 1.5, both not significant). The mRNA vaccine group showed significantly improved 5-year overall survival (37.9% vs. 23.4%, HR = 0.59, 95% CI: 0.52–0.66; P < 0.001). The survival benefit remained unchanged after adjustment, confirming the robustness of the finding. Survival curves demonstrated persistent benefit across time points up to 60 months.
Conclusion: The mRNA COVID-19 vaccination shortly after PD-1/PD-L1 inhibitor initiation is associated with improved 5-year overall survival in hepatocellular carcinoma/liver cancer patients. These findings align with prior evidence in other cancers treated with ICIs, suggesting vaccine-induced immune priming may enhance immunotherapy efficacy. Limitations include retrospective design, possible uncontrolled confounding, and incomplete 5-year follow-up for some patients who started therapy more recently. Prospective studies

are warranted to validate these results and explore underlying immunological mechanisms.

THU-363
Serum exosome-related lipids could detect MASLD-associated hepatocellular carcinoma

Jian Huang[1], Zhongguo Zhou[2], Arresha Nazeer[2], Julian L. Griffin[3], Mark R Thursz[1], Nadia Guerra[2], Pinelopi Manousou[1]. [1]*Saint Mary's Hospital, London, United Kingdom;* [2]*Imperial College London, London, United Kingdom;* [3]*University of Aberdeen, Aberdeen, United Kingdom*
Email: jian.huang20@imperial.ac.uk

Background and aims: The incidence of MASLD associated HCC is increasing worldwide, yet effective blood-based biomarkers for early surveillance are lacking [1]. Exosomes are stable in serum and carry molecular cargo reflective of tumour biology, making them an attractive source of non-invasive biomarkers [2,3]. While exosomal nucleic acids and proteins have been widely studied, the diagnostic potential of exosome-associated lipids remains poorly explored. This study aimed to identify exosome-associated lipids that distinguish MASLD-associated HCC from MASLD and to assess their translational potential as a surveillance tool.
Method: Serum exosomes were isolated from 110 patients (38 MASLD; 72 MASLD-associated HCC). Untargeted lipidomics profiling was performed using liquid chromatography–mass spectrometry (LC-MS). Multivariate analyses, including principal component analysis (PCA) and partial least squares discriminant analysis (PLS-DA), alongside Mann–Whitney U testing, were used to identify differentially lipids. KEGG pathway enrichment analysis assessed biological relevance. Least absolute shrinkage and selection operator (LASSO) regression was applied to derive a parsimonious lipid panel suitable for clinical translation.
Results: Exosome-associated lipids demonstrated clear separation between MASLD and MASLD-associated HCC in both PCA and PLS-DA analyses, indicating strong discriminatory capacity at the lipidome level (Figure A and B). A total of 49 exosome-associated lipids differed significantly between groups, including 34 exosome-lipids with upregulation and 15 exosome-lipids with downregulation in MASLD-associated HCC (Figure C; $P < 0.05$). Pathway enrichment analysis revealed involvement of glycerophospholipid metabolism, consistent with the lipid composition of exosomal membranes (Figure D, table 1). LASSO regression refined these 49 exosome-lipids into a 14-lipid panel with minimal redundancy and robust classification performance (Figure E). These 14 exosome-lipid set was visualized via heatmap to confirm consistent separation across individual patients, supporting feasibility for real-world application (Figure F).
Conclusion: Exosome-associated lipid remodelling represent a distinct molecular feature of MASLD-associated HCC. A 14-lipid exosomal panel shows strong potential as invasive biomarker set for discriminating MASLD-associated HCC from MASLD. These findings support exosomal lipidomics as a promising translational approach for the development of surveillance and diagnostic strategies.

THU-364
Intensive care admission patterns and outcomes in hepatocellular carcinoma patients on systemic therapy

Rex Wan-Hin Hui[1], Matthew Shing Hin Chung[1], Lu Li[1], Xianhua Mao[2], CL Chiang[1], Carlos King Ho Wong[1], Ian Chi Kei Wong[1], Ka Shing Cheung[1], Stephen Chan[3], Man-Fung Yuen[1], Wai-Kay Seto[1], Lung Yi Loey Mak[1]. [1]*The University of Hong Kong, Pok Fu Lam, Hong Kong;* [2]*Stanford University, Stanford, United States;* [3]*The Chinese University of Hong Kong, Sha Tin, Hong Kong*
Email: huirex@connect.hku.hk

Background and aims: Patients with advanced hepatocellular carcinoma (HCC) are conventionally triaged out of intensive care unit (ICU) admission due to poor prognosis. Yet with improving survivorship from systemic therapies, ICU admission for HCC patients may become more common. We assessed the ICU admission patterns and outcomes in HCC patients on systemic therapies.
Method: HCC patients who received systemic therapies (immune checkpoint inhibitors [ICIs] or tyrosine kinase inhibitors [TKIs]) between 2008 and 2024 were identified from a territory-wide cohort. The reasons for ICU admission were classified as liver-related events, treatment-related events, or non-liver events. ICU procedures and survival were analyzed. The Sequential Organ Failure Assessment (SOFA) score was calculated with patient parameters at ICU admission.
Results: Among 5403 HCC patients who received systemic therapy, 147 patients (2.7%) were admitted to ICU (51 on ICIs [3.1% of ICI patients]; 96 on TKIs [2.1% of TKI patients]). The mean age was 62.8 years, 89.1% were male, and 90.5% had cirrhosis. The median interval from systemic therapy initiation to ICU admission was 6.4 (1.9–17.5) months, and the length of ICU stay was 5 (3–11) days. The 28-day and 90-day survival were 68.7% and 51.7% respectively. Mechanical ventilation, vasopressors, cardiopulmonary resuscitation, and renal replacement therapy was utilised in 42.9%, 34.7%, 6.8%, and 6.1% of patients respectively. 61 (41.5%), 49 (33.3%), and 37 patients (25.2%) were admitted for liver-related events, non-liver events, and treatment-related events respectively. The most common liver-related event requiring admission was variceal bleeding (49.2% of liver-related events), while the most common non-liver event was sepsis (42.9% of non-liver events). 8 patients (15.7% of ICI patients) were admitted for immune-related adverse events (myocarditis: 4, diabetic ketoacidosis: 2, adrenal crisis: 1, pneumonitis: 1). The only independent predictors of 28-day and 90-day mortality were admission for liver-related events (28-day HR 2.200 [95%CI 1.156–4.187]; 90-day HR 1.856 [95%CI 1.037–3.320]; both $p < 0.05$) and higher SOFA score (28-day HR 1.249 [95%CI 1.151–1.355]; 90-day HR 1.161 [95%CI 1.080–1.248]; both $p < 0.001$). ICI or TKI use had no impact on survival (all $p > 0.05$).
Conclusion: Liver-related events were the most common reason for ICU admission in HCC patients on systemic therapies. The reason for admission and baseline SOFA score have prognostic implications and may be used for ICU triage.

THU-365
Oral cholate challenge test stratifies hepatotoxicity risk after liver-directed therapy for hepatocellular carcinoma

Maarouf Hoteit[1], Michael McRae[2], Joanne Imperial[3], Greg Everson[3]. [1]*University of Pennsylvania, Philadelphia, Pennsylvania, United States;* [2]*Custom DX Solutions LLC, Houston, Texas, United States;* [3]*HepQuant, LLC, Denver, Colorado, United States*
Email: michael.mcrae@hepquant.com

Background and aims: Liver-directed therapy (LDT) for hepatocellular carcinoma (HCC) carries a risk of serious liver toxicity, but the risk is not accurately predicted. We previously published experience with the relatively complex HepQuant SHUNT test indicating potential for more accurate risk prediction. In this analysis, we evaluated a simplified test version, the oral cholate challenge test (HepQuant DuO) of liver function and physiology, for predicting outcome after LDT.
Method: We conducted a prospective cohort study of patients undergoing LDT for HCC. We evaluated cholate clearance at baseline and 4–10 weeks after (T1) LDT in 11 patients. Hepatotoxicity was defined as the development of a new complication of cirrhosis or an increase in Child-Pugh score by ≥2 points. The Test involved an oral dose of deuterium-labelled (d4-) cholate, blood draws at 20 and 60 minutes, and subsequent measurement of the d4-cholate by LC-MS/MS. Test parameters were calculated, including Portal Hepatic Filtration Rate (HFR), a measure of the clearance of oral d4-cholate, and the Disease Severity Index (DSI), a measure of global liver disease severity from 0 (healthy) to 50 (severe dysfunction). Changes in DSI from baseline to T1 were analyzed using Wilcoxon signed-rank test.

Results: Four patients (36%) were Child-Pugh A and seven (64%) were Child-Pugh B. Patients were BCLC stage A (64%) or BCLC stage B (36%). LDT modalities were transarterial chemoembolisation (46%) or external beam radiotherapy (55%). From baseline to T1, there were trends towards reduction in portal HFR (4.7 [2.5–16.3] mL/kg/min to 3.8 [2.3–16.6] mL/kg/min, p = 0.097) and worsening DSI (30.2 [15.3–38.0] to 32.8 [15.2–38.7], p = 0.097). There was no significant change in MELD (12 [9–13] to 11 [10–12], p = 0.72) or Child-Pugh score (7 [5–8] to 7 [6–8], p = 0.15). Hepatotoxicity was observed in 43% of Child-Pugh B patients and none of the Child-Pugh A patients; and in 75% of patients with a baseline DSI > 35 and none of the patients with DSI < 35.
Conclusion: The oral cholate challenge test may better define baseline disease severity and may be more sensitive to change in liver function induced by LDT than traditional measures.

Background and aims: Hepatocellular carcinoma (HCC) remains a major cause of morbidity and mortality among patients with chronic hepatitis B (CHB). Existing HCC risk scores are largely based on baseline variables and do not account for longitudinal changes over time. We aimed to develop and validate a longitudinal predictive model for HCC using time-dependent Cox regression.
Method: We retrospectively analyzed 4,431 patients with CHB followed between 2009 and 2022. After excluding patients with viral co-infections, early HCC, or incomplete data, 2,245 patients were included. The cohort was randomly divided into a training set (n = 1,685) and a test set (n = 560). Time-varying covariates, including demographic, clinical, and laboratory variables, were modeled using a time-dependent Cox regression approach. Predictive performance was evaluated using the concordance index (C-index), Brier score, and comparisons with established HCC risk models.
Results: During follow-up, 120 patients developed HCC. Independent predictors of HCC included age, sex, platelet count, cirrhosis, serum albumin, and α-fetoprotein (AFP). These variables were incorporated into the final model (PSU HCC score): (0.023 × age) – (0.627 × female sex) –(0.847 × albumin) –(0.005 × platelet count [$\times 10^3$]) + (1.052 × $\log_{10}$AFP) + (1.817 × cirrhosis). In the test cohort, the PSU HCC score demonstrated excellent discrimination (C-index 0.909; 95% CI, 0.870–0.947) and good calibration, outperforming ALBI, aMAP, REACH-B, CU-HCC, PAGE-B, and mPAGE-B scores. Risk stratification revealed significantly higher cumulative HCC incidence among patients in the high-risk group.
Conclusion: The PSU HCC score is a longitudinal prediction model that integrates dynamic clinical and laboratory parameters and provides superior HCC risk prediction in patients with CHB compared with existing models. This approach may support individualized, risk-based HCC surveillance strategies.

THU-367
Risk and predictors of HCC in a cohort of 1,395 treatment-naïve chronic hepatitis delta patients with F0-F2 fibrosis
Habiba Kamal[1,2], Ganbolor Jargalsaikhan[3], Sanjaasuren Enkhtaivan[3], Karin Lindahl[1], Bekhbold Dashtseren[3], Oyungerel Lkhagva-Ochir[3], Tuvshinjargal Ulziibadrakh[3], Andreas Bungert[3], Elisabetta Degasperi[2,4], Pietro Lampertico[2,4,5], Heiner Wedemeyer[2,6,7], Naranjargal Dashdorj[3], Soo Aleman[1,2].

Email: habiba.khodir.kamal@ki.se

Background and aims: Chronic hepatitis D (CHD) is associated with a higher risk of HCC than mono-chronic hepatitis B (CHB). The knowledge is limited on the risk for HCC in patients with CHD with mild to moderate fibrosis (F0-F2).
Method: We conducted a retrospective study of adults (≥18 years) with CHD attending a hepatology center in Mongolia during 2015–2025. Patients with prior HCC, hepatic decompensation, or transplantation, anti-HDV treatment, or advanced liver fibrosis and/or cirrhosis were excluded. Advanced fibrosis and cirrhosis were ruled out if liver stiffness measurements (LSM) ≥10.0 kPa, platelet count $<150 \times 10^9$ cells/L, and no clinical or radiological features of cirrhosis. The incidence rate (IR) and cumulative incidence of HCC were analyzed by Kaplan-Meier method, and the predictors of HCC were identified using Cox regression models. The cut-off age for annual HCC IR surpassing 0.2%; the cost-effective HCC surveillance threshold in non-cirrhotic CHB, was evaluated.
Results: Overall, 1,395 individuals with CHD were included, with baseline characteristics: median age 39.5 years, 178 (12.8%) < 30 years, females 61.5%, elevated ALT 73.5%, median HDV RNA 5.2 (IQR 3.9, 6.1) $\log_{10}$ IU/mL, and median LSM of 7.0 (IQR 5.8, 8.3) kPa. During a median follow-up of 7.5 (IQR 5.6, 8.7) years, 123 (8.8%) progressed to cirrhosis at an IR of 1.31% with 5- and 10-year risks of 5.9% and 13.2%, respectively. While 47 (3.4%) developed HCC, at an IR of 0.48%, with 5- and 10-year risks of 1.7%, and 5.6%, respectively. In patients without ever cirrhosis diagnosis, HCC IR was 0.25%, with 5- and 10-year risks of 1.3% and 2.6%, respectively. In multivariable analyses, predictors of HCC were older age (aHR = 1.08, 1.06–1.11), elevated ALT (aHR = 3.94, 1.18–13.12) and elevated GGT (aHR = 3.42, 1.75–6.68). None developed HCC in the age group 18–29 years. Males and females surpassed the 0.2% HCC surveillance threshold at a mean age of 35.1 (95% CI 32.0–43.7), and 33.6 (31.4–43.7) years, respectively. Similar findings were noted by excluding those who developed cirrhosis during follow-up.
Conclusion: This study demonstrates a relatively high risk for HCC in untreated Asian patients with F0-F2 fibrosis on long-term, with an annual risk of HCC exceeding 0.2% when age > 30 years for males and females. Our results suggest therefore starting HCC surveillance at this age-cut off in patients with CHD, regardless of fibrosis stage. More data are needed to confirm our findings.

THU-368
Magnetic resonance elastography and cirrhosis outcome risk estimator (CORE) score as independent predictors of hepatocellular carcinoma in chronic hepatitis
Kie Kinjo[1], Nobuharu Tamaki[1], Yutaka Yasui[1], Hiroyuki Nakanishi[1], Kaoru Tsuchiya[1], Namiki Izumi[1], Masayuki Kurosaki[1]. *[1]Musashino Red Cross Hospital, Tokyo, Japan*
Email: 19Kie.K.00@nms.ac.jp

Background and aims: In chronic liver disease, liver fibrosis is the most important predictor of hepatocellular carcinoma (HCC). Recently, the CORE (Cirrhosis Outcome Risk Estimator) risk score has been developed to predict the risk of major liver disease in the general population. CORE is calculated using age, sex, AST, ALT, and γ-GTP, and estimates the 10-year risk of liver disease development. In this study, we evaluated whether magnetic resonance elastography (MRE), a marker of liver fibrosis, and CORE are useful predictors of HCC development in patients with chronic liver disease.
Method: A total of 2,653 patients who underwent MRE between 2015 and 2024 were included. Blood tests performed within one month before or after the initial MRE were used to calculate the CORE score. The primary outcome was the development of HCC.
Results: Among the 2,653 patients, 56.4% were male. The underlying etiologies of chronic liver disease were hepatitis C virus infection in 47.7% and metabolic dysfunction-associated steatotic liver disease in 17.9%. The median age (interquartile range [IQR]) was 68 (58–76) years. When stratified by the MRE cutoff for advanced fibrosis (3.6 kPa), the cumulative incidence of HCC at 1, 3, and 5 years was 3.2%, 8.3%, and 12.8% in patients with MRE ≥3.6 kPa, compared with 0.5%, 2.3%, and 3.9% in those with MRE <3.6 kPa (P < 0.001). Receiver operating characteristic analysis identified an optimal CORE cutoff of 0.27% (it means 10-year predicted liver disease risk). The cumulative HCC incidence at 1, 3, and 5 years was 2.6%, 7.1%, and 11.0% in patients with CORE ≥0.27%, compared with 0.2%, 1.2%, and 3.1% in those with CORE <0.27% (P < 0.001). Although CORE successfully stratified HCC risk, the observed incidence of HCC was higher than the risk predicted by CORE. After adjustment for MRE, CORE, diabetes mellitus, dyslipidemia, and hypertension, the hazard ratio (HR) (95% confidence interval [CI]) was 2.27 (1.4–3.7) for MRE ≥3.6 kPa and 2.62 (1.4–5.0) for CORE ≥0.27%. CORE risk score was an independent risk factor for HCC development, independent of liver fibrosis status.
Conclusion: In patients with known chronic liver disease, CORE risk score independently predicted the development of HCC in addition to MRE. CORE score was developed for the general population; however, in patients with chronic liver disease, the actual risk of HCC development was higher than the 10-year liver disease risk estimated by CORE, indicating that careful interpretation of CORE is required in this population.

THU-369
Characteristics of hepatocellular carcinoma in the real-world Italian PITER-B/Delta cohort

Giuseppina Brancaccio[1], Maria Giovanna Quaranta[2], Maria Elena Tosti[2], Barbara Coco[3], Maurizia Brunetto[3,4], Giovanni Battista Gaeta[5], Loreta Kondili[2,6] and PITER Collaborating Investigators[2]. *[1]Link Campus University, Rome, Italy; [2]Istituto Superiore Di Sanita', Rome, Italy; [3]University Hospital of Pisa, Pisa, Italy; [4]University of Pisa, Pisa, Italy; [5]University of Campania "Luigi Vanvitelli", Naples, Italy; [6]UniCamillus-Saint Camillus International University of Health Sciences, Rome, Italy*
Email: ggbrancaccio@gmail.com

Background and aims: Chronic hepatitis Delta virus (HDV) infection increases the risk of hepatocellular carcinoma (HCC) by two- to three-fold compared with hepatitis B virus (HBV) monoinfection. This study was aimed to update clinical and macro-pathological characteristics of HCC in patients with HDV infection compared with HBV monoinfection.
Method: HCC cases were retrospectively retrieved from the cross-sectional PITER-B/Delta cohort. The HCC cases included in this analysis were enrolled between 2019 and 2024 across 36 participating centers. Centers were queried to collect data at first HCC diagnosis, including macro-pathological characteristics and treatments received. HCC was diagnosed according to standard imaging criteria. Group comparisons were performed using standard statistical methods.
Results: Among 212 HCC cases, 178 were included in the analysis: 42 (23.6%) anti-HDV–positive and 136 with HBV monoinfection. Detectable HDV-RNA was found in 29 of 36 tested patients. HDV-HCC patients were younger than HBV-HCC patients (median age 60 vs. 65 years; $p = 0.009$), with women primarily driving this difference (57 vs. 71 years; $p = 0.031$), while the difference among men was marginal (62 vs. 65 years; $p = 0.08$). Compared with HBV patients, those with HDV infection were more frequently non-Italian and showed more advanced liver disease, as shown by lower platelet counts, higher AST, ALT, GGT, bilirubin and AFP levels, higher Child–Pugh class, presence of CSPH. HCC was diagnosed during US surveillance in 89.5% of HDV patients and 82.3% of HBV patients (p = ns). No differences were observed between groups in nodular presentation (94.9% vs. 90.0%), number of nodules (≤ 3 in 86.5% vs. 93.9%), largest nodule diameter (2.3 vs. 2.5 cm), presence of metastases (7.9% vs.7.9%), or being within the Milan criteria (55.0% vs. 66.7%). Comorbidities were similarly distributed between the two groups. Liver transplantation was more frequent among HDV patients (23.8% vs. 7.3%; $p = 0.009$), whereas surgical resection tended to be more common in HBV patients (36.0% vs. 26.2%).
Conclusion: This study provides a contemporary clinical and epidemiological snapshot of HDV-associated HCC, showing that despite similar tumor stage at diagnosis compared with HBV monoinfection, HDV-related HCC occurs at a younger age, in the setting of more advanced liver disease, and is more frequently associated with liver transplantation need, defining a distinct clinical profile beyond tumor burden.

THU-370
Effectiveness of a structured surveillance program for early detection of hepatocellular carcinoma in contemporary patients with advanced chronic liver disease

Georg Kramer[1,2,3,4], Carina Pichler[1], Lorenz Balcar[1,2,3,4], Georg Semmler[1,2,3], Benedikt Simbrunner[1,2,3], Mathias Jachs[1,2,3], Lukas Hartl[1,2,3], Benedikt Hofer[1,2,3], Christian Sebesta[1,2,3], Paul Thöne[1,2,3], Marlene Hintersteininger[1,2,3], Michael Trauner[1,3], Mattias Mandorfer[1,2,3], Thomas Reiberger[1,2,3], Matthias Pinter[1,4], Bernhard Scheiner[1,2,3,4]. *[1]Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [2]Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [3]Clinical Research Group MOTION, Medical University of Vienna, Vienna, Austria, Vienna, Austria; [4]Vienna Liver Cancer (HCC) Study Group, Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, Vienna, Austria*
Email: georg.kramer@meduniwien.ac.at

Background and aims: Hepatocellular carcinoma (HCC) surveillance is recommended in patients with advanced chronic liver disease (ACLD), yet real-world adherence is heterogeneous and often assessed using binary or semi-quantitative metrics. We aimed to longitudinally quantify HCC surveillance adherence using a continuous, time-based metric and to evaluate its association with clinical outcomes. In addition, we report on the diagnostic yield of a structured re-linkage initiative among patients who missed routine surveillance.
Method: In 639 ACLD patients enrolled into the prospective Vienna Cirrhosis Study (VICIS; NCT03267615) between 2017 and 2024 and receiving regular in-house care, HCC-surveillance adherence was analyzed using the proportion of time covered (PTC), assigning a six-month coverage window to each imaging assessment. Associations between PTC and outcomes were evaluated using adjusted Cox regression models and internally validated in a propensity score matched cohort (age, sex, etiology, Child-Pugh score [CPS]) via Fine-Gray competing-risk models. Patients overdue for surveillance were targeted through a prospective and structured re-linkage program.

Results: Median imaging-based PTC was 83% (IQR 60–98%). Over a median follow-up of 43 months, 47 patients (7.4%) developed HCC, of whom 47% were diagnosed at an early stage (Barcelona Clinic Liver Cancer 0/A). PTC was non-linearly associated with early HCC-detection showing a strong increase once coverage exceeded 85% of follow-up time. Biannual imaging was associated with a 6.6-times higher likelihood of early-HCC detection compared with annual imaging (HR 6.57; 95% CI 2.38–18.11). After propensity score-matching, high surveillance adherence (PTC ≥85%) was associated with early-HCC detection (adjusted subdistribution hazard ratio [SHR]: 2.44; p = 0.015) and option for curative treatment (adjusted SHR: 2.60; p = 0.024) independent from age, sex and CPS, while PTC ≥85% tended toward improved post-HCC survival (SHR: 0.37, p = 0.087). Among 52 patients overdue for surveillance who were actively re-linked to imaging, 8 (15%) had a new suspect hepatic lesions detected, including one biopsy-verified HCC.
Conclusion: In a contemporary ACLD cohort, sustained high-intensity HCC surveillance is strongly associated with earlier tumor detection and increased likelihood to receive curative treatment. Continuous adherence metrics and proactive re-linkage strategies may improve surveillance effectiveness in routine care.

THU-371
Clinical benefit of perioperative prophylactic antibiotics in hepatocellular carcinoma (HCC) patients undergoing transcatheter arterial chemoembolization (TACE)
Junying Li[1]. [1]*Hepatology Unit, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China, Hepatology Unit, Zengcheng Branch, Nanfang Hospital, Southern Medical University, Guangzhou, China, Guangzhou, China*
Email: 2292921780@qq.com

Background and aims: Clinical evidence supporting the use of prophylactic antibiotics to prevent infection and improve outcomes in patients undergoing transarterial chemoembolization (TACE) for hepatocellular carcinoma (HCC) remains limited. This study aimed to evaluate the association between perioperative prophylactic antibiotic administration and the risk of post-TACE infection.
Method: This retrospective cohort study included HCC patients who underwent TACE between January 2022 and December 2025. Patients in the prophylactic antibiotic group received 1.5 g of cefuroxime sodium 30 minutes prior to TACE, while those in the control group received no prophylactic antibiotic intervention. The primary outcomes were the incidence of infection within 30 days postoperatively, defined by procalcitonin (PCT) ≥ 0.66 ng/mL or C-reactive protein (CRP) ≥ 28 mg/L. Secondary outcomes included the diagnosis of systemic inflammatory response syndrome (SIRS), total hospitalization cost, and length of hospital stay (LOS). Outcomes were compared between the two groups to assess the necessity of prophylactic antibiotics for TACE.
Results: A total of 286 eligible patients were enrolled, with 123 receiving prophylactic antibiotics and 163 not. No statistically significant differences were observed between the antibiotic group and the non-antibiotic group in the incidence of infection (defined by PCT ≥ 0.66 ng/mL: p = 0.142; defined by CRP ≥ 28 mg/L: p = 0.679) within 30 days postoperatively. Additionally, there were no significant differences in the rate of SIRS (p = 0.097), total hospitalization cost (p = 0.475), or LOS (p = 0.413) between the two groups.
Conclusion: Perioperative prophylactic use of antibiotics in patients undergoing TACE is not significantly associated with a reduced risk of postoperative infection, shorter LOS, or lower hospitalization costs. Large-scale prospective studies and randomized controlled trials (RCTs) are warranted to further validate these findings.

THU-372-YI
The genetic alterations in circulating tumor cells correlate with the clinical outcomes of hepatocellular carcinoma by large-scale whole-genome sequencing
Siqi Liao[1], Zhiji Chen[1], Song He[1], Zhihang Zhou[1]. [1]*The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China*
Email: zhouzhihang@cqmu.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) accounts for 70–90% of primary liver cancers, often diagnosed at advanced stages. Despite advances in systemic and locoregional therapies, outcomes remain poor due to tumor heterogeneity and drug resistance. Tissue biopsy is limited by invasiveness and sampling bias. Circulating tumor cells (CTCs) offer a minimally invasive "liquid biopsy" for real-time genomic profiling. This study aims to characterize the HCC genomic landscape using CTCs and assess its diagnostic and prognostic potential.
Method: CTCs from 267 treatment-naïve HCC patients were enriched via CTC-100 microfluidics; 134 CTC pools underwent whole genome amplification (WGA)/whole-genome sequencing (WGS). Somatic mutations were analyzed for signatures, SV burden, and clinical correlations. HepG2 spike-ins validated workflow fidelity. Consensus clustering revealed two molecular subtypes; survival analyses used Kaplan–Meier and Cox models.
Results: CTC count correlated significantly with advanced tumor stage and poor prognosis (P < 0.05). Notably, 61.8% (1,848/2,992) of CTCs showed low EpCAM expression, indicating marked phenotypic heterogeneity. WGS delineated the genomic landscape of HCC CTCs. Co-mutations in NAV2, SPTAN1, DOCK6, and PI4KA were significantly associated with shorter overall survival (P < 0.05) and predicted outcomes in BCLC-C patients receiving targeted therapy, immunotherapy, or interventional treatment. Unsupervised clustering defined two molecular subtypes: Cluster 1 responded better to targeted therapy, while Cluster 2 benefited more from immunotherapy. CTC-enriched mutations were identified in MUC16, NOTCH1, ZFHX3, and KMT2D. Structural variant (SV) analysis revealed ARRB2 as the most frequently altered gene; deletions (DELs) predominated in ARRB2, LDLRAD2, FOXL2, C1QB, NELFE, UBXN11, and KMT2B, whereas duplications (DUPs) were enriched in TMEM161A, MAST3, LTBP3, and MYH7B. Higher SV or DEL burden (above median) correlated with worse survival (P < 0.05). Two loci—chr11:71,238,675 and chr11:71,249,563—were significantly linked to poor prognosis.
Conclusion: This large-scale WGS study of HCC CTCs delineates a genomic framework that uncovers novel biomarkers for prognosis prediction, therapy response stratification, and potential drivers of CTC biology, advancing the clinical application of liquid biopsy in HCC management.

THU-377-YI
Shifting aetiology and clinical landscape of hepatocellular carcinoma over four decades: from viral hepatitis to metabolic dysfunction–associated steatotic liver disease in 1,960 patients
Kai Lim[1], Wei-Lun Liou[2], Chee-Kiat Tan[2]. [1]*Singapore Health Services, Singapore General Hospital, Singapore, Singapore;* [2]*Department of Hepatology and Gastroenterology, Singapore General Hospital, Singapore, Singapore*
Email: limkai94@gmail.com

Background and aims: Metabolic dysfunction–associated steatotic liver disease (MASLD) is emerging as a major contributor of hepatocellular carcinoma (HCC) globally. Long-term data of its impact in multi-ethnic Asian populations is limited. We describe temporal changes in aetiology, clinical characteristics, HCC stage and treatment patterns over four decades in Singapore, with a focus on MASLD-related HCC.
Method: Patients with HCC were prospectively enrolled from 1980 to the present. Temporal trends across decades were assessed using poisson regression. MASLD-related HCC was compared with

non–MASLD-related HCC overall for demographics, liver disease severity, BCLC stage, and treatment patterns.
Results: A total of 1,960 patients were included. Aetiology shifted significantly over time. Proportion of MASLD-related HCC increased from 14.6% in 1990–1999 to 42.4% in 2020–present (incidence rate ratio per decade 1.29, $p < 0.001$) with a corresponding decline in hepatitis B-related HCC. Over the decades, patients were older (mean age 60 to 69 years; $p < 0.001$) with declining male predominance (84.4% to 70.6%, $p < 0.001$). Ethnic composition also changed, with fewer Chinese (89.5% to 81.4%) and more Malays (6.8% to 11.5%; $p = 0.006$). Liver biochemistry demonstrated favourable shifts - higher albumin (33 to 36 g/L), lower bilirubin (42 to 27 μmol/L), lower prothrombin time (14 to 12 sec), higher proportion of Child–Pugh A (49.5% to 64.5%), ALBI grade 1 (13.0% to 32.7%), and lower AFP level (AFP < 20 μg/L: 17.1% to 62.5%) (all $p < 0.001$). In contrast, platelet count declined (217 to 169×10^9/L, $p < 0.001$) and FIB-4 scores worsened ($p = 0.011$). BCLC stage and HCC treatment patterns also changed significantly over time, with more early stage HCC (9.1% in 1990–1999 vs 64.0% in 2020–present) and more curative (11.0% in 1990–1999 vs 53.5% in 2020–present) and locoregional therapy (11.5% vs 24.3%)($p < 0.001$). Compared with non-MASLD HCC, MASLD-HCC occurred in older patients (mean age 69 vs 62 years, $p < 0.001$), was less male predominant (68.5% vs 82.2%, $p < 0.001$) and was associated with lower AFP level (AFP < 20 μg/L: 48.1% vs 37.4%, $p < 0.001$) and higher FIB-4 categories (advanced fibrosis: 72.7% vs 67.1%, $p = 0.006$).
Conclusion: The transition from viral to MASLD as a dominant driver of HCC in Singapore, a multi-ethnic Asian country, is accompanied by changes in demographics, liver disease characteristics, HCC stage and treatment patterns. These findings provide important context for refinement of our HCC surveillance strategies.

THU-378
Potential limitations of Fib-4 in selecting MASLD patients for HCC surveillance – impact of fibrosis burden on tumour stage and survival in MASLD-related HCC compared with non-MASLD HCC in 1,960 patients over 4 decades
Kai Lim[1], Wei-Lun Liou[2], Chee-Kiat Tan[2]. *[1]Singapore Health Services, Singapore General Hospital, Singapore, Singapore; [2]Department of Hepatology and Gastroenterology, Singapore General Hospital, Singapore, Singapore*
Email: limkai94@gmail.com

Background and aims: The impact of fibrosis burden (FB) on hepatocellular carcinoma (HCC) detection and survival in metabolic dysfunction–associated steatotic liver disease (MASLD) remains unclear. We examined the association between FB assessed by FIB-4, tumour stage at diagnosis and overall survival (OS) in MASLD-related HCC, with comparison to non-MASLD-related HCC.
Method: Patients with HCC were prospectively enrolled between 1980 and the present. FB was assessed by FIB-4 categories (< 1.3, 1.3–2.67, > 2.67). Tumour stage was classified using BCLC criteria, with early stage defined as BCLC 0/A. Associations with stage were analysed using logistic regression, and OS by Kaplan–Meier and multivariable Cox regression. Sensitivity analyses incorporated surveillance status. Parallel stratified analyses were performed in non-MASLD related HCC.
Results: Among 1,960 patients, 447 (22.8%) had MASLD-related HCC, where 83.7% had cirrhosis and 72.7% had high FB (FIB-4 >2.67). High FIB-4 was associated with older age (mean 70 vs 58 years, $p < 0.001$), less male predominance (63.7% vs 82.1%, $p = 0.009$) and worse liver function - lower albumin (33 vs 36 g/L, $p = 0.001$) and higher bilirubin (40 vs 24 μmol/L, $p = 0.006$). After adjustment for age, gender and decade, higher FIB-4 was significantly associated with earlier BCLC stage (FIB-4 > 2.67 vs FIB-4 < 1.3, aOR 0.23, $p = 0.015$). Whereas, in non-MASLD related HCC, higher FIB-4 was independently associated with advanced BCLC stage (aOR 3.19, $p < 0.001$). In MASLD-related HCC, this association was no longer significant after adjustment for surveillance, suggesting surveillance-related stage migration. Despite earlier BCLC stage, higher FIB-4 remained independently associated with worse OS in MASLD-related HCC (aHR 2.20, $p = 0.001$) after adjustment for gender, BCLC stage, decade and surveillance status. Curative-intent treatment rates also did not differ across FIB-4 categories in MASLD-related HCC ($p = 0.78$). In non-MASLD related HCC, higher FB was also associated with poorer OS (aHR 1.62, $p < 0.001$).
Conclusion: In MASLD-related HCC, higher FB assessed by FIB-4 was associated with earlier BCLC stage at diagnosis, largely driven by surveillance, but did not translate into improved OS. The persistent adverse prognostic impact of higher FIB-4, despite earlier detection, likely reflects underlying hepatic vulnerability that potentially limits curative treatment. This suggest that reliance on FIB-4 alone to guide selection of MASLD patients for HCC surveillance might not be ideal.

Email: ryanlimyanzhe21@gmail.com

Background and aims: Prognostic models for hepatocellular carcinoma (HCC) may have limited accuracy. We aimed to construct and validate a novel prognostic model for HCC that incorporates biomarkers for liver function and tumor characteristics.
Method: Consecutive participants with HCC from four international tertiary institutions in Asia and the U.S. comprised the derivation (n = 627) and validation (n = 270) cohorts. The Liver Cancer Risk predictioN (LCRN) Index was constructed using a gradient-boosted decision tree model based on the Cox proportional hazards framework. The discriminative performance of the LCRN Index was evaluated using Harrell's concordance index (C-index) and the area under the receiver operating curve (AUC), and compared to the albumin bilirubin grade (ALBI) and Barcelona Clinic for Liver Cancer (BCLC) staging. Model calibration was assessed using the integrated Brier score and Arjas plots.
Results: The median (IQR) age was 66.0 (58.0–73.0) years, median (IQR) body mass index was 23.9 (22.1–25.9) kg/m^2 and 78% were male. The LCRN Index comprised type 2 diabetes mellitus, ascites, hepatic encephalopathy, albumin, bilirubin, AFP and diameter of largest tumor nodule. In the validation cohort, the LCRN Index (C-

index: 0.7885; 1-year AUC: 0.89; 3-year AUC 0.83; 5-year AUC 0.78) outperformed the ALBI grade (C-index: 0.6710; 1-year AUC: 0.75; 3-year AUC 0.69; 5-year AUC 0.65) and BCLC stage (C-index: 0.6730; 1-year AUC: 0.73; 3-year AUC 0.69; 5-year AUC 0.66) for prognosticating HCC. The LCRN Index demonstrated better calibration compared to the ALBI grade and BCLC stage.
Conclusion: If further validated, the LCRN Index may be a useful tool for prognosticating HCC.

Exploring the impact of mitochondrial biomarkers on HCC risk according to etiologic drivers: a multicenter study
Miriam Longo[1], Annalisa Cespiati[1,2], Erika Paolini[1], Marica Meroni[1], Daniel Smith[1,2], Anna Alisi[3], Luca Miele[4,5], Andrea Dalbeni[6,7], Giorgio Soardo[8], Anna Ludovica Fracanzani[1,2], Paola Dongiovanni[1]. *[1]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Università degli Studi di Milano, Milano, Italy; [3]Bambino Gesù Children's Hospital, IRCCS, Roma, Italy; [4]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy; [5]University of Sacred Heart, Roma, Italy; [6]Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy; [7]University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy; [8]University of Udine, Udine, Italy*
Email: paola.dongiovanni@policlinico.mi.it

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) overcame HCV and alcohol-related hepatitis (ALD), becoming the main cause of hepatocellular carcinoma (HCC). We recently showed that circulating mitochondrial (mt-) biomarkers (*D-loop*, ccf-COXIII) increase in MASLD patients and accurately predict HCC risk. However, it remains to elucidate whether these biomarkers are MASLD-specific. We aim to: (1) assess *D-loop* and ccf-COXIII levels in a multicenter cohort of 1231 HCV, ALD and MASLD patients of whom 332 with HCC; (2) develop new models for HCC diagnosis employing mt-biomarkers and compare them with standard scores (aMAP, Fib4, APRI, Forn's index, Fibro-alpha).
Method: *D-loop* and ccf-COXIII were measured by qRT-PCR. Their levels were compared across either etiologies or within each etiology group (MASLD vs MASLD-HCC; ALD vs ALD-HCC; HCV vs HCV-HCC). Multivariate analyses were adjusted for age, gender, BMI, diabetes (T2DM) and presence of cirrhosis. Random forest (RF) analysis, a machine learning method, was exploited to build-up new diagnostic tools.
Results: MASLD-HCC subjects had higher BMI, T2DM rate and serum lipids compared to HCC from other etiologies ($p < 0.01$). In this subgroup, the mean size of primary nodules was larger than ALD-HCCs or HCV-HCC patients, as well as a greater number of non-cirrhotic MASLD-HCC cases were recorded ($p < 0.05$). *D-loop* levels raised in MASLD-HCC patients compared to MASLD ones regardless of cirrhosis and, at multivariate analysis, it independently associated with HCC of metabolic origin ($p < 0.05$), suggesting *D-loop* as a MASLD-specific biomarker. Conversely, ccf-COXIII levels significantly increased in all HCC patients with cirrhosis, independently of etiology ($p < 0.0001$), supporting that its release is primarily driven by advanced tissue damage. The *D-loop* based prediction model, generated with RF, for HCC risk and applied to the entire cohort reached a higher AUC (78%) compared to reference scores, but without reaching the statistical significance, likely reflecting the biomarker's specificity for MASLD etiology. Conversely, the new diagnostic tool based on ccf-COXIII levels outperformed existing non-invasive tests, for HCC detection across patients with mixed etiologies, demonstrating 85% of accuracy.
Conclusion: High *D-loop* levels identify MASLD-HCC risk, even in noncirrhotic cases which are outside HCC clinical screening, while ccf-COXIII has a broader clinical utility for HCC monitoring in patients with different chronic liver diseases.

THU-381
Combining observation and patient data to predict malignancy progression in LI-RADS 3–4 observations
David Marti-Aguado[1], Subin Heo[2], Melissa Lou Silva[3], David Nam[3], Sedighe Hosseini Shabanan[3], Colter S. Sirlin[3], Tanya Wolfson[3], Claude Sirlin[3], Sang Hyun Choi[2]. *[1]Incliva - Instituto De Investigación Sanitaria, Valencia, Spain; [2]Department of Radiology and Research Institute of Radiology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea., Seoul, Korea, Rep. of South; [3]University of California San Diego, La Jolla, United States*
Email: davidmmaa@gmail.com

Background and aims: LI-RADS category 3 (LR-3) and 4 (LR-4) observations are considered indeterminate, with variable and unpredictable risk of progression to malignancy including hepatocellular carcinoma (HCC), underscoring the need for risk-stratification. The aim of this study was to develop a risk-stratification algorithm combining per-observation and per-patient models for predicting 3-year progression to malignancy for LR-3 and LR-4.
Method: This retrospective study included patients with ≥1 LR-3 or LR-4 observation on CT/MRI per LI-RADS v2018. The primary endpoint was 3-year progression to malignancy (HCC or non-HCC malignancy). Per-observation and per-patient multivariable models for predicting 3-year progression were created from baseline data. Each model's cross-validated area under the curve (AUC) and its 95% confidence interval were calculated. Observations and patients were classified as low or high-risk based on Youden-based probability thresholds. A risk-stratification algorithm was created by combining the per-observation and per-patient classifications to yield four risk groups (A: low-risk observation in low-risk patient; B: low-risk observation in high-risk patient; C: high-risk observation in low-risk patient; D: high-risk observation in high-risk patient). The diagnostic performance of the risk-stratification model for predicting 3-year progression was compared to that of a 4-point ordinal LI-RADS-based stratification based on LI-RADS category ± ancillary features favoring malignancy.
Results: A total of 147 patients (34% women) with 245 observations (178 LR-3, 67 LR-4) were included. Within 3 years, 103 patients progressed to malignancy. The per-observation model AUC was 0.67 (0.57–0.76) and the per-patient model AUC was 0.61 (0.50–0.72). Cumulative incidence of progression within 1-to-3 years was 4–25%, 23–33%, 20–40%, and 56–78% for observations in Groups A, B, C, and D, respectively, based on the risk-stratification algorithm. The risk-stratification model AUC, sensitivity (Sn), specificity (Sp), and total accuracy were 0.71, 73%, 69%, 71%. The ordinal LI-RADS categorization AUC, Sn, Sp, and total accuracy were 0.66, 65%, 63%, 64%. Although diagnostic performance was slightly higher, differences were not significant ($p = 0.05$ for total accuracy).
Conclusion: A risk-stratification algorithm that combines per-observation and per-patient models shows promise for identifying LR-3/4observations with high likelihood of progression.

THU-382-YI
Performance of HCC risk scores in patients with advanced chronic liver disease: a multicenter cohort study
Mohamed Moussa[1], Koos de Wit[2], L.C. Baak[3], Dave Sprengers[1], Raoel Maan[1], Adriaan J. van der Meer[1], Stan van Wijk[1], Emma Kleij[1], Roy Dwarkasing[4], Willem Pieter Brouwer[1], Femme Dirksmeier-Harinck[5], Jordan J. Feld[6], Harry L.A. Janssen[1,6], R. Bart Takkenberg[2], Milan J. Sonneveld[1]. *[1]Erasmus university medical center, Department of gastroenterology and hepatology, Rotterdam, Netherlands; [2]Amsterdam university medical center, Department of gastroenterology and hepatology, Amsterdam, Netherlands; [3]OLVG hospital, Department of gastroenterology and hepatology, Rotterdam, Netherlands; [4]Erasmus university medical center, Department of radiology and nuclear Medicine, Rotterdam, Netherlands; [5]Franciscus*

Hospital, Department of gastroenterology and hepatology, Rotterdam, Netherlands; [6]Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada
Email: m.moussa@erasmusmc.nl

Background and aims: Patients with advanced chronic liver disease (ACLD) are at risk of developing HCC and are therefore recommended to undergo bi-annual HCC surveillance. The increasing prevalence ACLD is causing a significant burden on healthcare systems. Individualised risk prediction would be helpful to identify patients in whom surveillance could be safely deferred. This study assessed the performance of two HCC risk scores, the aMAP score and the Toronto HCC risk Index (THRI) in patients with ACLD in the Netherlands.
Method: We included adults with ACLD from three sites in the Netherlands. Exclusion criteria were follow-up time <6 months, missing risk score data or prior HCC. THRI and aMAP scores were calculated as previously reported, classifying patients into low, intermediate, and high-risk groups. Kaplan–Meier analysis was used to estimate cumulative HCC according to risk score categories.
Results: A total of 1,531 patients were included. The most common liver disease etiologies were steatotic liver disease (SLD; n = 453, 30%), hepatitis C virus (HCV; n = 371, 24%), and hepatitis B virus (HBV; n = 242, 16%). The majority were male (63%), and the median age was 53 years (IQR: 44–61). The median baseline CTP was 5 (IQR: 5–7), and 366 (24%) had a history of decompensated cirrhosis. A total of 196 patients developed HCC. Overall, the HCC cumulative incidence was 7.2% (5%CI: 5.7–8.7) in 5 years. The median THRI was 200 (IQR: 136–254), and the number of patients with a low, intermediate, and high THRI was 269 (18%), 746 (49%), and 516 (34%). The 5-year HCC cumulative risk was 0.5% (95%CI: 0.0–1.6), 6.1% (95%CI: 4.1–8.1), and 12.2% (95%CI: 8.9–15.4) for those with a low, intermediate, and high THRI, p < 0.01. The median aMAP was 55 (IQR: 49–61), and the number of patients with a low, intermediate, and high aMAP was 437 (29%), 645 (42%) and 449 (29%). The 5-year HCC cumulative risk was 2.9% (95%CI: 1.2–4.6), 6.1% (95%CI: 3.9–8.2), and 13.1% (95%CI: 9.7–16.4) for those with a low, intermediate, and high aMAP. Reducing the aMAP cut-off to 40, resulted in a lower residual risk of HCC in this subgroup but also reduced the number of patients identified as low risk to 6% (compared to 18% for THRI).
Conclusion: THRI and aMAP can be used to stratify HCC risk in patients with cirrhosis, but THRI appeared to be the most effective at identifying patients with a 5-year negligible risk of HCC. Deferral of HCC surveillance should be considered in patients at low predicted risk based on THRI.

THU-383
Addition of the GAAD score to imaging improves classification of non-cirrhotic focal liver lesions

Mohamed Moussa[1], Dave Sprengers[1], Vera Ketting[1], Christian Ramakers[2], Robert A. de Man[1], Roy Dwarkasing[3], Harry L.A. Janssen[1,4], Antonius van Herwaarden[5], E.T.T.L. Tjwa[6], Milan J. Sonneveld[1]. *[1]Erasmus university medical center, Department of gastroenterology and hepatology, Rotterdam, Netherlands; [2]Erasmus university medical center, Department of Clinical Chemistry, Rotterdam, Netherlands; [3]Erasmus university medical center, Department of radiology and nuclear Medicine, Rotterdam, Netherlands; [4]Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada; [5]Radboud university medical center, Department of Laboratory medicine, Nijmegen, Netherlands; [6]Radboud University Medical Center, Department of gastroenterology and hepatology, Nijmegen, Netherlands*
Email: m.moussa@erasmusmc.nl

Background and aims: Accurate diagnosis of HCC is challenging in patients without cirrhosis, and biopsy is therefore frequently required. We evaluated the additive value of the GAAD score, which is based on patient age, sex and serum values of AFP and PIVKA-II, in non-cirrhotic patients with focal liver lesions who underwent contrast-enhanced imaging (CE-imaging).
Method: We performed a multi-center prospective study in two tertiary referral clinics in the Netherlands and enrolled all consecutive patients presenting with focal liver lesions in a non-cirrhotic liver. For the current analysis, all patients who underwent CE-imaging were included if there was also a histological assessment of focal liver lesion. The diagnostic accuracy of the GAAD score was assessed at its predefined cutoff score of 2.57.
Results: We analysed 167 patients. The median age was 56 years (IQR: 38–72), and the majority were Caucasian (90%). Liver disease was present in 40% (n = 67), with SLD being the most common etiology (34%; n = 57). HCC was diagnosed in 59 (35%) cases. Patients with HCC were older (median age 70 vs. 49, p < 0.01), and more often male (44% vs. 15%, p < 0.01). The median GAAD score was higher in patients with HCC (8.38 vs. 0.24, p < 0.01). The GAAD score offered excellent discrimination for HCC with an AUC of 0.94 (95%CI: 90–97). At a threshold of 2.57, the sensitivity, specificity, PPV, and NPV were 81%, 91%, 83%, and 90%, respectively. Imaging was considered suggestive of HCC in 40% (n = 67), amongst whom 52 (PPV 77.6%) had HCC. In patients with a high suspicion of HCC based on imaging, a GAAD score of ≥2.57 increased the probability of HCC from 77.6% to 95.7%. Conversely, imaging was not suggestive of HCC in 100 (60%), of whom 7 (NPV: 93%) had HCC. In these patients, A GAAD score <2.57 reduced the probability from 7% to 4.5% (NPV: 95.5%), whereas a GAAD score >2.57 increased the probability of HCC to 27.3%.
Conclusion: In this cohort of non-cirrhotic patients with focal liver lesions, the GAAD score was highly predictive of HCC. In patients with a high likelihood of HCC based on imaging characteristics, a positive GAAD score can be used to rule-in HCC, whereas in patients with a low likelihood of HCC based on imaging, a GAAD score <2.57 can be used to help rule-out HCC. These findings support the use of the GAAD score in the classification of focal liver lesions in patients without cirrhosis.

THU-384
Post-cholecystectomy syndrome affects ultrasound visualization in non-obese viral-related advanced chronic liver disease ACLD: implications of gallbladder removal for Li-RADS-based hepatocellular carcinoma (HCC) surveillance

Marcello Dallio[1], Mario Romeo[1], Fiammetta Di Nardo[1], Carmine Napolitano[1], Paolo Vaia[1], Claudio Basile[1], Antonio Scafuri[1], Marco Niosi[1], Luigi Vitale[1], Alessandro Federico[1].
[1]Hepatogastroenterology Division, Department of Precision Medicine, University of Campania Luigi Vanvitelli; Piazza Miraglia 2, 80138, Naples (Italy), Naples, Italy
Email: marcello.dallio@unicampania.it

Background and aims: The LI-RADS Visualization Score (Li-RADSVS) standardizes ultrasound (US) adequacy for hepatocellular carcinoma (HCC) surveillance in advanced chronic liver disease (ACLD), distinguishing score A (optimal), B (suboptimal), and C (poor visualization). Scores B/C reduce US sensitivity, prompting Magnetic Resonance Imaging (MRI)/ Computerized Tomography (CT) use. Severe obesity and Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD)-related steatosis are known to impair Li-RADSVS. Post-cholecystectomy syndrome (PCS), characterized by continuous bile flow, altered motility, and meteorism, may hinder hepatic US visualization. However, its impact on Li-RADSVS in non-obese, non-MASLD viral-related ACLD remains unexplored.
Method: Hospitalized non-obese, non-MASLD viral-related (chronic HBV/HCV infection) cACLD patients were enrolled into observation (Obs, 2015–2020, n: 106) and validation (Vld, 2021–2025, n: 102) cohorts. ACLD diagnosis was confirmed by liver stiffness measurement (LSM >15 kPa). Demographic, clinical, pharmacological, and surgical data were collected; patients on UDCA or antimeteorics were excluded. After a 3-day standardized diet, fasting US was performed on day 4 by three blinded operators assigning Li-RADSVS (A/B/C) via electronic case report forms. Interobserver agreement (Cohen's kappa) was assessed. Patients were stratified by cholecystectomy

status (PCS vs no-PCS). Obs patients with a unanimous score C underwent MRI/CT, and the focal liver lesion (FLL) missing rate (i.e., FLL undetected by none of the three operators) was evaluated.
Results: Weighted Cohen's kappa ranged from 0.40–0.70 (Obs) and 0.38–0.72 (Vld) (Table 1). PCS prevalence was 40.2% (Obs) and 38.2% (Vld), with significantly higher score C rates vs no-PCS (Obs: 44% vs 23%, p = 0.034; Vld: 42% vs 21%, p:0.027). Multivariate analysis (adjusted for sex, age, Body Mass Index, etiology) identified prior cholecystectomy as independently associated with poor visualization [Obs: aHR 1.325, p: 0.002; Vld: aHR 1.221, p: 0.001], along with time since surgery >2 years [Obs: aHR 1.105, p: 0.031; Vld: aHR 1.136, p: 0.038]. In Obs score C patients undergoing CT/MRI, FLL missing was reported in 39% of cases.
Conclusion: Prior cholecystectomy significantly impairs US visualization in non-obese, non-MASLD viral-related ACLD, reducing LI-RADSVS and impacting HCC surveillance accuracy.

THU-385
Cholangiocarcinoma in individuals with chronic liver diseaseis diagnosed earlier leading to better prognosis

Email: jesusmaria.banalesasurmendi@bio-gipuzkoa.eus

Background and aims: Cholangiocarcinoma (CCA) is a lethal cancer with rising incidence and mortality worldwide. Chronic liver disease (CLD) is recognised as an important risk factor, but its impact on tumour presentation and outcomes remains poorly defined. We aimed to compare the clinical course of CCA in patients with and without CLD.
Method: We retrospectively analysed 3,743 patients diagnosed with CCA between 2010 and 2024 across participating international centres. Patients were classified as CLD if a diagnosis of cirrhosis, primary sclerosing cholangitis (PSC), viral hepatitis, or other chronic liver condition preceded their cancer diagnosis, and non-CLD otherwise. Demographic, clinical, biochemical, and outcome data were compared.
Results: Patients with CLD (n = 993) were more frequently male (67% vs. 53%) and younger (63 vs. 66 years) than non-CLD (n = 2,750) individuals. They more often presented with intrahepatic tumours (64% vs. 42%), better performance status (ECOG 0: 53% vs. 35%), lower CA19.9 levels (56 vs. 135 U/mL), and earlier stage disease (localized: 57% vs. 43%; metastatic: 23% vs. 31%). Accordingly, curative-intent surgery was more common (60% vs. 48%), resulting in improved median overall survival (mOS: 12.2 vs. 11.1 months, $p < 0.05$) and higher 5-year survival (OR: 1.64, $p < 0.01$), particularly in intrahepatic CCA (mOS: 14.2 vs. 11.1 months, $p < 0.001$; 5-year survival OR: 2.05, $p < 0.001$). Treatment response across modalities did not differ. Within the CLD cohort, prior diagnosis of primary sclerosing cholangitis and cirrhosis were strongly associated with earlier-stage CCA detection.
Conclusion: Patients with pre-existing CLD are more likely to be diagnosed with CCA at an earlier stage, contributing to improved survival. These findings support evaluation of structured surveillance programs in high-risk CLD populations.

THU-386
Heterogeneity in hepatocellular carcinoma screening across social determinants of health phenotypes
Lauren Nephew[1], Allie Carter[1], Dipika Gupta[2]. *[1]Indiana University School of Medicine, Indianapolis, United States; [2]Indiana Univesity School of Medicine, Indianapolis, United States*
Email: lnephew@iu.edu

Background and aims: Disparities in hepatocellular carcinoma (HCC) outcomes are shaped by intersecting social determinants of health (SDOH), yet most studies examine individual risk factors in isolation. Using latent class analysis (LCA), we previously identified six SDOH phenotypes associated with progressively worse stage at diagnosis, receipt of curative therapy, and survival. Because timely HCC screening improves early detection and outcomes, we examined whether adverse outcomes across SDOH-based latent classes were attributable to differences in HCC screening.
Method: We analyzed 4,117 adults with HCC in the Indiana Statewide Cancer Registry (2009–2020). LCA identified six risk classes based on demographics, insurance, marital status, occupation, area social deprivation, and geographic access. Minimal Barriers; Publicly Insured, Married Females; 3 Publicly Insured, Unpartnered Males; Rural and Geographically Distant; Structurally Marginalized; and 6) Unseen and Uninsured. Patients were attributed to a health system

based on longitudinal engagement within 24 months before diagnosis. Screening outcomes included any screening (imaging/AFP), routine imaging (imaging only), and routine screening (imaging & AFP) within a two-year lookback period, excluding the 90 days before diagnosis. Univariable logistic regression compared screening outcomes across classes using the lowest-risk class as reference.

Results: 1,905 patients met attribution criteria. Latent classes demonstrated graded differences in stage at diagnosis, receipt of curative therapy, and mortality. Among attributed patients, 47.8% received any screening and 18.6% received routine screening. Compared with the reference group, patients in the Unseen and Uninsured class were less likely to receive any screening (OR 0.62, p = 0.029), routine imaging (OR 0.48, p = 0.002), and routine screening (OR 0.30, p < 0.001). Patients in the Rural and Under-supported class were also less likely to receive any screening (OR 0.73, p = 0.044) and routine imaging (OR 0.65, p = 0.008). In contrast, the Structurally Marginalized class demonstrated screening rates comparable to the reference group for any screening (OR 0.96, p = 0.801) and routine imaging (OR 0.98, p = 0.898), despite worse stage at diagnosis and survival.

Conclusion: SDOH-based latent classes reveal heterogeneity in HCC screening patterns. Worse outcomes among some high-risk groups may not be fully explained by screening failure alone, underscoring the need for class-specific, precision outreach strategies.

THU-387

Identify liver tumors from ultrasound images through ensemble learning integrated with the ordered weighted averaging operator

Hsiao-Ching Nien[1,2], Jonathan Lee[3], Jong-Yih Kuo[4,5], Ti-Feng Hsieh[4], Chih-Horng Wu[6], Jin-Chuan Sheu[6], Pei-Lien Chou[7]. *[1]The Good liver foundation Taiwan and the Department of Family Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Associate Professor, Center for General Education, National Taiwan University, Taipei, Taiwan; [3]National Taiwan University, Taipei, Taiwan; [4]National Taipei University of Technology, Taipei, Taiwan; [5]National Taipei University of Technology, Taipei; [6]National Taiwan University Hospital, Taipei, Taiwan; [7]The YUAN High-Tech Development Co., Ltd, Taipei, Taiwan*
Email: jykuo@ntut.edu.tw

Background and aims: Liver tumors are one of the main causes of death in the Pan-Asia region. Its high prevalence rate and case fatality rate make early diagnosis and treatment even more crucial. Ultrasound examination, as a noninvasive and easy-to-access tool, plays a vital role in screening liver tumors. However, it is somewhat limited by the quality of ultrasound images and the operation skills of the physicians. In this work, we propose an approach to integrating ensemble learning to increase the accuracy and precision of the diagnosis.

Method: By utilizing ensemble learning, we combine four models: YOLO v7, ResNet, EfficientNet, and RegNet, and integrate these models with Hard Voting, Soft Voting, and Ordered-Weighted-Averaging (OWA) operator. A dataset from the National Taiwan University Hospital of 4,599 ultrasound images taken from 1,576 patients, covering 10 types of tumors, was used to dichotomize benign versus malignant tumors. Model evaluation metrics include Precision, Recall, AUC, and Accuracy.

Results: The experiment results indicated that applying ensemble learning for binary classification achieved accuracies of 0.849, 0.688, 0.623, and 0.725 in Accuracy, Recall, Precision, and AUC, respectively. For the 8-class classification, applying ensemble learning achieved accuracies of 0.769, 0.303, 0.413, and 0.787 in Accuracy, Recall, Precision, and AUC, respectively, indicating a potential solution for the early diagnosis and clinical application of liver tumors.

Conclusion: This work developed multiple ensemble models based on ensemble learning, integrated with the OWA, Hard Voting, and Soft Voting methods, and evaluated their performance in perspective. In the model integration, there are two primary issues: one is that ensemble learning may reduce the contributions from stronger models and meanwhile introduce interference from weaker models; and the other is that assigning the model weights remains a challenge. To address these issues, we applied the OWA operator to provide an adjustable weighting mechanism, simplifying the model integration and alleviating the side effects from the weaker models. The experimental results indicate that OWA can effectively enhance the performance of ensemble models, resulting in a more balanced integration model and providing a more efficient solution for image classification tasks.

THU-393-YI

Comparison of sarcopenia and liver frailty indices for overall survival in hepatocellular carcinoma patients treated with first-line Atezolizumab-Bevacizumab

Asier Rabasco Meneghetti[1,2], Philippe Sultanik[3], Claudia Campani[4,5], Charles Roux[6], Zunamys Itzel Carrero[1], Dan-Adrian Popica[6], Giuliana Amaddeo[7], Marie Lequoy[8], Clemence Hollande[9], Sarah Mouri[3], Mathilde Wagner[10], Vincent Plaforet[6], Sabrina Sidali[4,9], Maxime Ronot[11], Marika Rudler[3], Alain Luciani[12], Olivier Sutter[13], Eléonore Spitzer[3], Hélène Regnault[7], Sanaa El Mouhadi[10], Violaine Ozenne[8], Nathalie Ganne-Carrié[4,14], Mohamed Bouattour[15], Jean Charles Nault[4,14], Dominique Thabut[3,16], Jakob Nikolas Kather[1,17,18], Manon Allaire[3,4,19]. *[1]Else Kroener Fresenius Center for Digital Health, Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, Dresden, Germany; [2]German Cancer Consortium (DKTK), Partner site Dresden, German Cancer Research Center (DKFZ), Heidelberg, Germany; [3]APHP Sorbonne University, Pitié Salpêtrière Hospital, Hepatogastroenterology unit, Paris, France; [4]INSERM UMR 1138, Centre de recherche des Cordeliers, Paris, France; [5]Department of Experimental and Clinical Medicine, Internal Medicine and Hepatology Unit, University of Firenze, Firenze, Italy; [6]AP-HP Sorbonne Université, Hôpital Universitaire Pitié-Salpêtrière, Service de radiologie interventionnelle, Paris, France; [7]Department of Hepatology, Henri Mondor University Hospital, Assistance Publique-Hôpitaux de Paris, Créteil, France; [8]AP-HP Sorbonne Université, Hôpital Universitaire Saint Antoine, Service d'Hépato-gastroentérologie, Paris, France; [9]Liver Cancer Unit, Assistance Publique - Hôpitaux de Paris, Beaujon University Hospital, Clichy, France; [10]AP-HP Sorbonne Université, Hôpital Universitaire Saint Antoine, Service d'Imagerie, Paris, France; [11]Department of Radiology, Assistance Publique - Hôpitaux de Paris, Beaujon University Hospital, Clichy, France; [12]Department of Medical Imaging, Assistance Publique-Hôpitaux de Paris, Henri Mondor-Albert Chenevier University Hospital, Créteil, France; [13]Interventional Radiology Unit, Hôpital Avicenne, Hôpitaux Universitaires Paris-Seine-Saint-Denis, AP-HP, Bobigny, France; [14]AP-HP Sorbonne Paris Nord, Hôpitaux Universitaire Paris Seine Saint-Denis, Service d'Hépatologie, Bobigny, France; [15]AP-HP, Hôpital Beaujon, Liver Cancer and Innovative Therapy, CLICHY, France; [16]Sorbonne Université, INSERM, Centre de recherche Saint-Antoine (CRSA), Institute of Cardiometabolism and Nutrition (ICAN), Paris, France; [17]Department of Medicine I, University Hospital Dresden, Dresden, Germany; [18]Medical Oncology, National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, Germany; [19]Genomic Instability, Metabolism, Immunity and Liver Tumorigenesis laboratory, Equipe Labellisée LIGUE 2023, Paris, France*
Email: asier.rabasco@tu-dresden.de

Background and aims: Sarcopenia is associated with worse outcomes in patients with hepatocellular carcinoma (HCC). However, its prognostic value in patients treated with first-line Atezolizumab-Bevacizumab (AtezoBev), remains uncertain. In this study, we compared volumetric CT-derived muscle with conventional L3-level skeletal muscle index (L3-SMI) for predicting overall survival (OS) in a multicentric French cohort of patients with unresectable HCC treated with AtezoBev. The liver Frailty Index (LFI) was also evaluated in a predefined subset of patients.

Method: Patients from 5 French liver centres receiving AtezoBev as first line systemic therapy with CTs within 3 months before treatment

initiation were included. OS was defined from treatment initiation to death from any cause or last follow-up. Sarcopenia was assessed using a volumetric muscle-to-bone ratio (BOA pipeline), L3-SMI and Day-0 LFI (subset, n = 46). Weighted Cox models adjusted for clinical covariates were fitted. Performance was assessed through leave-one-centre-out concordance indices (C-Index). Stratification was evaluated by Kaplan-Meier (KM) curves and log-rank tests.
Results: Among 338 included patients, 293 (87%) were male, median age was 66.6 years, 244 (72%) presented with cirrhosis, 187(55%) were treatment-naive, 213 (63%) were BCLC stage C, 133 (39%) presented with type 2 diabetes and 185 (55%) presented with arterial hypertension. Median OS was 14 months, 240 patients (71%) died during follow-up, including 35 (10%) before the first AtezoBev response assessment. In univariate analysis, the volumetric index was associated with OS (HR 0.80, 95%CI 0.66–0.97, p = 0.020) as was L3-SMI (HR 0.74 95%CI 0.61–0.89; p < 0.001) whereas LFI was not (HR 1.14, p = 0.45). After adjustment for confounders, both the volumetric index (HR: 0.80, 95%CI 0.68–0.94, p = 0.005) and L3-SMI (HR 0.74, 95% CI 0.65–0.84, p < 0.001) remained independently associated with OS. Corresponding C-Indices were 0.59 (95%CI 0.53–0.65) and 0.61 (95% CI 0.56–0.67). KM curves showed significant stratification for the volumetric index (p = 0.035) but not for L3-SMI (p = 0.076).
Conclusion: In unresectable HCC patients treated with first-line AtezoBev, both volumetric and L3-derived sarcopenia indices were independently associated with OS, whereas the liver frailty index was not, likely due to limited sample size. Volumetric sarcopenia assessment provided superior risk stratification and is feasible in routine practice, suggesting potential added value over other OS markers in this setting.

THU-394

MASLD-related hepatocellular carcinoma in cirrhotic and non-cirrhotic patients: a real-world analysis from the ITA.Li.Ca. cohort

Lucia Ragozzino[1], Alessio Mastro[1], Claudia Campani[2], Arianna Toscano[2], Tancredi Vincenzo Li Cavoli[1], Valentina Adotti[1], Tommaso Zurli[1], Fabio Marra[1]. *[1]Università degli Studi di Firenze, Firenze, Italy; [2]Dipartimento di Medicina Sperimentale e Clinica, Firenze, Italy*
Email: lucia.ragozzino@unifi.it

Background and aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of hepatocellular carcinoma (HCC), which may develop with or without cirrhosis. The study aimed to assess differences in tumour burden, treatment access, and outcomes between cirrhotic and non-cirrhotic MASLD-related HCC.
Method: Data from the ITA.Li.Ca. database (27 centres, 2003–2022) were retrospectively analysed. Patients with MASLD-related HCC and no other liver disease aetiologies were included. Baseline clinical, biochemical, and tumour features were compared according to cirrhosis status. Tumour response was classified according to mRECIST criteria.
Results: Among 903 eligible patients, 273 (30%) were non-cirrhotic. Only 25% were under ultrasound surveillance; 64% showed no significant fibrosis by FIB-4. Cirrhotic patients were more often obese and diabetic, with worse liver function (MELD 9.7 vs 8.5; p < 0.001). Non-cirrhotic patients had larger tumours (≥50% parenchymal involvement 15% vs 8%; p = 0.01) but similar rates of vascular invasion and metastases.Almost half of non-cirrhotic cases lacked histological confirmation despite recommendations.When we separately analysed cirrhotic and non-cirrhotic patients not undergoing surveillance, non-cirrhotic patients had bigger tumours (p value <0,001), although without differences in tumour spread.This difference was also confirmed in patients undergoing semi-annual surveillance (10% vs. 2.6%, p = 0.029).In the whole cohort, no significant differences in overall survival were observed between cirrhotic and non-cirrhotic patients, regardless of the treatment they received.Non-cirrhotic patients underwent more resections (64% vs 31%), while cirrhotics received more ablation (27%) and transplantation (15%). Tumour burden remained higher in non-cirrhotics irrespective of surveillance. Overall survival did not differ by cirrhosis status or treatment type (log-rank p > 0.05 for all).
Conclusion: MASLD-related HCC in non-cirrhotic patients presents with greater tumour burden but comparable survival to cirrhotic HCC. Despite guideline recommendations, biopsy is often omitted in non-cirrhotic cases. Treatment selection should prioritise tumour and liver function characteristics rather than the presence of cirrhosis. These findings highlight the need for tailored surveillance strategies in noncirrhotic MASLD.

THU-395

Attention-based multiple instance learning for classification of focal liver lesions using contrast-enhanced ultrasound

Adil Oezsoy[1], Tom Luedde[1], Janik Hohmann[1], Pompilia Radu[2], Annalisa Berzigotti[2], Jakob Nikolas Kather[3], Ralph Stetter[4], Georg Kunze[5], Tobias Paul Seraphin[1], Michael Kallenbach[1]. *[1]Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [2]Bern University Hospital, University of Bern, Bern, Switzerland; [3]Else Kroener Fresenius Center for Digital Health, Technical University Dresden, Dresden, Germany; [4]Klinikum Worms, Worms, Germany; [5]Schwarzwald-Baar Klinikum Villingen-Schwenningen, Villingen-Schwenningen, Germany*
Email: adil.oezsoy@hhu.de

Background and aims: Accurate characterization of focal liver lesions (FLLs) remains challenging in clinical practice. Contrast-enhanced ultrasound (CEUS) is a reliable, low-cost modality, but interpretation depends on the examiner's experience. Prior AI-based CEUS studies often require resource-intensive preprocessing and lack external validation. This study applied a weakly supervised attention-based multiple instance learning approach to classify FLLs and validated performance on external cohorts.
Method: Retrospectively collected multicenter data from four FLL types—focal nodular hyperplasia (FNH), hemangioma, hepatocellular carcinoma (HCC), and metastasis—were analyzed. Deep learning features were extracted from CEUS images using a pretrained convolutional neural network. A class-balanced 20% test set was held out, while the remaining data were used to train a classifier with grid search and five-fold cross-validation, selecting hyperparameters based on mean AUROC. The final model ensembled the five best cross-validation models and was evaluated on the internal test set and three external cohorts.
Results: The in-house dataset included 370 patients (FNH n = 52, hemangioma n = 149, HCC n = 67, metastasis n = 102). The final model achieved an average AUROC of 0.79 during cross-validation. On the held-out test set, AUROCs were 0.81, 0.77, 0.87 and 0.92 for FNH, hemangioma, HCC, and metastasis, respectively. In external validation, AUROCs for the first cohort (25 patients, same machine, cohort 1) were 0.89, 0.69, 0.87, and 0.71 and for the second cohort (39 patients, same machine, cohort 2) were 0.72, 0.68, 0.61, and 0.62. For the third cohort (19 patients, cohort 3) a different ultrasound machine was used, resulting in AUROCs of 0.21, 0.66, 0.56, and 0.65 for FNH, hemangioma, HCC, and metastasis, respectively. Post-hoc explainability analyses were performed to better understand the decision process of the model.
Conclusion: Weakly supervised MIL demonstrated robust performance in classifying FLLs using CEUS data during cross-validation and on the held-out test set, without requiring extensive preprocessing. Exam set-up, machine type and user-dependent artefacts influence the model's overall performance, whilst explainability analyses can provide insight into stable learnt features. Further research and larger cohorts are needed to confirm the clinical utility of such algorithms.

THU-396

Prognostic nutritional index as a predictor for survival in hepatocellular carcinoma patients with concurrent metabolic dysfunction-associated steatotic liver disease

Tsai Shin-Yu[1], Chun-Ting Ho[1,2], Yi-Chen Lin[3], Chia-Jung Ho[1], Yi-Hsiang Huang[4], Ming-Chih Hou[5], Jaw-Ching Wu[6], Chien-Wei Su[7]. *[1]Taipei Veterans General Hospital, Department of Medicine, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University Yangming Campus, Ph.D. Program of Interdisciplinary Medicine, Taipei, Taiwan; [3]Linkou Chang Gung Memorial Hospital, Department of Medicine, Taoyuan City, Taiwan; [4]Taipei Veterans General Hospital, Department of Medical Research, Taipei, Taiwan; [5]Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [6]National Yang Ming Chiao Tung University Yangming Campus, Institute of Clinical Medicine, Taipei, Taiwan; [7]Taipei Veterans General Hospital, Division of General Medicine, Department of Medicine, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and aims: Metabolic dysfunction–associated steatotic liver disease (MASLD) has emerged as a major etiology of chronic liver disease and may influence the prognosis of hepatocellular carcinoma (HCC). However, evidence regarding noninvasive serum biomarkers (NISB) for predicting the prognosis of HCC patients with MASLD remain limited. This study aimed to evaluate the prognostic ability of NISBs on predicting outcomes in this population.
Method: Between 2015 and 2023, 460 consecutive patients with HCC and concurrent MASLD who underwent curative hepatic resection at a single tertiary center were retrospectively analyzed. Associations between NISBs or prognostic scores and overall survival (OS) were evaluated using the Cox proportional hazards model. The Akaike information criterion (AIC) was used to compare the predictive performance among the prognostic nutritional index (PNI), albumin–bilirubin (ALBI) score, fibrosis-4 (FIB-4) score, and lymphocyte-to-monocyte ratio (LMR).
Results: After a median follow-up of 48 months (interquartile range, 25–71 months), 92 patients (20.0%) died, yielding a 5-year OS rate of 78.4% (95% confidence interval, [CI], 74.1–82.7%). Independent predictors of poor OS in multivariable Cox regression analysis included serum albumin <4 g/dL, creatinine >1.2 mg/dL, aspartate aminotransferase >45 U/L, tumor size >5 cm, and high histologic grade. Among the NSIBs, PNI demonstrated the best prognostic performance with the lowest AIC (879.797), followed by ALBI (896.214), FIB-4 (903.551), and LMR (911.328). Patients with PNI <45 had significantly lower 5-year OS rates than those with PNI ≥45 (68.2% vs. 87.6%, $p < 0.001$; hazard ratio 2.31, 95% CI 1.52–3.50). This survival difference was particularly pronounced in patients with preserved liver function (Child–Pugh class A) and in those without cirrhosis. Subgroup analyses consistently demonstrated poorer survival in the low-PNI group across most clinical strata, including age (>65 vs. ≤65 years), tumor size (≤5 cm vs. >5 cm), BCLC stage (0/A), and the presence or absence of microvascular invasion (all $p < 0.05$).
Conclusion: PNI, calculated from serum albumin concentration and peripheral lymphocyte count, serves as a simple and effective prognostic score for predicting postoperative survival in patients with HCC patients with concurrent MASLD and had consistent performance in different subgroups.

THU-397

Imaging spectrum of giant hepatic hemangioma with diffuse hepatic hemangiomatosis: nine case series

Ki Choon Sim[1], Beom Jin Park[1], Min Ju Kim[1], Deuk Jae Sung[1], Na Yeon Han[1], Yeo Eun Han[1], Seungha Cha[1], Tae Hyung Kim[2]. *[1]Department of Radiology, Korea University Anam Hospital, Seoul, Korea, Rep. of South; [2]Department of Gastroenterology, Korea Unversity Anam Hospital, Seoul, Korea, Rep. of South*
Email: kspringsim@korea.ac.kr

Background and aims: Giant hepatic hemangioma accompanied by diffuse hepatic hemangiomatosis is a rare entity in adults and can mimic infiltrative hepatic malignancies. While individual case reports have described its imaging characteristics, larger case series remain limited. This study aims to summarize the radiologic features and clinical characteristics of patients with giant hemangioma and coexisting diffuse hepatic hemangiomatosis.
Method: A retrospective radiologic database search was performed using the keyword "diffuse hepatic hemangiomatosis." Thirteen adult patients with imaging findings suspicious for diffuse hepatic hemangiomatosis were identified. Clinical information, laboratory data, contrast-enhanced CT, multiphasic liver MRI, and available pathology reports were reviewed. Imaging features—including enhancement patterns, lesion distribution, and associated hepatic abnormalities—were systematically analyzed.
Results: A total of 13 patients met the imaging criteria for diffuse hepatic hemangiomatosis. Among them, 9 patients had both CT and MRI available for comprehensive radiologic evaluation. Typical imaging findings included peripheral nodular enhancement with progressive fill-in in giant hemangiomas and innumerable small T2-hyperintense nodules consistent with diffuse hepatic hepatic hemangiomatosis. Pathologic confirmation was obtained in 3 patients, all demonstrating cavernous hemangioma or hemangiomatosis without evidence of malignancy. However, one of them subsequently required an additional hepatectomy due to progression of diffuse hepatic hemangiomatosis. Follow-up imaging demonstrated overall stability in the majority of cases.
Conclusion: This case series highlights characteristic radiologic findings of giant hepatic hemangioma with diffuse hemangiomatosis in adults. Recognition of this pattern is essential to avoid misdiagnosis as infiltrative malignancy. CT and MRI provide complementary diagnostic information, and pathology—though not always required—can confirm the vascular benign nature. Conservative management appears appropriate in patients with preserved liver function and stable imaging features.

THU-398

Hepatocellular carcinoma in Budd Chiari syndrome: characteristics and risk factors

Marinela Stoian[1,2]. *[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Internal Medicine Dr Ioan Cantacuzino Hospital, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Internal Medicine Dr Ioan Cantacuzino Hospital, Bucharest, Romania*
Email: marilenastoian@yahoo.com

Background and aims: To analyze the characteristics and the factors associated with the development of hepatocellular carcinoma (HCC) in patients with Budd-Chiari syndrome (BCS).
Method: A cohort of one hundred and two consecutive patients with BSC was retrospectively evaluated. A comprehensive investigation for underlying prothrombotic disorders was performed. Liver nodules were evaluated with serum alpha-fetoprotein (AFP) dosage and analysis imaging features (CT/MRI). Liver biopsy was obtained in presence of: diameter >2 cm or increase in size on surveillance imaging, number ≤2, portal washout and /or increase in AFP level. Nodules were diagnosed as benign when none of these criteria were fulfilled. HCC invading hepatic veins or inferior vena cava (IVC) were excluded.
Results: Patients characteristics were: female sex (n = 70), mean age at diagnosis 37 years, mean follow up period 7 years, IVC obstruction in 12 patients, myeloproliferative diseases in 48/49 patients (55%), liver nodules in 34 patients. Treatment consisted of oral anticoagulation in all patients, hepatic veins angioplasty in 20 patients, porto–systemic shunt in 49 patients (TIPS in 18 patients and surgical shunt in 32 patients) and seventeen patients received liver transplantation. Hepatocellular carcinoma was diagnosed in 9 cases. Liver parenchyma adjacent to HCC showed severe fibrosis or cirrhosis

in 7 cases. Hepatitis B and C markers were negative in all HCC cases. In univariate analyses including age, sex, alcohol consumption, prothrombotic disorders, IVC obstruction, portal vein obstruction, disease duration and BSC treatment, three factors were associated with HCC development: male sex (6/9, 67% vs. 26/93, 28%. p = 0.026), factor V Leiden (4/8, 50% vs. 15/80, 18.5%, p = 0.06) and IVC obstruction (7/9, 78% vs.5/93, 5%, p < 0.001). In multivariate analysis, only IVC was associated with HCC (p < 0.0001, OR = 78, IC = 10.8–560.7). Porto-systemic shunt did not increase the risk of HCC (4/32, 12.5% vs. 5/70, 7%). Serum AFP level had very high predictive value to distinguish HCC from benign nodules: AFP >10 ng/ml (n = 8/8, PPV = 100%, mean: 1546 ng/ml, range: 13–10400 ng/ml) vs. AFP<10 ng/ml (n = 22/23, NPV = 96%, mean: 3.5 ng/ml, range: 1–7 ng/ml).
Conclusion: The incidence of HCC in BCS (1.6% per year) is similar to that reported in other chronic liver disease and is associated with IVC obstruction, male sex and factor V Leiden. High serum alpha-fetoprotein level appears to be a useful screening tool in this population.

THU-399

Predicting early recurrence of hepatocellular carcinoma after resection: a machine learning model integrating clinical data and llm-structured pathological features

Tung-Hung Su[1,2,3], Hung-Ning Tung[4], Yen-Ning Hsu[5], Fen-Fang Chen[2], Chia-Chang Wen[6], Shou-Wu Lee[7], Teh-Ia Huo[8], Chien-Chang Lee[9], Jia-Horng Kao[2,3,10,11]. [1]*Department of Medical Research, National Taiwan University Hospital Hsin-Chu Branch, Hsin-Chu, Taiwan;* [2]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan;* [3]*Hepatitis Research Center, National Taiwan University Hospital, Taipei, Taiwan;* [4]*Department of Internal Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsin-Chu, Taiwan;* [5]*Center of Intelligent Healthcare, National Taiwan University Hospital, Taipei, Taiwan;* [6]*Information Technology Office, National Taiwan University Hospital, Taipei, Taiwan;* [7]*Division of Gastroenterology, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan;* [8]*Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan;* [9]*Department of Information Management, Ministry of Health and Welfare, Taipei, Taiwan;* [10]*Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan;* [11]*Department of Medical Research, National Taiwan University Hospital, Taipei, Taiwan*
Email: tunghungsu@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) remains one of the most deadly cancers worldwide. Surgical resection is the mainstay of curative treatment for early-stage HCC; however, postoperative recurrence is not uncommon and significantly compromises long-term prognosis. We aimed to develop a model integrating clinical and pathological features to predict early (2-year) recurrence after resection.
Method: We established a retrospective cohort of HCC patients who underwent curative resection using data from the Integrated Medical Database (iMED) of National Taiwan University Hospital. Clinical, laboratory, and imaging data were curated and standardized. The pathologic features—including tumor size, number, differentiation, microvascular invasion, satellite nodules, capsule invasion, location, and fibrosis stage were converted into structured variables using the Meta Llama 3.3 multilingual large language model (LLM). Six machine learning algorithms (Logistic Regression, XGBoost, LightGBM, CatBoost, SVM, and Random Forest) were trained on 80% of cases and tested on the remaining 20%.
Results: A total of 1061 HCC patients and 59 clinicopathologic features were included for modeling. Among the tested models, the CatBoost classifier demonstrated the best predictive performance, with an AUROC of 0.791 and an accuracy of 0.756. Using a threshold of 0.476, the sensitivity, specificity, and positive predictive value, and F1-score were 0.674, 0.822, 0.753, and 0.711, respectively. Key predictors of early recurrence included trabecular histologic subtype, BCLC staging, microvascular invasion, tumor volume, and integrated clinicopathologic stage.
Conclusion: By leveraging an LLM to structure pathological features, we developed a machine learning model that integrates clinicopathological data to predict early postoperative recurrence in HCC. Future work will expand the model by incorporating preoperative CT imaging and deep learning techniques to have a comprehensive multimodal framework.

THU-400

Re-evaluating the diagnostic value of alpha-fetoprotein for hepatocellular carcinoma in the direct-acting antiviral era

Yoshinori Takeda[1], Hiroshi Imamura[1], Hirofumi Ichida[1], Akio Saiura[1]. [1]*Juntendo University, Tokyo, Japan*
Email: yo-takeda@juntendo.ac.jp

Background and aims: Direct-acting antivirals (DAAs) achieve sustained virological response (SVR) in most hepatitis C virus (HCV)–infected patients, suppressing hepatic inflammation and lowering baseline alpha-fetoprotein (AFP) levels in the absence of hepatocellular carcinoma (HCC). In parallel, an epidemiological shift toward non-viral HCC, in which background liver disease is associated with lower baseline AFP, has been observed. These changes may improve AFP diagnostic performance; however, whether AFP accuracy has improved in the post-DAA era remains unclear. We evaluated temporal changes in baseline AFP levels and AFP diagnostic performance for HCC in the post-DAA era, with des-γ-carboxy prothrombin (DCP) as a reference.
Method: We retrospectively analyzed 388 patients who underwent curative hepatectomy for HCC (2009–2022). AFP and DCP values measured 4 months postoperatively in patients who remained recurrence-free for at least 1 year were used as surrogate non-HCC reference values (n = 257), representing baseline AFP levels. Patients were stratified into pre-DAA (before August 2016) and post-DAA (September 2016 onward) cohorts, reflecting DAA widespread DAA adoption in Japan. Diagnostic accuracy of AFP and DCP was assessed using AUROC. Optimal AFP cut-offs were evaluated using several ROC-based approaches, including the Youden index. Factors associated with elevated baseline AFP were examined by multivariable regression.
Results: In the post-DAA era, the proportion of HCV non-SVR HCC declined markedly (24% to 5%; $P < 0.001$), whereas non-viral HCC increased numerically (58% to 66%; $P = 0.093$). Baseline (post-operative) AFP levels were significantly lower in the post-DAA cohort than in the pre-DAA cohort (median 3 [IQR 2–4] vs. 4 [3–7] ng/mL; $P < 0.001$), while preoperative AFP levels did not differ between eras. AFP AUROC improved from 0.702 to 0.793 (DeLong P = 0.014), whereas DCP performance was unchanged (P = 0.934). Owing to this upward shift of the ROC curve, an AFP cut-off value of 5 ng/mL achieved higher specificity without a substantial loss of sensitivity in the post-DAA era. Multivariable analysis identified HCV non-SVR status and cirrhosis as independent determinants of higher baseline AFP.
Conclusion: In the post-DAA era, suppression of hepatic inflammation and an increasing proportion of non-viral HCC are associated with lower baseline AFP levels and improved diagnostic performance of AFP for HCC. An AFP cut-off of 5 ng/mL appears appropriate for contemporary HCC diagnosis.

THU-401

Epidemiology and factors affecting survival of intrahepatic cholangiocarcinoma: a population-based study of 12,138 patients

Aya Abdelhameed[1], Ker Shiong Tan[2], Mohamed Mortagy[2], Benjamin E White[2], John Ramage[2]. [1]*Alexandria University Faculty of Medicine, Alexandria, Egypt;* [2]*Basingstoke And North Hampshire Hospital, Basingstoke, United Kingdom*
Email: aya.abdelhameed@hhft.nhs.uk

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is a rare malignant neoplasm, characterised by its aggressive nature and poor prognosis. Mortality remains high with limited curative options. Previous studies report increasing incidence of iCCA up to 2017 when compared to extrahepatic cholangiocarcinoma. This study aims to determine the recent trends in the epidemiology of iCCA from 2011 to 2022 and the factors affecting the overall survival (OS) of patients with iCCA.
Method: A total of 12,138 patients with iCCA diagnosed between 2011 and 2022 were extracted from the American Surveillance, Epidemiology, and End Results (SEER) database using ICD-10 anatomy code C22.1 and ICD-O-3 morphology code 8160/3. Incidence trends were examined. Kaplan-Meier (KM) plots were generated for the cohort and categorical variables. Univariable and multivariable Cox regression were performed, generating hazard ratios (HR) and confidence intervals (CI).
Results: The incidence of liver cholangiocarcinoma has significantly increased from 165 patients/100,000 in 2011 to 465 patients/100,000 in 2022. The incidence of stage 4 is decreasing, and the incidence of stage 1 is increasing from 2011 to 2022. Most patients were male (50.9%) with a median age of 67 years, and the majority lived in metropolitan areas (90.1%). The most common TNM stage is stage 4 (50%). Only 19.4% of patients underwent resection, with 0.8% having total resection with liver transplant. Most patients did not receive radiotherapy (85.3%), while a majority received chemotherapy (57.3%). Overall survival at 12, 36, 60 and 120 months were 42.0%, 17.1%, 10.8% and 5.7%, respectively. Multivariable Cox regression showed that advanced age (HR 1.01), male sex (HR 1.19), patients who lived in non-metropolitan areas (HR 1.11), advanced TNM stage and patients who did not undergo surgery (HR 3.41) were statistically associated with worse overall survival ($p < 0.05$). However, patients who received radiotherapy (HR 0.60) or chemotherapy (HR 0.38) were statistically associated with higher overall survival ($p < 0.05$).
Conclusion: The incidence of iCCA has almost tripled from 2011 to 2022, possibly due to increasing investigations. Further research is needed to explain this significant increase in incidence. iCCA has poor OS, which is associated with advanced age, male sex, living in non-metropolitan areas (despite increasing incidence in metropolitan areas), and advanced stage. Undergoing surgery, receiving radiotherapy or chemotherapy are associated with higher OS.

THU-402
Evaluation of the ASAP model for detecting hepatocellular carcinoma in Thai patients with chronic liver disease, including those with negative alpha fetoprotein

Nutcha Pinjaroen[1], Claire Chen[2], Jenna Bedrava[3], Kittichote Duangnum[4], Pisit Tangkijvanich[1]. [1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of medicine, Chulalongkorn University, Bangkok, Thailand;* [2]*Medical & Scientific Research, Core Diagnostic, Abbott Laboratories, Singapore, Singapore;* [3]*Clinical Statistics, Core Diagnostic, Abbott Laboratories, Singapore, Singapore;* [4]*Medical Affairs, Core Diagnostic, Abbott Laboratories, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide. Current HCC surveillance based on biannual ultrasound and alpha-fetoprotein (AFP) testing has suboptimal sensitivity, especially in AFP-negative (<20 ng/mL) patients. Multivariable algorithms such as ASAP (Age, Sex, AFP, and PIVKA-II) are emerging as promising tools for improved HCC detection. This study evaluated the clinical performance of ASAP in a cohort of chronic liver disease (CLD) patients from Thailand, including those with negative AFP.
Method: This case-control study included 978 patients: 445 with first-time HCC and 533 with non-HCC chronic liver disease (CLD), both with mixed etiologies. HCC was diagnosed per APASL guidelines and staged using the Barcelona Clinic Liver Cancer (BCLC) system, with early-stage defined as BCLC 0 or A. Fibrosis stage and cirrhosis status in non-HCC controls were determined by FibroScan and histopathology. Serum AFP and PIVKA-II were measured using Abbott Alinity assays. Diagnostic performance of ASAP and individual biomarkers was assessed using receiver operating characteristic (ROC) curves, corresponding area under the curve (AUC) values, and sensitivity calculations at a fixed specificity of 90%. Comparisons between AUCs were performed using DeLong's paired test.
Results: ASAP showed significantly better performance (AUC = 0.92) than individual biomarkers (0.85 for AFP and 0.86 for PIVKA-II) for distinguishing HCC from CLD ($p < 0.001$). Among patients with advanced fibrosis or cirrhosis, ASAP yielded an AUC of 0.90 (95% CI: 0.88–0.93) for all-stage HCC and 0.86 (95% CI: 0.83–0.90) for early-stage HCC, with sensitivities of 78.0% and 68.0%, respectively, at a fixed specificity of 90%. In the AFP-negative subgroup, which included 245 HCC cases, ASAP detected 151 cases, nearly half of which (48%) were at an early stage. In this group, ASAP achieved an AUC of 0.84 (95% CI: 0.80–0.87) and sensitivity of 62.4% at 90% specificity, significantly outperforming PIVKA-II alone (AUC = 0.79; 95% CI: 0.74–0.83; $p < 0.001$), for distinguishing all-stage HCC from advanced fibrosis/cirrhosis controls.
Conclusion: The ASAP model demonstrated strong clinical performance in detecting HCC, even among patients with negative AFP results. Integrating ASAP into HCC surveillance programs has the potential to optimize cancer detection, particularly for individuals with negative AFP results or inconclusive imaging findings.

THU-403
Tumor burden score as prognostic factor in newly diagnosed hepatocellular carcinoma

Aki Uutela[1,2], Heli Vajavaara[1,2], Vera Nevasuo[2], Helena Isoniemi[1,2], Arno Nordin[1,2], Pia Osterlund[2,3,4,5]. [1]*Helsinki University Hospital, Helsinki, Finland;* [2]*University of Helsinki, Helsinki, Finland;* [3]*Tampere University Hospital, Tampere, Finland;* [4]*University of Tampere, Tampere, Finland;* [5]*Karolinska Institutet, Stockholm, Sweden*
Email: aki.uutela@hus.fi

Background and aims: Both interventional and medical treatments for hepatocellular carcinoma (HCC) are evolving, and accurate prognostic tools are needed to provide optimal treatment intensity. The aim of this study was to provide real-world evidence of prognostic value of tumor burden score (TBS) for newly diagnosed HCC patients (pts).
Method: All 639 adult pts with HCC at Helsinki University Hospital in 2010–2020 were included. Minimum follow-up was 33 months. Milan criteria were used for transplantation. Kaplan-Meier and Cox regression were used. TBS was calculated as $TBS^2 = (\text{size of largest nodule})^2 + (\text{number of nodules})2$.
Results: Median age was 68 years and 76% were male. Underlying liver diseases were alcohol-related (29%), MASLD (23%), viral (16%), not specified (16%) or other (17%). TBS was associated with survival in the whole HCC cohort with median overall survival (mOS) 59 months (5-year OS rate 49%) for low <3.36, 31 (29%) for medium 3.36–13.74, and 5 (11%) for high >13.74 TBS ($p < 0.001$). TBS was not statistically significant for liver transplantation pts (n = 112), mOS not reached (85%) vs 158 (77%) vs not applicable (NA) for low/medium/high TBS respectively ($p = 0.39$) or resection pts (n = 96) 75 (70%) vs. 66 (51%) vs 58 (48%; $p = 0.31$). Local ablation pts (n = 90) had inferior OS per TBS; 53 (40%) vs 35 (18%) vs NA ($p = 0.007$). No statistical significance was noted for TACE pts (n = 156); 37 (23%) vs 25 (20%) vs NA ($p = 0.46$) or systemic anticancer therapy (SACT, n = 61) NA vs 15 (6%) vs 6 (13%) ($p = 0.58$). In palliative care only (n = 124) TBS mattered; 18 (0%) vs 7 (5%) vs 3 (0%; $p < 0.001$). In multivariate analysis for OS primary treatment modality was strongest; transplantation ref., resection HR 3.9 [95% CI 2.4–6.3], ablation 7.2 [4.5–11.5], TACE 10.3 [6.1–15.9], SACT 13.3 [8.1–21.8], and palliative care 18.4 [11.9–28.3]. Child-Pugh score (A ref., B 1.9 [1.5–2.3], and C 2.8 [1.9–4.1]), ECOG (PS0–1 ref., PS2 1.3 [1.0–1.7], and PS3–4 1.9 [1.3–2.7]), and TBS (low ref., medium 1.6 [1.3–

2.1], and high 2.7 [1.7–3.6]) remained independent prognostic factors. Substituting TBS with another tumor burden model, Seven-eleven, in the multivariate model yielded similar results, but with lower HR (low 7–11 ref., medium 1.3 [1.0–1.7], and high 1.8 [1.5–2.3]).
Conclusion: In this study, we show that TBS, together with other markers, has independent prognostic value, i.e., matters in treatment planning. If the patient meets criteria for liver transplantation or resection, good results are achievable also for pts with medium TBS.

THU-404
Predictive value of MRI parameters in the development of hepatocellular carcinoma in liver cirrhosis
Monique van Wijk[1], Jasper van Leengoed[1], Laura Boer[1], Job van der Palen[1], Donald Bouman[1], Maureen Guichelaar[1]. [1]*Medisch Spectrum Twente, Enschede, Netherlands*
Email: maureenguichelaar@yahoo.com

Background and aims: Liver cirrhosis is a key risk factor for hepatocellular carcinoma (HCC) development, however reliable predictive biomarkers are lacking. Different MRI sequences provide non-invasive variables of (changes) in liver parenchyma. Diffusion weighted imaging (DWI) evaluates diffusion and perfusion which can be quantified (b-values and derived apparent diffusion coefficient; ADC), reflecting perfusion, edema and possibly inflammation. Proton density fat fraction (PDFF) is used to measure fat fraction of the liver. This study aims to evaluate the value of these MRI parameters in predicting HCC development in liver cirrhosis.
Method: This single-center retrospective cohort study included patients who underwent annual MRI-based surveillance for hepatocellular carcinoma (HCC) between 2010 and 2024. Patients who developed hepatocellular carcinoma (HCC) were compared with a control cohort randomly selected from the remaining non-HCC population. MRI scans were analyzed for b-values and ADC (mm^2/s) using mean values from nine regions of interest in both hepatic lobes. Various MRI-derived quantitative parameters were studied, including absolute and ratios of several b-values (b0, b150, b400 and b800), liver volume (cm^3), and proton density fat fraction (PDFF; %).
Results: A total of 84 cirrhotic patients were included of which 35 developed HCC. The study population included 49 men (58%) with a mean age of 69.4 ± 9.8 years; the most common underlying liver disease was MASLD (n = 33, 39%). There were no differences between HCC and control patients, except smoking. The overall follow-up time was 58.7 ± 33.3 months. Patients who developed HCC had significant increased b-values in MRI scans at 1 and 2 years preceding HCC development. No correlations were found with other MRI parameters, including liver volume, PDFF and iron content. Two multivariate logistic regression models were tested, which included MRI derived b variables (b0 and the ratio of b0 and b150) at 2 and 1 year before HCC development, showing AUC of resp. 0.81 and 0.83 for HCC development.
Conclusion: This study demonstrates that MRI-derived quantitative parameters of the liver parenchyma (i.g. diffusion-weighted imaging–derived b-values) are associated with changes predictive of hepatocellular carcinoma (HCC) development. Multivariate logistic regression models incorporating these b-values demonstrated good predictive performance, highlighting their potential for early HCC risk stratification, which warrants further studies.

THU-409
Accurate detection of cholangiocarcinoma in primary sclerosing cholangitis by DNA methylation biomarkers in bile and plasma
Hege Marie Vedeld[1], Sigurd Breder[1], Heidi Pharo[1], Hans Petter Brodal[1], Evy Marie Thorkildsen[1], Sara Brandt-Winge[1], Erik von Seth[2], Marit Grimsrud[1], Sheraz Yaqub[1], Tom Hemming Karlsen[1], Krzysztof Grzyb[1], Vemund Paulsen[1], Martti Färkkilä[3], Annika Bergquist[2], Lars Aabakken[1], Kirsten Muri Boberg[1], Trine Folseraas[1], Guro Lind[1]. [1]*Oslo University Hospital, Oslo, Norway;* [2]*Karolinska University Hospital, Stockholm, Sweden;* [3]*Helsinki University Hospital, Helsinki, Finland*
Email: h.m.vedeld@ous-research.no

Background and aims: Current methods for early detection of cholangiocarcinoma (CCA) in individuals with primary sclerosing cholangitis (PSC) lack accuracy, often resulting in CCA diagnosis at advanced, non-curative stages. This study aimed to identify DNA methylation biomarkers in liquid biopsies for earlier and more reliable detection of CCA in PSC.
Method: Reduced representation bisulfite sequencing was used to analyze tissue samples from individuals with CCA (n = 10) and PSC (n = 9), resulting in the identification of 12 candidate DNA methylation biomarkers. Targeted analyses of the biomarker candidates were performed by droplet digital PCR (ddPCR). Following quality control and verification of the assays in tissue samples, four candidates were selected for evaluation in two extensive cohorts of bile (n = 272) and plasma (n = 128) samples from individuals with PSC and/or CCA. Individuals were categorized into three groups: i) concomitant PSC and CCA (PSC-CCA), ii) PSC with a clinical diagnosis of CCA 3–12 months after sample collection (PSC to CCA), and iii) PSC alone (no diagnosis of CCA more than 36 months after sample collection).
Results: Four biomarkers (A–D) demonstrated perfect discrimination (AUC = 1.00) between PSC-CCA and PSC alone in tissue samples. In bile, all four biomarkers achieved an AUC above 0.9 for distinguishing PSC-CCA (n = 20) from PSC alone (n = 207). A two-biomarker panel (A and B) reached 95% sensitivity and 90% specificity, while adding biomarkers C and D increased specificity to 97% with sensitivity maintained at 90%. Notably, the two-biomarker panel identified all eight PSC to CCA cases (100% sensitivity), derived from individuals with PSC who were clinically diagnosed with CCA 3–12 months after bile collection. Performance remained strong in plasma, where an alternative two-biomarker panel (B and C) achieved 70% sensitivity and 90% specificity for distinguishing PSC-CCA (n = 17) and PSC alone (n = 101).
Conclusion: We report four DNA methylation biomarkers that discriminate CCA from PSC with high accuracy in bile and promising performance in plasma. The ability to detect CCA months before clinical diagnosis suggests that these biomarkers may improve surveillance and enable earlier, potentially curative interventions in individuals with PSC. Prospective validation in larger cohorts is warranted to confirm their clinical utility.

THU-410
Global trends in primary liver cancer between 2000 and 2023
Shahid Khan[1], Mathew Vithayathil[1], Terry Yip[2], Hashem El-Serag[3]. [1]*Imperial College London, London, United Kingdom;* [2]*The Chinese University of Hong Kong, Sha Tin, Hong Kong;* [3]*Baylor College of Medicine, Houston, United States*
Email: mathew.vithayathil@doctors.org.uk

Background and aims: Primary liver cancer (PLC) encompasses hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (iCCA). The global burden of PLC is increasing in the 21st century, characterized by high lethality and significant absolute increases in new cases and deaths between 2000 and 2023. This study used the Global Burden of Diseases Study 2023 to characterise global trends in PLC incidence and mortality, identify key aetiological shifts, and highlight urgent public health priorities.
Method: Incidence, mortality, and aetiology data for PLC between 2000 and 2023 were collected for countries/terroritories from the Global Burden of Diseaes Study 2023. Global and country-specific age-standardised incidence (ASIR) and mortality (ASMR) rates were determined across the study period. Underlying liver disease aetiology data relating to PLC, including alcohol-related liver disease (ArLD), hepatitis B (HBV), hepatitis C (HCV) and metabolic-dysfunction associated steatotic liver disease (MASLD) were reviewed for each global region. Average annual percentage change (AAPC) outlined trends in incidence and mortality.

Results: The overall global burden of PLC has been increasing, with the absolute number of new cases and deaths increasing significantly (59.4% and 55.8%, respectively) between 2000 and 2023. Although age-standardised incidence and mortality rates declined since 2000, there has been a reversal in this decline since 2020. In particular, HBV- and HCV-associated rates, after historical declines, showed a concerning rebound starting circa 2020. Viral hepatitis (HBV and HCV) remained the dominant cause globally, but its proportion is decreasing. MASLD showed the greatest average annual increase in new cases. There is global variation in PLC-related liver disease aetiology, with HBV predominant in East Asia and Sub-Saharan Africa, HCV in the Middle East, North Africa, Northern America, and Latin America, and ArLD in Europe and Australasia. MASLD rates showed a consitent rise across all regions.
Conclusion: The global burden of primary liver cancer continues to rise, with a concerning reversal of historical declines in incidence and mortality since 2020. An increase in viral hepatitis related PLC during this time and the consistent rise of MASLD rates across the 21st century underscores an urgent need for sustained public health intervention and clinical action.

THU-412
Oral-gut microbiome is associated with sarcopenia in HCC patients following radiotherapy

Qingqing Hu[1], Xiaowei Xu[1]. [1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*
Email: ivyhu@zju.edu.cn

Background and aims: Patients with advanced cancer following radiotherapy often suffering from radiation-induced sarcopenia(RIS), however, evidence-based research on the role of oral-gut microbiome in predicting sarcopenia during radiotherapy in patients with advanced hepatocellular carcinoma (HCC)remains scarce. The aim of this study was to assess the correlation between oral-gut microbiota changes during radiotherapy and the extent of sarcopenia in HCC patients.
Method: 228 patients who received radiotherapy were enrolled. The diversity and species differences of both the oral and gut microbial community were tested by 16 S rRNA sequencing and bioinformatics analysis.
Results: The sarcopenia group had greater microbial abundance and species diversity. In gut microbiome, we observed significant alterations represented by an increase in Lactobacillus and Streptococcus while in oral microbiome the relative abundance of Actinomycetaceae, Endodontalis and Intermedia were particulary increased in sarcopenia group, suggesting a potential association between the sarcopenia and oral-gut microbiome. Furthermore, Prevotella, Streptococcus, parvula and mucilaginosa were identified as potential diagnostic and prognostic biomarkers of sarcopenia. The association network analysis also revealed an imbalance in species diversity and ecological diversity in both oral and gut microbiome of sarcopenia.
Conclusion: The oral-gut microbiome is associated with radiation-induced sarcopenia, which has important manifestations in the clinical management of RIS patients. The exact mechanisms through which the oral-gut microbiota influence sarcopenia remain to be elucidated.

Multi-omics integration identifies a precise prognostic signature of survival in advanced HCC

Fengna Yan[1], Feixiang Xiong[1], Wang Yang[1], Zhou Yang[1], Wu Tong[1], Ji Xiaomin[2], Zhang Xuejie[1], Chen Dandan[1], Jian Wei[3], Jiang Yuyong[1], Yixin Hou[1]. [1]*Beijing Ditan Hospital, Capital Medical University, Beijing, China;* [2]*Beijing Ditan Hospital, Capital Medical Universit, Beijing, China;* [3]*Beijing Friendship Hospital, Capital Medical University Beijing, Beijing, China*
Email: m18239211525@163.com

Background and aims: Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide, with over 70% of patients diagnosed at intermediate or advanced stages where curative treatments are no longer feasible. Current prognostic tools are inadequate to capture the heterogeneity of outcomes in this population, underscoring the critical need for integrated predictive models that incorporate multimodal data.
Method: Plasma samples were collected from 242 patients with advanced HCC (BCLC B–D) who received first-line systemic therapy at two medical centers, between January 2020 and December 2023. Plasma proteomic profiling was performed using the DB4000 Deep Blood DIA Proteome platform with data-independent acquisition and Astral mass spectrometry. Proteomic differences between survivors and non-survivors were assessed via principal component and differential abundance analyses. Candidate biomarkers were validated by ELISA, after which their cellular origins and prognostic relevance were explored using single-cell RNA sequencing of HCC tissues.
Results: Among 242 HBV-HCC patients with 1-year follow-up, 90 (37.2%) died. Using mRMR and LASSO regression, we identified 15 proteins associated with 1-year survival. Multivariate logistic regression further refined a model incorporating four proteins (EGFLAM, HTRA3, ADGRG2, AGXT) and two clinical variables (K+, GGT). The model demonstrated strong predictive performance (AUC: 0.939, accuracy: 0.841, $p < 0.05$) and good clinical utility for decision curve analysis. All biomarkers except AGXT were significantly upregulated in deceased patients (FDR-adjusted $p < 0.05$), and ELISA confirmed these trends. The model effectively stratified mortality risk across treatment subgroups (conservative vs. ICI-based). Single-cell transcriptomics revealed predominant expression of these proteins within the tumor microenvironment.
Conclusion: This study comprehensively analyzed the plasma proteomic landscape of HCC, providing a promising blood-based tool for precision immunotherapy and predicting the risk of death in patients with advanced HCC.

Email: ken.liu@health.nsw.gov.au

Background and aims: Patients with chronic liver disease and cirrhosis at risk of hepatocellular carcinoma (HCC) are living longer. Current guidelines provide no unified recommendations on when to stop HCC surveillance. We explored clinician practices and attitudes towards stopping HCC surveillance.
Method: A 27-item web-based survey was administered between August and October 2025 and distributed via gastroenterology and hepatology society mailing lists and professional networks through study group contacts. Responses were analysed using chi-squared tests with adjustment for multiple comparisons.
Results: 504 clinicians from 23 countries across 6 continents completed the survey. Most respondents were male (63%), gastroenterology/hepatology consultants (69%), working in metropolitan public hospitals (70%), and performed HCC surveillance using transabdominal ultrasound with alpha-fetoprotein (80%). Most respondents agreed that stopping HCC surveillance should be considered in older patients or those with limited life expectancy (81%), yet discussions with patients were infrequent (10% never; 34% rarely; 36% sometimes). Only 30% felt that HCC guidelines provide useful recommendations on stopping surveillance. Major barriers included lack of clear guidelines, fear of HCC development after stopping surveillance, and concern about giving patients mixed messages. Key patient factors influencing decisions were performance status, estimated life expectancy, comorbidities and ability to safely undergo HCC treatment (≥80% rated as important or very important). Roughly half of respondents would not stop surveillance based on age alone in patients with cirrhosis (49%) or non-cirrhotic chronic hepatitis B (50%) if functional status was good. The most commonly nominated age to stop surveillance was 81–85 years (21%). Younger clinicians (<50 years and/or <5 years post-training) were more likely to prioritise age and nominate a specific cut-off. Respondents from Asia were more likely to continue surveillance in elderly patients or those with limited life expectancy (29% vs 16% strongly agree, p = 0.002), whereas Western respondents were more likely to offer stopping surveillance (62% vs 26% strongly agree, p = 0.002).
Conclusion: Clinicians recognise the appropriateness of stopping HCC surveillance in selected elderly patients, yet practice remains inconsistent and patient discussions are infrequent. Lack of guidance and fear of adverse consequences highlight a critical evidence gap to inform future guidelines.

Anti-GARP reverts immune suppression and extends overall survival in a MASH-HCC murine model resistant to anti-PDL1 +anti-VEGFA therapy

Júlia Huguet-Pradell[1,2,3], David Camell-Raventos[1,2,3], Elisa Fernández-Martínez[1], Anthony Lozano[1,4,5], Tiago de Castro[1], Marcus Zeitlhoefler[1], Ugne Balaseviciute[1,2,3], Albert Gris-Oliver[2,3], Daniela Sia[1], Roser Pinyol[2,3], Josep M Llovet[1,2,3,6]. *[1]Mount Sinai Liver Cancer Program, Divisions of Liver Diseases, Department of Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA., New York City, United States; [2]Liver Cancer Translational Research Group, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clínic, Catalonia, Spain, Barcelona, Spain; [3]Facultat de Medicina i Ciències de la Salut, Universitat de Barcelona, Catalonia, Spain, Barcelona, Spain; [4]Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, New York., New York City, United States; [5]The Precision Immunology Institute, Icahn School of Medicine at Mount Sinai, New York, New York City, United States; [6]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Catalonia, Spain., New York City, United States*
Email: julia.huguet@mssm.edu

Background and aims: Atezolizumab (aPDL1) + bevacizumab (aVEGFA) (atezo+bev) is a first-line standard-of-care (SOC) treatment for advanced hepatocellular carcinoma (aHCC) with objective responses in ~30% of cases. Clinical benefit is hindered in non-viral HCC, including metabolic dysfunction-associated steatohepatitis (MASH)-related cases, a raising etiology. MASH-HCCs are enriched in TGFß signaling, associated with resistance to atezo+bev. The bioavailability and Treg-related immunosuppressive effect of TGFß1 ligand is controlled by GARP receptor. Hence, we hypothesize that GARP blockade might revert immune suppression and overcome resistance to aPDL1+aVEGF (SOC) in MASH-HCC.
Method: We used an immune-genetic MASH-HCC model combining diet-induced steatohepatitis with *MYC* and *CTNNB1* overexpression (hydrodynamic gene delivery), driving atezo+bev resistance. After tumor onset, animals were treated with SOC+anti-GARP (triple combination), SOC alone or placebo until the end of the study. Spectral cytometry was conducted at day 14 to assess changes in the tumor microenvironment (n = 5/arm). Remaining animals were followed for overall survival (OS) analysis (n = 7/arm). GARP expression was correlated with immune features in three independent cohorts of HCC patients (n = 559).
Results: SOC+anti-GARP significantly extended OS compared to placebo (median of 68 vs 59 days, p = 0.045), as opposed to SOC alone (p = 0.21). From the immune perspective, the triple combination shifted central memory to tumor-resident CD8+ T cells (p = 0.031) accompanied by an increase in total CD8+ (p = 0.003) and CD4 + (p = 0.016) T cells compared to placebo, suggesting a locally active T-cell response. Accordingly, tumors from SOC+anti-GARP-treated mice presented increased effector (p = 0.036) and exhausted CD8+ T cells

($p = 0.007$). Among CD4+ T cells, the triple combination increased antigen-experienced ($p = 0.045$) and showed a trend of the ratio between tissue-resident memory and Tregs ($p = 0.053$) when compared to the rest. None of these changes were observed with SOC alone. In HCC patients, high GARP expression significantly correlated with immune exhaustion (FC vs rest >1.5 in 87% of cases), with an increase of Treg infiltration, highlighting a group of patients that may benefit from this combination.
Conclusion: Our findings highlight GARP as a promising therapeutic target whose blockade restores antitumor immune infiltration and extends survival OS when added to SOC in an immunotherapy-resistant murine model of MASH-HCC.

Using patient-led genetics to identify new therapeutic targets in metastatic cholangiocarcinoma
Paula Olaizola[1], Mollie Wilson[1], Nicholas Younger[1], Kostas Gournopanos[1], Aleksandra Rozyczko[1], Andreea Gradinaru[1], Colm O Rourke[2], Jesper Andersen[2], Luke Boulter[1]. [1]*Institute of Genetics & Cancer, The University of Edinburgh, Edinburgh, United Kingdom;* [2]*Biotech Research and Innovation Centre (BRIC), Department of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*
Email: luke.boulter@ed.ac.uk

Background and aims: Cholangiocarcinoma (CCA) includes a diverse range of biliary malignancies with dismal prognosis. Tumors are often diagnosed when patients present locally-advanced or metastatic disease, limiting the access to potentially curative surgery. The genetic heterogeneity of CCAs has been reported, indicating that the most common gain-of-function mutations in *K-RAS* and *IDH1*, and *FGFR2*-translocations only occur in 16%, 10% and 15% of patients, respectively. These activating mutations exist in a complex genomic landscape where many genes are mutated at low frequencies. The role of these heterogeneously mutated genes in CCA progression is unknown and their potential to modify the effect of more common mutations remains to be studied. Here, we investigate the genetics behind CCA dissemination, describing how cell intrinsic changes impact on cancer cell behavior and shape the tumor microenvironment making it permissive to metastasis.
Method: Analyzing whole genome/exome sequencing data from 277 patients diagnosed with intrahepatic CCA we identified a patient-led list of CCA mutations. We then developed an *in vivo* screen where we expressed gain of function *K-Ras*^{G12D} with a CRISPR/Cas9 gRNA library targeting genes mutated in the patient data. Immunohistochemistry was performed to characterize the primary and metastatic tumors and their microenvironments. Using CRISPR/Cas9-mediated gene silencing, we interrogated whether these low frequency mutations promote epithelial-to-mesenchymal transition, migration and tumor dissemination in human CCA cells.
Results: The *in vivo* screening showed that mutant *K-Ras* in combination with our gRNA library led to tumor development within 8 weeks. Exome sequencing of these tumors identified CRISPR-induced mutations in 53 genes which facilitated mutant *K-Ras*-induced tumor growth. We found a range of chromatin modifiers, including *Ncor1* and *Bap1*, that upon deletion, together with *Tp53* loss and *K-Ras*^{G12D} overexpression, resulted in metastatic CCA. Histological analysis of the primary tumors with metastatic potential revealed phenotypic changes in cancer cells as well as differences in the fibroimmune stroma. Furthermore, deletion of *NCOR1* or *BAP1* in human CCA cell lines increased their migratory and invasive capacities.
Conclusion: Low-frequency mutations in chromatin modifying genes, such as *Ncor1* or *Bap1*, cooperate with common driver mutations to promote tumor progression and dissemination by altering cancer cell properties and modifying the tumor microenvironment.

SIRPA as a novel regulator of T cell apoptosis in hepatocellular carcinoma: implications for immunotherapy
Xue Zhang[1], Liying Ren[1], Shaoping She[1], Hongsong Chen[1], Dongbo Chen[1]. [1]*Peking University Hepatology Institute, Beijing, China*
Email: zxx20010205@163.com

Background and aims: Immune checkpoint inhibitors (ICIs) were effective in only 20% of advanced hepatocellular carcinoma (HCC), suggesting the presence of additional immune evasion mechanisms.
Method: In this study, we employed a CRISPR library to screen key genes associated with T-cell apoptosis and identified differentially expressed genes (DEGs) in tumor-infiltrating lymphocytes (TILs) from HCC patients with high concentrations of interleukin-2 (IL-2). Integration analysis revealed signal regulatory protein alpha (*SIRPA*) as a novel regulator of T cell apoptosis in HCC, distinct from its classical role as a macrophage inhibitory receptor. In addition, the function of SIRPA was verified in vivo and in vitro using Sirp$\alpha^{-/-}$ mice and T cells derived from PBMC.
Results: *In vitro*, *SIRPA* deficiency reduced apoptosis in human and mouse T cells, while its overexpression promoted apoptosis. *In vivo*, the degree of tumor suppression strongly correlated with *Sirp*α deficiency in T cells, with even haploinsufficient *Sirp*α exerting anti-tumor effects. After macrophage depletion, *Sirp*$\alpha^{-/-}$ mice showed significantly increased proportions of functional $CD8^+$ T cells in peripheral blood and tumor tissues, along with elevated granzyme B (GZMB) levels compared to wild-type (WT) mice, confirming that *Sirp*α deficiency in T cells resists apoptosis. Notably, in adoptive immunotherapy, TCR-T cells overexpressing *SIRPA* exhibited significantly reduced killing function, and tumor-bearing mice receiving *Sirp*$\alpha^{-/-}$ $CD3^+$ T cells inhibited tumor growth compared to those receiving T cells from WT. Mechanistically, SIRPA upregulated EGR4 to activate the Bcl-2/Bax pathway, promoting T-cell apoptosis.
Conclusion: Targeting *SIRPA* may suppress HCC progression by inhibiting T-cell apoptosis, offering a novel immunotherapeutic strategy.

ERAL1 blocks RPL12-mediated ribosome-associated quality control to inhibit mitophagy and promote HCC lung metastasis
Li Zhou[1], Manqiu Hu[1], Song He[1], Zhihang Zhou[1]. [1]*The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China*
Email: zhouzhihang@cqmu.edu.cn

Background and aims: Lung metastasis is the primary cause of mortality in hepatocellular carcinoma (HCC). Through *in vivo* CRISPR library screening, we identified the mitochondrial ribosome assembly factor ERAL1 as a key driver of metastasis. Recent studies highlight that cytosolic ribosomes on the mitochondrial surface regulate organelle function via ribosome-associated quality control (RQC). We discovered that ERAL1 interacts with the cytosolic ribosomal protein RPL12 at the outer mitochondrial membrane (OMM). This study aims to elucidate the mechanism by which ERAL1 modulates RPL12—a potential novel organelle autophagy receptor—to inhibit mitophagy and promote HCC lung metastasis.
Method: We utilized genome-wide CRISPR screening in mice to identify metastasis drivers. Clinical relevance was validated using 50 HCC lung metastasis samples and TCGA datasets. Functional roles were assessed via invasion assays and orthotopic lung metastasis models in mice. Mechanistically, we employed Co-IP, GST-pulldown, and immunofluorescence to map ERAL1-RPL12 interactions. Mitophagic flux was quantified using TEM, the mt-Keima reporter system, and LC3/p62 turnover under oligomycin stress. Rescue experiments were performed using ERAL1 mutants and OMM-tethered RPL12 constructs.
Results: ERAL1 is significantly up-regulated in lung metastases and correlates with poor patient prognosis. *In vitro* and *in vivo* assays confirmed that ERAL1 promotes HCC metastasis. While ERAL1 had negligible effects on mitochondrial translation efficiency, it

significantly reduced ROS and oxygen consumption rates (OCR) while stabilizing membrane potential. Notably, ERAL1 inhibited mitophagy, with transcriptomics showing suppressed autophagy pathways. We found that ERAL1 binds RPL12 on the OMM; its import competitively reduces RPL12 colonization on the membrane. This depletion prevents the recruitment of the E3-ligase Parkin and downstream LC3-mediated autophagy. Crucially, artificially tethering RPL12 to the OMM restored mitophagy levels even in ERAL1-overexpressing cells, confirming that the loss of membrane-bound RPL12 drives this suppression.

Conclusion: Our findings reveal a novel mechanism where ERAL1 promotes HCC metastasis by evading RQC-mediated mitophagy. By reducing RPL12 OMM colonization, ERAL1 protects mitochondria from autophagic clearance, effectively distinguishing physiological protein import from pathological channel clogging. Targeting the ERAL1-RPL12 axis offers a potential therapeutic strategy for metastatic HCC.

Single-cell spatial profiling of cellular architecture in human hepatocellular carcinoma

Claudia Arnedo-Pac[1,2,3], Yi Yin[2], Jo Heffer[4], Ania Piskorz[4], Raheleh Rahbari[3], Matthew Hoare[2,5], Sarah Aitken[1,4,6,7]. *[1]MRC Toxicology Unit, University of Cambridge, Cambridge, United Kingdom; [2]Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom; [3]Wellcome Sanger Institute, Hinxton, United Kingdom; [4]Cancer Research UK - Cambridge Institute, University of Cambridge, Cambridge, United Kingdom; [5]Department of Medicine, University of Cambridge, Cambridge, United Kingdom; [6]Center of Molecular and Cellular Oncology, Yale Cancer Center, New Haven, CT, United States; [7]Department of Pathology, Yale University School of Medicine, New Haven, CT, United States*
Email: ca606@cam.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy, affecting more than 900,000 individuals annually and ranking third among cancer-related causes of death worldwide. Despite the growing clinical burden, comprehensive characterisation of the cellular composition of HCC and its tumour microenvironment in large clinical cohorts is relatively sparse. Chronically injured tissues typically exhibit cellular heterogeneity which can contribute to tumour progression, immune evasion, and therapeutic resistance. Here, we sought to generate a high-resolution spatial transcriptomics atlas of HCC across a large, clinically well-annotated cohort.

Method: We analysed liver tissue from 103 patients with solitary HCC undergoing liver transplantation (82% male; mean age 47 ± 16 years), encompassing diverse disease aetiologies including hepatitis C (48.5%), alcohol-related liver disease (22.3%), and metabolic dysfunction-associated steatotic liver disease (9.7%). Formalin-fixed paraffin-embedded samples from tumour edge, tumour core, and paired cirrhotic background liver were assembled into tissue microarrays (TMAs). Spatial transcriptomics experiments were conducted using the 10x Xenium In Situ platform, profiling 477 genes at single cell resolution. Spatially resolved expression data were used to perform cell phenotyping and spatial composition analyses.

Results: We mapped over three million cells from 312 tissue cores across the cohort, retrieving on average 27,000 cells per donor. For most patients (85%), paired data from both HCC and background cirrhotic liver was available. Preliminary analyses recapitulate the major cellular compartments of HCC and cirrhotic livers, including the tumour parenchyma, stromal cells, and diverse immune populations. Spatial mapping of these cell populations identifies distinct cellular neighbourhoods and patterns of co-localisation suggestive of cell-cell interactions.

Conclusion: We present a novel large-scale spatial transcriptomics dataset at single-cell resolution across more than 100 HCC patients. This will allow deep interrogation of the tumour-microenvironment crosstalk underlying HCC pathogenesis, progression, and prognosis. Furthermore, this dataset represents a valuable resource to the hepatology and cancer biology communities.

Email: emilia.schlaak@uniklinik-freiburg.de

Background and aims: Response to immune checkpoint inhibition (ICI) in hepatocellular carcinoma (HCC) depends on the functional state of intratumoral $CD8^+$ T cells. Progenitor exhausted T cells (Tpex) sustain immune reinvigoration, whereas terminally exhausted T cells (Tex) are largely refractory to checkpoint blockade. Whether a spatial immune architecture captures these functional exhaustion states and predicts pathological response to neoadjuvant ICI in early-stage HCC remains unclear.

Method: Paired baseline biopsies and post-treatment resection specimens from the PRIME-HCC trial (NCT03682276), evaluating neoadjuvant nivolumab plus ipilimumab in resectable BCLC A HCC, were analysed (n = 27). Tumors were assigned to immune-enriched, immune-compartmentalised, or immune-depleted immunotypes based on $CD8^+$ T cell density and spatial distribution. Imaging mass cytometry enabled spatially resolved single-cell profiling of $CD8^+$ T cell exhaustion states, including Tpex ($PD\text{-}1^+TCF\text{-}1^+$) and Tex ($PD\text{-}1^+TOX^+$). Radiological response was available in n = 25 patients and pathological response in n = 20 patients.

Results: Immune-enriched tumours demonstrated markedly superior pathological responses, with frequent pathological complete response, compared with immune-compartmentalised and immune-depleted tumours. Patients with a radiological response showed significantly higher intratumoural CD8 T cell counts following therapy. Mechanistically, immune-enriched tumours were characterised at baseline by intratumoural enrichment of progenitor exhausted CD8 T cells, whereas non-responding tumours were predominantly enriched in terminally exhausted CD8 T cells. Following neoadjuvant immune checkpoint inhibition, responders exhibited an expansion of proliferating PD-1+ CD8 T cells within the

tumour microenvironment, whereas non-responding tumours failed to show effective immune reinvigoration.
Conclusion: A simplified immune classification reflects the spatial availability of progenitor exhausted CD8$^+$ T cells and serves as a surrogate of the Tex/Tpex balance in HCC. This immune architecture determines the capacity for immune reinvigoration and pathological response to neoadjuvant ICI. Immune classification-guided patient stratification may therefore enable the selection of neoadjuvant immunotherapy strategies in early-stage HCC but remains to be validated in prospective studies.

TP53/ARID1A-driven macrotrabecular and TERT/BAP1-enriched microtrabecular tumors represent two distinct histomorphological subtypes of non-cirrhotic hepatocellular carcinoma

Khushboo Agrawal[1], Archana Rastogi[1], Pramod Gautam[1], Viniyendra Pamecha[1], Vanya Garg[1], Nirupma Trehanpati[1], Shiv Kumar Sarin[1], Gayatri Ramakrishna[1]. [1]*Institute of Liver And Biliary Sciences, New Delhi, India*
Email: rgayatri@ilbs.in

Background and aims: Non-cirrhotic hepatocellular carcinoma (NC-HCC) represents ~20% of HCC and is increasingly associated with MASLD and chronic HBV. Integrated links between tumor architecture, immune features, and genomic drivers remain limited. Aim to identify architectural histotypes and correlate them with underlying genetic/molecular landscape.
Method: Resected NC-HCCs (N = 53) underwent integrated histologic, immunohistochemical (IHC), and genomic analysis. Architectural patterns were correlated with p53, β-catenin, EpCAM, CK19, MSI status, CD8$^+$ T-cell infiltration, and immune checkpoints. Targeted NGS (40-gene panel) was performed in 33 tumors, with *TERT* promoter mutation validation by digital droplet PCR (ddPCR).
Results: Microtrabecular (MiT) architecture was most prevalent (56.6%), followed by macrotrabecular (MaT;20.8%), compact (CP;15%), and pseudoglandular (PSGL; 7.5%). NASH was predominant etiology (49%), followed by HBV (26.4%) and cryptogenic (22.6%). MiT and CP patterns enriched in NASH associated tumors. MaT tumors were more frequent in HBV and associated with higher AFP levels (P = 0.028). CP tumors showed a notable female predominance. On IHC, MaT tumors demonstrated nuclear p53, universal EpCAM+ (P = 0.027), higher CTLA-4 expression, and MSI stability (P = 0.021). In contrast, MiT tumors showed molecular heterogeneity with lower expression of nuclear p53 and EpCAM expression, increased CD8$^+$ T-cell infiltration, and MSI instability (30%) of cases. CP and PSGL tumors were largely immune-excluded. PSGL tumors exhibited nuclear β-catenin, membranous CK19 and PD-1 enrichment. Frequent somatic alterations involved *TP53* and *RB1* (55% each), followed by *TERT* (42%), *BAP1* (27%), and *ARID1A* (18%). *RB1* mutations constituted a common molecular variant across all four histotypes. MaT tumors were enriched for *TP53* mutations (88%) with *ARID1A* co-alterations (P = 0.04). MiT tumors harbored recurrent *TERT* C228T promoter mutations (38%), often with *BAP1* alterations, and were mutually exclusive with *TP53* (P = 0.05). CP tumors showed near-universal *RB1* loss. *TERT* C228T was also validated by dd-PCR in all NGS-positive cases (N = 14), with additional low-abundance detections in 3 NGS-negative tumors.
Conclusion: Integrated profiling identified two major NCHCC clusters: a MaT, *TP53* driven, EpCAM-enriched, immune-cold subtype with high recurrence (78%), and a MiT, *TERT* C228T driven subtype with immune infiltration and long RFS (60%). *TERT* C228T emerges as a promising biomarker for molecular screening via sensitive ddPCR.

Patient-derived liver organoids as a translational platform to validate GPC3-targeted nanoparticles for image-guided liver cancer surgery

Zulihumaer Aizimuaji[1], Shizhong Yang[2], Jinrun Liu[2], Zeyu Zhang[3], Kai Ma[2], Jiahong Dong[2]. [1]*Tsinghua University, Beijing, China;* [2]*Beijing Tsinghua Changgung Hospital, Beijing, China;* [3]*Beihang University, Beijing, China*
Email: zulhumar0102@163.com

Background and aims: Accurate visualization of liver cancer margins remains a major challenge during surgical resection. Glypican-3 (GPC3) is a tumor-associated antigen highly expressed in hepatocellular carcinoma (HCC) and certain metastatic liver cancers but absent in normal hepatocytes. This study established a patient-derived liver organoid platform to validate the tumor selectivity of a GPC3-targeted nanoparticle (TJ12-NP) and to bridge its application to image-guided liver cancer surgery.
Method: TJ12-NP was synthesized and labeled with Cy5 or indocyanine green (ICG) for different experimental settings. Cy5-labeled TJ12-NP was used to evaluate tumor-specific uptake in patient-derived organoids representing normal liver, HCC, and colorectal liver metastasis (CRLM). Organoid identities were confirmed by marker profiling through immunostaining. Confocal microscopy was applied to visualize nanoparticle localization, and live–dead assays assessed cytocompatibility. ICG-labeled TJ12-NP was further tested *in vivo* in Huh-7-bearing nude mice for fluorescence imaging and fluorescence-guided tumor resection.
Results: Cy5-TJ12-NP exhibited strong and specific accumulation in GPC3-positive HCC organoids and comparable uptake in CRLM organoids, whereas minimal signal was observed in normal liver organoids, confirming tumor-selective targeting. The nanoparticles were well tolerated by organoid. In vivo, ICG-TJ12-NP enabled high-contrast tumor visualization, achieving a markedly higher tumor-to-background ratio compared with untargeted controls and facilitating complete fluorescence-guided resection.
Conclusion: This study establishes patient-derived liver organoids as a robust translational platform for validating molecularly targeted nanoparticles. The integration of organoid-based specificity testing with preclinical imaging demonstrates a clinically relevant pathway toward precision, image-guided liver cancer surgery.

Email: luca.di_tommaso@hunimed.eu

Background and aims: Hepatocellular carcinoma (HCC) is among most common cancer and the 3rd reason of cancer-related deaths worldwide. Most patients present with advanced HCC (aHCC) but available treatments can achieve an objective response rate of about 30%. Given these therapeutic limitations, new approaches are essential. In this study, we generated HCC derived-PDOs (HCC-PDOs) and used them to identify novel therapeutic agents against HCC.

Method: HCC surgical and biopsy tissues were processed and cultured to generate PDOs. Established PDOs were characterized with hepatocytic and biliocytic markers. Those positive to hepatocytic markers were considered true HCC-PDOs and used for a massive drug screening with 270 compounds. Drug efficacy was established by cell viability assay, and Z-scores were used for ranking. Top ten drugs were further analyzed with various doses. We also tested the same HCC-PDOs with standard 1st and 2nd lines systemic therapy agents for aHCC.
Results: True HCC-PDOs were generated in 4/52 HCC samples (8%). Biopsies yielded a higher success rate 2/9 (22%) than surgical samples 2/43 (5%). In 7/52 (13%) cases, the organoids expressed biliocytic markers. The massive drug screening showed, in all HCC-PDOs, consistent results for nine compounds. Among them, dinaciclib, homoharringtonine, volasertib, mocetinostat, and daunorubicin, have bene already reported as effective on HCC. Three compounds, osimertinib, D1, and D2, are already used for EGFR-mutant lung cancers. Finally, one compound, D3, inhibits replication. Among standard treatments, only sorafenib inhibited HCC-PDOs.
Conclusion: The identification of dinaciclib and homoharringtonine as potent agents aligns with recent literature on novel HCC drugs, and validates the robustness of our approach and the potential of our results. Moreover, our results disclosed a significant potential for some drug repurposing. A recent study showed that cerinitib, a drug targeting ALK mutation in advanced non-small cell lung cancer, inhibits β-catenin mutated HCC via non-canonical WNT pathway independent of ALK (J Hep Reports, 2025). Our data disclosed two compounds, D1 and D2, effective in EGFR-mutant lung cancers, which promise to be effective, off label, also on HCC. In keeping with this, osimertinib, another drug highlighted by the screening on HCC-PDO and currently used for EGFR-mutant lung cancer, has been reported as effective also in HCC (J. Cancer Res. Clin. Oncol., 2023; Plos One, 2023).

Email: giada.allaviligiardi@unifi.it

Background and aims: hERG1 is a voltage-gated potassium channel normally found in excitable cells, but it is often overexpressed in tumors, where it interacts with β1 integrin and activates cancer-related pathways. Intrahepatic cholangiocarcinoma (iCCA) is an aggressive liver malignancy with limited treatment options. This study aimed to investigate the role of hERG1 and its downstream signaling in iCCA biology.
Method: hERG1 expression was assessed in three iCCA cell lines, and functional studies were performed using siRNA-mediated silencing (sihERG1) and pharmacological inhibition (E4031). Cellular behavior was evaluated through standard assays, and molecular and structural changes were analyzed using qRT-PCR, Western blotting, electron microscopy, and transcriptomics.
Results: hERG1 silencing led to a 75–80% reduction in mRNA and protein expression but did not impact proliferation or viability. In contrast, both genetic silencing and pharmacological inhibition significantly reduced cell motility and impaired angiogenesis, as shown by reduced tube formation in HUVECs exposed to si hERG CCA conditioned media. Gene expression analyses revealed downregulation of epithelial mesenchymal transtion (EMT) and angiogenesis markers. Key oncogenic pathways, including FAK, PI3K, and AKT, were notably suppressed. Ultrastructural analysis showed endoplasmic reticulum swelling and increased vesicular trafficking, indicating cellular stress and altered membrane turnover. Transcriptomic analysis revealed a common profile of gene alteration, mainly in vesicular trafficking, transmembrane ion regulation, and extracellular matrix reorganization, highlithing a broader impact of hERG1 on intracellular dynamics.
Conclusion: hERG1 plays a critical role in supporting motility and angiogenic potential in iCCA cells without affecting proliferation. Its inhibition alters key oncogenic and cellular processes, positioning hERG1 as a promising therapeutic target in iCCA.

Email: allama5@hotmail.fr

Background and aims: Atezolizumab–bevacizumab (AtezoBev) is the standard first-line therapy for unresectable hepatocellular carcinoma (HCC), but predictive biomarkers of response are lacking. We aimed to identify baseline and early immune features associated with treatment outcomes.
Method: We conducted a prospective study of patients receiving first-line AtezoBev, integrating longitudinal immune profiling at baseline and 3 weeks after treatment initiation, including peripheral blood mononuclear cell (PBMC) immunophenotyping (17 markers), serum cytokine profiling (31 proteins), and paired whole-blood RNA sequencing. Tumor RNA-sequencing data from the GO30140 and IMbrave150 trials were analyzed (209 patients treated with AtezoBev and 58 with sorafenib), with external validation in an independent cohort of metastatic MSI-H colorectal cancer (n = 163).
Results: Longitudinal blood samples were available for 31 patients (median age 65 years; 87% male); 29% experienced radiological progression at 6 months. Patients with disease control had higher baseline circulating γδ T-cell levels (2.2% vs. 0.7%, $p = 0.008$), which were associated with longer progression-free survival (PFS; HR 0.71, 95% CI 0.55–0.92; $p = 0.009$), as well as higher baseline IL-18 plasma levels ($p = 0.01$). At the tumor level, a high γδ T-cell transcriptional signature was associated with higher response rates ($p < 0.01$), longer PFS ($p < 0.001$), and longer overall survival (OS; $p = 0.003$) in AtezoBev-treated patients, but not in those receiving sorafenib. This γδ T-cell signature outperformed the AtezoBev Response Score (ABRS) for OS and PFS prediction. Consistently, in an independent

MSI-H colorectal cancer cohort, a high γδ T-cell signature was associated with longer PFS (p = 0.034). During treatment, an early increase in circulating $CD8^+PD\text{-}1^+$ T cells was associated with longer PFS, whereas an increase in $CD8^+TIGIT^+$ T cells predicted shorter PFS. Paired transcriptomic analyses revealed early induction of T cell–associated interferon-γ signaling in responders, with higher circulating IFN-γ levels compared with progressors.
Conclusion: High baseline circulating and intratumoral γδ T-cell levels, together with early $CD8^+PD\text{-}1^+$ T-cell expansion before the second infusion, predict response to AtezoBev, supporting immune profiling as a valuable tool to guide early treatment decisions in HCC.

WED-237-YI
Spatially resolved multi-omic analysis reveals metabolic niche-dependent regulatory T cell programs in hepatocellular carcinoma
Leonard Bellersheim[1], Mehreen Khan Bhettani[1], Maegen Fleming[1], Elisavet Kodela[1], Alexander Morrell[1], Virag Sagi-Kiss[2], Anthony Baptista[1], Mzamo Mbelle[1], Roberto Savoldelli[1], Diana Marin-Correa[1], Thomas Dowe[1], Marwo Habarwaa[1], Zoltan Takats[2], Yoh Zen[1], Alberto Sanchez-Fueyo[1], Cheng Zhang[1], Niloufar Safinia[1]. *[1]King's College London, London, United Kingdom; [2]Imperial College London, London, United Kingdom*
Email: Leonard.bellersheim@kcl.ac.uk

Background and aims: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related death worldwide. Regulatory T cells (Tregs) infiltrate HCC and inversely correlate with patient survival, yet mechanisms enabling Treg adaptation in the tumor microenvironment (TME) remain unclear. We previously demonstrated that intratumoral Tregs exhibit marked transcriptional and metabolic reprogramming compared to their circulating or non-tumoral counterparts, which display metabolic quiescence and susceptibility to apoptosis. We hypothesise that Treg heterogeneity is spatially resolved, reflecting distinct metabolic niches within the TME, and that targeting Treg adaptation or disrupting these niches could restore anti-tumor immunity.
Method: We generated a spatial-omics multimodal dataset comprising 8 MASLD-associated, treatment-naïve HCC cases, integrating spatial transcriptomics (Xenium), spatial protein profiling (Akoya), spatial metabolomics (LA-REIMS), spatial metallomics (LA-ICP-MS), and H&E histopathology. Data were analysed using a customised bioinformatic pipeline and supplemented with public and proprietary scRNA-seq datasets. Building on prior clinical observations, we established a cohort of 150 HCC specimens obtained through surgical resection at King's College Hospital. Immunohistochemical (IHC) staining for FOXP3 and CD3 was conducted, with subsequent semi-automated quantitative analysis and integration with clinicopathological metadata.
Results: Spatial multi-omic integration of 8 specimens generated a unified dataset combining single-cell transcriptomic and protein profiles with niche-level metallo-metabolic features. This enabled comprehensive characterization of the HCC TME, revealing major cell populations and transcriptional heterogeneity within the Treg compartment. Analysis identified conserved spatial niches with increased tumoral metallo-metabolic heterogeneity. Tregs exhibited niche-specific intratumoral enrichment and differential gene expression, validated in two independent scRNA-seq datasets. IHC staining confirmed elevated Treg numbers in tumoral versus non-tumoral tissue, with highest densities in inflamed tumors.
Conclusion: Our findings demonstrate that Tregs infiltrate distinct spatial niches within the HCC TME, exhibiting niche-specific transcriptional programs and gene signatures. Therapeutic strategies targeting Treg adaptation or metabolic niche remodelling may represent novel approaches to alleviate immunosuppression and enhance anti-tumour immunity in HCC.

WED-238
Neuroimmune regulation of macrophages in steatotic liver disease-related hepatocellular carcinoma
Liyana Binte Abdullah[1], Otsuka Masayuki[1], Jannah Mohamed Nasir Nurul[1], Marie Reolo[1], Jiawei Wu[1], Wei Qiang Leow[2], Ziyao Chen[3], Mathias Heikenwälder[3], David Tai[4], Valerie Chew[1]. *[1]Translational Immunology Institute (TII), SingHealth-DukeNUS Academic Medical Centre, Singapore, Singapore; [2]Department of Anatomical Pathology, Singapore General Hospital, Singapore, Singapore, Singapore; [3]Division of Chronic Inflammation and Cancer, German Cancer Research Centre, Heidelberg, Germany, Heidelberg, Germany; [4]Division of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore, Singapore*
Email: liyana@u.duke.nus.edu

Background and aims: Steatotic liver disease-related hepatocellular carcinoma (SLD-HCC) is an emerging metabolic subtype marked by poor response to immunotherapy. While immunosuppression in SLD-HCC is increasingly recognised, the contribution of neural regulation – particularly its influence on macrophages – remains unclear. This study examines how peripheral neuroimmune circuits shape macrophage-driven immune activity in SLD-HCC.
Method: We integrated single-cell transcriptomics from two hepatocellular carcinoma patient cohorts (n = 34) with cytometry by time-of-flight (CyTOF) and spatial transcriptomics from an additional cohort (n = 12) to characterise the SLD-HCC tumour microenvironment. Key findings were validated using in vitro macrophage models, multiplex immunohistochemistry in an independent cohort of 104 patients, and an immunotherapy-treated cohort to assess clinical relevance. Ongoing in vivo studies aim to further define neuroimmune regulation in SLD-HCC.
Results: We uncovered a neuroimmune mechanism centred on crosstalk between lipid-associated macrophages (LAMs) and vagal signalling that contributes to impaired immunotherapy response in SLD-HCC. CyTOF revealed macrophage enrichment in SLD-HCC, while two independent single-cell RNA sequencing datasets revealed LAMs as a neuron-responsive subset expanded within the steatotic tumour microenvironment. Spatial transcriptomics and multiplex immunohistochemistry localised LAMs near vagal fibres, supporting a structural basis for this interaction. Mechanistically, the vagus nerve modulates macrophages through the cholinergic anti-inflammatory pathway (CAP). CAP activation or inhibition altered LAM immunoregulatory states in vitro, linking impaired neuroimmune regulation to immunosuppressive LAM function in SLD-HCC.
Conclusion: Vagal-macrophage crosstalk is a key neuroimmune mechanism driving immunosuppression in SLD-HCC. LAMs emerge as a neuron-responsive population regulated through CAP, and reduced vagal activity in MASH limits LAM activation, contributing to chronic inflammation and tumour progression. The vagus-LAM axis represents a potential therapeutic target to improve antitumour immunity in SLD-HCC.

Genomic and epigenomic profiling of hepatocellular carcinoma in liquid biopsy
Lauren Brotherton[1,2], Ning Wang[1], Maxwell Bladen[1], Jerick Guinto[1], Dineika Chandrananda[1], Sarah Ftouni[1], Alexander Thompson[2], Jessica Howell[2], Sarah-Jane Dawson[1]. *[1]Peter MacCallum Cancer Centre, Melbourne, Australia; [2]St Vincents Hospital, Melbourne, Australia*
Email: lauren.andersson@svha.org.au

Background and aims: The non-invasive diagnosis of hepatocellular carcinoma (HCC) through radiology is limited by variable sensitivity for small lesions, cost, accessibility and the lack of tumour tissue acquisition for molecular analysis. There is an urgent and unmet need to develop highly sensitive and specific biomarkers for the diagnosis and management of HCC. Analysis of circulating tumour DNA (ctDNA) through 'liquid biopsy' provides an opportunity for non-invasive assessment of tumour dynamics in real time. Harnessing a multiomic

approach combining genomic, epigenomic and non-genomic features of ctDNA has potential to improve the sensitivity and specificity of ctDNA detection. The ease of clinical translatability in part depends on simplified analytical workflows. In this study, we aimed to evaluate a novel single workflow for multiomic ctDNA profiling in HCC.

Method: Plasma for ctDNA analysis was collected from patients with HCC, chronic liver disease (CLD) and healthy controls at baseline and longitudinal time points. Application of a novel six-letter library preparation '*Duet evoC*' (Biomodal) enabled the analysis of genomic and epigenomic (5-methylcytosine and 5-hydroxymethylcytosine) features to single base pair resolution. Whole genome sequencing was performed to a targeted depth of 30X coverage. Non-parametric analysis was performed for each feature including copy number, fragment length and alpha and beta based approach to methylation analysis.

Results: A total of 233 patients were recruited including 102 HCC (all disease stages), 81 CLD and 50 healthy controls. A step wise increase in genomic instability across disease stages was identified in HCC compared to CLD and healthy patients ($p < 0.001$). HCC samples were also enriched for shorter ctDNA fragment size compared to CLD and healthy individuals ($p < 0.01$). Differentially methylated regions of 5mC and 5hmC enabled sensitive detection of ctDNA in HCC cases ($p < 0.01$). Differential methylation was identified across genes implicated in HCC pathogenesis such as tumour suppressor gene *CDKN2*A.

Conclusion: Analysis of ctDNA using a novel library preparation and sequencing platform enables multiomic feature detection to distinguish HCC from CLD and healthy controls.

Mechanical cues from fibrotic liver matrix rewire mitochondrial dynamics in hepatocellular carcinoma

Alicia Calé[1,2], Petra Elblová[1,2], Hana Andělová[1], Laura Moran[3], Adriana De Bonis[3], Alejandro Hionides[3], Yulia Nevzorova[3], Jan Kubovciak[4], Milan Jirsa[5], Martin Kveton[5], Mariia Lunova[5], Francisco Javier Cubero[3], Oleg Lunov[1]. *[1]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic; [2]Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic; [3]Universidad Complutense De Madrid, Madrid, Spain; [4]Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic; [5]Institute for Clinical & Experimental Medicine, Prague, Czech Republic*
Email: lunov@fzu.cz

Background and aims: Hepatocellular carcinoma (HCC) arises in a fibrotic and mechanically heterogeneous extracellular matrix, but the transition from mechanical properties of the extracellular matrix to metabolic and therapeutic responses in tumor cells remains unclear. Mitochondria have been recognized as mechannosensitive organelles. The role of KEAP1 as a redox sensor may link these two signals. We sought to evaluate a role for extracellular matrix mechanical properties controlling mitochondrial dynamism, redox state, and drug resistance in HCC via KEAP1.

Method: Human HCC cells were plated on collagen-coated elastic substrates mimicking physiological and fibrotic liver stiffness. Mitochondrial morphology and dysfunction, as well as KEAP1-Nrf2 pathway activation, were analyzed with high resolution imaging and biochemical assays. The extent of RNA transcriptional repurposing was determined with bulk RNA-sequencing assays. These effects were validated with migration assays, cell proliferative assays, and chemotherapy sensitivity assays. The relevance of these findings was confirmed with quantitative biochemical assays and multiplex immunohistofluorescence staining with mouse and human tissues.

Results: Higher matrix stiffness caused rapid mechanotrophic migration and higher proliferation rates of HCC cells. KEAP1 expression followed a biphasic, time-dependent response to stiffness and controlled mitochondrial remodeling via a KEAP1/BCL-2/DRP1 pathway. Stiffer matrices increased mitochondrial fusion, decreased reactive oxygen species, and transcriptionally activated antioxidant and glycolytic pathways and caused nuclear translocation of nuclear factor erythroid 2–related factor 2. RNA sequencing analysis showed reduced expression of genes involved in mitochondrial division and enriched pathways for glycolysis, including AGE–RAGE signaling. Functionally, cells cultured on stiffer matrices contained higher cisplatin and sorafenib-resistant cells. Moreover, collagen-positive areas within HCC tissues co-localized with increased KEAP1 and mitochondrial protein expression.

Conclusion: The extracellular matrix stiffness functions as a bioactive modulator for the organization, redox state, and drug resistance of mitochondria in HCC. The findings of these studies demonstrate that KEAP1 functions as a mechanosensitive sensor and integrator of tumor adaptation. The extracellular matrix stiffness emerges as an essential and targetable component within the tumor microenvironment.

Email: gcanos@recerca.clinic.cat

Background and aims: Atezolizumab and bevacizumab combination (atezo+bev) is a first-line treatment for advanced hepatocellular carcinoma (aHCC). Cancer-associated fibroblasts (CAFs) promote tumor survival through immunosuppression; however, their heterogeneity and clinical relevance in HCC remain unclear. Our aim was to characterize CAF subtypes in HCC and assess their association with response to atezo+bev.

Method: Seven single-cell RNA sequencing (scRNA-seq) datasets encompassing 197 HCCs (422,561 cells) were integrated to generate an HCC-based atlas to define CAF transcriptional state. CAF-specific single-cell gene signatures were generated and used to deconvolute CAF composition in early and aHCC ($n = 918$) using BayesPrism. Associations with established molecular and immune HCC classifications were assessed. Differential gene expression analysis and LASSO regression were applied to bulk RNA-seq data from 386 atezo+bev-treated HCCs to derive a CAF-based non-response signature (AB-CAF). Predictive performance was benchmarked against published immunotherapy response signatures and externally tested in the

IMbrave150 trial cohort. Associations with clinical outcomes were evaluated.
Results: Single-cell data integration showed that CAF accounted for 5% of early stage and 15% of aHCC cellular compartments ($p < 0.001$). Five transcriptionally distinct CAF were identified. The iMyo/*POSTN* subtype was predominant across stages, accounting for 63% of CAF in early HCC and 90% in aHCC ($p < 0.001$). AB-CAF signature was associated with response (AUC 0.77; CI 0.71–0.83) and treatment-dependent survival (AB-CAF+ Median OS (mOS) 17.4 months vs AB-CAF- mOS NA; $p < 0.002$) as opposed to sorafenib-treated patients (AB-CAF+ mOS 13.4 months vs AB-CAF- mOS 7.5 months; $p = 0.103$); p of interaction = 0.002. In multivariate models, including previously reported atezo+bev response signatures, AB-CAF remained independently predictive of non-response (OR 4.26, 95% CI 2.45–7.58; $p < 0.001$). Mechanistically, AB-CAF+ tumors were significantly enriched in the Immune Excluded, Non-Proliferation/*CTNNB1* subclass, whereas AB-CAF- tumors exhibited an Immune Active Progenitor/Proliferation profile (both $p < 0.001$).
Conclusion: A scRNA-seq HCC atlas revealed that CAFs constitute a major cellular component of HCC and comprise five subtypes, with iMyo/*POSTN* CAFs predominating across disease stages. AB-CAF gene signature was independently associated with non-response to atezo+bev, highlighting the tumor stroma as a key determinant of immunotherapy outcomes.

WED-243
Hepatic iron metabolism dysregulation promotes metabolic dysfunction-associated steatohepatitis induced hepatocellular carcinoma in preclinical models
Sahiba Chahal[1,2], Vikram Patial[1,2]. [1]*Pharmacology and Toxicology Laboratory, Dietetics & Nutrition Technology, CSIR-Institute of Himalayan Bioresource Technology, Palampur, India;* [2]*Academy of Scientific and Innovative Research (AcSIR), Ghaziabad, India*
Email: sahibachahal.me@gmail.com

Background and aims: Dysregulated hepatic iron metabolism has been associated with metabolic dysfunction-associated steatohepatitis (MASH) induced hepatocellular carcinoma (HCC). This study aims to assess the effect of MASH on hepatic iron metabolism and its role in the progression of HCC in preclinical models of MASH-induced HCC.
Method: MASH-HCC was induced by incorporating high fat-high carbohydrate (HF-HC) diet in addition to weekly CCl4 (i.p.) in C57BL/6 mice. The study comprised of four groups to evaluate the effect of HF/HC on hepatic iron metabolism. The naïve group was fed with standard chow diet. Sixteen weeks into the study, two of the groups were either supplemented with ferric ammonium citrate (FAC) as source of iron or given deferoxamine mesylate salt (DFX-MS) as iron chelator in addition to HF/HC. Similar conditions were mimicked *in-vitro* wherein human hepatic cell line was treated with free fatty acids, pro-inflammatory cytokine TNF-alpha, FAC, and DFX-MS to check the role of iron metabolism on HCC.
Results: High calorie intake significantly elevated body weight and liver weight, as compared to control group. Similar trend was observed in FAC group; however, a reduction in body weight and liver weight was observed in DFX groups. The liver injury markers and triglyceride level showed similar trends in the FAC and disease group as compared to the DFX and naïve group. The gross anatomical analysis of liver showed the multiple nodules of varying sizes in disease and FAC group. Histopathology of liver revealed multiple nodules scattered throughout the tissue, steatosis, inflammation, vacuolated cells, and trabecular patterns in the disease and FAC groups. Prussian blue staining showed hepatic iron accumulation across groups as compared to naïve group and Masson's Trichrome staining showed the extent of fibrosis. DFX group showed the reduced lesion severity, fibrosis and iron overload. In addition, iron regulatory gene also showed the preventive effect of DFX on hepatic iron overload and HCC progression. These results were further confirmed on the human hepatic cell line by analysing the expression of iron-related genes, lipid accumulation and inflammation.
Conclusion: MASH development disrupts iron homeostasis, leading to iron overload in the liver. Interventions that counteract hepatic iron accumulation may offer a promising therapeutic approach to prevent progression to HCC.

WED-244-YI
Generation and characterization of a murine BRAF V600E driven cholangiocarcinoma model
Shreya Chakraborty[1], Denise Schlösser[1], Hakan Tomac[1], Lisa Wende[1], Silke Marhenke[1], Tilman Brummer[2,3], Arndt Vogel[1,4,5], Anna Saborowski[1]. [1]*Medizinische Hochschule Hannover, Hannover, Germany;* [2]*University Of Freiburg, Freiburg im Breisgau, Germany;* [3]*Insitute of Molecular Medicine and Cell Research, Brummer, Freiburg, Germany;* [4]*Toronto General Hospital, Toronto, Canada;* [5]*Princess Margaret Cancer Centre, Toronto, Canada*
Email: chakraborty.shreya@mh-hannover.de

Background and aims: Cholangiocarcinoma (CCA) is an aggressive biliary cancer with limited treatment options. The $BRAF^{V600E}$ mutation is a targetable driver in a subset of CCA patients, yet responses to BRAF targeted therapies are often transient due to rapid resistance. The molecular mechanisms driving adaptive resistance and the emergence of drug-tolerant persister cells remain elusive. This study aims to elucidate signaling adaptations following MAPK pathway inhibition in $BRAF^{V600E}$ mutant CCA.
Method: Murine liver organoids carrying $BRAF^{V600E}$ mutation and *Trp53* deletion were transplanted subcutaneously into immunocompetent mice. Tumors were used to derive two cell lines, designated as OBPI and OBPII. Cells were treated with BRAF inhibitors (Dabrafenib, Encorafenib), MEK inhibitor (Trametinib), and EGFR/HER2 inhibitors (Gefitinib, Neratinib), alone or in combination. Cell proliferation and ERK phosphorylation were assessed and phospho-RTK arrays were performed. OBPII cells were also evaluated *in vivo* under Dabrafenib, Trametinib, or combination treatment.
Results: Both cell lines exhibited high IC_{50} values for BRAF inhibitors, exceeding clinically relevant concentrations, with only moderate effects on proliferation and rapid feedback activation within 24 hours: ERK phosphorylation was initially suppressed but rebounded within 6 hours of treatment. pRTK analysis revealed basal EGFR and HER2 activation, with HER2 phosphorylation re-emerging after transient suppression by BRAF inhibition. Subsequent inhibition of EGFR2 and EGFR/HER2 fully abrogated ERK reactivation. In contrast, both cell lines were highly sensitive to Trametinib, showing sustained ERK suppression. Prolonged MEK inhibition induced a reversible, non-proliferative state, with cells resuming proliferation upon drug withdrawal. *In vivo*, Dabrafenib had minimal effect on tumor growth, whereas Trametinib significantly inhibited progression.
Conclusion: Our data suggest that $BRAF^{V600E}Trp53^{-/-}$ CCA cells rapidly adapt to BRAF inhibition through EGFR/HER2-driven feedback reactivation of ERK signaling, leading to intrinsic resistance. In contrast, MEK inhibition enforces durable MAPK suppression but induces a reversible persister cell state characterized by cellular quiescence rather than cell death. These findings identify adaptive RTK signaling and cellular persistence as critical barriers to MAPK-targeted therapy in CCA, underscoring the need for rational combination strategies to overcome resistance and prevent disease relapse.

WED-245

Differential NK cell residency and immunosuppressive ILC remodeling define subtype-specific tumor-microenvironments in cholangiocarcinoma

Sachin Chauhan[1], Livia Schmidt[1], Tijana Ristic[1], Suparna Dey[1], Anna Riddermann[2], Nora Nevermann[2], Heiner Wedemeyer[1], Linda Feldbruegge[2], Moritz Schmelzle[2], Bernd Heinrich[1].
[1]*Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany;*
[2]*Department of General, Visceral and Transplant Surgery, Hannover Medical School, Hannover, Germany*
Email: heinrich.bernd@mh-hannover.de

Background and aims: Cholangiocarcinoma (CCA) is a highly lethal malignancy with limited therapeutic options and modest responses to immunotherapy. Despite pronounced biological heterogeneity between intrahepatic (iCCA) and perihilar CCA (pCCA), current treatment strategies remain uniform. Innate lymphoid cells (ILCs), including natural killer (NK) cells, are key regulators of tissue immunity, yet their role in shaping subtype-specific tumor microenvironments (TME) in CCA remains poorly defined. We aimed to characterize the composition and functional states of ILCs across anatomical subtypes of CCA.
Method: Tumor and matched non-tumor tissue were obtained from 11 CCA patients (7 iCCA, 4 pCCA). Median age of the cohort was 72.5 years. None of the patients had a diagnosis of ulcerative colitis or primary sclerosing cholangitis. Mononuclear cells were isolated and analyzed using high-parameter spectral flow cytometry with a 31-marker ILC-focused panel. Multi-dimensional analyses were performed using FlowJo v10.10.
Results: CCA tumor tissue displayed a consistent shift in ILC composition characterized by expansion of mature cKIT$^-$ ILC2s and a significant reduction of ILC3s compared with non-tumor tissue, independent of subtype. Depletion of CCR6$^+$ ILC3s was most pronounced in iCCA tumors, whereas pCCA showed uniformly low CCR6$^+$ ILC3 frequencies. NK cell analysis revealed reduced circulating NK cells (cNK) and a relative enrichment of tissue-resident NK cells (trNK) within tumors, accompanied by increased expression of CXCR6, CD49a, and the inhibitory receptor NKG2A. This tumor-associated cNK-to-trNK shift was most evident in iCCA, while pCCA exhibited elevated baseline frequencies of trNKs. Functionally, activated KLRG1$^+$CD25$^+$ ILC2s were selectively enriched in pCCA tissue, whereas early-activated CD25$^+$ trNKs increased in tumor tissue across subtypes.
Conclusion: CCA is characterized by pronounced, subtype-specific remodeling of the innate immune landscape, including loss of protective ILC3s and accumulation of immunosuppressive ILC2s and dysfunctional tissue-resident NK cells. Divergent NK cell differentiation states in iCCA and pCCA suggest distinct immunological constraints and therapeutic vulnerabilities. These findings highlight the importance of subtype-resolved innate immune profiling to inform tailored immunotherapeutic strategies in cholangiocarcinoma.

WED-246

Malignant ascites as a liquid biopsy for dominant neoantigen discovery in advanced liver cancer

Dongbo Chen[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, Beijing, China*
Email: chendongbo338@163.com

Background and aims: Neoantigen-based immunotherapy represents a promising strategy for liver cancer, yet its clinical application is limited by the frequent unavailability of tumor tissue in advanced-stage patients. Malignant ascites, often enriched with tumor cells, provides a potential liquid biopsy source for neoantigen discovery. This study aimed to identify dominant neoantigens in malignant ascites from patients with advanced liver cancer and to evaluate their potential as targets for personalized immunotherapy.
Method: Ascites samples were collected from patients with cirrhosis and advanced liver cancer. Tumor cells were isolated by flow cytometry as 7-AAD$^-$ CD45$^-$ CD326$^+$ (P7) cells. For low-input samples (<2000 cells), RNA and DNA were amplified using Smart-seq2 and whole-genome amplification. Whole-exome and RNA sequencing were performed to identify somatic mutations. Candidate neoantigens were predicted using VEP and NetMHCpan-4.1, accounting for HLA loss of heterozygosity. Neoantigen-specific T-cell responses were assessed by tetramer staining, flow cytometry, ELISPOT, and ELISA.
Results: We established a robust workflow enabling sequencing of rare tumor cells from malignant ascites. Advanced liver cancer patients exhibited significantly higher numbers of P7 tumor cells in ascites compared with peripheral blood and cirrhotic controls. Single-cell analysis demonstrated partial overlap between mutations in ascites-derived tumor cells and matched primary or metastatic lesions. Predominant C > T/G > A substitutions were observed, corresponding to COSMIC signatures 1, 3, 12, 15, and 30. Multiple candidate neoantigens were identified, including those derived from TOP3A, TUBB6, NUTM2G, SND1, FGD2, NFKBIZ, and CLDND1. Neoantigen-specific T cells were detected in ascites and exhibited high CD39 expression. Notably, an HLA-A*02:01–restricted SND1-derived neoantigen elicited strong T-cell responses, indicating dominant immunogenicity.
Conclusion: Malignant ascites serves as a feasible and informative liquid biopsy for dominant neoantigen identification in advanced liver cancer. This strategy enables personalized neoantigen discovery in patients lacking tumor tissue and supports the development of individualized immunotherapeutic approaches.

WED-247

Multi-ancestry genome-wide association meta-analysis of hepatocellular carcinoma identifies eight novel risk genes including MYC, MAP3K9, DHRS1, and MTTP

Ifechukwuamaka Chinaka[1], Annabelle Schofield[2], Lewis Roberts[3], Christopher Amos[4], Vincent Chen[5], Younghun Han[4], Manal Hassan[6], Shishir Shetty[7], Jake Mann[7,8]. [1]*St James Hospital, Dublin, Ireland;* [2]*University of Birmingham, Birmingham, United Kingdom;* [3]*Mayo Clinic, Rochester, United States;* [4]*University of New Mexico, Albuquerque, United States;* [5]*University of Michigan, Ann Arbor, United States;* [6]*University of Texas, MD Anderson Cancer Centre, Houston, United States;* [7]*Department of Immunology & Immunotherapy, School of Infection, Inflammation and Immunology, College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom;* [8]*Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom*
Email: ifechinaka@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is the 3rd top cause of cancer death globally. It typically arises on a background of cirrhosis, which can be caused by any aetiology of liver disease. HCC may also develop in non-cirrhotic individuals, particularly in chronic hepatitis B virus (HBV) infection and in metabolic dysfunction-associated steatotic liver disease (MASLD). Identification of genetic risk factors is critical to mitigate rapidly growing burden of HCC. Here, we aimed to establish novel genetic drivers of HCC across ancestries at a population level through a large meta-analysis of all-cause HCC.
Method: Here, we performed a multi-ancestry meta-analysis (MAMA) of HCC GWAS, which included transcriptome-wide and regulome-wide association analyses. In doing so, we identified eight novel loci as putative risk genes for HCC and established a baseline for future studies with inclusion of diverse ancestries. We included 15 cohorts comprising of 17,329 HCC cases and 2,424,298 controls in this meta-analysis.

Results: We found 15 genome-wide significant (P < 5×10–8) germline loci, 6 novel in/near *GCKR*, *MTTP*, *ADH5*, *MYC*, *MAP3K9*, and *GABPB2*. *MAP3K9*, *TERT*, and *GABPB2* variants act independently of cirrhosis on both co-localisation analysis and sensitivity analyses. There was significant ancestral heterogeneity in 6 loci including variants in the HLA locus that had divergent effects on HCC risk between East Asian and European ancestries. Fine-mapping identified 11 potentially causal coding variants, including p.Leu446Pro in GCKR and p.Asp418Glu in MEN1. *MEN1*, *MYC*, and *TERT* are all involved in the beta-catenin pathway transactivation complex. Transcriptome-wide analysis identified enrichment of germline-encoded *DHRS1* in HCC. Regulome-wide analysis replicated the germline signal for *EPHA2* and found a novel chromatin accessible region containing genes *ZNF367* and *HABP4*. Finally, we demonstrated that population-level genetic architecture for HCC overlaps with steatotic and viral liver disease, and individuals with genetic risk for lower BMI have higher risk of HCC.
Conclusion: Genetic risk for HCC is determined by germline susceptibility to beta-catenin pathway activation and cirrhosis. HCC is driven by both heterogenous and homogenous genetic factors across ancestries, which require further ancestral diversity in liver GWAS to fully dissect.

WED-248

Circulating miRNAs as predictive biomarkers of response to immunotherapy in hepatocellular carcinoma (HCC)

Salvatore Corallo[1,2], Barbara Oliviero[1], Alessia La Gaipa[1], Cristian Bassi[3], Massimo Negrini[3], Clara Vianello[4], Daniela Cicognini[1], Stefania Mantovani[1], Francesca Fornari[4]. *[1]Fondazione Irccs Policlinico San Matteo, University of Pavia, Pavia, Italy; [2]University of Pavia, Pavia, Italy; [3]Università degli Studi di Ferrara, Ferrara, Italy; [4]University of Bologna, Bologna, Italy*
Email: s.corallo@smatteo.pv.it

Background and aims: Immunotherapy has changed the treatment of advanced HCC, but early identification of patients who do not respond remains a challenge due to the lack of predictive biomarkers. Circulating microRNAs (miRNAs) have emerged as promising non-invasive biomarkers that reflect tumor biology, disease progression, and treatment response. This study aimed to characterize the serum miRNome in patients with advanced HCC receiving immunotherapy-based systemic treatment [atezolizumab plus bevacizumab (atezo-be) or tremelimumab plus durvalumab (durva-treme)] to identify a molecular signature associated with treatment response.
Method: Serum samples were collected from 10 patients (discovery cohort) with advanced HCC treated with atezo-bev (n = 8) or durva-treme (n = 2) at 3 months (T3) after treatment start. Patients were stratified into responders (R, n = 6) and non-responders (NR, n = 4) based on radiological response, defined as partial or complete response according to RECIST 1.1 criteria. High-throughput miRNome profiling, differential expression, and hierarchical clustering analyses were performed to identify discriminatory signatures. For validation, serum samples were collected at multiple time points [baseline, before the second therapy cycle (T1), and T3] from an independent cohort of 20 HCC patients treated with the same regimens and analyzed by quantitative polymerase chain reaction.
Results: Unsupervised hierarchical clustering of serum miRNA expression profiles and differential expression analysis revealed clear segregation between R and NR, identifying a subset of miRNAs differentially expressed between the two groups at T3. Notably, miR-942-5p was the most statistically significant variable, exhibiting marked upregulation in responders. Other key miRNAs contributing to the discriminatory signature included the oncogenic miR-21-5p, miR-483-5p, and the hepato-specific miR-122-5p. Selected miRNAs were subsequently validated in the independent validation cohort, confirming their differential expression patterns.
Conclusion: Our preliminary analysis suggests a serum miRNA signature at 3 months of therapy that may differentiate responders from non-responders. The observed differential expression pattern highlights miRNAs as candidate markers for monitoring treatment response. These findings provide a basis for further investigating the role of liquid biopsy in guiding personalized therapeutic strategies.

From primary tumor to metastasis: stemness dynamics in intrahepatic cholangiocarcinoma

Margherita Correnti[1], Marco Erreni[2], Marina Sironi[3], Matteo Ramazzotti[4], Monika Lewinska[5], Jesper Andersen[5], Colm O Rourke[5], Cedric Coulouarn[6,7], Fabio Pagni[8], Mario Urso[8], Diego Calvisi[9], Luca Di Tommaso[10], Stefania Recalcati[1], Fabio Marra[11], Chiara Raggi[11]. *[1]University of Milan, Dept. of Biomedical Sciences for Health, Milan, Italy; [2]Humanitas Clinical and Research Center, Dept. of Immunology, Rozzano, Italy; [3]Humanitas Clinical and Research Center, Dept. of Immunopharmacology, Rozzano, Italy; [4]University of Florence, Dept of Experimental and Clinical Biomedical Sciences, Florence, Italy; [5]University of Copenaghen, Biotech Research and Innovation Center, Copenaghen, Denmark; [6]University of Rennes, CHU Rennes, Service de Chirurgie Hépatobiliaire et Digestive, Rennes, France; [7]Inserm, Rennes, France; [8]University of Milano-Bicocca, Dept. of Medicine and Surgery, Pathology, Monza, Italy; [9]University of Regensburg, Institute of Pathology, Regensburg, Germany; [10]Humanitas University, Dept. of Biomedical Sciences, Rozzano, Italy; [11]University of Florence, Dept. of Experimental and Clinical Medicine, Florence, Italy*
Email: margherita.correnti@gmail.com

Background and aims: The aggressiveness of intrahepatic cholangiocarcinoma (iCCA) relies on keytumor features such as cellular plasticity, self-renewal capacity, and metastatic potential, collectively described as tumor stemness. Molecular mechanisms driving the maintenance and evolution of stemness features during iCCA progression remain poorly understood. This study aims to characterize the dynamics of stemness-related traits in primary and metastatic iCCA, identify key molecular pathways that sustain tumor cell plasticity, and explore their role in disease dissemination. By elucidating these features in vivo, we seek to uncover novel targets to disrupt tumor stemness and hinder disease progression.
Method: Taking advantage of a 3D sphere culture system (SPH) as a model for cancer stem cells, an orthotopic mouse model was developed through intrahepatic injection of Luciferase-GFP-transfected SPH cells obtained by both established and primary iCCA cells. Disseminated GFP+ tumor cells in target organs (lungs, spleen, peritoneum, mesenteric lymph nodes) and blood were analyzed via FACS. GFP+ cells from primary and metastatic lung tumors were isolated by FACS for molecular profiling using pathway-focused qRT-PCR arrays. These findings were validated in human metastatic and non-metastatic iCCA samples through immunohistochemistry and correlated with clinical and pathological data.
Results: SPH cells were responsible for a great tumor spread in all secondary organs analyzed, especially those derived from MTCHC-01 primary cells. The absence of CD45-/GFP+ tumor cells in the blood of animals suggested that lymphatic circle is the preferential via to iCCA dissemination. Notably, lung SPH-disseminated cells showed up-regulation of many tested stem-like, epithelial-to-mesenchymal transition, angiogenesis and drug resistance related genes compared to SPH-primary tumor cells. A panel of 34 genes commonly up-regulated was found in all SPH-disseminated cells. High expression of some of these genes were correlated with a significantly lower 5-years and disease-free survival of 289 iCCA patients. Among these, TSPAN13 and WNT5A are of particular importance. Expression levels of these 2 genes-derived proteins were significantly up-regulated metastatic CCA specimens compared to non-metastatic ones.
Conclusion: Our data indicate that a core stemness program is maintained during iCCA progression, with TSPAN13 and WNT5A emerging as key markers of stemness and metastasis.

WED-250

Chemoprevention of hepatocellular carcinoma by next-generation antipsychotic aripiprazole

Nevena Slovic[1], Sumit Mishra[2], Paul Subhojit[2], Marine Oudot[1], Frank Jühling[1], Hiroaki Kanzaki[2], Julien Moehlin[1], Anouk Charlot[1], Margaux Denos[1], Sarah Durand[1], Courtney Katz[2], Cloé Gadenne[1], Emanuelle Felli[3], Joachim Lupberger[1], Emilie Crouchet[1], Yujin Hoshida[2], Thomas Baumert[1]. Email: ecrouchet@unistra.fr

Background and aims: Hepatocellular carcinoma (HCC) is the most common form of liver cancer and is a major global health burden, ranking sixth in incidence and third in cancer-related mortality. Despite therapeutic advances, treatment options for advanced liver disease and HCC are limited and strategies to prevent HCC development are lacking. Serotonin signaling is known to play a functional role in metabolic dysfunction, steatosis, inflammation and fibrosis. Aripiprazole is an FDA-approved third generation antipsychotic, which modulates multiple serotonin receptor signaling pathways. In this study, we investigated the potential of aripiprazole as an HCC chemopreventive strategy.
Method: Aripiprazole's targets expression was assessed in clinical liver tissues at mRNA and protein levels. The therapeutic potential of aripiprazole was examined in a rat model of MASH-induced HCC induced by choline-deficient L-amino acid-defined and high-fat diet. To decipher the mechanism of action, RNA-sequencing (RNA-Seq) was performed on rat liver tissues. The effect of aripiprazole was validated in different liver cell compartments by perturbation studies using patient-derived liver myofibroblasts, a monocyte-derived macrophage model and HCC cancer cells. Finally, we analyzed the impact of aripiprazole treatment on tumor microenvironment (TME) by combining a multicellular patient-derived tumorspheroid model and single cell RNA-Seq.
Results: Analyses of clinical liver tissues showed that aripiprazole's targets are expressed in different liver cell compartments including fibroblasts, macrophages and epithelial cancer cells, and that target gene expression is associated with fibrotic liver diseases and HCC. In a rat model of MASH-induced HCC, aripiprazole prevents liver disease progression and HCC development by modulating fibrogenesis related pathways and inflammation. Mechanistically, aripiprazole exerts antifibrogenic and anti-inflammatory effects by modulating the phenotype of liver fibroblasts and macrophages. Moreover, perturbation studies in cancer cell models showed that aripiprazole prevents tumor initiation and reduces cell proliferation via inhibition of the cMET and ERK pathways and perturbation of mitochondrial functions. Finally, treatment of patient-derived tumorspheroids demonstrated that aripiprazole modulates immune responses in the TME.
Conclusion: Collectively, these findings suggest that treatment with aripiprazole is a clinically relevant approach for HCC chemoprevention.

WED-251-YI

Impact of dual immune checkpoint blockade on the tumor immune microenvironment and determinants of therapeutic response in hepatocellular carcinoma

Kazuma Daiku[1], Yuta Myojin[1], Kazuki Maesaka[1], Kumiko Shirai[1], Kazuhiro Murai[1], Yuki Makino[1], Yuki Tahata[1], Yoshinobu Saito[1], Hayato Hikita[1], Takahiro Kodama[1]. [1]*Department of Gastroenterology and Hepatology, Graduate School of Medicine, The University of Osaka, Suita, Japan*
Email: t-kodama@gh.med.osaka-u.ac.jp

Background and aims: Dual immune checkpoint blockade (durvalumab plus tremelimumab) improves outcomes in advanced hepatocellular carcinoma, but treatment-induced microenvironmental changes and determinants of resistance remain incompletely understood. We profiled therapy-associated changes and searched for tumor-intrinsic factors linked to resistance.
Method: A heterogeneous murine hepatocellular carcinoma model was generated by hydrodynamic injection of a pooled library of 10 oncogene cDNA constructs with unique barcodes. Mice received anti–PD-L1 plus anti–CTLA-4 antibodies. Bulk tumor RNA profiling was performed. Immune cells from early responding tumors and from tumors with acquired resistance after prolonged treatment were analyzed by single-cell RNA sequencing (scRNA-seq). Barcode sequencing estimated intratumoral oncogene clone frequencies. In addition, we generated an Mcl1-overexpressing Hep55.1c cell line and evaluated dual blockade in a subcutaneous syngeneic mouse tumor model.
Results: Dual blockade prolonged overall survival compared with untreated and monotherapy groups, and complete responses occurred only with combination therapy. Responding tumors showed higher Cd8, Cd4, and Foxp3 expression, whereas resistant tumors showed lower Cd8 and Cd4 expression. Gene signature–based cell-type scoring indicated higher endothelial and fibroblast scores in resistant tumors. ScRNA-seq demonstrated increased intratumoral CD8+ and CD4+ T cells in responders, while resistant tumors had reduced lymphocytes and increased myeloid cells, including neutrophils; regulatory T cells increased only modestly. Barcode analysis showed enrichment of MCL1-driven clones in resistant tumors. In the syngeneic subcutaneous Hep55.1c model, Mcl1 overexpression reduced tumor regression under dual blockade and was associated with reduced Cd4 expression.
Conclusion: Dual immune checkpoint blockade promotes intratumoral T-cell infiltration and antitumor activity. Tumor barcoding and functional validation implicate an MCL1-associated program as a potential mediator of resistance in hepatocellular carcinoma, which may be associated with suppression of CD4+ T cells.

WED-252

Platelet-induced mitochondrial transfer promotes hepatocellular carcinoma progression

Meng Zhang[1], Yaping Li[1], Muqi Wang[1], Chenrui Liu[1], Yikai Wang[1], Wenhao Wang[1], Hanxiang Dang[1], Yigan Zhang[2], Zhong-ji Meng[2], Shuangsuo Dang[1]. [1]*The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China;* [2]*Taihe Hospital, Hubei University of Medicine, Shiyan, China*
Email: zhangmeng8388@126.com

Background and aims: Platelets are increasingly recognized as active regulators within the tumor microenvironment and play important roles in hepatocellular carcinoma (HCC) progression. Intercellular mitochondrial transfer has emerged as a novel mechanism regulating tumor cell behavior; however, whether platelet–tumor interactions promote HCC progression through mitochondrial transfer remains unclear. This study aimed to investigate platelet-associated mitochondrial transfer, its potential modes of intercellular communication, and its functional significance in HCC progression.
Method: HCC cell lines Hep3B and Huh7 were co-cultured with platelets isolated from patients with HCC under direct-contact or Transwell conditions. Scanning electron microscopy was used to visualize tunneling nanotube (TNT)-like intercellular structures, while transmission electron microscopy assessed mitochondrial ultrastructural changes in tumor cells. Platelet mitochondria were fluorescently labeled to trace their transfer into HCC cells. Mitochondrial membrane potential and intracellular reactive oxygen species (ROS) levels were evaluated by flow cytometry. Tumor cell migratory capacity was assessed using functional assays. Pharmacological inhibitors targeting TNT formation or extracellular vesicle release were applied to explore potential routes of mitochondrial transfer.
Results: Direct contact with platelets isolated from HCC patients significantly enhanced Hep3B and Huh7 cells migration compared

with indirect co-culture. TNT-like structures connecting platelets and tumor cells were observed by scanning electron microscopy, accompanied by increased mitochondrial abundance in tumor cells on transmission electron microscopy. Fluorescence tracing confirmed the presence of platelet-derived mitochondria within HCC cells. Functionally, co-culture with HCC patient–derived platelets stabilized mitochondrial membrane potential and reduced intracellular ROS levels in tumor cells. Inhibition of either TNT formation or extracellular vesicle release markedly attenuated platelet-induced mitochondrial alterations and the associated enhancement of tumor cell migration.
Conclusion: Platelets promote hepatocellular carcinoma progression by transferring mitochondria and enhancing mitochondrial functional stability in tumor cells. Multiple intercellular communication pathways, including TNT-like structures and vesicle-dependent mechanisms, may cooperatively mediate platelet–tumor interactions, highlighting potential therapeutic targets in HCC.

WED-253
Modeling human innate and adaptive immunity in hepatocellular carcinoma: evaluating anti-IL-8 and anti-PD-L1 immunotherapy in humanized mice
Zenzi De Vos[1,2,3], Lander Heyerick[1,2], Aline Baekelandt[1,2], Hannah Stocks[4,5], Andy Wullaert[4,5], Rania Matthys[1,2], Emine Gökce[6], Anne Hoorens[7], Sarah Raevens[2,6,8], Anja Geerts[2,6,8], Xavier Verhelst[2,6,8], Sander Lefere[2,6,8], Hans Van Vlierberghe[2,6,8], Lindsey Devisscher[1,2,3]. *[1]Department of Basic & Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Ghent University, Ghent, Belgium; [2]Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium; [3]Cancer Research Institute Ghent, Ghent, Belgium; [4]VIB-UGent Center for Inflammation Research, VIB, Ghent, Belgium; [5]Department of Biomedical Sciences, Cell Death Signaling Laboratory, University of Antwerp, Antwerp, Belgium; [6]Department of Gastroenterology and Hepatology, Ghent University Hospital, Ghent, Belgium; [7]Department of Pathology, Ghent University Hospital, Ghent, Belgium; [8]Department of Internal Medicine and Paediatrics, Hepatology Research Unit, Ghent, Belgium*
Email: zenzi.devos@ugent.be

Background and aims: Hepatocellular carcinoma (HCC) patients suffer from inadequate treatment options, in part attributable to the lack of human-relevant models that include key components of the immunosuppressive tumor microenvironment (TME) of human HCC.
Method: We present two novel humanized immune system (HIS) mouse models, co-transplanted with orthotopic human HCC, to investigate human HCC in the context of human monocyte/macrophage (Myeloid-HIS-HCC) or human T cell (T cell-HIS-HCC) responses. Mice were treated with immunotherapy directed to innate (anti-IL-8 antibody (n = 11) or IgG isotype control (n = 10) in Myeloid-HIS-HCC mice) or adaptive (anti-PD-L1 antibody (n = 7) or IgG isotype control (n = 6) in HCC patient-T cell-HIS-HCC mice) immunity.
Results: In Myeloid-HIS mice, injection of human hematopoietic stem and progenitor cells resulted in efficient engraftment in peripheral blood of human monocytes, DCs and NK cells, of which the latter were significantly lower in HCC-bearing mice ($p = 0.048$). Engraftment in the liver and HCC tumors was dominated by human macrophages. Gene expression of tumor-associated macrophage markers (*ICAM1* $p = 0.031$), immune checkpoints (*PDL1* $p = 0.046$) and tumor-promoting markers (*HIF1A* $p = 0.049$ and *IL6* $p = 0.015$) were higher in anti-IL-8-treated Myeloid-HIS-HCC mice, compared to control-treated mice, without differences in tumor size. In T cell-HIS mice, human peripheral blood mononuclear cells mainly resulted in engraftment of human T cells. Tumor growth was significantly lower in T cell-engrafted HCC mice compared to nongrafted HCC mice. Regulatory T cell engraftment tended to be higher in mice engrafted with HCC patient-derived cells compared to mice with cells derived from healthy donors, which was reversed upon anti-PD-L1 treatment ($p = 0.025$). In line, gene expression of T cell activation markers was lower, and tumor marker gene expression was higher, in HCC patient-humanized compared to healthy-humanized mice, which was reversed upon anti-PD-L1-treatment (*GZMB* $p = 0.049$ and *IFNG* $p = 0.044$).
Conclusion: We propose two novel preclinical humanized immune system models with high translational value. In both models, alterations in the TME of HCC related to human innate or adaptive immunity can be evaluated, demonstrating its relevance as immunotherapy-evaluating platforms. In addition, HCC patient-derived T cell-HIS-HCC mice appear promising as tool for personalized medicine.

WED-254
UCHL1 inhibition by LDN57444 potentiates sorafenib response in hepatocellular carcinoma: a preclinical study
Kylian Decroix[1,2,3], Elias Van De Vijver[1,3], Delphine Burggraeve[1,3], Lindsey Devisscher[2], Marleen Van Troys[1], Hans Van Vlierberghe[3]. *[1]Actin and Cell Migration Lab, Department of Biomolecular Medicine, Ghent University, Ghent, Belgium; [2]Department for Basic and Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Ghent University, Ghent, Belgium; [3]Hepatology Research Unit, Department Internal Medicine and Pediatrics, Liver Research Center, Ghent University, Ghent, Belgium*
Email: kylian.decroix@ugent.be

Background and aims: Hepatocellular carcinoma (HCC) is the most prevalent form of liver cancer worldwide. Despite recent advances in immunotherapy, treatment efficacy remains inadequate. Long-term effectiveness of second-line tyrosine kinase inhibitors is often limited by complex resistance mechanisms and adverse effects. Deubiquitinase UCH-L1 is frequently upregulated in advanced HCC and correlates with poor prognosis. Hence, this study aims to unravel whether UCH-L1 inhibition using LDN-57444 enhances sorafenib efficacy in HCC.
Method: UCH-L1 expression was analysed in TCGA-LIHC datasets and patient-derived HCC tissues. Sorafenib-LDN57444 effects were evaluated *in vitro* using the Hep3B HCC cell line in 2D cell-based assays and the 3D spheroid invasion assay. In vivo efficacy of the drug synergy was assessed in an orthotopic xenograft mouse model. Tumour growth, proliferation markers and oncogenic signaling activation were examined by Western blotting, RT-qPCR and immunohistochemistry.
Results: In silico data-analysis revealed that UCH-L1 was significantly upregulated in HCC tumours versus non-tumour tissue, associated with reduced overall survival. Low-dose sorafenib induced UCH-L1 protein and mRNA upregulation. Paradoxically, this promoted invasiveness in Hep3B spheroids and was accompanied by sustained MEK1/2-ERK1/2 pathway activation and upregulation of EMT- and immune escape markers: PD-L1 and SNAI-1. Notably, the sorafenib-LDN57444 combination not only produced strong synergistic cytotoxic effects *in vitro*, but also reverted sorafenib-driven MAPK activation and suppressed spheroid invasion. Consistently, LDN57444 co-treatment markedly inhibited tumour growth and reduced proliferation of Hep3B xenografts, improving sorafenib outcome *in vivo*.
Conclusion: UCH-L1 plays a regulatory role in sorafenib-induced adaptive resistance in HCC. Pharmacological UCH-L1 inhibition with LDN57444 synergizes with sorafenib to enhance anti-tumour efficacy, suppress invasiveness and potentially overcome resistance mechanisms. This supports the development of UCH-L1-targeted combination strategies as a promising, novel therapeutic avenue in advanced HCC.

DNA replication stress as a therapeutic target in hepatocellular carcinoma

Nina Desboeufs[1,2], Peter Leary[1], Chenhui Zhao[1], Sarah Kollar[3], Lapkwan Chan[1], André Fitsche[3], Alex Schmidt[3], Lara Planas-paz[3], Salvatore Piscuoglio[4], Federico Dona[4], Silvia Incalcaterra[4], Laura Summermatter[3], Anne-Laure Leblond[3], Katharina Endhardt[3], Adrian Kobe[5], Gilbert Puippe[5], Charlotte Ng[6], Sandro Nuciforo[6], Markus Heim[7], Luigi Terracciano[4], Chantal Pauli[3], Andreas E. Kremer[8], Massimo Lopes[1], Achim Weber[1]. *[1]University of Zurich, Institute of Molecular Cancer Research, Zurich, Switzerland; [2]University Hospital Zurich, Department of Pathology and Molecular Pathology, Zurich, Switzerland; [3]University Hospital Zurich, Department of Pathology and Molecular Pathology, Zurich, Switzerland; [4]Humanitas Research Hospital, Department of Biomedical Sciences, Rozzano, Italy; [5]University Hospital Zurich, Institute of Diagnostic and Interventional Radiology, Zurich, Switzerland; [6]University Hospital Basel, Department of Biomedicine, Basel, Switzerland; [7]University Hospital Basel, Division of Gastroenterology and Hepatology, Basel, Switzerland; [8]University Hospital Zurich, Department of Gastroenterology and Hepatology, Zurich, Switzerland*
Email: desboeufs@imcr.uzh.ch

Background and aims: Hepatocellular carcinoma (HCC) is one of the most prevalent cancers worldwide and poses significant challenges in treatment due to its high heterogeneity. Despite the high clinical need for new systemic therapies, precision oncology for HCC is still in its infancy. This study aimed to investigate whether DNA replication stress, defined as the slowing or stalling of replication fork progression, could be targeted for systemic treatment of HCC.
Method: We developed a DNA replication stress-based signature for HCC using bulk RNA-seq datasets and weighted-gene co-expression network analysis (WGNCA). To assess the signature's association with drug response, we established HCC patient-derived organoids (HCC-Org) using a novel protocol for drug testing studies. We also conducted mid-throughput drug screening with compounds targeting replication stress and performed optimised single-cell and single-molecule assays to explore vulnerabilities in HCC-Org.
Results: We identified a subset of HCC patients with elevated replication stress scores, which were associated with poorer prognosis. Targeting ataxia telangiectasia and rad3-related protein (ATR) demonstrated robust efficacy in a subset of HCC-Org models, whether used alone or in combination with inhibitors of poly (ADP-ribose) polymerase (PARP) or WEE1. Of note, the drug response was associated with the level of replication stress and replication fork slowdown.
Conclusion: These findings emphasise the potential of ATR inhibitors, both as monotherapy and combination therapy, that leverage the intrinsic replication stress present in a subset of HCC, thereby opening up an avenue for precision oncology in HCC.

WED-256

Loss of secreted and transmembrane protein 1 modulates drug sensitivity and resistance in hepatocellular carcinoma

Cyrollah Disoma[1,2], Gabriela Bosoi[1,3], Georgia Zancotti[1,2], Deborah Bonazza[4], Paola Tarchi[5], Claudio Tiribelli[1], Caecilia Sukowati[1,6]. *[1]Liver Cancer Unit, Fondazione Italiana Fegato ONLUS, Trieste, Italy; [2]Doctoral School of Molecular Biomedicine, Department of Life Sciences, University of Trieste, Trieste, Italy; [3]Master Course of Medical and Diagnostic Biotechnology, Department of Life Sciences, University of Trieste, Trieste, Italy; [4]Surgical Pathology Unit, Azienda Sanitaria Universitaria Giuliano Isontina, Trieste, Italy; [5]Surgical Clinic, Azienda Sanitaria Universitaria Giuliano Isontina, Trieste, Italy; [6]Eijkman Research Center for Molecular Biology, Research Organization for Health, National Research and Innovation Agency (BRIN), Jakarta, Indonesia*
Email: cyrollah.disoma@fegato.it

Background and aims: Drug resistance remains a major challenge in the treatment of hepatocellular carcinoma (HCC). Despite recent advances in systemic therapies, many patients do not gain long-term clinical benefit from assigned targeted therapies. Following an *in silico* screening, Secreted and Transmembrane Protein 1 (*SECTM1*) was identified as a novel resistance gene whose role in HCC and drug resistance had not been studied in clinical samples and in HCC models.
Method: Lenvatinib-resistant cells were generated through acute, stepwise, and continuous chronic drug exposure to Hep3B, Huh7, and JHH6 HCC cell lines, followed by the calculation of Lethal Concentration 50 (LC_{50}) values. Its functional role was evaluated using siRNA-mediated *SECTM1* knockdown, cell viability, wound healing, and CCK-8 cell proliferation assays. SECTM1 expression was quantified by RT-qPCR and Western blotting and in parallel, assessed in 60 paired HCC and their adjacent non-tumoral clinical samples.
Results: Acute (48h) and chronic (>60 days) lenvatinib exposure in HCC cell lines resulted in *SECTM1* up-regulation with increased LC_{50} values. JHH6 cells, an undifferentiated HCC cell line, displayed higher SECTM1 levels at both the mRNA and protein levels compared to well-differentiated cells Hep3B and Huh7. *SECTM1* gene knockdown resulted in slower cell proliferation and wound-healing capacity and altered determinant markers of Epithelial to Mesenchymal Transition (*CDH1, COL1A1, CDH2, SNAI1, SNAI2*, and *VIM*). *SECTM1* knockdown significantly enhanced lenvatinib sensitivity, implicating SECTM1 as a mediator of drug resistance and survival signaling. In clinical samples, SECTM1 is more expressed in HCC than its adjacent non-HCC tissues both at the RNA and protein level, consistent with The Cancer Genome Atlas (TCGA) cohort. Patients with high *SECTM1* expression have poorer prognosis with lower median months of HCC recurrence compared to patients with low *SECTM1* expression ($p < 0.05$). Stratification by clinicopathological features revealed significant differences according to sex and disease stages.
Conclusion: SECTM1 mRNA and protein were upregulated in HCC tissues ($p < 0.05$). High *SECTM1* expression was associated with early HCC recurrence, both in TCGA and in our own cohort. *SECTM1* gene knockdown decreased HCC cell proliferation and aggressiveness, while enhancing drug sensitivity. Overall, SECTM1 could be a potential therapeutic target to overcome drug resistance or improve treatment outcomes.

WED-257

Sexual dimorphism in GPC3 (rs2267531) and PNPLA3 (rs738409) genetic risk profiles during HBV-related liver disease progression

Kubilay Göçücü[1], Demet Yılmaz Karadağ[2], Coskun Ozer Demirtas[3], Feyza Gunduz[4], Fatih Eren[5]. *[1]İstanbul Kent Üniversitesi Sağlık Hizmetleri Meslek Yüksekokulu, Patoloji Laboratuvar Teknikleri, İstanbul, Türkiye; [2]Marmara Üniversitesi Gastroenteroloji Enstitüsü, İstanbul, Türkiye; [3]Marmara Üniversitesi Tıp Fakültesi Gastroenteroloji Bilim dalı, İstanbul, Türkiye; [4]Marmara Üniversitesi Tıp Fakültesi Gastroenteroloji Bilim Dalı, İstanbul, Türkiye; [5]Recep Tayyip Erdoğan Üniversitesi Tıp Fakültesi, Marmara Üniversitesi Tıp fakültesi, Rize Merkez, Türkiye*
Email: kubilay.gocucu@kent.edu.tr

Background and aims: *GPC3* (Glypican-3) is a key oncofetal protein in hepatocellular carcinoma (HCC). Due to its X-linked location (Xq26.2), its genetic impact may vary by sex. Hepatocellular carcinoma (HCC) exhibits a lower incidence in females, and variations in the X-linked *Glypican-3 (GPC3)* gene (Xq26.2) are suggested to influence its etiopathogenesis. *GPC3* serves as an alternative diagnostic biomarker for HCC, activating proto-oncogenes via the Wnt/β-catenin signaling pathway. We aimed to investigate the potential relationship between the *GPC3* rs2267531 promoter polymorphism and *PNPLA3* rs738409 in the progression from chronic hepatitis B (CHB)—the primary cause of HCC in Turkey—to cirrhosis and HCC.

Method: A total of 294 participants were enrolled, comprising 119 healthy controls, 57 patients with CHB, 34 with HBV-related cirrhosis, and 84 with HBV-related HCC. Genotyping was performed using the rhAMP SNP Assay with the allelic discrimination method on the LightCycler® 480 (Roche) platform, and results were validated by Sanger sequencing. Data were stratified by sex to account for X-linked inheritance, and logistic regression models adjusted for age were utilized to determine Odds Ratios (OR).
Results: In males, the *GPC3* G-allele was significantly protective against cirrhosis (OR: 0.11, P = 0.0061). Conversely, females showed no association during the cirrhosis stage (P = 0.76) but demonstrated a highly significant risk association with HCC (P = 0.0016), with 100% of female HCC patients (n = 13) carrying the G/C genotype. Dominant model analysis further revealed that the *GPC3* rs2267531 C/C genotype was significantly higher in controls compared to CHB (P = 0.040) and cirrhosis (P = 0.042) groups, suggesting a protective role. Haplotype interaction analysis revealed a significant sex-specific synergy between *GPC3* and *PNPLA3* (P-interaction = 0.028).
Conclusion: This study represents the first analysis of *GPC3* rs2267531 promoter variants in a Turkish population. *GPC3* acts as a sex-dimorphic marker in HBV progression, serving as a primary gatekeeper against cirrhosis in males while functioning as a critical oncogenic driver in females, likely influenced by X-inactivation patterns. While the C/C genotype appears protective against CHB and cirrhosis, and the G/C genotype against HCC in certain models, these findings highlight the necessity of sex-stratified genetic screening in clinical practice.

Email: luca.fabris@unipd.it

Background and aims: Cholangiocarcinoma (CCA) is an aggressive primary liver malignancy with increasing incidence worldwide, particularly the intrahepatic subtype (iCCA). Although hepatic fibrosis has been implicated in CCA development, its role in coagulation imbalance and cancer-associated thrombosis (CAT) remains unclear. This study investigated the relationship between advanced liver fibrosis, hemostasis activation, CAT, and clinical outcomes in patients with iCCA.
Method: Fifty patients with iCCA undergoing curative liver resection were studied. Graft wedge biopsies served as controls (n = 10). Histological evaluation was performed in formalin-fixed, paraffin-embedded samples using the Ishak Fibrosis Score (IFS, 0–6). Immunohistochemistry assessed tissue factor (TF), factor X (FX), fibrinogen, and von Willebrand factor (vWF). As readout of CAT, portal vein microthrombosis was quantified using Martius Scarlet Blue (MSB) staining. Correlation between TF expression and outcomes were evaluated by Kaplan-Meier survival analysis. Immunofluorescence analysis of TF and FX was performed on patient-derived iCCA organoids (PDOs, n = 10). Extracellular vesicles (EVs) isolated from PDO culture media were characterized by flow cytometry (FC) using Calcein-AM, EpCAM-PE, and Annexin V. TF levels in PDO supernatants were quantified by ELISA. EV-induced platelet activation was assessed by FC using CD41, CD62P, and Annexin V.
Results: Compared with controls, iCCA patients exhibited a pro-coagulant phenotype with increased coagulation activation and impaired fibrinolysis. Patients with advanced fibrosis (IFS 4–5, n = 16) showed significantly higher TF, FX, vWF, and fibrinogen expression than those with IFS ≤3 (n = 34). Fibrosis severity correlated with TF expression by malignant bile ducts and with the number of portal vein microthrombi ($p < 0.05$). High TF expression by malignant bile ducts was significantly associated with reduced disease-free survival and overall survival. PDO analyses confirmed marked TF and FX expression and demonstrated TF release into culture supernatants. EVs derived from PDOs significantly promoted platelet activation.
Conclusion: Advanced hepatic fibrosis is closely associated with CAT in patients with iCCA and is linked to increased TF expression by malignant cholangiocytes, driving platelet activation. By contributing to a prothrombotic tumor microenvironment, TF associates with disease progression and adverse clinical outcomes in iCCA patients.

Single-cell and bulk transcriptomics uncover the cellular ecosystem of vascular invasion in intrahepatic cholangiocarcinoma
Jianing Fan[1], Meng Tong[1], Junjie Xu[1], Qianqian Wang[1], Yangyang Xie[1], Kainan Lin[1], Xiujun Cai[1], Yunkun Lu[1], Xiao Liang[1]. [1]*Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: fjn020116@163.com

Background and aims: Intrahepatic cholangiocarcinoma (ICC) is an aggressive liver malignancy with rising global incidence and limited therapeutic options. Vascular invasion (VI) is a hallmark of advanced disease, correlating with early recurrence and dismal prognosis, yet its tumor microenvironment (TME) drivers remain elusive.
Method: We analyzed single-cell RNA sequencing (scRNA-seq) data from 25 ICC samples to systematically characterize the cellular composition and molecular features associated with VI. Bulk RNA-seq data and multiplex immunofluorescence were integrated to validate our findings. Subsequently, cell–cell communication analysis was conducted, and key candidate genes were further validated utilizing RT-qPCR. Finally, functional validation was performed through endothelial sprouting assays using inhibitors and ICC-derived cancer-associated fibroblast (CAF) cell lines with specific genes knockdown.
Results: We identified a distinct subset of tumor-specific CAFs (tCAFs) that were significantly enriched in VI-positive tumors. Functional analyses revealed that tCAFs were closely related to hypoxia and angiogenesis pathways. Furthermore, scRNA-seq data also showed a notable increase in endothelial cells in VI-positive tumors. Cell-cell communication analysis demonstrated that tCAFs promoted VI primarily through VEGF signaling interactions with endothelial cells. Integrative bioinformatics and RT-qPCR validation pinpointed 3 key genes (*PTGS2*, *SLC2A1*, and *PLOD2*) in tCAFs. In endothelial sprouting assays, inhibition of *SLC2A1* exerted a pronounced suppressive effect on sprouting. Consistently, sprouting assays based on ICC-derived CAF cell lines with *SLC2A1* knockdown confirmed that downregulation of *SLC2A1* significantly reduced endothelial sprouting capacity.
Conclusion: Collectively, our study defines a VI-associated cellular ecosystem and molecular landscape in ICC, indicating that tCAFs drive VI via VEGF-mediated interactions with endothelial cells, with *SLC2A1* playing a critical role. These findings provide mechanistic

insights into VI development and identify *SLC2A1* as a potential therapeutic target with clinical relevance for advanced ICC.

Generation and characterization of a novel synthetic notch chimeric antigen receptor (CAR) targeting T cells to hepatocellular carcinoma: designed to prevent T-cell activation induced by soluble hepatitis B virus envelope antigens

Yudi Gao[1], Fuwang Chen[1], Zhe Xie[1], Tao Jin[2], Luis Contreras[1], Jochen Wettengel[1,3], Ke Zhang[2], Ulrike Protzer[1,3]. [1]*Institute of Virology, Technical University of Munich/Helmholtz Munich, Munich, Germany;* [2]*SCG Cell Therapy Pte Ltd, Singapore, Singapore;* [3]*German Center for Infection Research (DZIF), Munich partner site, Munich, Germany*
Email: yudi.gao@tum.de

Background and aims: Chimeric antigen receptor (CAR) T cell therapy offers a promising approach not only for cancer therapy but also for chronic viral infections. However, circulating viral antigens binding to the CAR may activate CAR-T cells or restrict their killing capacity in an unwanted fashion. We designed a logic-gate Synthetic Notch (SynNotch) CAR that can only be activated on HBV-positive cells, but not by soluble HBsAg.

Method: We fused a single-chain fragment that recognizes the tumor antigen glypican 3 (GPC3) as a gate antigen to human Notch, thereby activating the expression of an S-CAR, which recognizes the HBV envelope protein (HBVenv) on HBV-positive cells. We engineered single and SynNotch S-CAR T cells via co-transduction of lentivirus and characterized the function of GPC3-SynNotch-S-CAR T cells on HBVenv ± /GPC3 ± hepatoma cells. Inducible S-CAR expression and T-cell activation were measured by IFN-γ ELISA and flow cytometry. T-cell-killing was monitored by the xCELLigence real-time cell analyzer. To determine specificity, the analysis was performed with and without the addition of HBsAg, and using HBV-negative and HBV-positive GPC3+ HepG2 cells. The T-cell killing specificity was then analyzed using the Incucyte system for real-time fluorescence imaging.

Results: GPC3-SynNotch-S-CAR T cells expressed the S-CAR upon recognition of GPC3 on target cells and SynNotch activation after 24–36 h. Unlike S-CAR T cells, GPC3-SynNotch-S-CAR T cells were not activated when incubated with soluble HBsAg and selectively killed dual antigen GPC3+/HBVenv+ HepG2 cells, but not cells that were only positive for HBVenv or GPC3. In mixed target cell cultures, GPC3-SynNotch-S-CAR T cells eliminated GPC3+/HBVenv+ cells with high specificity and efficiency. Compared to the constitutively active S-CAR-construct, T cells transduced with the inducible GPC3-SynNotch-S-CAR exhibited a comparable or even stronger IFN-γ secretion and killing capability on HepG2-Env+, and HBV-infected HepG2-NTCP cells.

Conclusion: The inducible GPC3-SynNotch-S-CAR is a promising candidate for redirecting T cells to HBV-positive hepatocellular carcinoma (HCC) that express GPC3. It demonstrated superior sensitivity and specificity compared to non-inducible S-CARs and prevented T-cell activation induced by soluble HBsAg. This proves that the SynNotch "IF-THEN" logic gating has strong potential to reduce off-target toxicity and enables programmable, modular responses.

WED-261

Exploring hepatocellular carcinoma through a neuroendocrine lens: the somatostatin system as an intricate source of tumour evaluation strategies and therapeutic vulnerabilities

Background and aims: Despite the recent advances in management and treatment (i.e., BCLC updates, immunotherapy implementation), hepatocellular carcinoma (HCC) remains a complex clinical challenge due to high intra- and intertumoral heterogenic response to drugs, boosted by a rapidly evolving aetiologic landscape (i.e., the rising incidence of metabolic dysfunction-associated steatotic liver disease, MASLD). Thus, further research in novel biomarkers and therapeutic approaches is needed. In this work, we aim to explore the somatostatin (SST) endocrine system, which is a well-established line of diagnosis and treatment in pituitary and neuroendocrine tumours, in HCC and MASLD.

Method: Gene expression was evaluated using 2 internal retrospective cohorts [R1 (n = 93), R2 (n = 102)], 7 MASLD *in silico* cohorts [n = (45–109)/cohort], 6 HCC *in silico* cohorts [n = (65–369)/cohort] and 4 human liver cell lines. Sample clustering in TCGA-LIHC was implemented using Python (YellowBrick package). In a subset of R1 (n = 25), immunohistochemistry (IHC) for the SSTR1, SSTR2 and SSTR5 receptors was performed. Cell lines were subjected to *in vitro* functional assays (proliferation, colony and hepatosphere formation) to test the antitumoral capacity of natural peptides (SST and cortistatin, CST) and clinically relevant synthetic SST analogues (SSAs: octreotide, lanreotide, pasireotide, BIM-23926, BIM-23120 and BIM-23206).

Results: SST receptors (SSTRs) expression was lower in MASLD and HCC compared to control tissue, associated to complex patterns of tumour aggressiveness (e.g., less expression in men, non-recurring and surviving patients) and complemented by histological and subcellular localization [IHC: hepatocellular (SSTR1, SSTR2) and vascular (SSTR5)]. Cell lines mimicked this expression pattern, with HepG2 (low) and Hep3B (intermediate tumoral aggressiveness) showing the highest SSTRs expression. Clustering discriminated between SSTR1-expressing (more benign) and SSTR2-expressing (neuroendocrine-leaning, more aggressive) HCC samples. *In vitro*, antitumoral responses were observed for CST and SSAs in the functional assays in the different cell lines.

Conclusion: Neuroendocrine profiling in MASLD-HCC offers a novel framework for understanding these diseases, providing new potential avenues for tumour assessment and personalised therapeutic options. This work was funded by ISCIII (FI21/00141, DTS22/00057, PI23/00652, co-funded by the European Union), MICIU (FPU21/04833), JdA (PI-0046-2024), UCO, FSEEN and CIBERobn.

Role of the NADPH oxidase 4 in regulating endoplasmic reticulum stress and autophagy in liver tumor cells

Gemma Gonfaus-Ortiz[1,2], Paula Segalés[1,2], Irene Peñuelas-Haro[1,2], Ismael Sánchez-Vera[3], Joan Gil[3], Esther Bertran[1,2], Isabel Fabregat[1,2]. [1]*TGF-beta and Cancer Group - Oncobell Program. Bellvitge Biomedical Research Institute (IDIBELL). Email: ggonfaus@idibell.cat

Background and aims: NADPH oxidase (NOX) isoforms are distinctively expressed in different liver cell types. NOX1 and NOX2 behave as promoters of hepatocellular carcinoma (HCC), however recent findings postulate NOX4 as a negative regulator of HCC. Our group described that after silencing NOX4, liver tumor cells enhance their proliferative and migratory capacity, increasing glycolysis and oxidative phosphorylation (OXPHOS). We aim to better understand the molecular mechanisms regulated by NOX4 that could explain its tumor suppressor role.
Method: Loss- and gain-of-function approaches for NOX4 were performed in HCC cell lines. Proteomic, metabolomic, and transcriptomic, as well as functional analyses, were employed.
Results: Endoplasmic reticulum (ER) stress and autophagy are described as cellular stress response mechanisms, and ER stress can induce autophagy in cancer cells to promote organelle recycling and proliferation. Given the strong crosstalk between NOX4, mitochondrial morphology, and oxidative phosphorylation (OXPHOS), we wondered whether alterations in NOX4 levels affect cellular metabolism under ER stress conditions. Electron microscopy revealed increased mitochondrial size in NOX4-silenced cells, as well as tighter contacts at mitochondria-associated membranes compared to control cells. ER stress stimuli with tunicamycin or thapsigargin led to alterations in the PERK pathway, with increased ATF4 protein levels and transcriptional activity in NOX4-silenced cells. Under ER stress, these cells also showed a significant reduction in OXPHOS compared to untreated conditions. Furthermore, NOX4 knockdown resulted in increased apoptotic markers, including caspase-3 activity and elevated cleaved PARP and BIM levels. In parallel, differences were observed in autophagy-related signalling pathways and in sequestosome 1 protein levels. Transcriptomic analysis of autophagy-related genes revealed opposite expression patterns following NOX4 overexpression/silencing. Consistently, autophagic flux was increased after NOX4 silencing and reduced upon overexpression. Notably, inhibition of autophagy with bafilomycin A1 in NOX4-silenced cells led to a decrease in OXPHOS. Additionally, when blocking ER stress with ISRIB, the autophagic flux diminished significantly, indicating that ATF4 might be involved in the regulation of autophagy.
Conclusion: NOX4 loss in HCC cells increases ATF4-mediated ER stress and autophagy-driven metabolic shift towards oxidative metabolism.

WED-263
Cirrhotic MASLD-HCC exhibits distinct immunosuppressive traits within the tumor microenvironment and is associated with poorer outcomes in patients treated with atezolizumab-bevacizumab

Albert Gris-Oliver[1], Guillem Cano-Segarra[1], Ezequiel Mauro[1], Ana Hernández[1], Anna Vila-Escoda[1,2], Marta Piqué-Gili[1], Judit Peix[1], Roser Pinyol[1], Josep M Llovet[1,2,3]. [1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [2]*Mount Sinai Liver Cancer Program, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States;* [3]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain*
Email: agris@recerca.clinic.cat

Background and aims: The impact of metabolic dysfunction-associated liver disease (MASLD) on immunotherapy response in advanced hepatocellular carcinoma (aHCC) remains unclear. As a major risk factor and prognostic determinant, cirrhosis critically shapes the tumor microenvironment (TME). Our aim is to assess the impact of MASLD-HCC with or without cirrhosis, and their associated TME composition, on the efficacy of immunotherapy in aHCC.
Method: A multicenter retrospective cohort (2019–2023) of 239 patients treated with first line atezolizumab and bevacizumab (atezo +bev) was collected. Transcriptomic profiles were used for molecular and functional characterization and deconvoluted with BayesPrism to define tumor immune infiltration.
Results: The cohort had a median age of 69 years old, was predominantly male, and 67% had cirrhosis. BCLC stages B and C accounted for 29% and 68% of the patients, respectively. The main etiology was viral (28%), followed by MASLD (21%). The median overall survival (OS) follow-up was 12 months (IQR 6–17). Median OS was shorter in MASLD patients (12.2 vs 18.6 months, HR 1.56 [95% CI: 1.02–2.37], p = 0.039). Among the 49 MASLD-HCC patients, the presence of cirrhosis (n = 26, 53%) was associated with shorter OS (9.89 vs 16.72 months, HR 2.82 [95% CI 1.27–6.25], p = 0.011), and remained independently associated with mortality (HR 3.24 [95% CI 1.25–8.35], p = 0.015) together with ECOG-PS 2 (HR 8.42 [95% CI 1.81–39.24], p = 0.007), after adjustment for AFP ≥ 400 ng/ml, and macrovascular invasion. When comparing gene expression profiles of cirrhotic versus non-cirrhotic MASLD-HCC, both subgroups were enriched in the non-inflamed class (91% and 73%, p = 0.14); however cirrhotic tumors harbored significantly higher proportion of naïve CD8 T cells (p = 0.047), gamma-delta T cells (p = 0.044), and 2 macrophage subtypes associated with resistance to atezo+bev [TREM2+ (p = 0.014) and SPP1+ (p = 0.010)], and CXCL10+ macrophages (p = 0.017), the latter being linked to response to atezo+bev only in the absence of $TREM2^+$ macrophages.
Conclusion: Cirrhotic MASLD-HCC independently predicts mortality in patients with HCC treated with atezo+bev and is characterized by a distinct TME enriched in immunosuppressive cells associated with resistance to atezo+bev.

WED-264
A glypican-3 targeted chimeric antigen receptor T cell product secreting programmed cell death ligand 1 and vascular endothelial growth factor blockers shows durable tumor shrinkage in advanced hepatocellular carcinoma

Xiaowen He[1], Hao Guo[1], Qi Yang[1], Xingwu Dong[1], Xiaofeng Feng[1]. [1]*Oricell Therapeutics Co., Ltd., Shanghai, China*
Email: peterhe@oricell.com

Background and aims: Systemic programmed cell death ligand 1 (PD-L1) plus vascular endothelial growth factor (VEGF) antibody therapy improves outcomes in unresectable hepatocellular carcinoma (HCC), yet durable benefit remains limited and systemic exposure can drive toxicity. OriC902 is a X-CAR rapid-manufacture-process based glypican-3 (GPC3) targeting chimeric antigen receptor T cell (CAR-T) product engineered to secrete PD-L1 and VEGF blockers to create a spatio-temporal profile and enable three-drug-in-one synergy.
Method: Proof-of-concept data were generated with the OriC902 construct manufactured by a conventional CAR-T process. Antibody secretion were confirmed with Huh7 co-culture assay (effector: target 1:1, 120 h). In $GPC3^+$ Huh7 xenografts, low-dose OriC902 construct CAR-T was compared with second-generation GPC3 CAR-T and with CAR-T plus systemic anti-PD-L1 and anti-VEGF. Tumor growth, interferon-gamma, intratumoral CAR-T abundance/exhaustion, CD31, and plasma versus tumor antibody distribution were measured. Separately, X-CAR manufacture was benchmarked versus conventional manufacture process.
Results: The OriC902 construct CAR-T secreted PD-L1 and VEGF blockers (hundreds of ng/mL) in vitro and improved tumor control at low CAR-T dose versus second-generation CAR-T and combination therapy. Plasma-to-tumour concentration folds were reduced relative to the combination therapy (anti-VEGF approximately 80 to approximately 10; anti-PD-L1 approximately 60 to approximately 2). Confocal imaging showed lower CD31 and higher human CD3 infiltration, consistent with vascular normalization. Intratumoral flow cytometry showed 11,819 versus 39 CAR-T cells/mg tumor mass and fewer exhaustion-marker-positive CAR-T cells (6.4% versus 28.6%). X-CAR manufacture process enabled vein-to-vein under 10 days and improved CAR-T phenotype and potency and in vivo expansion in models.

Conclusion: A GPC3 CAR-T secreting anti-PD-L1 and anti-VEGF can normalize tumor vasculature and enhance T cell trafficking, supporting a spatio-temporal delivery concept that may boost efficacy while limiting high systemic antibody exposure. Based on the "three-in-one" synergy evidence and the in vivo performance of X-CAR–process-based CAR-T cells, an investigator-initiated clinical trial of OriC902 has been initiated.

WED-265

Spatial profiling of the tumour immune microenvironment in hepatocellular carcinoma identifies regulatory T cell–mediated immune exclusion

Nicholas Hannah[1,2,3,4,5], Tony Huang[5], Catherine Mitchell[2,5], Rita Busuttil[6], Siddharth Sood[2,3], Alex Boussioutas[6,7]. [1]*The Royal Melbourne Hospital, Parkville, Australia;* [2]*The University of Melbourne, Parkville, Australia;* [3]*Northern Health, Epping, Australia;* [4]*Western Health, Footscray, Australia;* [5]*Peter Maccallum Cancer Centre, Melbourne CBD, Australia;* [6]*Monash University, Clayton, Australia;* [7]*The Alfred, Melbourne CBD, Australia*
Email: nicholas.hannah2@mh.org.au

Background and aims: Hepatocellular carcinoma (HCC) often presents at an advanced stage and is linked to poor survival. Greater insight into the spatial distribution of immune cells within the tumour microenvironment may inform prognosis and guide therapeutic strategies. This study performed a comprehensive whole-slide spatial analysis of T-cell subsets in HCC.
Method: Archival glypican-3 (GPC3)–positive HCC tissue samples from a tertiary liver centre were analysed. Associated clinicopathological and survival data were included. Multiplex immunohistochemistry (mIHC) was conducted using OPAL 6-plex and DAPI. Whole-slide images were evaluated with HALO and the SPIAT R package. The antibody panel comprised CD3, CD4, CD8, FOXP3, PD-L1, and GPC3.
Results: Twenty-two samples were analysed (median age 71 years; 77% male; 68% cirrhosis; 41% viral aetiology). $CD3^+CD4^+FOXP3^+$ regulatory T cells (Tregs) were significantly enriched near $GPC3^+$ HCC cells compared to other immune phenotypes, with a median cell percentage within 100 μm of 6.12% (IQR 3.25–16.8). In contrast, $CD3^+CD8^+$ cytotoxic T lymphocytes (CTLs) were excluded from the tumour, indicated by a median cross-K area under the curve of –0.110 (IQR –0.256 to 0.120), consistent with spatial repulsion. Entropy gradient analysis revealed increased spatial attraction of Tregs to $GPC3^+$ tumour cells (standardised residual +3.56, $p < 0.001$), which was associated with worse overall survival (HR 6.38, 95% CI 0.78–52.07; $p = 0.047$). Similarly, low intratumoral CTL entropy correlated with poorer survival (HR 4.62, 95% CI 0.95–22.43; $p = 0.037$). Hierarchical clustering identified 371 immune cell neighbourhoods, defining seven immune phenotypes: immune-excluded ($n = 14$), inflamed ($n = 5$), immune-desert ($n = 1$), and other ($n = 2$), with the immune-excluded, Treg-enriched phenotype being most prevalent ($n = 13$).
Conclusion: Whole-slide spatial analysis shows that regulatory T cells preferentially localise to $GPC3^+$ HCC tumour nests, while cytotoxic T lymphocytes are relatively excluded. These spatial immune features are linked to poorer survival, supporting the presence of an immunosuppressive tumour microenvironment. Regulatory T cells may be a rational therapeutic target in HCC.

WED-266

SULT2A1 restrains hepatocellular carcinoma progression by fostering cholic acid 7-sulfate-mediated CD8+T cell cytotoxicity via CREB–IL-2Rβ–mTORC1 signaling

Wei He[1], Weifen Xie[2]. [1]*Department of Gastroenterology, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China, Shanghai, China;* [2]*Department of Gastroenterology, Changzheng Hospital, Naval Medical University, Shanghai, China, Shanghai, China*
Email: weifenxie@medmail.com.cn

Background and aims: Hepatocellular carcinoma (HCC) remains a fatal malignancy exhibiting limited immunotherapy responses. Cytotoxic $CD8^+$T cells are critical players in tumor clearance through cytokine secretion, yet it remains obscure how bile acid metabolism in liver cancer shapes the antitumor immune responses of $CD8^+$T cells. Sult2a1, which is preferably expressed by hepatocytes, sulfates cholic acid into cholic acid 7-sulfate (CA7S) in liver. Here, we identified Sult2a1 as a key suppressor in HCC progression by bolstering the cytotoxicity of $CD8^+$T cells.
Method: We analyzed transcriptomic and proteomic data from HCC patients to interrogate Sult2a1 alteration. The expression of Sult2a1 was evaluated through immunohistochemistry (IHC) and western blotting (WB). The anti-tumor effect of Sult2a1 was validated by subcutaneous and spontaneous HCC models. Mass spectrometry, flow cytometry, surface plasmon resonance and CRE-driven luciferase assays were employed to identify the membrane receptor for CA7S. The effectiveness of CA7S supplementation alone or in combination with anti-PD-1 antibody was assessed in vivo. The downstream mechanism of CA7S-driven $CD8^+$T function enhancement was elucidated by multiomics-based integration of scRNA-seq, ATAC-seq and RNA-seq data. We also analyzed a tissue microarray of liver tumor samples ($n = 90$) from HCC patients to elucidate the correlation between HNF4alpha and Sult2a1. Furthermore, the transcription of Sult2a1 by HNF4alpha was validated by Cut&Tag qPCR and luciferase reporter assays.
Results: Transcriptomic and proteomic analyses revealed a drastic down-regulation of Sult2a1, particularly in advanced stages of HCC. We then confirmed the loss of Sult2a1 by IHC and WB in human specimens. Specifically, Sult2a1 inhibited liver tumor growth in immunocompetent but not in immunodeficient mouse models. ScRNA-seq analysis of spontaneous liver tumors indicated an increased fraction of liver-infiltrating cytotoxic $CD8^+$T cells upon Sult2a1 administration. Mechanistically, Sult2a1-derived CA7S activated GPBAR1, leading to enhanced CREB–IL-2Rβ–mTORC1 signaling and boosted the anti-tumor capacity of $CD8^+$T cells. CA7S and anti-PD-1 treatment synergistically inhibited HCC growth. In addition, HNF4alpha, the master transcriptional regulator in liver, was responsible for enhancing Sult2a1 transcription.
Conclusion: The Sult2a1-derived metabolite CA7S fosters $CD8^+$T cell function and sensitizes liver tumors to anti-PD-1 immunotherapy, offering a promising therapeutic avenue for HCC.

WED-267

Single-Cell RNA sequencing identifies molecular concordance between circulating tumor cells and primary tumor nuclei in hepatocellular carcinoma

Monica Higuera[1], Agnes Soriano-Varela[1,2,3], Elena Vargas-Accarino[1,4], Maria Montesinos[1], Maria Torrens[1,2], Beatriz Minguez[1,2,3,4]. [1]*Liver Cancer Research Group, Liver Diseases, Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain;* [2]*Liver Unit, Hospital Universitario Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain;* [3]*Department of Medicine, Campus de la UAB, Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain;* [4]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain*
Email: beatriz.minguez@vallhebron.cat

Background and aims: Circulating tumor cells (CTCs), shed from primary tumors into the bloodstream, represent a promising biomarker for cancer diagnosis, prognostication and monitoring. Despite recent advances in CTC detection and enumeration, their comprehensive molecular characterization remains limited. In this study, we aimed to establish a robust workflow for the isolation and transcriptomic profiling of CTCs to delineate their molecular features and clarify their role in hepatocellular carcinoma (HCC) progression.
Method: Eighteen patients with HCC undergoing surgical resection were prospectively enrolled. Peripheral blood samples were collected

at baseline and every three months during follow-up. CD45+ cells were depleted, and remaining cells were labeled with EpCAM, Pan-Cytokeratin and Glypican-3 for sorting and quantification. Whole-transcriptome sequencing was performed on CTCs and matched tumor nuclei from fresh-frozen tissue of six patients with early-stage HCC. Cell types were annotated using reference liver and tumor datasets, and CNV analysis assessed aneuploidy.
Results: CTCs levels did not show significant fluctuations during the 12 months following surgical resection, however, the proportion of CTCs was identified as an independent risk factor for HCC recurrence in this cohort. Single-cell RNA sequencing of CTCs revealed a distinct cellular profile characterized by high expression of hepatic (HSPA1A, KRT8, GPC3) and epithelial (EPCAM) markers. On average, 10.3 ± 3.3 cells per sample were molecularly classified as CTCs. CNV analysis demonstrated a high prevalence of aneuploid cells within this population. Single-nucleus RNA sequencing matched tumor tissue identified multiple cell populations, including tumor, immune, Kupffer, stellate, and endothelial cells. The proportion of tumor cells varied widely across samples (5.2%-51.3%) and exhibited differential expression of canonical HCC markers and elevated levels of aneuploidy. Comparative transcriptomic analysis revealed an approximately 50% overlap among the top expressed genes between CTC and tumor cell clusters.
Conclusion: This preliminary study demonstrates that single-cell RNA sequencing enables robust molecular discrimination of CTCs from other circulating cell populations. By non-invasively capturing tumor-specific features, this approach provides a powerful framework for characterizing tumor heterogeneity and intratumoral microenvironment, offering a potential alternative to invasive tissue biopsies for molecular profiling in HCC.

WED-268
Generalist SAM based foundation models outperform medically fine-tuned variants in dynamic liver ultrasound segmentation
Janik Hohmann[1,2], Adil Oezsoy[1], Tom Luedde[1,2,3], Tobias Paul Seraphin[1], Michael Kallenbach[1]. [1]*Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital Dusseldorf, Medical Faculty at Heinrich-Heine-University, Düsseldorf, Germany;* [2]*Zentrum für Digitale Medizin (ZDM), Heinrich-Heine-University Düsseldorf, Faculty of Medicine and Mathematics and Natural Sciences at Heinrich-Heine-University, Düsseldorf, Germany;* [3]*CIO - Center for integrated Oncology, Aachen, Bonn, Cologne, Düsseldorf, University Hospital Düsseldorf, Medical Faculty at Heinrich-Heine-University, Düsseldorf, Germany*
Email: janik.hohmann@med.uni-duesseldorf.de

Background and aims: Ultrasound is the first-line modality for detection and follow-up of focal liver lesions (FLLs), yet image interpretation and annotation remain highly operator-dependent and difficult to standardize. Recent foundation models such as Meta's Segment Anything Model (SAM) family offer powerful zero-shot segmentation capabilities, but their robustness for real-world liver ultrasound videos and across lesion types has not been systematically evaluated.
Method: We assessed the latest SAM-based models (SAM2 tiny, SAM2 large, SAM3, and MedSAM2 variants) on a real-world dataset of 40 B-mode ultrasound videos comprising benign and malignant FLLs. Models were evaluated in a zero-shot setting using bounding box and mask prompts, with frame-wise expert annotations as reference. Segmentation accuracy (Dice Similarity Coefficient, DSC), tracking failure rates, prompt robustness, and lesion-specific performance were analyzed. To support practical deployment, we developed TagMed, a locally deployed, privacy-preserving annotation platform integrating interactive segmentation models with structured human-in-the-loop (HITL) workflows.
Results: Generalist foundation models consistently outperformed medically fine-tuned MedSAM2 variants in dynamic ultrasound tracking. With bounding box prompts, SAM2 tiny achieved the highest overall performance (median DSC 0.93), followed by SAM3 and SAM2 large (median DSC 0.92). In contrast, MedSAM2 models showed lower accuracy and pronounced instability, with substantially higher tracking failure rates (up to 42.5%) compared to SAM3 (15.2%). Prompt modality strongly influenced performance: SAM2-based models were highly sensitive to mask initialization, whereas SAM3 maintained robust performance across prompt types (median DSC 0.92 for both box and mask prompts). Benign lesions were segmented more reliably than malignant lesions, with metastases representing the most challenging subtype. Minimal re-prompting improved segmentation stability across all models and especially MedSAM2 performance, reducing variability and failure rates.
Conclusion: Generalist SAM models enable accurate and robust zero-shot segmentation and tracking of focal liver lesions in ultrasound videos, outperforming specialized medical variants in dynamic imaging scenarios. Integrated into the TagMed platform, these models support efficient, privacy-preserving, human-in-the-loop annotation workflows and provide a practical solution for scalable dataset creation and ultrasound research.

WED-269
A serum-based biomarker of type VI collagen degradation (C6M) is associated with increased risk of hepatocellular carcinoma development
Sebastian Howen Rode[1], Andressa de Zawadzki[1], kt Shenoy[2], Leena Mohan[3], Morten Karsdal[1], Jane I. Grove[4], Diana Julie Leeming[1], Guruprasad Aithal[4]. [1]*Nordic Bioscience, Biomarkers & Research, Herlev, Denmark;* [2]*Sree Gokulam Medical College and Research Foundation, Population Health and Research Institute, Trivandrum, India;* [3]*Population Health and Research Institute, Trivandrum, India;* [4]*National Institute of Health Research (NIHR) Nottingham Biomedical Research Centre, Nottingham University Hospitals NHS Trust and University of Nottingham, Nottingham Digestive Diseases Centre, Translational Medical Sciences, School of Medicine, University of Nottingham, Nottingham, United Kingdom*
Email: sero@nordicbio.com

Background and aims: The progression from cirrhosis to hepatocellular carcinoma (HCC) is driven by epithelial damage, high fibroblast activity, and altered immune and repair responses. Liver inflammation disrupts the balance of extracellular matrix (ECM) protein synthesis and degradation. In HCC patients, type VI collagen remodeling is increased and linked to higher mortality, while elevated elastin levels are associated with greater HCC incidence. To identify predictors of HCC development, we investigated two biomarkers indicative of type VI collagen degradation (C6M) and neutrophil-mediated elastin degradation (ELP-3).
Method: Serum levels of the biomarkers nordicC6M (type VI collagen fragment released by matrix metalloproteinase-2) and nordicELP-3 (elastin fragment released by proteinase-3) were measured in a prospective longitudinal cohort of 349 patients with cirrhosis during surveillance for HCC. 38/349 patients developed HCC after baseline inclusion. The prognostic utility of C6M and ELP-3 for HCC was assessed using competing risk analysis of cumulative incidence (Aalen-Johansen), with death as competing event, and hazard ratios (HR) estimated by the Fine-Gray subdistribution hazard model with 95% confidence intervals (CI).
Results: The cumulative incidence of HCC was stratified by biomarker tertiles (baseline levels) and used to identify thresholds that distinguish patient groups with lower versus higher HCC incidence. Patients with baseline C6M levels above 465 ng/mL exhibited an increased risk of HCC events (HR = 2.07 [CI 1.08–3.97], p = 0.028, 36 events/330 patients) compared to patients below this threshold. Stratification based on biomarker changes from baseline to 6 months (median time) showed that patients who decreased in C6M (HR = 3.40 [CI 1.43–8.06], p = 0.006, 23 events/58 patients) or ELP-3 (HR = 2.51 [CI 1.18–5.37], p = 0.017, 26 events/65 patients) presented a

higher risk of HCC, potentially reflecting a "cold" fibrotic state (low inflammation).
Conclusion: Cirrhosis patients with a higher baseline level of type VI collagen degradation were at increased risk of developing HCC, supporting that high ECM turnover precedes HCC development. Decreasing rates of type VI collagen and neutrophil-mediated elastin degradation within 6 months of baseline were predictive of HCC during surveillance, indicating ECM turnover and immune activity decline during HCC development. In summary, both baseline levels and early changes in C6M and ELP-3 provide prognostic utility for HCC risk stratification.

WED-270
From transporter to oncogenic driver: N-linked glycosylation enhances oncogenic capabilities of SLC29A2 in hepatocellular carcinoma
Yu-Hsuan Hsu[1,2], Chia-Yi Chou[1], Yuh-Shan Jou[1]. [1]*Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan;* [2]*Program in Molecular Medicine (MMP), National Yang Ming Chiao Tung University, Taipei, Taiwan*
Email: or75369@ibms.sinica.edu.tw

Background and aims: SLC29A2 (solute carrier family 29 member 2) is an equilibrative nucleoside transporter that mediates nucleoside uptake across cellular membranes. Our prior study demonstrates that SLC29A2 is frequently upregulated in multiple cancers, with marked amplification in hepatocellular carcinoma (HCC). Despite its significance in liver tumor progression, the functional contributions and underlying mechanisms of SLC29A2 remain poorly understood. We discovered that SLC29A2 undergoes N-linked glycosylation at residues N48 and N57 within its first extracellular loop. Since disrupting these modifications significantly attenuates SLC29A2-mediated oncogenesis, we aimed to characterize how this specific modification governs SLC29A2-driven HCC malignancy.
Method: The functional impact of SLC29A2 glycosylation was evaluated using site-directed mutagenesis of the N48 and N57 residues. Transcriptomic analysis was performed to identify differentially regulated pathways between glycosylated and non-glycosylated SLC29A2 forms. The molecular mechanism was further validated through protein stability assays and nuclear translocation analysis of NF-Kappa B subunits. To assess therapeutic potential, pharmacological inhibition of the downstream effector NIK (NF-Kappa B inducing kinase) was conducted using the selective inhibitor B022.
Results: Transcriptomic profiling revealed that glycosylated-SLC29A2, unlike its non-glycosylated counterpart, significantly enhances HCC cell proliferation and migration by selectively activating the non-canonical NF-Kappa B pathway. Mechanistically, glycosylated-SLC29A2 strongly downregulates cIAP1 expression, which stabilizes NIK and promotes the nuclear accumulation of the NF-Kappa B subunits p52 and RelB. Furthermore, pharmacological inhibition of NIK with B022 completely abrogated the oncogenic phenotypes induced by glycosylated-SLC29A2. These results establish glycosylation as a master regulator of SLC29A2-driven malignancy and underscore the essential role of the NIK-dependent non-canonical NF-Kappa B axis in mediating its tumor-promoting functions.
Conclusion: Our findings unveil a new, glycosylation-dependent oncogenic function of SLC29A2 that drives HCC progression through a non-canonical NF-Kappa B signaling program. By characterizing this unique post-translational modification, we establish glycosylated-SLC29A2 as a promising target for the development of specialized monoclonal antibodies, offering a novel therapeutic framework for patients with advanced HCC.

Circulating lipid signatures drive mitochondrial stress and inflammatory remodelling in non-cirrhotic MASLD-associated hepatocarcinogenesis
Jian Huang[1], Zhongguo Zhou[2], Arresha Nazeer[3], Julian L. Griffin[3], Nadia Guerra[2], Mark R Thursz[1], Pinelopi Manousou[1]. [1]*Saint Mary's Hospital, London, United Kingdom;* [2]*Imperial College London, London, United Kingdom;* [3]*University of Aberdeen, Aberdeen, United Kingdom*
Email: jian.huang20@imperial.ac.uk

Background and aims: A substantial proportion of hepatocellular carcinoma (HCC) arising in metabolic dysfunction–associated steatotic liver disease (MASLD) develops in the absence of cirrhosis, limiting surveillance eligibility and delaying diagnosis. We previously identified six circulating lipid species (PG_(38:6), DG_(34:1), LPI_(17:1), SM_(34:1), CerPE_(38:1), Cer_(37:1)) selectively upregulated in non-cirrhotic MASLD-associated HCC (n = 19). This study aimed to define the mechanisms through which these lipids may contribute to early hepatocarcinogenesis and to assess their translational relevance.
Method: HepG2 cells were treated with the pre-identified lipids. Mitochondrial dysfunction was assessed by reactive oxygen species (ROS) generation and mitochondrial membrane potential collapse. Lipid-induced inflammatory remodelling was evaluated by cytokine secretion profiling. Integrated STRING, KEGG, MitoCarta 3.0, and TCGA-HCC datasets were used to identify lipid-regulated metabolic–inflammatory modules with clinical relevance.
Results: All six lipids induced a convergent mitochondrial stress phenotype characterised by increased ROS and loss of membrane potential (Figure B and C). Despite belonging to distinct lipid classes, each lipid activated specific mitochondrial–metabolic signalling pathways, including PGS1–TAZ, SGMS1–SPTLC2, SAMD8–SPTLC2, and CerS3–SGMS1–SPHK2. Lipid stimulation selectively increased IL-8 and IFN-γ (numbers) secretion rather than broad inflammatory activation. Integrated network analysis identified the MBOAT7–LYPLAL1 axis downstream of LPI_(17:1) as the only pathway showing strong interactions with IL-8 and IFN-γ and significant correlation with their expression in TCGA-HCC samples ($P < 0.05$; $r = 0.34$).
Conclusion: Non-cirrhotic MASLD-associated HCC lipids induce a shared mitochondrial stress and selective inflammatory programme that may facilitate early hepatocarcinogenesis. The convergence on the MBOAT7–LYPLAL1 axis supports their translational potential as early-stage biomarkers and highlights mitochondrial–metabolic inflammatory pathways as therapeutic targets prior to cirrhosis onset.

WED-272
Enhanced detection of hepatocellular carcinoma using combined biomarker panels including alpha-fetoprotein, alpha-fetoprotein-L3, des-gamma-carboxyprothrombin and the galad score
Trung Huynh[1], Khanh Pham[1]. [1]*Tam Anh Hospital, Ho Chi Minh city, Viet Nam*
Email: nnphong.bvndong@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) remains a major global health burden, and early detection is crucial for improving outcomes. Conventional tools such as imaging and AFP have limited accuracy, prompting increased interest in emerging biomarkers including AFP-L3, DCP/PIVKA-II, and the GALAD score. However, evidence on the diagnostic performance of these markers-particularly GALAD-remains scarce in Southeast Asia. Vietnam, with its high prevalence of chronic hepatitis B and aflatoxin exposure, lacks robust comparative studies evaluating these biomarkers within the same cohort. This study therefore assessed the diagnostic accuracy of AFP, AFP-L3, DCP, and GALAD for detecting HCC in a Vietnamese population, with potential relevance for broader application across Southeast Asia.

Method: A cross-sectional study was conducted at Tam Anh Hospital, Ho Chi Minh City, Vietnam, from March to October 2025. A total of 83 patients with histologically confirmed HCC and 83 patients with chronic hepatitis or cirrhosis were enrolled. Serum AFP, AFP-L3, and DCP levels were measured, and GALAD scores were calculated. Diagnostic performance was assessed using sensitivity, specificity, and area under the receiver operating characteristic curve (AUC). Biomarkers were compared individually and in combination, with subgroup analyses stratified by BCLC stage.
Results: AFP >8.5 ng/mL and AFP-L3 >3.85% showed moderate sensitivity (72.3% and 77.1%) and high specificity (91.6% and 86.7%). DCP >33.5 mAU/mL and GALAD >2.19 demonstrated superior diagnostic accuracy, with sensitivities of 91.6% and 85.5%, specificities of 92.8% and 95.2%, and identical AUCs of 0.957. Both DCP and GALAD significantly outperformed AFP and AFP-L3 ($p < 0.05$), with no significant difference between them ($p > 0.05$). Combined biomarker panels further improved performance, with the AFP–AFP-L3–DCP panel achieving the highest sensitivity (95.2%). In advanced HCC (BCLC ≥B), GALAD (AUC 0.939) outperformed AFP and AFP-L3 and was comparable to DCP. None of the biomarkers reliably differentiated very early (BCLC 0) from early-stage HCC (BCLC A).
Conclusion: DCP and GALAD exhibit superior diagnostic accuracy compared with AFP and AFP-L3, particularly in advanced HCC. Combining multiple biomarkers further enhances detection, although none effectively distinguish very early from early-stage disease. These findings support the clinical utility of DCP and GALAD and highlight the need for improved strategies to identify very early-stage HCC.

WED-273
Cathepsin A promotes immune evasion in hepatocellular carcinoma by driving tumor-associated macrophage polarization
Jie Jiang[1], Xiangwen Zhang[1], Wenbin Tang[1], Jin Yang[1], Zhuan Li[1].
[1]*Hunan Normal University, Changsha, China*
Email: zhuanli@hunnu.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide and is characterized by a profoundly immunosuppressive tumor microenvironment, which limits the efficacy of immune therapy. Tumor-associated macrophages (TAMs) are key components of this microenvironment but the upstream signals driving their pro-tumorigenic polarization remain poorly defined. Cathepsin A (CTSA) is aberrantly expressed in several malignancies, but its role in HCC immune regulation is unclear. This study aimed to elucidate the function of CTSA in HCC progression, with a particular focus on TAMs polarization and immune microenvironment remodeling.
Method: CTSA expression was analyzed in TCGA database and in human HCC specimens using immunohistochemistry, multiplex immunofluorescence, and flow cytometry. Associations with patient prognosis, M2-like macrophage markers, and CD8-positive T cell infiltration were evaluated. CTSA was genetically silenced in hepatocellular carcinoma cells using CRISPR–Cas9 technology. Macrophage polarization was assessed using transwell co-culture systems. Receptor identification and downstream signaling pathways were investigated by mass spectrometry, RNA sequencing, and proteomic analyses. Therapeutic efficacy was evaluated in an orthotopic HCC mouse model treated with a CTSA inhibitor in combination with PD1 blockade.
Results: CTSA was significantly upregulated in HCC and was associated with poor overall survival. CTSA silencing markedly suppressed tumor growth i*n vivo*. Importantly, CTSA expression positively correlated with infiltration of M2-like TAMs and inversely correlated with CD8-positive T cell infiltration in clinical samples. Functional studies demonstrated that hepatocellular carcinoma-derived CTSA actively promoted macrophage polarization toward an immunosuppressive M2 phenotype, thereby fostering a "cold" tumor microenvironment. Combined cathepsin A inhibition and immune checkpoint blockade resulted in enhanced antitumor efficacy *in viv*o.
Conclusion: CTSA is a poor prognostic marker and driver of immune evasion in HCC via promoting M2-like TAMs polarization to create an immunosuppressive microenvironment and immunotherapy resistance. Targeting CTSA might offer novel strategy to inhibit tumor progression and convert immunologically "cold" tumors into immunotherapy-responsive phenotypes.

Investigating the immunomodulatory role of the extracellular matrix in hepatocellular carcinoma
Kavitha Kirubendran[1], Sara Campinoti[1], Bruna Almeida[1], Roberto Savoldelli[1], Maya Medic[1], Elena Palma[1], Antonio Riva[1], Shilpa Chokshi[2], Luca Urbani[1]. [1]*Roger Williams Institute of Liver Studies, King's College London, London, United Kingdom;* [2]*Peninsula Medical School, University of Plymouth, Plymouth, United Kingdom*
Email: k.kirubendran@researchinliver.org.uk

Background and aims: Immune-targeted therapies, specifically T-cell-directed approaches, are becoming central to treatment strategies for patients with hepatocellular carcinoma (HCC), a leading cause of cancer-related mortality. The extracellular matrix (ECM) is a dynamic regulator of the immune system; in cancer it is actively remodelled and dysregulated, influencing immune cell infiltration, cytokine signalling and function. Recent studies increasingly demonstrate that ECM proteins exhibit immunomodulatory functions within the liver microenvironment, yet their specific role in modulating immune phenotypes present in HCC remains unclear. Here, we explore the direct impact of ECM proteins on T-cell phenotypes in patient-derived models of HCC to understand their role in immune regulation.
Method: We decellularised HCC-precision cut tissue slices (dPCTS) from both tumour and adjacent non-tumour liver tissue from resected HCC samples. Decellularisation efficiency was evaluated using H&E staining and DNA quantification, and ECM composition was analysed with mass spectrometry-based proteomics. dPCTS were co-cultured with human circulating and intrahepatic immune cells from HCC patients. Immune phenotype and interactions in response to dPCLS exposure were assessed via flow cytometry and deep spatial phenotyping.
Results: The optimised decellularisation process efficiently removed cells from HCC-derived PCTS whilst preserving intact matrix architecture, retention of matrix-bound proteins and endotoxin-free conditions. After 3-day of co-culture, immune cells successfully interacted with and adhered to dPCTS. Upon ECM exposure, preliminary analysis showed distinct immune cell distributions, particularly among T-cell subsets, revealing differences of cell-ECM interactions between circulating and intrahepatic immune cells, and between adjacent and tumour ECM, with resulting differences in phenotype. Proteomics analysis revealed upregulation of distinct matrix proteins in HCC relative to adjacent tissue (e.g. COL3A1, THBS1, VCAN, FBN1, EFEMP1), which may drive these immune cell responses.
Conclusion: Our findings confirm that the dPCTS model supports immune cell-matrix interactions, revealing distinct immune cell distributions upon ECM exposure. This suggests that dysregulated ECM proteins may influence T-cell phenotypic changes within the TME, supporting a mechanistic role for these proteins as a barrier to immunotherapeutic cancer treatments.

WED-275

Longitudinal elevation of IL-10 following atezolizumab plus bevacizumab is associated with favorable response and survival in advanced hepatocellular carcinoma

Soon Kyu Lee[1], Jung Hyun Kwon[1], Sung Won Lee[1]. [1]*The Catholic University of Korea, College of Medicine, Seoul, Korea, Rep. of South*
Email: blackiqq@gmail.com

Background and aims: We previously reported that early increases in interleukin-10 (IL-10) and tumor necrosis factor-α (TNF-α) levels following atezolizumab plus bevacizumab (Ate/Bev) therapy predict survival in patients with advanced hepatocellular carcinoma (HCC). In this study, we aimed to longitudinally assess serial cytokine changes and evaluate their association with treatment response and survival in advanced HCC patients receiving Ate/Bev.
Method: We prospectively enrolled 154 consecutive patients with advanced HCC who were treated with Ate/Bev between July 2022 and June 2025. Of these, 54 patients who provided blood samples at three time points—before initiation of Ate/Bev, prior to the second cycle, and prior to the fourth cycle—were included in the cytokine analysis. Serum levels of IL-2, IL-6, IL-10, IL-12, IL-17, interferon-γ (IFN-γ), and TNF-α were measured at each time point, and temporal changes in cytokine levels were examined. The primary endpoint was overall survival, while secondary endpoints included associations between cytokine patterns and treatment response.
Results: During a mean follow-up of 11.4 months, 42 patients (77.7%) died. The median age was 66.0 years, with most patients being male (92.6%), and the predominant etiology was viral-related HCC (85.2%). Serial changes in IL-2, IL-6, IL-12, IL-17, IFN-γ, and TNF-α levels were not significantly associated with overall survival. In contrast, IL-10 levels significantly increased following Ate/Bev treatment ($p = 0.01$), particularly among patients who achieved disease control ($p = 0.022$). Changes in IL-10 levels were positively correlated with changes in the CRP levels ($r = 0.38$, $p = 0.004$). Notably, patients exhibiting an increase in IL-10 levels demonstrated significantly better survival compared with those showing a decrease ($p = 0.042$). In multivariable analysis, an increase in IL-10 levels remained an independent predictor of overall survival in advanced HCC patients treated with Ate/Bev.
Conclusion: Our findings suggest that serial changes in cytokine levels—particularly IL-10—following Ate/Bev therapy may serve as a useful biomarker for monitoring treatment response and predicting clinical outcomes in patients with advanced HCC.

WED-276

IRE1α-mediated downregulation of CYP7A1 drives MASH-HCC progression and immune evasion via regulation of cholesterol metabolism

Fan Li[1], Yiming Wang[2], Hao Wang[1], Ling Lu[1], Ming Ni[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, Nanjing, China;* [2]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*
Email: drlifan1999@163.com

Background and aims: Metabolic dysfunction-associated steatohepatitis (MASH)-related hepatocellular carcinoma (HCC) is rising globally, exhibiting unique features like metabolic dysregulation and a poorer prognosis than viral HCC. Cholesterol is key in MASH-HCC progression, regulated by CYP7A1, the rate-limiting enzyme in bile acid synthesis. Clinically, CYP7A1 is significantly downregulated in MASH-HCC tumors and linked to worse outcomes, yet its regulatory mechanisms and functional roles are unclear. This study aims to clarify these aspects to identify novel therapeutic targets for MASH-HCC.
Method: Paired tumor/adjacent tissues from MASH-HCC patients were analyzed by metabolomic sequencing, scRNA-seq, and spatial transcriptomics to identify cholesterol metabolism alterations and confirm CYP7A1 downregulation. MASH-HCC mouse models were generated using hepatocyte-specific Ire1α-KO, Cyp7a1-KI, and Smo-KO mice. ChIP-seq, RNA-seq validated IRE1α-mediated CYP7A1 regulation. IP/MS, LLPS and FRAP assays characterized IRE1α lactoylation modification and RIDD activity. In vivo/in vitro experiments assessed the impact of IRE1α-CYP7A1 axis on cholesterol metabolism and Hedgehog signaling. Therapeutic effects of PD-1 mAb alone or combined with IRE1α inhibitor/CYP7A1-adenovirus were evaluated in MASH-HCC models to explore clinical translation.
Results: CYP7A1 is markedly downregulated in MASH-HCC tumor tissues and strongly associated with unfavorable prognosis. Lactylation of IRE1α induces LLPS, augmenting its RIDD activity and resulting in direct degradation of CYP7A1 mRNA. Reduced CYP7A1 expression causes aberrant cholesterol accumulation, which activates Hedgehog signaling in both tumor cells and Treg cells through SMO cholesterol modification, thereby accelerating tumor proliferation and immune evasion. Therapeutic targeting of the IRE1α/CYP7A1 axis effectively restores cholesterol metabolic homeostasis and potently suppresses tumor progression.
Conclusion: This study reveals a core mechanism driving MASH-HCC progression: hypoxia-induced IRE1α lactylation enhances its LLPS and RIDD activity, specifically degrading CYP7A1 to cause cholesterol accumulation; this accumulation exacerbates ER stress, transactivating IRE1α to form a self-reinforcing loop that ultimately activates Hedgehog signaling via SMO cholesterol modification to promote carcinogenesis and immune evasion. The study elucidates a novel "metabolism-stress" crosstalk paradigm, offering new targets for MASH-HCC diagnosis and therapy.

WED-361-YI

Central vagal dysfunction reshapes neutrophil and T cell immunity in hepatocellular carcinoma

Wenxuan Li[1], Jinghao Zhang[1], Liping You[1], Chao Zheng[1], Liyue Lu[1], Ziman Lu[1], Jian Su[1], Xiaji Yan[1], Zekun Liu[1], Xinyue Liu[1], Yuqi Liu[1], Yilin Wang[1], Yaxuan Cai[1], Fei Wu[1], Yueqiu Gao[1], Xiaoni Kong[1], Xuehua Sun[1]. [1]*Department of Liver Diseases, Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China*
Email: susan_sxh@shutcm.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) develops within a complex neuroimmune microenvironment, however the contribution of central parasympathetic activity to tumor immunity remains poorly understood.
Method: Mouse models of HCC were combined with neural modulation, immune profiling, and transcriptomic analyses. Human validation included resting-state functional MRI and immunological characterization of tumor specimens.
Results: We observed a marked reduction in central vagal activity during HCC progression in both mice and patients. Enhancing central vagal output suppressed tumor growth and reshaped the tumor immune microenvironment without altering overall leukocyte recruitment. Instead, vagal activity selectively reprogrammed neutrophils toward an immune-activating state associated with enhanced $CD8^+$ T-cell cytotoxicity. Transcriptomic and functional analyses revealed coordinated activation of inflammatory and immune effector programs in these neutrophils. Neuroimaging analyses revealed reduced brainstem vagal activity in patients with hepatocellular carcinoma compared with chronic hepatitis B controls. Peripheral stimulation of vagal pathways recapitulated this anti-tumor immune program in preclinical models. In parallel, analysis of tumor specimens demonstrated that increased intratumoral

infiltration of this neutrophil subset correlated with improved overall survival. Peripheral stimulation of vagal pathways recapitulated this antitumor immune program in preclinical models.
Conclusion: These findings uncover a brain–vagus–immune circuit that regulates neutrophil plasticity and antitumor immunity in HCC, and suggest neuromodulation as a potential therapeutic avenue for liver cancer.

WED-362
TRIM15 phase separation activates α-KG dehydrogenase through DLST condensate-mediated OGDH mono-ubiquitination to drive tumor metabolic plasticity
Hairui Li[1], Wencheng Shan[2], Fanzheng Meng[1]. [1]*The First Affiliated Hospital of USTC, Hefei, China;* [2]*The First Affiliated Hospital of USTC, Hefei, China*
Email: mengfz@ustc.edu.cn

Background and aims: Metabolic reprogramming enables Hepatocellular Carcinoma (HCC) cells to survive nutrient stress, yet the mechanisms linking metabolic flux to chromatin dynamics remain elusive. The α-ketoglutarate dehydrogenase (KGDH) complex controls the levels of α-ketoglutarate (α-KG), a critical cofactor for epigenetic enzymes. We aimed to identify stress-responsive E3 ubiquitin ligases and decipher how they coordinate KGDH plasticity and epigenetic remodeling to drive tumor progression under glutamine deprivation.
Method: We integrated glutamine-starvation proteomics with transcriptomic analysis of HCC tissues to identify candidate regulators. Mechanisms were dissected using immunoprecipitation-mass spectrometry, *in vitro* and live-cell liquid-liquid phase separation (LLPS) assays, and metabolic flux analysis. The functional impact was evaluated in hepatocyte-specific *Trim15*-knockout mice (*Trim15*$^{fl/fl}$ vs. *Trim15*$^{\Delta Alb}$), hydrodynamic tail-vein injection models, and patient-derived xenografts (PDX). Therapeutic strategies were tested using glutamine uptake inhibitors (V-9302) and DCLK1 inhibitors (DCLK1-IN-1).
Results: We identified TRIM15 as a key stress-responsive factor significantly upregulated in human HCC and glutamine-starved cells. Mechanistically, TRIM15 possesses intrinsically disordered regions (IDRs) that drive liquid-liquid phase separation. Upon stress, TRIM15 condensates sequester the KGDH subunit DLST, creating a specialized cytoplasmic compartment. This spatial organization facilitates the specific mono-ubiquitination of the OGDH subunit at Lys534. This modification stabilizes the KGDH complex and significantly amplifies its enzymatic activity. Functionally, activation of this axis accelerates α-KG catabolism, depleting intracellular α-KG levels. This metabolic shift inhibits α-KG-dependent histone demethylases, leading to the accumulation of H3K4me3 marks at the promoter of the stemness regulator *DCLK1*, thereby activating its transcription. Clinically, TRIM15 expression correlates with DCLK1 levels and poor prognosis in HCC patients. Pharmacologically, combined inhibition of DCLK1 and glutamine metabolism exerted synergistic antitumor effects in preclinical models.
Conclusion: TRIM15-mediated phase separation links mitochondrial metabolism to chromatin remodeling via the TRIM15-DLST-OGDH-DCLK1 axis. This study reveals a novel mechanism of metabolic plasticity and suggests targeting this axis to sensitize glutamine-addicted HCC to therapy.

WED-363
NAT10/ac4C drives intrahepatic cholangiocarcinoma by suppressing transposable elements via chromatin remodeling
Kainan Lin[1]. [1]*Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou City, China*
Email: 22218144@zju.edu.cn

Background and aims: Intrahepatic cholangiocarcinoma (ICC) is characterized by insidious onset, aggressive behavior, early metastasis, and a dismal 5-year survival rate below 10%. Although dysregulation of gene networks and chromatin dynamics in ICC tumorigenesis has been explored, the functional crosstalk between RNA epitranscriptomic modifications and nuclear regulatory events remains poorly understood. This study aims to uncover the role of RNA acetylation mediated by N-acetyltransferase 10 (NAT10) in ICC malignancy and to evaluate its therapeutic potential.
Method: Multi-omics profiling was performed to identify NAT10-dependent regulatory networks in ICC. The functional impact of NAT10 on mRNA stability and chromatin regulation was assessed through molecular and cellular assays. The NAT10–ac^{4}C–CHAF1A axis was mechanistically dissected using epigenomic and transcriptomic approaches. Pharmacological inhibition of NAT10 was tested in patient-derived xenograft (PDX) models and autochthonous ICC tumor models to evaluate therapeutic efficacy.
Results: NAT10 was identified as a critical driver of ICC progression. Integrated analyses revealed that NAT10-mediated N4-acetylcytidine (ac^{4}C) modification stabilizes mRNA of the chromatin assembly factor CHAF1A. The NAT10–ac^{4}C–CHAF1A axis epigenetically silences the nuclear transposable element HERV9NC, reducing double-stranded RNA accumulation. This silencing promotes ICC proliferation and migration while dampening intrinsic innate immune responses, leading to an immunosuppressive tumor microenvironment with diminished cytotoxic T-cell infiltration. Pharmacological inhibition of NAT10 significantly suppressed tumor growth in both PDX and autochthonous ICC models.
Conclusion: Our study establishes NAT10 as a master integrator linking RNA epitranscriptomic reprogramming to nuclear chromatin dynamics in ICC. The NAT10–ac^{4}C–CHAF1A–HERV9NC axis drives tumor progression and immune evasion, revealing NAT10 as a druggable vulnerability. These findings provide mechanistic insight into ICC pathogenesis and propose NAT10 inhibition as a promising therapeutic strategy for this aggressive malignancy.

Background and aims: Cholangiocarcinoma (CCA) is a highly aggressive liver cancer characterized by marked molecular heterogeneity, with limited therapeutic options, underscoring the need to identify targetable molecular drivers. Epigenetic regulators and metabolic enzymes are increasingly recognized as drivers of tumor

plasticity, representing increasingly druggable vulnerabilities. We aimed to identify epigenetic-metabolic dependencies associated with CCA aggressiveness, tumor microenvironment (TME), and tumor fitness.
Method: We performed analyses of multiple human intrahepatic and extrahepatic CCA transcriptomic cohorts, interrogating genes encoding epigenetic regulators (EpiGs) and metabolic enzymes (MGs) across molecular aggressiveness, prognostic groups, and TME contexts. Proteomic and metabolomic profiling was conducted in a TAZ/Akt-driven murine CCA model to validate transcriptomic findings.
Results: Several EpiGs were upregulated in iCCA and eCCA, including writers (*DNMT1*, *EZH2*, *SUZ12*), readers (*CBX3*, *PHF20L1*, *SMARCA4*), and erasers (*HDAC1*, *HDAC3*, *KDM5C*). However, some readers (*CHD5, SMARCA2*) were consistently downregulated in CCA. MGs functionally linked to epigenetic regulation were dysregulated (up: *GART*, *IDH2*, *TYMS*; down: *ALDH1L1*, *MAT1A*, *SHMT1*). Subsets of EpiGs (*HDAC1*, *HDAC2*, *PRDM8*, and *MECOM)* and MGs (*SHMT2*, *AHCYL2*, *ACSL5*) were linked to proliferative, poor-survival, and high-recurrence iCCA subclasses. TME analyses revealed distinct immune-stromal subclasses with coherent epigenetic and metabolic signatures. Upregulated EpiGs in the Immune-desert class (e.g., *CHD4*, *SUV39H1*, *SUZ12*) support the therapeutic rationale for combining epigenetic modulators with immunotherapy. Transcriptomic analyses in human and multi-omic analyses (transcriptomic, metabolomic, and proteomic studies) in mouse CCA livers highlighted rewiring of nucleotide, one-carbon, lipid, and mitochondrial pathways, with evidence of metabolic-epigenetic crosstalk.
Conclusion: Our study identifies a conserved and druggable epigenetic-metabolic axis underlying CCA aggressiveness, microenvironmental remodeling, and tumor fitness. By evaluating human patient stratification, functional genomics, and mouse multi-omics validation, we prioritize epigenetic and metabolic targets with high translational potential. These findings support the development of combination strategies incorporating epigenetic modulators, metabolic inhibitors, and immunotherapies for the precision treatment of CCA.

WED-365
dsDNA activates platelets via the cGAS-STING axis to drive TLS formation in hepatoblastoma

Lijie Ma[1], Shiming Gong[1], Zhenzhen Zhan[1], Mingxuan Feng[1], Qiang Xia[1]. [1]*Department of Liver Surgery, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*
Email: gongshiming521@sjtu.edu.cn

Background and aims: Hepatoblastoma (HB) is the most common malignant liver tumor in children. Although neoadjuvant chemotherapy (NAC) renders 60–70% of initially unresectable cases operable, the biological basis for the significant heterogeneity in response remains unclear. Studies of adult cancers at the single-cell level have shown that NAC can either 'heat up' or 'cool down' the tumor microenvironment (TME), but equivalent pediatric data are lacking. We therefore set out to generate the first high-resolution, cell-type-resolved map of the HB TME before and after NAC and identify the cellular and molecular circuits that determine therapeutic outcome.
Method: NAC-naïve biopsy cores and post-NAC surgical specimens were collected from SIOPEL-HR-risk patients (PLADO protocol). The following were performed: single-cell RNA sequencing (n = 12), spatial transcriptomics sequencing (n = 4), bulk RNA sequencing (n = 67), multiplexed immunofluorescence and an in vivo co-culture experiment. Animals were treated with cisplatin or platelet depletion (anti-CD42b) or a cGAS-STING inhibitor (H-151). Tumor growth, necrosis and immune infiltration were assessed by flow cytometry and histology.
Results: We constructed a high-resolution, dynamic cellular landscape remodeled by NAC and its associations with therapeutic response. NAC markedly induces substantial remodeling of the HB TME, reshaping B-cell populations and forming tertiary lymphoid structure (TLS), which are strongly associated with the therapeutic response. The density of intra-tumoral TLS significantly correlated with pathological necrosis and the rate of complete tumor resection. Mechanistically, NAC induces tumour cell necrosis, releasing double-stranded DNA (dsDNA) that activates platelets via the cGAS-STING axis. This, in turn, induces B-cell infiltration and activation via the PF4-CXCR4 axis, resulting in favourable outcomes. However, platelet depletion or cGAS-STING inhibition abolished B-cell influx and blunted tumour response.
Conclusion: Using an integrated, single-cell, spatial framework, we demonstrate that NAC converts the pediatric HB TME from immune-poor to immune-rich via a platelet-orchestrated circuit. Targeting this axis (e.g. with STING agonists or platelet factor 4 (PF4) supplementation) is a rational strategy for augmenting the response to NAC in HB and possibly other childhood solid tumors.

WED-366
Tumor–neuron signaling as a functional axis within the cholangiocarcinoma microenvironment

Lorenzo Mainardi[1], Maria Gemma Nasoni[2], Mirella Pastore[1], Alessia Giachi[1], Micheole Menotta[2], Fabio Marra[1], Francesca Luchetti[2], Chiara Raggi[1]. [1]*University of Florence, Firenze, Italy;* [2]*University of Urbino, Urbino, Italy*
Email: chiara.raggi@unifi.it

Background and aims: Tumor innervation is increasingly recognized as a critical component of the tumor microenvironment in solid malignancies; however, its role in cholangiocarcinoma (CCA) remains poorly defined. We investigated the existence and functional relevance of tumor–neuron interactions in CCA.
Method: An indirect co-culture system was established using SB1 murine CCA cells and HT22 mouse hippocampal neuronal cells. Neuronal differentiation following exposure to CCA-conditioned medium (CCA-CM) was assessed by morphological analysis, cell viability assays, transmission electron microscopy and flow cytometry. Furthermore, the expression of neuronal markers has been investigated by immunofluorescence and Western blotting. Phosphoproteomic profiling was performed to identify signaling pathways activated by tumor-derived factors. In a bidirectional approach, the effects of neuron-derived CM on CCA cells were evaluated by assessing viability, invasive capacity, and sphere-forming ability.
Results: Exposure to CCA-CM induced marked neurite outgrowth and neuron-like morphological remodeling in HT22 cells without significantly affecting cell viability, accompanied by modulation of neuronal marker β-tubulin III. Phosphoproteomic analysis revealed signaling pathway activation comparable to that observed during standard neuronal differentiation, with enrichment of processes related to actin cytoskeleton remodeling, adherens junction organization, and synaptic signaling, including dopaminergic synapse pathways. Tumor-derived cues selectively regulated phosphoproteins involved in neurite extension, cell adhesion, and signal transduction. Conversely, CM from differentiated HT22 cells enhanced CCA cell viability, invasiveness, and sphere formation capacity.
Conclusion: CCA cells release soluble factors capable of reshaping neuronal phenotype and signaling, supporting a functional tumor–nerve crosstalk. Reciprocally, neuron-derived factors promote malignant traits in CCA cells, potentially contributing to disease progression.

WED-367

Transitional hepatocytes and immunosuppressive macrophages drive NASH-associated liver cancer revealed by single-cell transcriptomics

Firdian Makrufardi[1]. [1]*Faculty of Medicine, Universitas Negeri Yogyakarta, Sleman, Indonesia*
Email: firdian.makrufardi@uny.ac.id

Background and aims: Non-alcoholic fatty liver disease (NAFLD), particularly its progressive form non-alcoholic steatohepatitis (NASH), has emerged as a major etiological factor in hepatocellular carcinoma (HCC), surpassing traditional viral causes due to rising obesity rates and metabolic syndrome prevalence. The cellular dynamics and transformation of hepatocytes during disease progression remain poorly defined. This study aims to characterize the hypoxia-associated inflammatory landscape underlying the transition from NASH to HCC using integrated single-cell RNA sequencing (scRNA-seq) data.
Method: We analyzed single-cell transcriptomic datasets encompassing liver samples from healthy individuals and patients at various NAFLD stages, including NASH and HCC. Quality control, dimensionality reduction, and clustering were conducted using the Seurat pipeline. Subpopulation-specific markers were identified, and pseudotime trajectory analysis was applied to trace hepatocyte transformation. Gene regulatory networks were reconstructed via SCENIC analysis. Additionally, a murine NASH-to-HCC progression model was used to validate key cellular and molecular findings.
Results: Transcriptomic profiling revealed a distinct hepatocyte population characterized by elevated CYP7A1 expression, predominantly found in pre-neoplastic liver regions. These transitional hepatocytes displayed gene signatures associated with stress responses, inflammation, and cancer-related pathways, while exhibiting reduced expression of healthy hepatocyte markers. Progressive activation of HIF1A signaling indicated a central role of hypoxia in driving this phenotypic shift. Furthermore, macrophage subtypes showed a notable polarization: RACK1+ macrophages transitioned into immunosuppressive TREM2+ cells in response to the hypoxic microenvironment. These TREM2+ macrophages, enriched in NASH and HCC samples, were found to be recruited by tumor cells via the CCL15-CCR1 chemokine axis, thereby contributing to a suppressive immune milieu and fostering tumor development.
Conclusion: This study provides an integrative single-cell view of how hypoxia orchestrates both hepatocyte transformation and immune modulation in NASH-associated hepatocarcinogenesis. The identification of CYP7A1+ transitional hepatocytes and TREM2+ macrophages as key players highlight potential cellular and molecular targets for early intervention in NAFLD-related liver cancer.

WED-368

Genome-wide association of MRC1 with FIB-4 disentangles non-invasive fibrosis assessment from HCC

Francesco Malvestiti[1], Stefania Mira[2], Martina Tranchina[3], Oveis Jamialahmadi[4], Rosellina Mancina[4], Serena Pelusi[3], Giulia Periti[3], Luisa Ronzoni[3], Lorenzo Miano[2], Daniele Marchelli[2], Alessandro Cherubini[3], Elia Casirati[3], Laura Cerami[3], Jessica Rondena[5], Irene De Matteis[3], Andrea Siciliano[3], Gian Paolo Caviglia[6], Marta Guariglia[6], Chiara Rosso[6], Grazia Pennisi[7], Angelo Armandi[6], Antonio Liguori[8], Francesca Terracciani[9], Riccardo Perbellini[10], Giorgio Soardo[11], Alessandro Federico[12], Umberto Vespasiani Gentilucci[9], Luca Miele[8], Elisabetta Bugianesi[6], Roberta D'Ambrosio[10], Salvatore Petta[7], Daniele Prati[3], Stefano Romeo[13], Luca Valenti[14]. Email: francesco.malvestiti@unimi.it

Background and aims: Metabolic Associated Steatotic Liver Disease (MASLD) is the most prevalent chronic liver disease, that can progress to metabolic steatohepatitis (MASH), resulting in cirrhosis and hepatocellular carcinoma (HCC). Genetic variation play a major role in disease variability, but heritability remains largely unexplained, especially in the Italian population. The aim of this study was to identify novel genetic loci associated with non-invasively assessed liver fibrosis thorough a genome-wide association study (GWAS) in Italian individuals.
Method: We conducted a GWAS in the Milan Biobank (N = 6,963) enriched in people with MASH, with validation in the Uk Biobank (UKBB). The Fibrosis-4 Index (FIB-4) served as the primary quantitative trait. We provided functional characterization of *MRC1* locus to investigate its role during hepatic damage by exploiting public resources.
Results: Beyond the validation of the *PNPLA3* rs738409 variant as the main genetic driver of advanced liver disease ($p < 10^{-8}$), we highlighted a novel genome-wide significant protective association between the *MRC1* locus and FIB-4 (rs2461141 G > C, MAF = 0.462 $\beta = -0.071 \pm 0.012$, $p = 1.2 * 10^{-8}$). Replication in the UK Biobank (N > 400,000) validated *MRC1* locus as the leading hit for FIB-4 (rs56278466 G > T, MAF = 0.338, $R^2 = 0.52$, $D' = 0.98$, $\beta = -0.096 \pm 0.002$, $p = 8.45 * 10^{-559}$). MRC1 rs2461141 G > C variant associated with protection against ballooning in Milan Biobank (N = 430, $\beta = -0.09 \pm 0.04$, p = 0.030). eQTL analysis showed that rs2461141 G > C was associated with higher *MRC1* mRNA levels in immune cells (NES = 0.12; $p = 2.37 * 10^{-5}$) and within the liver ($\beta = 0.18 \pm 0.07$, p = 0.014). Vice versa, In an integrated, publicly available transcriptomic cohort composed of 341 MASLD patients, *MRC1* mRNA was down-regulated in MASH (p = 0.016, N = 14 vs 111 controls), necroinflammation (p = 0.018, N = 63 vs 62 controls) fibrosis stage (p = 0.044, F0 = 130; F1 = 82; F2 = 58; F3 = 55; F4 = 15) and hepatocellular ballooning (p = 0.007, N = 15 vs 110 controls). Paradoxically, despite lower FIB-4, in UKBB *MRC1* rs56278466 G > T was independently associated with an increased risk of HCC (OR[95% C.I.] = 1.19[1.04;1.36], p = 0.015), together with an increased risk of cancer of hepatic bile duct (OR[95%

C.I.] = 1.11[1.01;1.21], p = 0.023) and of gallbladder (OR[95% C.I.] = 1.17 [1.04;1.33], p = 0.009).
Conclusion: We identified *MRC1* as a novel FIB-4 susceptibility locus. Integrating genetic data with non-invasive biomarkers may contribute to enhancing risk stratification and precision medicine approaches for liver disease.

WED-369

Transforming growth factor-β signaling at the SMAD3 linker region promotes cancer cell plasticity and immunosuppression in hepatocellular carcinoma

Gregor Ortmayr[1], Theresa Hillinger[1], Hana Badlah[1], Pia Schuler[1], Goncalo Oliveira[2], Patrick Starlinger[3], Thomas Grünberger[4], Wolfgang Mikulits[1]. *[1]Medical University of Vienna, Vienna, Austria; [2]Czech Academy of Sciences, Prague, Czech Republic; [3]Mayo Clinic, Rochester, United States; [4]Clinic Favoriten, HPB Center, Health Network Vienna and Sigmund Freud Private University, Vienna, Austria*
Email: wolfgang.mikulits@meduniwien.ac.at

Background and aims: Hepatocellular carcinoma (HCC) is a challenging global health concern with increasing incidence. Systemic first-line therapy at advanced HCC stages includes treatment with immune checkpoint inhibitors (ICIs) in combination with anti-VEGF treatment. However, effective anti-tumor responses are achieved only in a minor subset of HCC patients due to immune evasion. We recently reported the molecular collaboration of transforming growth factor (TGF)-β and Gas6/AXL signaling driving an aggressive HCC phenotype linked to epithelial to mesenchymal transition (EMT). In particular, the aberrant phosphorylation of the SMAD3 linker region (SMAD3L) at serine 213 (pSMAD3L-Ser213) might modulate the tumor microenvironment (TME). As underlying mechanisms are an open issue, we aimed to assess how Smad3L-Ser213 signatures shape an immuno-suppressive TME.
Method: TGF-β/SMAD3L phosphorylation was analyzed by immunohistochemistry (IHC) in HCC patient samples. Substitution of pSMAD3L-Ser213 to mutant Smad3L-Ala213 was performed by CRISPR/Cas9 prime editing. Targets of AXL/TGF-β signaling were identified by RNA-seq analysis and VENN relations. Hypoxic niche factors and immune cell subsets were studied by multiplex IHC in HCC patient tissues.
Results: We addressed aberrant TGF-β/SMAD3L phosphorylation in HCC patients and identified pSMAD3L-Ser213 rather than pSMAD3L-Ser204/Ser208 as a predictor of poor survival. Substitution of pSMAD3L-Ser213 to mutant SMAD3L-Ala213 by prime editing and transcriptome profiling in HCC cells resulted in gene signatures correlating with a switch from EMT to partial EMT, immune response and better prognosis of patient's survival. Notably, we identified uridine phosphorylase 1 (UPP1) as a target of AXL/TGF-β, linking this signaling axis to metabolic adaptation under glucose restriction and hypoxia. Furthermore, spatial analysis of human HCC patient samples revealed that aberrant pSMAD3L-Ser213 and UPP1 co-localize with exhausted T cells and M2-polarized macrophages in hypoxic niches.
Conclusion: These data suggest that TGF-β/SMAD3L-Ser213 signaling is a critical determinant of the immunosuppressive TME, involving EMT. UPP1 represents a target of TGF-β/SMAD3 signaling, allowing metabolic adaption of HCC cells. Intervention with UPP1 together with ICI is considered as an auspicious strategy to combat HCC.

WED-370

DCLK1-positive tumor cells are associated with immune microenvironment in hepatocellular carcinoma: preliminary insights from a proof-of-concept study

Lorenzo Nevi[1], Maite G Fernandez-Barrena[2,3,4], Paolo Gallo[5], Veronic Gatti[6], Gianluca Masciana[7], Francesca Molinaro[1], Chiara Aiello[1], Tommaso Forcina[1], Chiara Taffon[8,9], Marco Caricato[7], Mario Cioce[6], Andrea Baiocchini[10], Umberto Vespasiani-Gentilucci[5], Matías A Avila[2,3,4], Simone Carotti[1,11]. *[1]Microscopic and Ultrastructural Anatomy Research Unit, Department of Medicine and Surgery, Università Campus Bio-Medico di Roma, Rome, Italy; [2]Solid Tumor Program, Hepatology Laboratory, Applied Medical Research Center (CIMA), University of Navarra, Pamplona, Spain; [3]Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas, Madrid, Spain; [4]Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain; [5]Operative Research Unit of Clinical Medicine and Hepatology, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy; [6]Department of Medicine, Laboratory of Molecular Medicine and Biotechnology, Università Campus Bio-Medico di Roma, Rome, Italy; [7]UOC Chirurgia Colorettale, Fondazione Policlinico Universitario Campus Bio-Medico di Roma, Rome, Italy; [8]Department of Medicine and Surgery, Research Unit of Anatomical Pathology, Università Campus Bio-Medico di Roma, Rome, Italy; [9]Anatomical Pathology Operative Research Unit, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy; [10]UOC Anatomia Patologica, Ospedale San Camillo Forlanini, Rome, Italy; [11]Predictive Molecular Diagnostics, Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy*
Email: lorenzonevi@hotmail.it

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality. Doublecortin-like kinase 1 (DCLK1) is a putative stem cell marker and a driver of tumor progression. Immune checkpoint inhibitors targeting the PD-1/PD-L1 axis have become a cornerstone of tumor treatment, but response heterogeneity requires novel targets. This study characterizes the spatial relationship between DCLK1+ tumor cells and immune subsets, assessing how PD-1 blockade impacts this landscape in a murine model.
Method: Orthotopic HCC model was performed in C57BL/6J mice by partial hepatectomy and intrahepatic injection of PM299L cells. Mice were treated with anti-PD-1 monoclonal antibody (intraperitoneal injection, twice weekly for 4 weeks) or a control solution (0.5% Methylcellulose, 0.1% Tween-80, human IgG isotype). DCLK1 expression and T cell subsets (CD3, CD4, CD8, FOXP3) were assessed by immunohistochemistry and immunofluorescence. To support preclinical data, 10 human HCC (hHCC) samples arising from metabolic dysfunction–associated steatotic liver disease were analyzed for the spatial proximity of DCLK1+ cells with inflammatory cell populations. hHCC-derived organoids were generated to assess DCLK1 distribution and characteristics.
Results: In mice, PD-1 blockade was associated with a significant remodeling of the immune tumor microenvironment (TME). Anti-PD-1 treated mice exhibited a marked increase in CD3+ cells ($p < 0.001$) compared to controls. This infiltration was characterized by the expansion of CD4+ ($p < 0.001$) and FOXP3+ cells ($p < 0.01$), indicating a complex immunomodulatory response. Quantitative analysis revealed a significant reduction in the DCLK1+ tumor area fraction ($p < 0.01$) in treated mice, suggesting a decrease in the burden of DCLK1-expressing cells following checkpoint blockade. Analysis of hHCC tissues demonstrated a distinct spatial architecture where DCLK1+ tumor cells were frequently located in close proximity to inflammatory infiltrates. Finally, in hHCC-derived organoids, DCLK1 expression was preferentially localized in the central core, identifying a cell subpopulation with putative undifferentiated/stem-like features.
Conclusion: In mice, targeting the PD-1 axis significantly alters TME composition, concurrently reducing the burden of DCLK1+ cells. Preliminary data from this study indicate that DCLK1+ tumor cells spatially cluster with specific immune subsets in hHCC. These findings position DCLK1 as a potential player in the immune-oncological landscape of HCC.

WED-371

PIVKAHigh VEGF-DHigh advanced hepatocellular carcinoma patients showed Aryl hydrocarbon receptor-dependent metabolic rewiring and immune exhaustion with poor outcomes post stereotactic body radiation therapy

Prabhjyoti Pahwa[1], Deepti Sharma[2], Pushpa Yadav[1], Sherin Thomas[3], Gayantika Verma[1], Gayatri Ramakrishna[1], Jaswinder Maras[1], Shiv Kumar Sarin[4], Nirupma Trehanpati[1]. [1]*Department of Molecular and Cellular Medicine, Institute of Liver and Biliary Sciences, New Delhi, India;* [2]*Department of Radiation Oncology, Institute of Liver and Biliary Sciences, New Delhi, India;* [3]*Department of Biochemistry, Institute of Liver and Biliary Sciences, New Delhi, India;* [4]*Department of Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India*
Email: trehanpati@gmail.com

Background and aims: Stereotactic body radiotherapy (SBRT) is an effective locoregional therapy for advanced hepatocellular carcinoma (aHCC), however, treatment efficacy remains unpredictable. A key determinant of treatment efficacy or anti-tumor immunity is immunometabolic reprogramming. Elevated levels of protein induced by vitamin K absence-II (PIVKA-II) and VEGF-D have poor prognosis in aHCC patients, but their impact on immune and metabolic responses is unclear. Therefore, we aimed to observe immunometabolic signatures influenced by PIVKA-II levels in aHCC patients treated with SBRT.
Method: PIVKA-II^{Low} VEGF-D^{Low} (PIVF-D^{Lo}; 711.1 ± 914.0 mAU/mL, 106.90 ± 53.8 pg/ml) and PIVKA-II^{High} VEGF-D^{High} (PIVF-D^{Hi} 91,491.16 ± 126,975.1 mAU/mL, 177.56 ± 123.59 pg/ml) aHCC patients (n = 30, age = 62 ± 9 years) were subjected to untargeted plasma metabolomics and immune checkpoint inhibitor expression on T cells at D0 (before SBRT), D5 (last day of SBRT), and D30 (30 days post-SBRT).
Results: In PIVF-D^{Lo} patients, overall survival/progression free survival was 27.7/22 months compared to 12.3/6 months in PIVF-D^{Hi}. PIVF-D^{Hi} patients showed persistently low glycolysis metabolites but enriched lipid metabolism and kynurenine-tryptophan metabolites (Acetyl-L-carnitine, 3-Amino-3-(4-hydroxyphenyl), 3-Hydroxykynurenine and 3-Indolepropionicacid) associated with Ahr activation at D0 through D30. Further, PIVF-D^{Hi} patients showed increased expression of LAG-3 (Lymphocyte Activation Gene 3, $p = 0.0183$) and TIGIT (T-cell immunoreceptor with immunoglobulin and ITIM domains, $p = 0.001$) on CD3^{+}T cells depicting T-cell exhaustion. However, PIVF-D^{Lo} patients had low LAG-3 ($p = 0.0154$) expression at baseline with enriched bile acid and OXPHOS associated metabolites (Glycolithocholate, 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid, S-Succinyldihydrolipoamide).
Conclusion: SBRT improves overall survival and progression free survival in PIVF-D^{Lo} patients by inducing immunometabolic reprogramming towards OXPHOS. In PIVF-D^{Hi} patients, a shift toward lipid-dependent metabolism with reduced glycolysis activates the Aryl hydrocarbon receptor, driving persistent immune checkpoint expression and T-cell exhaustion. Our data provides a strong rationale for combining SBRT with anti-TIGIT/LAG-3 immune checkpoint inhibitors to improve progression-free survival in advanced HCC.

WED-372

Baseline CD69 expressing T cells in peripheral blood associate with response to atezolizumab plus bevacizumab in hepatocellular carcinoma

Min Seo Park[1], Ji Won Han[1,2], Kwon Yong Tak[1,2], Jeong Won Jang[1,2], Hee Sun Cho[1,2], Pil Soo Sung[1,2]. [1]*The Catholic University Liver Research Center, Department of Biomedicine and Health Sciences, College of Medicine, The Catholic University of Korea, Seoul, Korea., Seoul, Korea, Rep. of South;* [2]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea., Seoul, Korea, Rep. of South*
Email: pssung@catholic.ac.kr

Background and aims: Atezolizumab plus bevacizumab (ATE/BEV) is a first-line therapy for advanced hepatocellular carcinoma (HCC), but objective responses occur in only 30–35%. CD69 marks activated/tissue-primed T cells. We asked whether baseline peripheral CD69+ T cell phenotypes predict response to ATE/BEV.
Method: Peripheral blood mononuclear cells (PBMCs) were collected before ATE/BEV (total n = 20; responders (R) n = 11, non-responders (NR) n = 9). Single-cell RNA sequencing (scRNA-seq) profiled baseline immune cells, and multiparameter flow cytometry validated CD69+ T cell subsets and co-expression of CD39, chemokine receptors (CXC chemokine receptor 4 (CXCR4), CXC chemokine receptor 3 (CXCR3), CX3C chemokine receptor 1 (CX3CR1), CXC chemokine receptor 6 (CXCR6)) and checkpoints (programmed cell death protein 1 (PD-1), TIGIT, and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4)). Response was defined by mRECIST at 3 weeks. Statistics: T-tests, two-sided $p < 0.05$.
Results: scRNA-seq showed higher CD69 expression in CD8 and CD4 T cells in R versus NR. Flow cytometry confirmed increased CD69+ T cell frequencies in R, most prominently within CD8 T cells. CD69+ CD39- CD8 T cells were enriched in R, whereas CD69- CD39+ CD8 T cells predominated in NR. CD69+ CD8 T cells co-expressing CXCR4, CXCR3, CX3CR1 or CXCR6 were generally more frequent in R, suggesting distinct baseline trafficking profiles. Checkpoint profiling showed higher PD-1+ CD69+ CD8 T cells in R and different distributions of TIGIT+ CD69+ and CTLA-4+ CD69+ subsets. Stratification by CD38 showed enrichment of both CD38- CD69+ and CD38+ CD69+ CD8 T cells in R, while CD38+ CD69- CD8 T cells were more abundant in NR.
Conclusion: Baseline peripheral CD69+ CD8 T cell states differ between responders and non-responders to ATE/BEV in HCC. CD69 defined CD8 subsets, including CD69+ CD39- and trafficking/checkpoint-associated populations, may support immune stratification and biomarker development.

WED-377

EZH2 leads liver sex-dimorphism in HCC development and progression

Vincenzo Alfano[1], Alexia Paturel[2], Giulia Canarutto[3], Massimiliano Cocca[1], Valerio Iebba[4], Alice Deshayes[5], Jennifer Rieusset[6], Francesca De Nicola[7], Jamila Faivre[5], Silvano Piazza[3], Massimo Levrero[1], Claude Caron de Fromentel[1], Francesca Guerrieri[5]. [1]*Lyon Hepatology Institute U1350 Inserm, Lyon, France;* [2]*Catholic University-Ucly, Lyon, France;* [3]*Icgeb, Trieste, Italy;* [4]*University of Trieste, Medical Sciences, TRIESTE;* [5]*Hôpital Paul-Brousse, Villejuif, France;* [6]*Carmen laboratory/U1060 Inserm, Lyon, France;* [7]*Instituto Nazionale Tumori Regina Elena, Rome, Italy*
Email: francesca.guerrieri@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC), the most frequent primary malignancy of the liver, is among the leading causes of cancer-related death worldwide. It has been reported that epigenetics, and in particular the trimethyl-transferase EZH2, plays an important role in liver oncogenesis and gut microbiome changes in HCC patients, but the relationship between them over the course of carcinogenesis is not clear. Finally, epidemiological reports indicate that the incidence of HBV-related HCC is higher in males, but the cause underlie this notion is largely unknown. Aim: The interplay between the trimethyl-transferase EZH2 and the microbiome in the hepatocarcinogenesis of X/Myc mice model.
Method: WT and X/Myc double transgenic mice, expressing in the liver both HBV HBx under control of viral regulatory elements and c-myc, were characterized by RNA-seq (Illumina) and spatial transcriptomics (GeoMx DSP Nanostring). 16s rRNA of mice stools was sequenced by Miseq Illumina platform at 10 and over 20 months, during liver carcinogenesis and at the development of HCC respectively.
Results: By using an HCC mouse model we observed a different transcriptome and gut microbiome according to the sex and along the

hepatocarcinogenesis. Thus, by GeoMx DSP we depicted a major role of EZH2 in male liver zonation during the preneoplastic phases and by Chip-seq we revealed a male specific non-canonical mechanism that implicates EZH2 in the modulation of the TCA/OXPHOS genes. Then, we found that at the first state of cell dysplasia the male microbiome, enriched in Gram – with the respect to female's bacteria, stimulates liver EZH2 that in turns contributes to increase mitochondrial fitness. This male-related mechanism highlighting the strong connection between liver epigenetic program and gut microbiome during the liver disease progression according to sex. As a strong confirmation, the in vivo EZH2 selective degradation with PROTAC MS177 had a significant effect on tumor growth exclusively in male mice.

Conclusion: We found that X/MYC females and males mice developed a different liver tumor (time and transcriptomic profile) and that they exhibited a specific transcriptomic/microbiota profile depending on the sex. Our findings expand the current understanding of how gut-liver axis contributes to liver carcinogenesis by controlling histones tri-methylation and mitochondrial activity and how all this pathway is sex-dependent.

WED-378

Sorpresa-HCC: a multicenter study on the changing epidemiology of HCC in cirrhosis

Email: tsarcina@unisa.it

Background and aims: Hepatocellular carcinoma (HCC) accounts for more than 90% of primary liver malignancies and is the second leading cause of cancer-related death worldwide. As cirrhosis—the main risk factor for HCC—has undergone major epidemiological changes in recent years, updated data on the clinical presentation of HCC in cirrhotic patients are needed.

To provide an updated overview of the epidemiology of newly diagnosed HCC and to assess the impact of major risk factors on its occurrence.

Method: In this prospective, multicenter study enrolled 1,195 patients with cirrhosis from 11 tertiary hepatology centers across Italy. Patients included those with a new diagnosis of cirrhosis or first referral to participating centers in 2024. Demographic, etiological, clinical, and laboratory data were collected at enrollment, including HCC diagnosis. Individual risk factors were analyzed using a multivariate logistic regression was assess to identify independent predictors of HCC.

Results: Among 1,195 enrolled patients (mean age 64 ± 11.6 years; 73% male), 232 had ALD, 345 MASLD, 80 MetALD, 246 HCV infection, 159 HBV infection, 72 autoimmune liver disease, and 63 other causes. 271 (22.7%) were diagnosed with HCC; 128 (47.2%) had a simultaneous first diagnosis of cirrhosis and HCC. Viral etiologies were the most frequent overall (40.6%), while MASLD was the predominant single etiology among patients with simultaneous cirrhosis and HCC (28.9%). HCC patients showed higher rates of HBsAg positivity (18.1%), HCV-RNA positivity (16.2%), and HCV-Ab positivity despite viral eradication (19.6%) compared with non-HCC patients. The high prevalence, among HCC patients, of HCV-Ab positive/HCV-RNA negative subjects supports the persistence of HCC risk even after viral eradication. On multivariate analysis, age, male sex, HCV infection (past or active), HBsAg positivity, and obesity were independently associated with HCC. Most HCC cases (55.7%) were diagnosed in Child-Pugh class A.

Conclusion: Despite the success of HBV vaccination, nucleos(t)ide analogue therapy, and curative DAA treatments for HCV, viral etiologies remain the main independent risk factor of HCC in cirrhotic patients even if the prevalence of MASLD among patients with simultaneous cirrhosis and HCC at first diagnosis seems growing overtime. The significant prevalence of HCC on cirrhosis at first diagnosis strongly reinforces the need of a careful clinical evaluation, case finding in the risk populations and surveillance in patients with cirrhosis.

WED-379

Oncostatin M modulates tumor-stroma interactions and promotes intrahepatic cholangiocarcinoma progression via JAK/STAT signaling

Nunzia Porro[1], Jessica Nurcis[2], Silvia De Siervi[3], Cristian Turato[3], Massimiliano Cadamuro[4], Maurizio Parola[2], Luca Fabris[5], Mirella Pastore[1], Gianluca Mattei[6], Alberto Magi[6], Krista Rombouts[7], Stefania Cannito[2], Fabio Marra[1], Alessandra Gentilini[1]. *[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [2]Unit of Experimental Medicine and Clinical Pathology, Department of Clinical and Biological Sciences, University of Turin, Turin, Italy; [3]Department of Molecular Medicine, University of Pavia, Pavia, Italy; [4]Department of Medicine and Surgery, University of Milano-Bicocca, Milan, Italy; [5]Department of Medicine, School of Medicine, University-Hospital of Padua, Padua, Italy; [6]Department of Information Engineering, University of Florence, Florence, Italy; [7]Regenerative Medicine and Fibrosis Group, Institute for Liver and Digestive Health, University College London, Royal Free Campus, London, United Kingdom*
Email: nunzia.porro@unifi.it

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is a highly aggressive and chemoresistant malignancy with poor prognosis. Emerging evidence indicates that oncostatin M (OSM) contributes to tumor progression by shaping the tumor microenvironment (TME) toward a pro-tumorigenic and immunosuppressive phenotype. This study aimed to investigate the role of OSM in iCCA biology and tumor-stroma interactions.

Method: Expression of OSM and its receptors was analyzed in human iCCA tissues by immunohistochemistry and RT-PCR. Two human iCCA cell lines (HuCCT-1, CCLP-1), primary iCCA cells, patient-derived organoids (PDOs), and the murine SB1 iCCA cell line were used. Cancer-associated fibroblasts (CAFs) and THP-1-derived macrophages were included as stromal components. Cell motility was assessed by chemotaxis and invasion assays. Protein expression was

evaluated by Western blotting and immunofluorescence. OSMR and gp130 were silenced using siRNA, and stable OSMR knockdown was generated in the murine iCCA cell line using shRNA. CAFs and macrophages were exposed to conditioned media (CM) from OSM-treated iCCA cells. RNA sequencing was performed on iCCA cells cultured on 3D matrix scaffolds and treated with OSM and the JAK1/2 inhibitor ruxolitinib.
Results: OSM and OSMR were overexpressed in human iCCA tissues compared to adjoining non-tumoral tissue, and were expressed in primary iCCA cells, PDOs, iCCA cell lines, and the murine SB1 cell line. OSM increased iCCA cell migration and invasion in iCCA cells. This effect was accompanied by cytoskeletal rearrangement and induction of epithelial-to-mesenchymal transition (EMT). OSM-induced motility was reduced by silencing the OSMR or gp130 and by pharmacological JAK1/2 inhibition. In iCCA PDOs, OSM induced marked EMT-associated phenotypic changes, which were effectively reverted by ruxolitinib. Transcriptomic analysis of OSM-stimulated iCCA cells revealed a JAK-dependent up-regulation of mesenchymal gene signatures and down-regulation of immune-related pathways, together with a JAK-independent activation of Wnt signaling. CM from OSM-treated iCCA cells enhanced CAF migration and promoted M2-like macrophage polarization.
Conclusion: The OSM/OSMR axis is a novel pro-tumorigenic system implicated in cholangiocarcinogenesis, with direct effects on tumor cell biology and modulation of the TME, highlighting its potential therapeutic relevance.

WED-380
Single-cell transcriptomic profiling of endothelial-to-mesenchymal transition in MASLD-associated liver carcinogenesis

Background and aims: MASLD is becoming the main risk for hepatocellular carcinoma (HCC). HCC is a highly vascularized tumor in which endothelial cells play a critical role in its initiation and progression, including in MASLD. Endothelial-to-mesenchymal transition (EndMT) is the process by which endothelial cells progressively lose their specific characteristics and acquire mesenchymal properties. While this phenomenon is extensively studied in cardiovascular and pulmonary diseases, it remains poorly explored in chronic liver disease and HCC. In this study, we aimed to investigate the dynamics of EndMT and decipher its potential contribution to MASLD-related HCC.
Method: Primary human liver endothelial cells (LEC) were immunomagnetically [CD146+] isolated from fresh liver tissue of MASLD patients with varying stages of steatosis, activity and fibrosis. Single-cell suspensions of LEC from HCC (n = 5) and non-tumoral liver (n = 14) were processed for single-cell RNA sequencing (scRNA-seq). In addition to a standard clustering process, independent component analysis was applied to the transcriptomic data to identify sub-phenotypes and their associated genes, defined by the top-contributing genes of each independent component. The identified signatures were subsequently projected onto independent open-access public scRNA-seq datasets to validate LEC subpopulations.
Results: scRNA-seq identified four distinct LEC populations organized along a differentiation continuum from liver sinusoidal endothelial cells (LSEC) to fibroblastic phenotypes. Based on gene expression profiling, these populations corresponded to 1- healthy LSEC (LSEC with neither capillarization nor EndMT, expressing *STAB-2, LYVE-1*), 2- capillarized LSEC (expressing *VWF, PECAM1*), 3-transitional LEC undergoing EndMT (expressing *FN1, VIM*), and 4- LEC with mesenchymal phenotype that fully completed transition (expressing *ACTA2, PDGFR-β*). Transitional LEC were enriched in cirrhosis and HCC samples, whereas mesenchymal LEC included HCC and MASLD-associated tissues, supporting a role for EndMT in HCC progression.
Conclusion: By illustrating the high plasticity of human LEC, this study supports the central role of LEC in HCC and highlights for the first time that EndMT occurs during MASLD-related liver carcinogenesis. By categorizing LEC into distinct subpopulations, we were able to pinpoint stage-specific markers of the EndMT process. Further analyses will determine whether EndMT could be reversed and targeted as a therapeutic strategy for HCC.

EEF1E1 drives immune evasion and tumor progression in hepatocellular carcinoma by sustaining EGFR signaling
Liying Ren[1], Dongbo Chen[1], Hongsong Chen[2]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Infectious Disease and Hepatology Center of Peking University People's Hospital, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, Beijing, China, Beijing, China;* [2]*Peking University People's Hospital, Peking University Hepatology Institute, Infectious Disease and Hepatology Center of Peking University People's Hospital, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, Beijing, China, Peking University Third Hospital, Beijing, China, Berijing, China*
Email: renliying.med@outlook.com

Background and aims: Despite the recent advances of immune checkpoint inhibitors, the clinical benefit in hepatocellular carcinoma (HCC) remains limited. Therefore, robust and clinically actionable biomarkers are urgently needed to identify patients most likely to respond to immunotherapy and to guide rational combination strategies. In our previous research, we identified EEF1E1 as a gene associated with HCC recurrence; however, its role within the tumor immune microenvironment (TIME) of HCC has not been elucidated.
Method: *EEF1E1* expression and its prognostic significance in HCC were assessed using an immunohistochemistry tissue microarray (n = 141), RNA-seq and spatial transcriptomics analysis. Pro-tumor effects were tested by gain/loss-of-function assays *in vitro* and *in vivo*, including an orthotopic tumor model. The impact on the TIME was profiled by single-cell RNA sequencing and multiparameter flow cytometry. EEF1E1-EGFR interaction was examined by co-immunoprecipitation and related signaling assays.
Results: *EEF1E1* was markedly upregulated in HCC tissues and served as an independent risk factor in HCC patients. *EEF1E1* promoted invasion and migration and epithelial-mesenchymal transition (EMT) *in vitro* and *in vivo*, and reshaped the TIME toward an immunosuppressive phenotype characterized by increased infiltration of PD-1$^+$ CD8$^+$ T cells. Further analyses showed that EEF1E1 interacted with epidermal growth factor receptor (EGFR) in protein level, impaired its endosomal-lysosomal degradation, and thereby promoted EGFR accumulation and sustained activation of EGFR-STAT signaling. Consistent with this mechanism, the EGFR inhibitor osimertinib reduced PD-1$^+$ CD8$^+$ T-cell infiltration. In combination with anti–PD-1 mAb, it produced superior antitumor effects compared with either monotherapy, Moreover, with tumors exhibiting high EEF1E1 expression deriving the optimal benefit from the combination therapy.

Conclusion: EEF1E1 drives aggressive biology and immune evasion in HCC by sustaining EGFR signaling, and may serve as a prognostic and predictive biomarker to guide combined PD-1 and EGFR blockade.

Cabozantinib reshapes the immune landscape of hepatocellular carcinoma through mitochondrial cGAS-STING signaling

Patricia Rider[1], Anna Tutusaus[1], Carlos Cuño-Gómiz[1], Flavia Savino[1], Aida Marsal[2], Neus Llarch[2], Gemma Iserte[2], Anna Colell[3], Pablo Garcia de Frutos[4], Tania Hernáez-Alsina[5], Marco Sanduzzi Zamparelli[2], Montserrat Marí[1], María Reig[6], Albert Morales[1]. *[1]IIBB-CSIC/IDIBAPS, CIBEREHD, BCLC, Barcelona, Spain; [2]IDIBAPS, CIBEREHD, BCLC, Hospital Clínic, Barcelona, Spain; [3]IIBB-CSIC/IDIBAPS, CIBERNED, Barcelona, Spain; [4]IIBB-CSIC/IDIBAPS, Barcelona, Spain; [5]Hospital Universitario San Pedro, Rioja Salud, Logroño, Spain; [6]IDIBAPS, CIBEREHD, BCLC, Hospital Clinic, Barcelona University (UB), Barcelona, Spain*
Email: amorales@clinic.cat

Background and aims: Despite recent advances in systemic therapies for hepatocellular carcinoma (HCC), predictive biomarkers and rational combination strategies remain limited. Activation of innate immune pathways such as cGAS-STING has emerged as a promising approach to enhance antitumor immunity. Identifying approved therapies that can engage this pathway through tumor-intrinsic stress responses is therefore of high translational relevance. Although cabozantinib improves outcomes, its ability to induce immunogenic mitochondrial stress and activate cGAS-STING-dependent immune signaling remains unexplored.
Method: Mitochondrial depolarization, reactive oxygen species production, and the release of immunogenic damage-associated molecular patterns (DAMPs), including mitochondrial DNA (mtDNA), HMGB1 and ATP, were assessed in conjunction with cGAS-STING pathway activation and type I interferon-stimulated gene (ISG) expression in hepatoma and macrophage models. Functional relevance was evaluated using mtDNA depletion and CRISPR-mediated STING knockdown. In vivo efficacy of cabozantinib alone or combined with the STING agonist DMXAA was tested in immunocompetent murine HCC models. Translational relevance was explored through multiplex serum proteomic profiling in two independent small cohorts of cabozantinib-treated HCC patients.
Results: Cabozantinib triggered mitochondrial stress in hepatoma cells, evidenced by loss of mitochondrial membrane potential, oxidative stress, and cytosolic leakage of mtDNA, accompanied by HMGB1 and ATP release. This immunogenic stress triggered robust ISG induction and cGAS-STING-dependent signaling, which was abrogated by mtDNA or STING depletion. In immunocompetent mouse models, cabozantinib reduced tumor growth and increased activation of tumor-infiltrating lymphocytes, effects further increased by DMXAA. Serum proteomic analysis from cabozantinib-treated patients revealed immune activation (e.g., GrzmB, HO-1, CAIX, CXCL13) and reduced angiogenic and immunosuppressive factors (e.g., VEGFR-2, ANGPT1/2, CCL17), consistent with preclinical results and associated with clinic outcome.
Conclusion: Cabozantinib exerts an immunomodulatory role in HCC through mitochondrial stress-dependent activation of the cGAS-STING pathway, reshaping the tumor immune microenvironment. These findings support rationale combination with STING-targeted strategies and the development of immune-related biomarkers to optimize treatment and stratify TKI-treated patients.

Liquid biopsy evaluation of KDM2A and NOTCH3 in hepatocellular carcinoma

Francesca Salani[1], Teresita Caruso[1], Federico Pratesi[1], Silvia Cesario[1], Irene De Giorgi[1], Maria Concetta Scavuzzo[1], Virginia Genovesi[1], Caterina Vivaldi[1], Piero Colombatto[2], Maurizia Brunetto[1], Gabriella Cavallini[1], Gianluca Masi[1], Vinicio Carloni[3], Laura Gragnani[1]. *[1]University of Pisa, Pisa, Italy; [2]Azienda Ospedaliero Universitaria Pisana, Pisa, Italy; [3]University of Florence, Firenze, Italy*
Email: laura.gragnani@unipi.it

Background and aims: The histone demethylase KDM2A is involved in transcriptional regulation and tumorigenesis. We previously identified, in hepatocellular carcinoma (HCC), a role for KDM2A in immune modulation and suggested a KDM2A–*Notch3* transcriptional axis. Although epigenetic factors are emerging as prognostic and diagnostic tools, their relevance as circulating biomarkers remains largely unexplored. This study aimed to investigate KDM2A and NOTCH3 levels in liquid biopsies from HCC patients and their association with clinical features.
Method: Exosomes were isolated from serum samples obtained from patients with advanced HCC (n = 18) using a commercial kit. HCC patients received either Atezolizumab/Bevacizumab (Atezo/Beva) or the STRIDE regimen. Exosomal KDM2A and Notch3 cargo was evaluated: mRNA level was quantified by RT-qPCR and normalized to a pool of healthy subjects (n = 9, HS); proteins were detected by Western Blot analysis. Circulating free KDM2A and NOTCH3 protein levels were measured using commercial ELISA kits in plasma samples from 20 HCC patients and 13 HS.
Results: Exosomal KDM2A mRNA levels were significantly higher in HCC patients compared with HS ($p < 0.01$). KDM2A levels significantly discriminated viral from non-viral HCC etiologies ($p = 0.036$; confirmed by the ROC curve: AUC = 0.818, $p = 0.007$). Longitudinal analysis revealed a significant reduction at cycle 5, compared with baseline ($p = 0.042$), with a median fold change of 0.20, showing a trend toward a greater decrease in the Atezo/Beva group vs STRIDE when stratified by treatment regimen. No KDM2A exosomal protein was detected in HCC and HS samples. Plasma free KDM2A protein levels were elevated in HCC patients compared to HS ($p = 0.047$). NOTCH3 protein (free and exosomal) and exosomal mRNA levels did not differ between HCCs and HS nor correlated with clinical features.
Conclusion: Free KDM2A and its exosomal-cargo mRNA are significantly increased in HCC vs HS. The exosomal mRNA discriminates viral from non-viral cancers, suggesting an etiology-dependent KDM2A modulation in HCC. Its significant reduction after therapy could have a potential utility for early treatment monitoring while the trend toward greater modulation after Atezo/Beva vs STRIDE may reflect a KDM2A role in angiogenesis in line with other tumor types (PMID 27029061). Exosomal and circulating Notch3-related molecules seem not suitable as peripheral biomarkers of HCC clinical features.

Transcriptomic reprogramming induced by zinc oxide nanoparticles in experimental hepatocellular carcinoma

Jorge Alejandro Salto-Sevilla[1,2], Scarlet Arceo-Orozco[1], Roberto Flores-Peña[1], Fernando Caloca Camarena[1], Rebeca Rosas-Campos[3], Marina Galicia Moreno[1], Edgar René López-Mena[4], Hugo Christian Monroy-Ramirez[1], Juan S. Armendáriz-Borunda[1,3]. *[1]Institute of Molecular Biology in Medicine and Gene Therapy, University Center for Health Sciences, University of Guadalajara, Guadalajara, Jalisco, Mexico; [2]Doctoral Program in Molecular Biology in Medicine, Department of Molecular Biology and Genomics, University Center for Health Sciences, University of Guadalajara, Guadalajara, Jalisco, Mexico; [3]Tecnologico de Monterrey, EMCS, Guadalajara, Jalisco, Mexico; [4]Tecnologico de Monterrey, Guadalajara, Jalisco, Mexico*
Email: jorge.salto4084@alumnos.udg.mx

Background and aims: Hepatocellular carcinoma (HCC) is linked to metabolic dysregulation, mitochondrial dysfunction, oxidative stress, and altered zinc homeostasis, all of which contribute to tumor progression and liver failure. Since zinc is crucial for redox balance and metabolic regulation, zinc oxide nanoparticles (ZnO-NPs) might enhance adaptive responses in HCC. However, their transcriptomic effects remain poorly understood.
Method: Male Wistar rats were randomly assigned to four groups (n = 6): control (CTL), receiving vehicle only; control treated with ZnO nanoparticles (CTL/ZnO-NPs; 50 mg/kg/week, oral); hepatocellular carcinoma (HCC), induced by diethylnitrosamine (DEN, 50 mg/kg/week, intraperitoneal) plus 2-acetylaminofluorene (2-AAF, 25 mg/kg/week, oral); and HCC treated with ZnO-NPs at the same doses. The experimental protocol lasted 18 weeks. Liver injury and fibrosis were evaluated by histology (H&E, Picrosirius Red, and immunohistochemistry). Molecular alterations were assessed by RNA sequencing (RNA-seq), Western blotting (NRF2, KEAP1), and dot blot analysis of global DNA methylation (5-meC). Serum ALT, GGT, and ALP levels, as well as hepatic GSH and MDA levels, were quantified. Data were analyzed using one-way ANOVA followed by Tukey's post hoc test ($p \leq 0.05$).
Results: ZnO-NPs treatment reduced liver injury, fibrosis, and HCC-associated markers (GPC-3 and alpha-fetoprotein), while maintaining liver structure. These effects were associated with decreased serum hepatic markers and reduced hepatic oxidative stress (as indicated by GSH and MDA), through a mechanism independent of NRF2. Transcriptomic analysis showed extensive remodeling, including activation of oxidative metabolism, mitochondrial biogenesis, antioxidant and DNA repair pathways, and suppression of multiple cancer-related signaling pathways (PPARs, FOXO, and mTOR). ZnO-NPs also induced transcriptomic upregulation of zinc transporters, including SLC39A2 and SLC39A4. Lastly, these molecular changes were associated with global DNA hypomethylation in HCC-associated liver tissue, as assessed by dot blot analysis.
Conclusion: ZnO-NPs induced coordinated transcriptomic reprogramming in HCC-associated liver tissue, restoring redox homeostasis and mitochondrial metabolic function while suppressing key oncogenic signaling pathways. This integrated molecular response is associated with reduced carcinogenic stress, improved hepatic integrity, and maintained liver function, supporting ZnO-NPs as a promising strategy in experimental HCC.

WED-385-YI
Galectin-3 inhibition supports HCC growth via pro-tumorigenic liver reprogramming

Paul Schneider[1], Frederic Speier[1], Felicia Schön[1], Laura Rosenberger[1], Maike Hartmann[1], Barbara Schroers[2], Shusruto Rishik[3], Andreas Keller[3], Jörn M. Schattenberg[4], Stephan Grabbe[1], Matthias Bros[1], Leonard Kaps[1,4]. *[1]University Medical Center Mainz, Mainz, Germany; [2]Tron, Mainz, Germany; [3]Helmholtz Istitute for Pharmacological Research, Saarbrücken, Germany; [4]Saarland University Medical Center, Homburg, Germany*
Email: leonard.kaps@uks.eu

Background and aims: Galectin-3 plays a central role in cell adhesion, macrophage polarization, and immune suppression in chronic liver inflammation. The oral Galectin-3 inhibitor Selvigaltin (GB1211) is currently under clinical evaluation for the treatment of liver fibrosis and has been considered safe for further clinical use (GULLIVER-2, NCT05009680). Given that liver fibrosis and cirrhosis represent key risk conditions for hepatocellular carcinoma (HCC), we investigated potentially altered HCC onset and progression risk following pharmacological Galectin-3 inhibition in a preclinical HCC model.
Method: Liver fibrosis was induced in C57BL/6JRj mice by repeated oral administration of carbon tetrachloride (CCl_4). Liver-specific tumors were established by subsequent intrasplenic injection of Dt81Hepa1-6 HCC cells. Beginning seven days after tumor induction, mice (n = 6 per group) received daily oral gavage of GB1211 (10 µg/kg) or vehicle control for 21 days. Tumor burden and immune cell composition were assessed on day 28 using histological analysis, flow cytometry, and RNA sequencing. On top Immunomodulatory effects of GB1211 were evaluated in primary murine immune cells.
Results: GB1211 treatment significantly reduced hepatic fibrosis, as evidenced by decreased collagen deposition and portal bridging (−42%; $p < 0.05$). However, despite its anti-fibrotic efficacy, GB1211 significantly increased intrahepatic tumor burden, reflected by elevated liver weights (+84%; $p < 0.01$), increased serum alpha-fetoprotein levels, and higher frequencies of $EpCAM^+$ tumor cells ($p < 0.05$). Immune profiling revealed a profoundly immunosuppressive tumor microenvironment, characterized by enhanced T-cell exhaustion ($CD8^+$ $PD\text{-}1^+$), skewing toward anti-inflammatory M2-like macrophages ($F4/80^+$, $CD206^+$), and suppression of pro-inflammatory M1 polarization ($F480^+$, $iNOS^+$, $CD86^+$). Transcriptomic analysis confirmed anabolic reprogramming with activation of cell-cycle, biosynthetic, and pro-tumorigenic signaling pathways including deregulation of tumor growth-promoting genes (+Arg1, +Vegfa, +IL10, +Tgfb1, +αsma, -IL1b).
Conclusion: Despite its anti-fibrotic benefits, Galectin-3 inhibition with GB1211 accelerates HCC progression by fostering an immunosuppressive tumor microenvironment. These findings emphasize the necessity for careful tumor surveillance in patients undergoing Galectin-3 inhibiting therapies in order to safely exploit the potential of Selvigaltin for treatment of liver fibrosis.

WED-386
Soluble fibroblast activation protein drives a signal transducer and activator of transcription 3 feedback loop in hepatocellular carcinoma

Deok Hwa Seo[1], Jae Yong Ryu[2], Eui-Soo Han[3], Ho Joong Choi[3], Young Kyoung You[3], Kwon Yong Tak[4], Jeong Won Jang[5], Pil Soo Sung[5]. *[1]Department of Medical Sciences, Graduate School of The Catholic University of Korea, Seoul, Korea, Rep. of South; [2]Department of Systems Biomedical Science, Soongsil University, Seoul, Republic of Korea, Seoul, Korea, Rep. of South; [3]Department of Surgery, The Catholic University of Korea, Seoul, Republic of Korea., Seoul, Korea, Rep. of South; [4]Division of Gastroenterology and Hepatology, Department of Internal Medicine, College of Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea, Seoul, Korea, Rep. of South; [5]Department of Medical Sciences, Graduate School of The Catholic University of Korea, Republic of Korea, Division of Gastroenterology and Hepatology, Department of Internal Medicine, College of Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea, Seoul, Korea, Rep. of South*
Email: smin0904@naver.com

Background and aims: Cancer-associated fibroblasts (CAFs) shape the hepatocellular carcinoma (HCC) microenvironment. Fibroblast activation protein (FAP), enriched in matrix CAFs, exists as membrane-bound and soluble FAP (sFAP), but the contribution of sFAP to CAF activation is unclear. We aimed to define FAP-positive CAF subsets and test whether sFAP sustains CAF activation via signal transducer and activator of transcription 3 (STAT3) signaling.
Method: We analysed single-cell RNA sequencing from human HCC (n = 3; 62,417 cells) and validated findings in patient-derived CAF cultures (n = 50) and serum samples (HCC n = 110; non-HCC controls n = 50). FAP-high and FAP-low CAFs were isolated by fluorescence-activated cell sorting. CAFs were exposed to recombinant human FAP (200 ng/mL, 24 h) and treated with a FAP inhibitor (FAPI-34, 8 µM) or

FAP small interfering RNA. Phospho-STAT3 and platelet-derived growth factor receptor beta (PDGFRB) were measured. In vivo validation used the syngeneic Hepa1-6 model (vehicle n = 4; FAP inhibitor n = 4; 5 mg/kg intraperitoneally, every 2 days for 14 days).
Results: Five CAF clusters were identified; FAP was enriched in matrix CAFs (76% of matrix CAFs vs 24% of other CAFs). Tumour-derived CAFs expressed more FAP than non-tumour fibroblasts (2.7-fold, $p = 0.032$), and serum FAP was higher in HCC (median 356 vs 245 ng/mL, $p = 0.041$). FAP-high CAFs showed higher STAT3 (1.9-fold) and PDGFRB (2.6-fold) than FAP-low CAFs ($p = 0.01$). Recombinant FAP increased phospho-STAT3 by 65% and PDGFRB by 2.1-fold ($p = 0.004$), whereas FAP inhibition or knockdown reduced phospho-STAT3 by 58% and PDGFRB by 46% ($p = 0.006$). FAP inhibition decreased intratumoral FAP-positive cells (64% vs 31%, $p = 0.008$) and reduced tumour volume by 38% at day 14 ($p = 0.02$).
Conclusion: sFAP sustains CAF activation through a FAP-STAT3-PDGFRB positive feedback loop and contributes to tumour growth in HCC. Targeting FAP disrupts this stromal programme and represents a strategy to remodel the HCC microenvironment.

WED-387
A translational model bridging in vitro and in vivo macrophage phenotypes in orthotopic liver tumours

Email: blanca.simon@ub.edu

Background and aims: Liver cancer, the third leading cause of cancer-related death worldwide, is frequently associated with chronic hepatic inflammation. Tumour-associated macrophages (TAMs) represent a major immune population within the tumour microenvironment and contribute to tumour progression. In this study, we have characterized the transcriptional profile and phenotype of TAMs in murine models of liver cancer and in complementary *in vitro* macrophage models.
Method: Murine BNL liver cancer cells were injected into healthy and fibrotic BALB/c mouse livers (fibrosis was induced by i.p. injections of CCl_4 for 8 weeks). $CD11b^+$ macrophages were isolated from tumour (T) and non-tumour (NT) regions by magnetic cell sorting after 4 weeks of tumour growth. RNA was isolated and sequenced from T and NT macrophages from fibrotic mice. Expression of anti-inflammatory markers (ARG1, IL10, CD36) and TAM-associated genes (ferroportin-1, VEGF-A) was analysed by Real-time PCR. TAM *in vitro* models were generated and characterized using RAW macrophages co-cultured with BNL cancer cells or stimulated with BNL cell-conditioned medium.
Results: Liver tumours developed in 90% of fibrotic mice versus 50% of non-fibrotic mice, and were smaller in fibrotic animals. In fibrotic mice, TAMs from T regions showed significantly higher expression of anti-inflammatory genes and VEGF-A compared with NT regions (ARG1, 13.0 vs 5.7; IL10, 3.8 vs 1.0; CD36, 16.0 vs 1.8; VEGF-A, 4.4 vs 1.0; all $p < 0.5$). These differences between T and NT regions were absent in non-fibrotic mice. Ferroportin-1 expression was reduced in T-region TAMs in both fibrotic (0.9 vs 2.7, $p < 0.01$) and non-fibrotic mice (0.1 vs 1.2, $p < 0.05$). Accordingly, RNA sequencing revealed lower expression of ferroportin-1 in T macrophages compared with NT macrophages (−1.6 vs −0.5). *In vitro*, ferroportin-1 expression was also decreased in macrophages co-cultured with tumour cells compared with those exposed to conditioned medium (0.2 vs 2.1, $p < 0.0001$). Macrophages co-cultured with BNL cell-conditioned medium displayed increased cell area and perimeter matching with TAM phenotypes.
Conclusion: TAMs exhibit region-specific and fibrosis-dependent transcriptional programs in experimental liver cancer. Direct macrophage-tumour cell interaction drives an intra-tumoural TAM phenotype, whereas exposure to tumour secretome resembles extra-tumoural macrophages. These *in vitro* models provide a refined framework to study TAM biology.

Email: mireia.tenagaritaonaindia@bio-gipuzkoa.eus

Background and aims: Cholangiocarcinoma (CCA) is a heterogeneous group of biliary malignancies with a poor prognosis. Krüppel-like factors (KLF) are a family of highly conserved and widely expressed transcription factors involved in a multitude of physiological and pathological processes in humans, including cancer. Specifically, dysregulation of expression and/or activity of KLF15 has been reported in several types of cancers but its role in CCA remains unknown. Here, we investigated the role of KLF15 during cholangiocarcinogenesis and evaluated its potential as a prognostic and therapeutic tool.
Method: KLF15 expression was assessed in human CCA tissues from 10 independent patient cohorts, as well as in human CCA cell lines. KLF15-overexpressing CCA cells were generated through lentiviral transduction. Cells were subsequently characterized for proliferation, survival, tumorigenicity, invasiveness, and overall aggressiveness both *in vitro* and *in vivo*.
Results: KLF15 expression was downregulated in human CCA tissues across 10 independent patient cohorts, compared to surrounding normal liver tissue or normal bile ducts, independently on the tumor mutational background. Notably, reduced *KLF15* levels correlated with worse overall and recurrence-free survival, was associated with tumor dedifferentiation and negatively correlated with various oncogenic, stemness, and epithelial-to-mesenchymal transition (EMT) markers. Additionally, *KLF15* downregulation was associated with gene hypermethylation in enhancer regions near the promoter in human CCA tumors and *in vitro* treatment with hypomethylating agents (e.g., zebularine) restored *KLF15* expression. *In vitro*, KLF15 protein and mRNA levels were also reduced in human CCA cell lines compared to normal human cholangiocytes (NHC). At the functional level, KLF15 overexpression diminished cell viability, proliferation, tumorigenicity, migration, invasion, and mitochondrial metabolism, without affecting cell death. *In vivo*, KLF15-overexpressing CCA cells exhibited reduced tumor growth rates after subcutaneous injection into immunodeficient mice. Furthermore, intratumoral injection of

KLF15-containing lentivirus into pre-established subcutaneous CCA tumors inhibited tumor growth compared to controls.
Conclusion: KLF15 act as a tumor suppressor in CCA, suggesting its potential as a diagnostic and prognostic biomarker as well as therapeutic target.

Email: pedromiguel.rodriguesvieira@bio-gipuzkoa.eus

Background and aims: Cholangiocarcinoma (CCA) is a heterogeneous group of biliary tumors with poor prognosis and limited treatment options. Potentially curative options include surgical resection; however, recurrence rates remain high. Robust tissue biomarkers to predict patient prognosis after tumor resection are urgently needed. This study aimed to identify and validate prognostic tissue biomarkers by combining mRNA expression and clinical information into machine learning (ML) models.
Method: A literature review was conducted to identify potential CCA tissue prognostic biomarkers, further validated through Cox PH overall survival (OS) analysis in five transcriptomic cohorts. An international cohort including tumor tissue from 221 patients undergoing tumor resection was assembled, and mRNA expression was analyzed by high-throughput TaqMan OpenArray RT-qPCR. Feature association with recurrence-free survival (RFS) and OS were obtained by Cox PH analyses. Six ML models were trained and evaluated using nested cross-validation, followed by feature reduction. Shapley Additive exPlanations values were used for interpretability.
Results: Among 496 candidate biomarkers for CCA identified in the literature, 52 harbored prognostic value in the Cox PH analysis in transcriptomic cohorts. In the multicenter validation cohort, Cox PH analyses, integrating relevant clinical features and gene expression, revealed 11 genes significantly associated with RFS and 25 with OS. The 11 RFS-associated genes, combined with 5 clinical variables, were used to train six predictive ML models, where the random survival forest (RSF) model showed the highest predictive accuracy. After feature importance–based selection, a final model incorporating 3 genes -*FSCN1*, *LDHA*, and *SLC2A1*- and 4 clinical variables achieved a test AUC of 0.748. This model significantly stratified patients into 2-years recurrence risk groups. In addition, a model for OS prediction using the same feature set achieved a test AUC of 0.69 and significantly stratified patients into risk groups of 5-year OS risk. *SLC2A1* was the top predictor in both models.
Conclusion: We identified and validated a robust panel of prognostic tissue biomarkers in CCA patients undergoing surgery. Integration of these biomarkers with clinical variables into ML-based prognostic models enabled accurate prediction of patient RFS and OS. These models hold promise for improving postoperative risk stratification and guiding personalized surveillance and therapeutic strategies in CCA.

Coffee-derived compounds enhance chemo and immunotherapy responses in in vitro and in vivo models of hepatocellular carcinoma

Leticia Valente[1], Tian Tian[2], Guilherme Romualdo[1]. *[1]Experimental Research Unit (UNIPEX), Medical School, São Paulo State University (UNESP), Botucatu, Brazil; [2]Instituto Vall d'Hebron, Barcelona, Spain*
Email: leticia.cardoso-valente@unesp.br

Background and aims: Hepatocellular carcinoma (HCC) is associated with high mortality and limited therapeutic response. Strategies combining bioactive compounds with conventional therapies have been proposed to enhance antitumor efficacy. This study investigated whether coffee-derived compounds modulate the effects of sorafenib (SOR) or atezolizumab plus bevacizumab (ATZ+BVZ) in *in vitro* and *in vivo* models of HCC.
Method: HepG2/C3A HCC cells and LX2 hepatic stellate cells were co-cultured in transwell or spheroid systems. EC50 values were calculated for caffeine (CAF), trigonelline (TRI), chlorogenic acid (CGA), caffeic acid (CA), kahweol (KWL), SOR, ATZ and BVZ after 24 or 48h using MTT assay. Coffee-derived compounds were subsequently combined with SOR or ATZ+BVZ at sub-effective EC50 fractions (1/5 or 1/10), and the combinatory index was calculated. Compounds exhibiting synergistic effects were selected for further *in vitro* assays (migration, invasion, and colony formation) and *in vivo* xenograft model. BALB/c nude mice were implanted with HepG2/LX2 cells, and tumors were treated with therapies [SOR, intragastric administration (i.g.); ATZ+BVZ, intraperitoneal] and/or bioactive compounds (i.g.).
Results: CGA, CA, and TRI showed antagonistic interactions when combined with SOR or ATZ+BVZ. In contrast, CAF and KWL enhanced the effects of SOR and ATZ+BVZ, exhibiting synergistic effects on the reduction of C3A/LX2 spheroid viability. CAF+KWL combination with chemo/immunotherapy further reduced colony formation and migration, and CAF+KWL combination with ATZ+BVZ also diminished tumor cell invasion. In the *in vivo* model, therapies did not modify SOR-induced reduction of tumor growth and number of VEGF-positive vessels by immunohistochemistry. Nonetheless, CAF or KWL combination with ATZ+BVZ had a pronounced effect on reducing tumor volume and weight compared to immunotherapy alone.
Conclusion: Findings indicate that CAF and KWL enhance the antitumor effects of chemo/immunotherapy in HCC, supporting the potential of coffee-derived compounds as adjuvant agents in treatment strategies.

WED-395-YI

Extracellular matrix remodeling and gender dimorphism in the progression of primary sclerosing cholangitis to cholangiocarcinoma

Camilla Venturin[1,2], Massimiliano Cadamuro[3], Romina Fiorotto[2], Lauren Malouin[2], Anna Palmiotti[2], Samantha Sarcognato[4], Matteo Fassan[1,4], Umberto Cillo[5,6], Enrico Gringeri[5,6], Claudia Mescoli[7], Paolo Simioni[1,8], Jesus Maria Banales[9], Mario Strazzabosco[2], Luca Fabris[1,2,8]. *[1]Department of Medicine (DIMED), University of Padua, Padua, Italy; [2]Department of Internal Medicine, Digestive Disease Section, Liver Center, Yale University, New Haven, United States; [3]School of Medicine and Surgery, University of Milan-Bicocca, Milan, Italy; [4]Pathology Unit, Azienda ULSS2 Marca Trevigiana, Treviso, Italy; [5]Department of Surgery, Oncology and Gastroenterology (DISCOG), University of Padua, Padua, Italy; [6]Hepatobiliary Surgery and Liver Transplantation Unit, Padua University-Hospital, Padua, Italy; [7]Pathology Unit, Padua University-Hospital, Padua, Italy; [8]Clinical Medicine 1 and Thrombotic and Haemorrhagic Disease Unit, and Haemophilia Center, Padua University-Hospital, Padua, Italy; [9]Dept. of Liver and Gastrointestinal Diseases, Biodonostia Health Research Institute, San Sebastian, Spain*
Email: camilla.venturin@unipd.it

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic biliary disease characterized by peribiliary fibrosis evolving to cholangiocarcinoma (CCA). Both PSC and CCA show exuberant extracellular matrix (ECM) accumulation. Mechanisms linking fibrosis to dysplasia and malignant transformation remain unclear due to the lack of suitable models capturing the sequence from PSC to CCA (CCA/PSC). We aimed to develop an animal model of CCA/PSC to assess ECM proteins up-regulated in CCA (Osteopontin (OPN), Tenascin C (TnC), Periostin (POSTN)) as potential biomarkers of early tumor lesions in PSC, using both male and female mice.
Method: Mdr2-WT and KO mice were treated from the 4th week of life with thioacetamide (TAA), a profibrogenic toxicant, and sacrificed at 12 and 24 weeks (n = 5/sex/group), compared with untreated mice (controls). Liver sections from mice and human PSC (n = 5) and CCA/PSC samples (n = 5) were stained by immunohistochemistry for OPN, TnC, and POSTN. Human CCA cell lines (HUCCT-1, EGI-1) and primary PSC cholangiocytes (n = 5) were treated (24h) with OPN (10nM), TnC (100nM), POSTN (100nM) to assess migration and expression of cancer stem cell (CSC) markers (CD133, CD44; RT-PCR).
Results: TAA-treated Mdr2-KO mice showed time-dependent progression from peribiliary fibrosis (12 weeks) to dysplasia and CCA (24 weeks). Male mice developed a more severe development toward CCA, though females displayed an earlier and more prominent ductular reaction ECM remodeling, particularly enrichment of POSTN, and increased OPN and TnC expression, was associated with development of pre-malignant and malignant biliary lesions in PSC. In human samples, OPN, POSTN, and TnC were overexpressed in CCA/PSC but not PSC alone, recapitulating mouse model findings. In cultured cells, OPN, TnC, and POSTN stimulated cell motility more in CCA than PSC cholangiocytes, whereas POSTN up-regulated CD133 and CD44 expression not only in CCA cells but also in PSC cholangiocytes.
Conclusion: Our mouse model recapitulates PSC–CCA progression, with a sex-dependent pattern. In both mice and human samples among ECM proteins, POSTN is consistently overexpressed in malignant lesions compared to PSC. *In vitro*, ECM proteins stimulate cancer cell migration, while POSTN induces a CSC-like phenotype in CCA and PSC cells, supporting its putative role in tumor initiation. ECM proteins may aid early CCA detection in PSC.

Email: avilae@recerca.clinic.cat

Background and aims: Atezolizumab+bevacizumab (atezo+bev) is a first-line therapy for advanced hepatocellular carcinoma (aHCC) with ~30% objective responses. Single-cell studies identified responses linked to $CD8^+$ T effector cells (CD8_Tex and Temra) and $CXCL10^+$ macrophages (Macro_CXCL10), and resistance to $TREM2^+$ macrophages (Macro_TREM2) and $CD14^+$ monocytes (Mono_CD14). We hypothesized that, beyond cell composition, immune spatial organization within the tumor microenvironment (TME) determines response to atezo+bev.
Method: Single cell spatial transcriptomics (ST) was performed on 27 aHCCs (9 atezo+bev responders and 18 resistant) using the Xenium Prime 5.000-gene panel (10x Genomics) customized with 100 additional genes. Distances between cells were computed using the *dbscan* package [radius(r) = 300 µm]. Tumor cell neighborhoods were analyzed (r = 25 µm). Ligand-receptor interactions between T cells and other TME cell populations were evaluated. Immune cell clusters were defined as groups of ≥3 immune cells within 100 µm, and were identified through a density-based algorithm. This spatial clustering was assessed using ST and multiplexed immunohistochemistry (mIHC) data.
Results: ST of 27 aHCCs yielded 4.6 million cells. The distribution of CD8_Tex and Temra, and Macro_CXCL10 cells in inflamed tumors differed by treatment response: in responders, these immune populations localized within the tumor and were closer to cancer cells ($p = 0.02$, $p = 0.08$, and $p = 0.1$, respectively). Moreover, in responders, tumor hepatocytes exhibited a significantly enriched lymphoid neighborhood (CD8_Tex, $CD4^+$Tcells, $CD8^+$Tcells, $CD4^+CXCL13^+$Tcells, $CD4^+$ Treg) composition and significantly higher rates of immune-recruting interactions, including PDL1–PD1, CXCL9-CXCR3 and CXCL10–CXCR3 ($p < 0.05$). Resistant tumors showed 10% of pure Macro_TREM2 (vs 0% in responders, $p = 0.009$), 27% of mixed Macro_TREM2–Mono_CD14 (vs 5%, $p = 0.03$) and 38% of mixed Macro_TREM2–$CD8^+$ T-cell clusters (vs 22%, $p = 0.04$); along with enrichment of the CXCL12–CXCR4 chemokine axis. Increased rates of Macro_TREM2-pure clusters ($p = 0.02$) and mixed Macro_TREM2-$CD8^+$ clusters ($p = 0.03$) was confirmed by mIHC.
Conclusion: Atezo+bev response in HCC is marked by intratumoral effector $CD8^+$ T cells and CXCL10_Macro, tumor hepatocytes enriched in lymphoid neighborhoods, and immune-recruiting ligand–receptor interactions, whereas resistance is driven by TREM2_Macro clusters and CXCL12–CXCR4 signaling.

Microbial pentadecanoic acid suppresses hepatocellular carcinoma progression by inhibiting NSUN5 methyltransferase activity

Ziyan Wang[1], Ziqi Liu[1], Yuxin Liu[1], Zhengjiang Li[1], Zhixian Lan[1,2], Routing Wang[1], Kaifeng Wang[3], Dekai Zheng[1], Yuchuan Chen[1], Yinghong Zhu[1], Jian Sun[1]. [1]*Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; State Key Laboratory of Multi-organ Injury Prevention and Treatment; Key Laboratory of Infectious Diseases Research in South China, Ministry of Education; Guangdong Provincial Key Laboratory for Prevention and Control of Major Liver Diseases; Guangdong Provincial Clinical Research Center for Viral Hepatitis; Guangdong Institute of Hepatology; Guangdong Provincial Research Center for Liver Fibrosis Engineering and Technology, Guangzhou, China;* [2]*Guangdong Provincial Key Laboratory of Gastroenterology, Department of Gastroenterology, Nanfang Hospital, Southern Medical University, Guangzhou, China;* [3]*Department of Preventive Medicine, Shantou University Medical College, Shantou, China*
Email: sunjian@smu.edu.cn

Background and aims: Gut microbial metabolites critically regulate the progression of hepatocellular carcinoma (HCC). Here, we screened a clinically derived library of plasma metabolites that were negatively associated with HCC progression and identified pentadecanoic acid (PEA), a gut microbial metabolite, as an inhibitor of HCC progression by suppressing the RNA m^5C methyltransferase activity of NSUN5.
Method: We recruited 37 non-HCC individuals and 39 HCC patients and analyzed the plasma differential metabolites between non-HCC individuals and HCC patients, as well as among HCC patients at different stages. Then, we constructed a plasma metabolite library negatively associated with HCC progression based on these differential metabolites and screened the library using experimental methods. Changes in PEA-producing microbiota were examined in fecal samples from other cohort. We verified the anti-HCC capability of PEA through *in vitro* and *in vivo* experiments. The potential target protein of PEA was pulled down using biotin-labeled PEA and identified by mass spectrometry analysis. The interaction and regulation of PEA on NSUN5 were examined using pharmacological and biochemical technologies. The role of NSUN5 in mediating the anti-HCC capability of PEA was verified through *in vitro* and *in vivo* functional and rescue experiments.
Results: After screening the metabolite library, PEA was identified as the sole metabolite that exhibited inhibitory effects against HCC cells while showing no inhibitory effects on normal hepatocytes. A significant enrichment of PEA-producing microbiota was observed in non-HCC individuals compared with HCC patients. PEA supplementation significantly suppressed HCC proliferation and progression both *in vitro* and *in vivo*. Mass spectrometry analysis revealed NSUN5 as a potential downstream target of PEA. We further demonstrated that PEA directly interacted with NSUN5 and inhibited the methyltransferase activity of NSUN5 by competitively blocking the binding of its substrate, S-adenosylmethionine (SAM). Both *in vitro* and *in vivo* functional and rescue experiments demonstrated that NSUN5 could be a key downstream target responsible for the anti-HCC effect induced by PEA.
Conclusion: Our findings show that microbial PEA may be negatively associated with the progression of HCC. We suggest that PEA serves as a potential inhibitor of HCC progression and report it as the small molecule capable of inhibiting NSUN5 methyltransferase activity and NSUN5-mediated HCC progression.

WED-398
An iron-dependent TFRChi subpopulation exploits postoperative niches to initiate hepatocellular carcinoma recurrence

Junyu Wu[1], Zhuofeng Jiang[1], Ning Wang[1]. [1]*The University of Hong Kong, Hong Kong, Hong Kong*
Email: ckwang@hku.hk

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer death globally, for which surgical resection is the primary treatment for early- to intermediate-stage patients. However, postoperative recurrence occurs in up to 70% of cases within five years, drastically reducing long-term survival rates compared to patients without recurrence. This study aims to identify the cellular mechanisms underlying HCC recurrence.
Method: Single cell RNA sequencing was used to identify the cell population enriched in recurrent HCC tumors and its molecular signature. A tracible HCC cell line were then established to observe the dynamic changes of this population in HCC recurrence. Mechanism underlying the maintanence and expansion of this population during HCC recurrence was explored in in vitro and in vivo models.
Results: An orthotopic GFP-expressing HCC model was established in immunocompetent C57BL/6J mice, followed by surgical resection. RNA-seq analysis of GFP^+ cells from primary and recurrent tumors revealed a significant enrichment of a TFRC-high subpopulation in recurrent disease. Pseudotime analysis indicated that these cells lacked stem-like properties but exhibited rapid cell cycle progression. A gene signature derived from this population served as a clear predictor of recurrence-free survival in HCC patients. To track these cells *in vivo*, we generated an HCC cell line with a tdTomato reporter knocked into the *TFRC* locus. Consistent with the RNA-seq data, the

tdTomato$^+$ population expanded specifically in recurrent tumors. Functionally, inducible knockdown of *TFRC* post-resection significantly suppressed tumor recurrence, whereas inducible *TFRC* expression promoted relapse. Mechanistically, TFRC overexpression accelerated cellular metabolism, increasing ATP production and driving cell cycle entry. This process depended on iron delivery within the post-operative microenvironment. Here, infiltrating Ly6C$^+$ pro-inflammatory macrophages fostered surgical inflammation, carried circulating iron, and created an iron-rich niche. Accordingly, iron chelation therapy significantly prevented postoperative HCC recurrence.
Conclusion: Our findings suggest that an iron-dependent expansion of TFRChi-expressing population mediated high chance of post-operative recurrence in HCC.

Establishing a multi-institutional patient-derived xenograft biobank for precision medicine in cholangiocarcinoma
Lisa Wende[1], Denise Schlösser[1], Gharaza Nasir[2], Parham Pourabbas Tahvildari[1], Elena Valenzi[2], Shreya Chakraborty[1], Silke Marhenke[1], Arndt Vogel[1,2,3], Anna Saborowski[1]. [1]*Medizinische Hochschule Hannover, Hannover, Germany;* [2]*Toronto General Hospital, Toronto, Canada;* [3]*Princess Margaret Cancer Centre, Toronto, Canada*
Email: wende.lisa@mh-hannover.de

Background and aims: Cholangiocarcinoma (CCA) is a rare and aggressive malignancy with pronounced molecular heterogeneity and limited therapeutic options. Biomarker-driven treatment strategies are hindered by the lack of representative preclinical models for functional investigation of targeted therapies. Patient-derived xenograft (PDX) models closely recapitulate patient tumors and provide a robust translational platform. This ongoing project aims to establish and expand a multi-institutional CCA PDX biobank and demonstrate its suitability for precision medicine.
Method: Tumor samples from patients with CCA are collected across collaborating institutions (currently Hannover Medical School, Germany, and Princess Margaret Cancer Center, Toronto, Canada) and engrafted into immunodeficient mice. Successfully engrafted models are expanded, cryopreserved, and annotated with clinical, pathological, and treatment-related metadata. Histological characterization is performed by immunohistochemistry, and molecular profiling includes whole-exome sequencing and transcriptome profiling. 2D and 3D cell lines are generated from successfully established PDX models to enable in vitro profiling and targeted drug testing. A virtual biobank infrastructure provides structured access to model-associated data for collaborative research.
Results: To date, the biobank comprises more than 50 established CCA PDX models and is continuously expanding. PDX tumors retain key histological and molecular characteristics across passages. Histopathological analyses reveal dynamic tumor-stroma remodeling with progressive replacement of human stroma by murine orthologues from early PDX generations onward, an important consideration for functional drug response studies. Key druggable alterations include FGFR2 fusions, ERBB2 amplification, and IDH1-, KRAS G12D and G12C mutations. Transcriptomic profiling demonstrates pronounced inter-patient heterogeneity among tumor samples, while matched normal liver tissues cluster closely together. A HER2-overexpressing PDX model was translated into an in vitro system and showed sensitivity to HER2-directed therapies, including neratinib and tucatinib.
Conclusion: This ongoing, multi-institutional and virtually accessible CCA PDX biobank represents a growing shared resource for functional evaluation of targeted therapies. Ongoing model expansion, integrated molecular profiling, and systematic drug screening will further enhance its value for collaborative precision oncology in CCA.

WED-401
AREG knockdown triggers Decorin-mediated EGFR activation and paracrine G1 arrest across species
Anna Potapova[1], Agnes Ong[1], Torsten Wuestefeld[2]. [1]*Genome Institute Of Singapore, Singapore, Singapore;* [2]*Lee Kong Chian School Of Medicine Nanyang Technological University, Genome Institute of Singapore, Singapore, Singapore*
Email: potapovaa@a-star.edu.sg

Background and aims: The senescence-associated secretory phenotype (SASP) mediates non-cell-autonomous effects of senescent hepatocytes, but its regulatory mechanisms remain poorly understood. While Amphiregulin (AREG) is known to activate EGFR in liver pathophysiology, its role in hepatocyte senescence is unknown. We hypothesized that AREG critically modulates SASP composition and paracrine senescence signaling.
Method: Oncogene-induced senescence (OIS) was established in immune-competent C57BL/6 mice by hydrodynamic tail vein delivery of NRasG12V in ~5% of hepatocytes. AREG expression was knocked down using two independent shRNAs. Liver tissues were analyzed by RNAseq, immunofluorescence co-staining (p21, p16, Ki67, SA-β-Gal, phospho-H2A.X), protein arrays, and Western blot. Paracrine effects were evaluated by treating human SNU398 liver cancer cells with supernatants from Areg-knockdown AML12 mouse hepatocytes. Human AREG knockdown was similarly validated in SNU398 cells.
Results: AREG specifically co-localized with senescence markers (p16, p21) in both OIS and oxidative stress-induced senescence. Paradoxically, Areg knockdown in OIS hepatocytes enhanced paracrine senescence signaling, evidenced by a significantly higher proportion of p21-positive, cell cycle-arrested hepatocytes beyond the NRas-expressing population ($p < 0.0367$). Following partial hepatectomy, this effect intensified, reducing Ki67-positive hepatocytes ($p < 0.0482$) and mitotic index ($p < 0.0007$). Mechanistically, protein array and transcriptomic analyses identified Decorin, a small leucine-rich proteoglycan, as a key SASP factor dramatically upregulated upon Areg knockdown in both mouse and human cells. Decorin mediated EGFR activation, leading to p21 upregulation and cyclin D1 downregulation, resulting in G1 phase blockade. Critically, supernatants from Areg-knockdown mouse hepatocytes significantly attenuated proliferation of human SNU398 liver cancer cells ($p < 0.0002$), demonstrating a conserved cross-species paracrine senescence effect.
Conclusion: AREG functions as a previously unrecognized SASP rheostat in senescent hepatocytes. Rather than simply being a SASP component, AREG knockdown reprograms the SASP to amplify Decorin-mediated paracrine growth suppression via EGFR activation. This conserved mechanism identifies AREG as a novel therapeutic target in liver cancer, where its inhibition may enhance senescence-based tumor surveillance through non-cell-autonomous pathways.

WED-402
DUSP10 rewires cholesterol biosynthesis and T cell infiltration to suppress hepatocellular carcinoma progression
Anliang Xia[1], Siyuan Liu[1], Shuyan Sheng[1], Shaobo Zhang[1], Kaipeng Hu[1], Beicheng Sun[1]. [1]*The First Affiliated Hospital of Anhui Medical University, Hefei, China*
Email: xiaanliang@ahmu.edu.cn

Background and aims: Cholesterol metabolism is a major driver of hepatocellular carcinoma (HCC) progression and a key regulator of the tumor immune microenvironment. Identifying genes that function as molecular bridges between metabolic reprogramming and immune infiltration is essential for elucidating HCC pathogenesis and developing precision therapies. This study aims to characterize

cholesterol-metabolic features in HCC and to uncover core molecular mediators that couple cholesterol metabolism with immune infiltration.
Method: We integrated single-cell RNA sequencing and metabolomic profiling from patients with HCC to identify genes involved in cholesterol metabolism and immune modulation. A liver-specific CRISPR/Cas9 knockout mouse model was generated to assess the impact of candidate genes on tumor malignancy. Transcriptomic, metabolomic, and proteomic analyses were employed to validate gene function and dissect underlying metabolic mechanisms. Remodeling of the immune microenvironment was evaluated using flow cytometry and multiplex immunohistochemistry. Finally, immune-cell flow sorting combined with lipid nanoparticle-mediated delivery was used to assess the potential therapeutic efficacy of a combinatorial strategy.
Results: Dual-specificity phosphatase 10 (DUSP10) was markedly downregulated in HCC tissues, and its high expression was strongly associated with favorable prognosis. Mechanistically, DUSP10 interacts with the deubiquitinase OTUD4 to stabilize INSIG1/2, thereby suppressing the cholesterol biosynthesis pathway and restraining tumor progression. Elevated cholesterol levels in the tumor microenvironment impaired $CD8^+$ T-cell infiltration, whereas DUSP10 promoted CXCL10-dependent T-cell recruitment by limiting cholesterol accumulation.
Conclusion: Targeting the DUSP10-OTUD4-cholesterol axis suppresses tumor malignancy while enhancing $CD8^+$ T-cell antitumor immunity through CXCL10. These findings identify DUSP10 as a central molecular node linking cholesterol biosynthesis to T-cell immune infiltration and highlight a promising metabolic-immune coupling axis for therapeutic intervention in HCC.

WED-403
Whole genome sequences reveal the presence of high structural variants in hepatocellular carcinoma of Fontan-associated liver disease
Taiji Yamazoe[1], Eiji Kakazu[1], Michitaka Matsuda[1], Masaaki Mino[1], Tatsuya Kanto[1]. *[1]Japan Institute for Health Security, Ichikawa, Japan*
Email: lb-19yamazoe@hospk.ncgm.go.jp

Background and aims: The Fontan-associated liver disease (FALD) is characterized by a congestive hepatopathy, develops liver cirrhosis and have a risk of hepatocellular carcinoma (HCC) after 15–20 years of the Fontan procedure. For understanding of hepatocarcinogenesis in FALD, we performed whole genome sequencing.
Method: We enrolled ten pairs of tumor and nontumor lesions from the surgically resected FALD HCCs. The pipelines of Mutect2 and Oncoanalyser were utilized after PCR-free sequence.
Results: The ages of the patients (n = 10) ranged from 21 to 43 years. The tumor subtypes of HCCs were primarily moderate-to-poorly differentiated HCCs or combined hepatocellular-cholangiocarcinomas. There were no single-nucleotide variants (SNVs) in the TERT promoter, TP53, CTNNB1, or ARID1A, but mutations in AXIN1 were identified in three cases. The tumor mutation burden (TMB) was comparable to liver tumor cohort in TCGA (LIHC cohort). In the COSMIC signatures, all ten FALD HCCs harbored the signatures related to homologous recombination deficiency (HRD), non-homologous end joining (NHEJ), and/or microhomology-mediated end joining (MMEJ), including SBS8, SBS39, ID6, and/or ID8. None of them had SBS3, which was seen in BRCA1/2 mutated tumors. The structural variants of deletion and translocation were significantly higher in FALD HCCs, compared to the Japanese HCC cohort in the ICGC (LIRI cohort). The copy number alterations (CNAs) are the result of chromosomal rearrangement. The copy number gains were observed in genes on chromosome 1q, including MCL1 and MDM4, and on chromosome 6p, including VEGFA. Moreover, CNAs in AXIN1 were also seen in three FALD HCCs without SNV in the AXIN1 gene. Given the typical absence of mutations in genes associated with homologous recombination DNA repair, it was hypothesized that the frequency of DNA double-strand breaks would exceed the capacity of the repair mechanisms. As a result, the commonly altered chromosomal changes in HCCs, including a gain of chromosome 1q and 6p, were also seen in FALD HCCs. The consensus clustering analysis of CNAs classified the HCCs in the LIHC cohort into four classes. The HCCs classified as the same class of FALD HCCs showed poor progression-free survival.
Conclusion: The FALD HCC has a unique genomic profile characterized by DNA double-strand break repair-related signatures and high structural variants, resulting in copy number alterations.

WED-409-YI
Spatial profiling reveals region-specific immune architectures and checkpoint distribution in extrahepatic cholangiocarcinoma
Dawei Yi[1], Valery Volk[1], Christoph Gerdes[1,2], Melanie Bathon[1], Josephine Reschke[1], Tanja Reineke-Plaaß[1], Friedrich Feuerhake[1], Anna Saborowski[1], Arndt Vogel[1,2,3]. *[1]Hannover Medical School, Hannover, Germany; [2]Princess Margaret Cancer Centre, Toronto, Canada; [3]Toronto General Hospital, Toronto, Canada*
Email: yi.dawei@mh-hannover.de

Background and aims: Extrahepatic cholangiocarcinoma (eCCA) is characterised by poor prognosis and limited response to systemic therapies. Increasing evidence suggests that the tumor immune microenvironment (TIME) plays a decisive role in disease progression and therapeutic vulnerability. In particular, the spatial arrangement of immune cell aggregates may determine immune activity or suppression within the tumor. This study aimed to characterise immune cell composition, checkpoint expression and spatial relationships in eCCA to identify immune phenotypes with potential clinical relevance.
Method: Ninety-four surgically resected and clinically annotated eCCAs were analysed. Multiplex immunohistochemistry combined with multispectral imaging was performed to detect various immune cell types, including T cells, B cells, macrophages, neutrophils, and immune checkpoint (IC) molecules such as PD-1, PD-L1, TIGIT, CTLA-4, LAG-3. Regions of interest representing tumor core, invasive margin, stromal regions and tertiary lymphoid structures (TLS) were selected. Image analysis and machine learning-based pipelines were applied for quantitative assessment and spatial profiling of the TIME.
Results: Spatial and intertumoral heterogeneity of immune infiltration was observed across the cohort. TLS were identified in most cases (74%) and were enriched for T cells (24%) and B cells (23%), whereas the tumor core showed sparse immune cell infiltration (6%), consistent with an immunosuppressive milieu. Only a minority of intratumoral T cells (10%) expressed immune checkpoints across regions, with most IC-positive cells showing single rather than dual IC expression. Checkpoint distribution differed by region, with PD-L1 (4%) being predominant within the tumor core, while TIGIT (3%) and PD-1 (2%) were more frequently detected in stroma and margin. Spatial proximity analyses revealed distinct neighbourhood patterns between immune cell subsets by region.
Conclusion: This comprehensive spatial analysis demonstrates that eCCA exhibits pronounced immune heterogeneity with region-specific immune architectures. The presence of TLS contrasts with immune-excluded tumor core and highlights potential mechanisms of immune escape. Differential spatial expression of immune checkpoints suggests that patient stratification based on immune architecture may improve the selection of immunomodulatory treatment strategies. These findings support the integration of

spatial immune profiling into future translational and clinical studies for eCCA.

WED-410

Moonlighting function of lysosomal CYP7A1 licenses p62-mediated autophagy activation to drive hepatocellular carcinoma

Yan Lou[1], Yunqing Qiu[1], Shuaibing Ying[1], Jinyao Dai[1], Yujing Wang[1]. [1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*
Email: yanlou@zju.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) remains a lethal malignancy, with its efficacy hampered by an incomplete understanding of the liver-specific metabolic microenvironment. Beyond their catalytic roles, metabolic enzymes possess non-canonical, "moonlighting" functions, yet their mechanisms in HCC are largely unexplored.
Method: Focusing on CYP7A1, its expression levels were evaluated via public datasets and analyses of 203 human HCC specimens. The association between CYP7A1 expression and prognosis was further assessed by a 5-year follow-up of 183 patients. Its functional role was validated using cell proliferation, colony formation, and migration assays. In vivo, CYP7A1 effects were examined by RNAi in diethylnitrosamine-induced HCC mouse models and patient-derived xenograft models. Finally, immunoprecipitation–mass spectrometry (IP-MS) and multi-omics analyses elucidated its regulatory role in autophagy.
Results: Clinical analyses demonstrated that CYP7A1 was significantly upregulated in HCC and correlated with poor prognosis. Mechanistically, CYP7A1 undergoes unique lysosomal translocation in tumor cells and directly binds the autophagy adapter p62 via its C-terminal domain. This interaction, independent of CYP7A1's enzyme activity, inhibits liquid-liquid phase separation (LLPS) of p62, which disrupts the p62-mTORC1 complex and alleviates mTORC1-mediated suppression of transcription factor EB (TFEB). Nuclear translocation of activated TFEB drives lysosomal biogenesis and autophagy flux, providing metabolic support for tumor cells. Concurrently, this signaling axis induces immune evasion by downregulating antigen presentation (MHC-I). Functionally, the catalytically dead mutant CYP7A1 (CYP7A1 R260L) fully restored the tumorigenic phenotypes suppressed by CYP7A1 knockdown, both in vitro and in vivo.
Conclusion: Collectively, we uncover a non-canonical function of CYP7A1 as a lysosomal signaling scaffold that integrates autophagy and immune regulation to promote HCC progression. Targeting the CYP7A1-p62 interaction interface may present a novel, liver-specific therapeutic strategy for HCC.

Montpellier, Montpellier, France;* [8]*Hepatology Programme, Center for Applied Medical Research (CIMA), IDISNA, University of Navarra, Pamplona, United States*
Email: lzapata@cicbiogune.es

Background and aims: Hepatoblastoma (HB), the most common pediatric liver cancer, remains a major challenge. Despite advances in surgery and chemotherapy, survival for aggressive or relapsed cases is still poor, highlighting the urgent need for new therapeutic strategies. Our previous work established NEDDylation, a post-translational modification that mainly activates cullin-RING ligases, as a key driver of HB progression. Building on these findings, we identified CAND1, a regulator of SCF complexes, as a novel NEDDylation-controlled target. This study aims to define the functional role of CAND1 and its regulation by NEDDylation, uncovering mechanisms that could be exploited for precision therapy.
Method: CAND1 expression was analyzed in HB patient samples and organoid models using bulk and single-cell transcriptomics. Functional assays were performed in HepT1, HepG2, and HB-284 cells following siRNA-mediated silencing. *In vivo*, HB was induced in C57BL/6 and ^{Bio}NEDD8 mice using the YAPS127A/N90-β-catenin model, followed by siRNA-mediated silencing of CAND1 to assess effects on tumor development and immune modulation. Predicted NEDDylation sites were disrupted in mutant constructs and tested *in vitro* to confirm regulatory mechanisms.
Results: CAND1 was markedly overexpressed in HB tissues and organoids, strongly associated with poor prognosis and aggressive molecular subtypes such as C2-pure and Epi-CB. Single-cell analysis confirmed its enrichment in tumor compartments. Silencing CAND1 significantly reduced cell viability and altered key markers of proliferation and senescence. Mutant constructs lacking NEDDylation sites exhibited functional impairment, validating the regulatory role of this modification. *In vivo*, tumors from CAND1-silenced mice showed reduced development and an immunomodulatory effect associated with CAND1 targeting.
Conclusion: These findings position CAND1 as a critical mediator of HB progression under NEDDylation control. Targeting this axis represents a promising therapeutic strategy for high-risk pediatric liver cancer, opening the door to combination approaches that enhance efficacy while minimizing systemic toxicity. This work provides a strong rationale for future translational studies aimed at integrating CAND1 inhibition into precision oncology frameworks.

CRISPR screen identifies GTF2E1 as a regulator of hepatocellular carcinoma immune escape via activating STAT3 to upregulate PD-L1 expression

Yi Zhan[1], Fei Xiao[1]. [1]*The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai City, Guangdong Province, China*
Email: zhany8@mail2.sysu.edu.cn

Background and aims: Epigenetic dysregulation is a highlighted hallmark of hepatocellular carcinoma (HCC) and plays an important role in tumorigenesis, progression and resistance to immunotherapy. However, the mechanisms underlying epigenetic modulation of immune checkpoints and how altered epigenetic landscapes in turn drive PD-L1 expression to facilitate HCC immune escape remain poorly understood. In this study, we aimed to elucidate the role of GTF2E1 in the transcriptional control of PD-L1 in HCC.
Method: We performed a CRISPR knockout screen to investigate epigenetic factors that contribute to PD-L1 expression in HCC cells. Flow cytometry, Western blotting, and quantitative real-time PCR (qPCR) assays were used to examine the regulatory role of GTF2E1 in PD-L1 transcription and translation. In vitro T cell co-culture

experiments were performed to evaluate the functional impact of GTF2E1 on HCC immune escape. CUT&Tag and RNA-seq were utilized to elucidate the molecular mechanisms by which GTF2E1 drives PD-L1 expression.
Results: We identified GTF2E1, a general transcription factor IIE subunit 1 that participates in RNA polymerase II-mediated transcription initiation, as a key epigenetic regulator of PD-L1 expression in HCC cells using the epigenetic-targeted CRISPR knockout screen. GTF2E1 promotes the expression of PD-L1 in HCC cells and facilitates tumor immune escape. Clinically, GTF2E1 is upregulated in HCC tissues and is associated with poor clinical outcomes in patients with this disease. Mechanistically, GTF2E1 regulates the STAT3 signaling pathway by modulating STAT3 expression. We found GTF2E1 knockout downregulated the expression level of STAT3 and subsequently reduced PD-L1 expression in HCC cells. Conversely, overexpression of GTF2E1 upregulated STAT3 expression and enhanced PD-L1 expression. It is indicated that GTF2E1 upregulated in HCC promotes tumor immune escape by increasing STAT3 expression to enhance PD-L1 expression.
Conclusion: Our study suggests that GTF2E1 has a crucial role in HCC immune escape by regulating the STAT3-PD-L1 axis, providing a potential therapeutic target for HCC immunotherapy. However, how GTF2E1 modulates STAT3 expression and transcriptional activity to regulate PD-L1 expression still needs further study. We hypothesize that GTF2E1 has the potential to bind to the promoter region of *STAT3* in hepatocellular carcinoma cells, which in turn affects STAT3 transcription and subsequent PD-L1 expression to facilitate tumor immune escape.

WED-414

Glypican-3-targeted orlistat-dopamine micelles enable programmed camptothecin delivery in hepatocellular carcinoma

Xiaqing Zhou[1], Shuangsuo Dang[1]. [1]*Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: xiaqingzhou@xjtu.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) is marked by hypoxia and lipid-metabolic dependency, contributing to chemoresistance and dose-limiting toxicity. Building on our pH-responsive orlistat-dopamine conjugate micelles that trigger an early oxidative insult followed by camptothecin-mediated DNA damage, we developed an HCC-targeted nanomedicine and assessed antitumor efficacy and liver safety.
Method: Camptothecin-loaded orlistat-dopamine micelles were fabricated by solvent-in-water emulsification and surface-conjugated with a glypican-3-binding peptide. Nanoparticles were characterized for size, polydispersity index, zeta potential, encapsulation efficiency and pH-dependent release. Uptake and cytotoxicity were tested in Huh7, HepG2 under normoxia and hypoxia, with immortalized hepatocytes as a non-tumor control. Reactive oxygen species (ROS), monoamine oxidase (MAO) dependence and fatty acid synthase (FASN) inhibition were evaluated. Efficacy and tolerability were assessed in an orthotopic HCC mouse model.
Results: Targeted micelles had a diameter of 160 nm (polydispersity index 0.22) with 93% camptothecin encapsulation and accelerated release at pH 6.0 versus pH 7.4 (72% versus 44% at 8 h). Glypican-3 targeting increased uptake 2.8-fold ($p < 0.01$) and reduced the half-maximal inhibitory concentration of camptothecin by 28- to 65-fold under hypoxia across cell lines and organoids, while maintaining low cytotoxicity in hepatocytes. Mechanistically, micelles induced an early ROS surge that was partially rescued by MAO-B inhibition, decreased FASN activity and lipid droplet content, and enhanced DNA damage and apoptosis at later timepoints. In vivo, targeted micelles reduced orthotopic tumor bioluminescence by 74% versus free camptothecin at day 14 ($p < 0.01$), prolonged median survival (45 versus 28 days), and did not increase serum alanine aminotransferase or aspartate aminotransferase compared with controls.
Conclusion: Glypican-3-targeted orlistat-dopamine micelles provide tumor-directed, pH-responsive camptothecin delivery with dual metabolic and oxidative sensitization, achieving robust HCC control with preserved liver safety.

Email: mathew.vithayathil@doctors.org.uk

Background and aims: Recurrence after thermal ablation in early-stage hepatocellular carcinoma (HCC) is high with a lack of clinical predictors. This study used pretreatment multiphase MRI-derived radiomic features to predict recurrence after ablation. Targeted RNA sequencing was used to determine drivers of radiomic signatures.
Method: 156 HCC patients undergoing ablation from the SORAMIC (NCT01126645) and Lausanne (NCT02859753) prospective phase 2 randomised control trials were reviewed. Radiomic features from pretreatment T1-weighted arterial, portal venous and delayed phase lesions were extracted. Radiomic models predicting 12-month recurrence for each phase were trained in the SORAMIC cohort using eight supervised machine learning models, including the state-of-the-art generative foundation model, TabPFN, and thirteen feature selection techniques. The best performing radiomic models were combined and integrated with clinical variables using ensemble learning. Patients were stratified using optimal threshold tuning. Model performance was externally validated in the independent Lausanne cohort. RNA sequencing was performed for radiomic risk-groups.
Results: The ensemble machine learning-based arterial phase radiomic model outperformed all clinical benchmarks and TabPFN in predicting recurrence in training (AUC 0.90, 95% CI 0.80–0.98) and external validation (AUC 0.74, 95% CI 0.61–0.87) cohorts. Arterial-portal venous and integrated radiomic-clinical models had comparable performance to the standalone arterial phase radiomic model. The arterial phase radiomic model stratified high-risk group had a significantly shorter median time-to-recurrence compared to the low-risk group in training (4.2 months, 95% CI 1.9–9.9 vs. 29.0 months, 95% CI 15.8–34.4; $p < 0.001$) and external validation (4.5

months, 95% CI 1.2–9.4 vs. 12.5 months, 95% CI 9.6–22.9; $p = 0.007$). Radiomic risk group was the only significant predictor of recurrence in multivariable Cox regression. Telomerase reverse transcriptase (TERT) expression was significantly enriched in the high-risk radiomic group.
Conclusion: Arterial phase radiomic-based models can predict recurrence after curative HCC ablation. Pretreatment MRI can identify patients at high-risk of recurrence for precision surveillance and adjuvant strategies.

Email: sarahcappuyns@hotmail.com

Background and aims: Recurrence of hepatocellular carcinoma (HCC) occurs in up to 70% of patients post liver resection (LR). Early-phase trials confirm safety of neoadjuvant immune checkpoint inhibitors (nICI) pre-LR. However, long-term outcomes of nICI have not been described.
Method: We performed a patient-level, pooled analysis of phase I/II nICI trials, collected as part of a global collaborative consortium (NeoHCC). We estimated objective response (ORR) and disease control rate (DCR) by RECIST 1.1, described time to recurrence (TTR), recurrence free (RFS) and overall survival (OS) outcomes and identified predictors of RFS.
Results: Of 143 patients with HCC, most BCLC 0-A (89%), 45% had cirrhosis, most often due to viral etiologies (63%). Patients received 2.8 cycles (median 2; range 1–10) of ICI-doublet (60%) or monotherapy (30%) and underwent LR 3.8 weeks after the first nICI dose (median 2.5; range 0–21). Six patients (4%) did not undergo LR, of which only one due to disease progression. ORR was 22% and DCR was 92%. At median follow-up of 42 months (95% CI 37–46mo), 37.7% patients recurred, median TTR and OS were not reached (NR) and median RFS was 50 months (95% CI 29.5-NR). Improved RFS was associated with achieving major pathological response (HR 0.24; $p < 0.001$), while prior locoregional therapy was associated with worse RFS (HR 2.14; $p = 0.014$).
Conclusion: Extended follow-up of NeoHCC confirms feasibility and anti-tumour efficacy of nICI with drop-out rates of 4%. RFS post nICI is favourable and warrants prospective testing of this strategy in randomised controlled trials.

TOP-422
Epigenetic dysregulation of the IL1B-driven inflammatory program drives resistance to anti–PD-1 therapy in hepatocellular carcinoma
Wenying Qiao[1], Xuefeng Huang[1], Xiaoyan Ding[1], Xi Wang[1], Ronghua Jin[1,*]. *[1]Beijing Ditan Hospital, Capital Medical University, Beijing 100015, China, Beijing, China*
Email: qiaowenying459@163.com

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality globally, with anti-PD-1 immunotherapy emerging as a promising therapeutic strategy. However, the clinical efficacy of immune checkpoint blockade remains limited, primarily due to complex and poorly understood immune evasion mechanisms. As an inflammation-driven cancer, HCC is profoundly shaped by pro-inflammatory cytokines, yet the upstream mechanisms controlling aberrant interleukin-1β (IL-1β) expression and their impact on immunotherapy resistance remain unclear.
Method: Baseline peripheral blood mononuclear cells (PBMCs) from patients with advanced hepatitis B virus (HBV)–related HCC were profiled by single-cell RNA sequencing (scRNA-seq) and bulk RNA-seq. Spatial transcriptomics (ST) and multiplex immunofluorescence (mIF) from an independent cohort were integrated. Epigenetic regulation was assessed by Assay for Transposase-Accessible Chromatin using sequencing and H3K4me3 chromatin immunoprecipitation sequencing, and therapeutic relevance was evaluated in subcutaneous and orthotopic HCC models treated with anti–IL-1β and anti–PD-1, alone or in combination. Survival associations were validated using GSE16757 from the Gene Expression Omnibus and The Cancer Genome Atlas-Liver Hepatocellular Carcinoma cohort.
Results: Single-cell and bulk transcriptomic analyses revealed a distinct $IL1B^+$ $CD14^+$ monocyte subset enriched in non-responders to PD-1 therapy, characterized by heightened inflammatory activity. Chromatin accessibility profiling demonstrated epigenetic activation at the IL1B locus in non-responders. Mechanistically, the histone demethylase KDM5A restrained IL1B transcription by restraining H3K4me3 deposition and AP-1 recruitment at the IL1B promoter, a regulatory control preserved in responders but lost in non-responders. Functionally, IL-1β promoted $CD8^+$ T-cell exhaustion by inducing upregulation of PD-1 and TIM-3, while combined IL-1β and PD-1 blockade reduced tumor growth, decreased TAM infiltration, and restored cytotoxic T-cell activity in murine subcutaneous and orthotopic HCC models.
Conclusion: Our study identifies the KDM5A–AP-1–IL1B epigenetic-inflammatory axis as a critical mechanism of resistance to PD-1 therapy and highlights dual IL-1β/PD-1 inhibition as a promising therapeutic strategy to overcome resistance to PD-1 blockade in HCC.

FRI-217

Real-world effectiveness of Durvalumab plus Tremelimumab in hepatitis C-associated hepatocellular carcinoma: an Egyptian multicenter cohort study

Mohamed AbdAllah[1], Wael Abdel-Razek[2], Mohamed Hassany[3], Wafaa El-Akel[4], tamer Elbaz[4], Eman Rewisha[2], Shahira El-Etreby[5], Imam Waked[2], Gamal Esmat[4]. *[1]Medical Research and Clinical Studies Institute, National Research Center, Giza, Egypt; [2]Department of Hepatology and Gastroenterology, National Liver Institute, Menoufia University, Menoufia, Egypt; [3]National Hepatology and Tropical Medicine Research Institute, Ministry of Health and Population, Cairo, Egypt; [4]Endemic Medicine Department, Faculty of Medicine, Cairo University, Cairo, Egypt; [5]Specialized medical hospital, Mansoura Faculty of Medicine, Mansoura University, Mansoura, Egypt*
Email: dr.mohamedabda@gmail.com

Background and aims: The Phase III HIMALAYA trial established the STRIDE regimen (durvalumab plus tremelimumab) as first line option for unresectable hepatocellular carcinoma (HCC), demonstrating a median overall survival (OS) of 16.4 months. However, real-world data specifically characterizing the effectiveness of this regimen in hepatitis c virus (HCV)-predominant populations remains limited. This study evaluates the early clinical outcomes and survival determinants of the STRIDE regimen in a real-world cohort of Egyptian patients with HCV-associated HCC.
Method: We conducted a multicenter retrospective analysis of 255 patients with unresectable HCC treated with durvalumab/tremelimumab. To address real-world attrition, effectiveness was assessed using a composite clinical benefit rate (CBR), defined as radiologically confirmed disease control or sustained clinical stability on treatment for >30 days. Primary endpoints included OS and CBR.
Results: The cohort included 255 patients (median age 64 years; 76% male), predominantly with Child-Pugh A liver function. The objective response rate (ORR) was 14.9% and the disease control rate (DCR/CBR) was 49.8%. While numerically lower than the HIMALAYA trial benchmarks (ORR 20.1%, DCR 60.1%), this reflects real-world heterogeneity. The median OS was not reached (>12 months median follow-up), indicating a robust survival signal comparable to or potentially exceeding the 16.4 months observed in the HIMALAYA trial. Among patients with evaluable imaging (n = 110), those achieving disease control had significantly superior survival compared to those with progressive disease (median OS: not reached vs. 12 months; p = 0.003).
Conclusion: In this real-world HCV-associated HCC cohort, the STRIDE regimen demonstrated a favorable effectiveness and sustained survival benefit, with the median OS not yet reached. Although objective response rates were modest compared to clinical trial settings, the survival trajectory confirms the regimen's effectiveness in patients with HCV.

FRI-218

Digital twin–based in-silico randomized trial evaluating immunotherapy plus TARE versus immunotherapy alone in advanced hepatocellular carcinoma

Joseph Ahn[1], Mingzhao Hu[1], Sori Lundin[1], Michael Luu[2], Hyunseok Kim[2], Neehar D. Parikh[3], Amit Singal[4], Cui Tao[1], Ju Dong Yang[2]. *[1]Mayo Clinic, Rochester, United States; [2]Cedars-Sinai Medical Center, Los Angeles, United States; [3]University of Michigan, Ann Arbor, United States; [4]University of Texas, Southwestern, Dallas, United States*
Email: ahn.joseph@mayo.edu

Background and aims: Combination therapy with immunotherapy plus transarterial radioembolization (TARE) shows promise for advanced hepatocellular carcinoma (HCC), but a randomized controlled trial (RCT) directly comparing these treatments is lacking. Digital twin technology using generative AI on real-world data enables virtual trials and personalized predictions. The aim of this study was to conduct an in-silico RCT using diffusion-generated synthetic patients to compare immunotherapy alone versus combination therapy in advanced HCC, with validation against real-world evidence.
Method: A Tabular Denoising Diffusion Probabilistic Model was trained on National Cancer Database data from 4323 advanced HCC patients (2017–2021; immunotherapy n = 3772, combination n = 551) to generate 2000 high-fidelity synthetic patients (Wasserstein = 0.015, r = 0.98, zero copies). This synthetic cohort was randomized 1:1, and OS was predicted via conditional generation. Kaplan-Meier and Cox analyses were performed and validated against propensity score–matched real-world data. Counterfactual digital twins were also created to estimate individualized OS under the opposite treatment assignment.
Results: In the in-silico RCT, combination therapy yielded a 7.2-month increase in median OS compared with immunotherapy alone (15.0 vs 7.8 months; HR = 0.54, 95% CI 0.49–0.60). Propensity-matched real-world analysis validated these findings with a 7.5-month benefit (16.7 vs 9.2 months; HR = 0.62, 95% CI 0.54–0.71), consistent across subgroups. Counterfactual digital twin predictions showed that immunotherapy-only patients would gain 3.6 months if switched to combination therapy (95% CI 3.06–4.03), whereas combination-therapy patients would lose 5.4 months if switched to immunotherapy alone (95% CI 3.71–6.93).
Conclusion: This in-silico trial showed a clinically meaningful survival advantage with combination therapy in advanced HCC, corroborated by real-world validation. While prospective RCTs remain necessary, these convergent findings demonstrate feasibility for AI-driven in-silico trials and suggest potential benefit of immunotherapy plus TARE in appropriate patients.

FRI-219

Biological oncological resectability for treatment selection in hepatocellular carcinoma

Kenta Aso[1], Yoshinori Takeda[1], Hirofumi Ichida[1], Akio Saiura[1]. *[1]Juntendo University School of Medicine, Tokyo, Japan*
Email: k.aso.xy@juntendo.ac.jp

Background and aims: Barcelona Clinic Liver Cancer (BCLC) staging is the most widely used treatment algorithm for hepatocellular carcinoma (HCC) and provides robust prognostic stratification. With recent advances in perioperative and systemic therapies, anatomical oncological resectability criteria (ORC) based on surgical feasibility have been proposed in Japan. In real-world practice, treatment selection incorporates biological tumor factors such as serum alpha-fetoprotein (AFP). We compared the prognostic stratification performance of BCLC and ORC after integrating AFP.
Method: Patients undergoing initial hepatectomy for HCC (2009–2023) were classified by oncological resectability criteria (ORC: resectable [R], borderline resectable 1 [BR1], and borderline resectable 2 [BR2]) and BCLC staging. Overall survival (OS) was compared. Patients in the ORC R group and those with BCLC very early or early stage with AFP ≥ 500 were reclassified into BR1 and intermediate stage, respectively, and OS was re-evaluated.
Results: Among 404 patients undergoing initial hepatectomy, the ORC distribution was R (n = 338), BR1 (n = 25), and BR2 (n = 41), and BCLC staging classified patients as very early (n = 60), early (n = 263), intermediate (n = 71), and advanced (n = 10). 5-year OS was lower in BR1 and BR2 than in R patients (51.7% vs. 74.8%, p = 0.020; 40.0% vs. 74.8%, p < 0.001), with no difference between BR1 and BR2 (51.7% vs. 40.0%, p = 0.260). 5-year OS in intermediate and advanced stages was lower than in very early + early stages (54.7% vs. 74.2%, p = 0.010; 35.0% vs. 74.2%, p = 0.010), with no difference between intermediate and advanced stages (54.7% vs. 35.0%, p = 0.240). After integrating AFP ≥ 500 ng/mL, patients were classified as R (n = 283), biological-BR+BR1 (n = 80), and BR2 (n = 41). 5-year OS decreased stepwise (75.7% vs. 63.0% vs. 40.0%), with worse OS in biological-BR+BR1 than in R (p = 0.008) and better OS than in BR2 (p < 0.001). AFP-integrated BCLC staging classified patients as very early + early (n = 270),

biological-BR + intermediate (n = 124), and advanced (n = 10), with lower 5-year OS in biological-BR + intermediate than in very early + early (59.7% vs. 75.4%, p < 0.001) and no difference versus advanced (59.7% vs. 35.0%, p = 0.263).
Conclusion: Combining ORC with AFP may offer a useful framework for identifying patients at high risk of poor postoperative survival in resectable disease and for guiding consideration of preoperative therapy in patients with resectable HCC.

FRI-220
Changing trends in disease severity and advances in treatments of hepatocellular carcinoma in Germany from 2005 to 2019: a nationwide population-based study
Josune Cabello Calleja[1], Wenyi Gu[1,2,3], Robert Schierwagen[1], Maximilian Joseph Brol[1], Frank Uschner[1], Martin McCoy[1], Sabine Klein[1], Kai-Henrik Peiffer[1], Julia Fischer[1], Michael Köhler[4], Philipp Schindler[4], Klaus Wethmar[5], Andreas Pascher[6], Martina Holstein[6], Michael Praktiknjo[1], Anton Gillessen[7], Florian Rennebaum[1], Jonel Trebicka[1,8,9]. *[1]Department of Internal Medicine B, University Hospital Muenster, Muenster, Germany; [2]Department of Gastroenterology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; Shanghai Institute of Digestive Disease, NHC Key Laboratory of Digestive Diseases, Shanghai, China; [3]Department of Internal Medicine I, University Hospital Frankfurt, Goethe University Frankfurt, Frankfurt, Germany; [4]Clinic for Radiology, University and University Hospital of Muenster, Muenster, Germany; [5]Department of Medicine A, Hematology, Oncology, Hemostaseology and Pneumology, University Hospital of Muenster, Muenster, Germany; [6]Clinic for General, Visceral and Transplant Surgery, University Hospital of Muenster, Muenster, Germany; [7]Department of Gastroenterology, Clinic for Internal Medicine, Herz-Jesu-Hospital, Muenster-Hiltrup, Germany; [8]Department of Gastroenterology and Hepatology, Odense University Hospital, Odense, Denmark; [9]European Foundation for Study of Chronic Liver Failure (E-CLIF), Barcelona, Spain*
Email: josune.cabello@ukmuenster.de

Background and aims: Hepatocellular carcinoma (HCC) is associated with complications and high mortality. Current management follows the Barcelona Clinic Liver Cancer algorithm. Since sorafenib approval in 2007, new therapeutic recommendations have been adopted, especially for systematic treatment of advanced HCC. We aimed to investigate the impact of complications and management on in-hospital mortality among HCC admissions.
Method: Using the diagnosis-related-groups and the German ICD/OPS codes, we analyzed hospital admissions with HCC during pre-checkpoint inhibitor era (2005–2020). The analysis focused on HCC-related complications, therapeutic interventions and all-cause in-hospital mortality. Trends were assessed with linear regressions and Mann-Whitney U-tests.
Results: Among 393,230 HCC hospitalizations in Germany, 117,787 admissions (30.0%) were associated with liver decompensations, especially ascites (21.6%). Bacterial infections exhibited the highest increase of 2.1-fold in 2016. In advanced stages, HCC admissions were complicated by organ failure, with respiratory failure (16,231 cases) showing the highest increase (6.2-fold in 2019), surpassing renal failure (33,936 cases; 2.9-fold in 2017). 126,980 HCC admissions received systemic treatment (42.5%), local-ablative (54.6%) or liver transplantation (LT) (2.8%). Local-ablative therapies—liver resection, ablation and transarterial treatments—were most frequently applied modalities in liver-limited HCC (56%), while systemic therapy consistently predominated in metastatic HCC. Among transarterial approaches, transarterial chemoembolization was more frequently performed than selective internal radiation (80.9%). Despite a higher number of liver resections performed, in-hospital mortality was comparable between resection (9.7 ± 1.4%) and LT (10.1 ± 2.4%), whereas systemic and transarterial therapies showed significantly lower mortality. Liver resection was linked to high rates of treatment-related infections (18.3%) and renal injury (10.1%), which were associated with a marked increase in mean in-hospital mortality (23.6 ± 5.8%).
Conclusion: Our study shows the natural history of HCC, and the central role of local-ablative therapies. It highlights the persistent need for more accurate and comprehensive pre-surgical evaluation due to ongoing treatment-related complications and associated high mortality, and transplant consideration as a curative treatment.

Background and aims: Immunotherapy-based combinations are the standard first-line treatment for advanced hepatocellular carcinoma (HCC), with atezolizumab–bevacizumab (AtezoBev) and durvalumab-tremelimumab (DurvaTreme) recommended options. Comparative real-world data between these regimens remain limited. We compared clinical outcomes, tumor response, and safety of AtezoBev versus DurvaTreme.
Method: This multicenter retrospective study (9 centers) included patients treated with first-line AtezoBev or DurvaTreme. Patients were matched 1:1 using propensity scores. Overall survival (OS), progression-free survival (PFS), disease control rate (DCR), objective response rate (ORR), and adverse events were analyzed.
Results: Among 1053 patients (908 treated with atezolizumab–bevacizumab and 145 with durvalumab–tremelimumab), 280 patients were included after matching. Baseline characteristics were well balanced between groups: approximately 60% had BCLC stage C disease, 35% had vascular invasion, 28% had extrahepatic spread, 60% were Child–Pugh class A, and 24% were ALBI grade 1. After a median follow-up of 20.1 months, OS was similar between AtezoBev and DurvaTreme (median 20.8 months vs. not reached; $p = 0.25$), while PFS was longer with AtezoBev (8.2 vs. 4.7 months; $p = 0.006$). DCR was higher with AtezoBev at first (80.2% vs. 52.4%) and best imaging response (81.0% vs. 54.1%; both $p < 0.001$), whereas ORR did not differ. Higher baseline albumin was independently associated with improved OS and PFS. Treatment type was not associated with OS, but DurvaTreme was independently associated with increased risk of progression (HR 1.49, $p = 0.006$). The presence of ≥3 tumor nodules was independently associated with lower ORR (OR 0.51, p = 0.031), and DurvaTreme was also associated with reduced ORR (OR 0.52, p = 0.038). In treatment-stratified analyses, ≥3 tumor nodules were

associated with a significantly lower ORR in the AtezoBeva cohort (OR 0.37, p = 0.017), while MASLD was associated with reduced ORR in the DurvaTreme cohort (OR 0.33, p = 0.033).
Conclusion: These findings support a tailored selection of first-line immunotherapy in advanced HCC based on liver function, tumor burden, and patient-specific characteristics. Further studies are needed to identify predictive factors of response in order to optimize treatment selection.

FRI-225
Durvalumab–Tremelimumab in advanced hepatocellular carcinoma: real-world data From the LOR-HCC (Lombardy, Italy real-world HCC group)

Background and aims: Dual immune checkpoint blockade with tremelimumab plus durvalumab (STRIDE) is an established first-line therapy for unresectable hepatocellular carcinoma (uHCC), but real-world evidence on safety, toxicity kinetics, and liver function dynamics remains limited. We aimed to evaluate tolerability, on-treatment changes in hepatic function and effectiveness, in a multicenter cohort of patients treated with STRIDE in routine practice.
Method: We conducted a retrospective analysis of prospectively collected data from 115 consecutive patients with uHCC treated with STRIDE across 12 centers in Lombardy, Italy. Clinical, biochemical, and radiological variables were recorded at baseline and throughout therapy. Adverse events were graded per CTCAE v5.0, and Child–Pugh was used to assess hepatic functional evolution. Temporal toxicity patterns were evaluated using smoothed hazard functions. Progression-free survival (PFS), overall survival (OS), and competing-risk cumulative incidence of progression and death were examined.
Results: Median follow-up was 8.9 months. More than 80% of adverse events occurred within the first 2 months; severe toxicities were infrequent. Child–Pugh deterioration from class A to B occurred in 7.8% of patients from baseline to day 28, increasing to 12.1% by day 56,. PFS was 5.7 months; median OS was not reached, with OS rates of 78.2% at 6 months and 53.3% at 18 months. Progression was the predominant early event, with cumulative incidence of 49.2% at 6 months.
Conclusion: In routine clinical practice, STRIDE shows reproducible effectiveness and a manageable safety profile, with adverse events incidence clustering early and stabilizing thereafter. Dynamic assessment of liver function shows that hepatic function declines modestly but still clinically meaningfully in affected patients.

Multimodal deep learning for predicting early progression in advanced hepatocellular carcinoma treated with atezolizumab-bevacizumab

Ciro Celsa[1], Salvatore Contino[2], Roberto Cannella[3], Simona Restuccia[1], Gaia Crescimanno[1], Luca Cruciata[2], Roberta Ciccia[1], Gaetano Giusino[1], Guido Cusimano[1], Sofia Calascibetta[1], Alessio Quartararo[1], Aurora Nicolosi[1], Giuseppe Cabibbo[1], Giansalvo Cirrincione[4], Roberto Pirrone[2], Calogero Cammà[1]. *[1]Section of Gastroenterology and Hepatology, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, University of Palermo, Palermo, Italy; [2]Department of Engineering, University of Palermo, Palermo, Italy; [3]Department of Biomedicine, Neuroscience and Advanced Diagnostics (BiND), University of Palermo, Palermo, Italy; [4]Université de Picardie Jules Verne, Amiens, Amiens, France*
Email: calogero.camma@unipa.it

Background and aims: Atezolizumab plus bevacizumab has emerged as the standard first-line therapy for advanced HCC, yet individual response remains heterogeneous and difficult to predict. We developed a multimodal artificial intelligence framework integrating clinical data and computed tomography imaging to predict six-month progression-free survival in patients receiving atezolizumab-bevacizumab.
Method: We retrospectively analysed 62 patients with advanced HCC treated with first-line atezolizumab-bevacizumab at a tertiary referral centre (University of Palermo, Italy). A deep learning architecture combining a convolutional neural network for CT image analysis (arterial, venous, and delayed phases) with a multilayer perceptron for structured clinical variables was developed. The model was trained to predict progression-free survival status at six months. Performance was evaluated using accuracy, precision, recall, F1-score, balanced accuracy, and area under the receiver operating characteristic curve. Results were compared with conventional logistic regression incorporating clinical variables alone.
Results: After a median follow-up of 15.9 months, median overall survival was 24.3 months (95% CI: 15.9–38.0). Twenty-three patients (37.1%) experienced progression or death within six months. The multimodal model achieved an AUC of 0.86, with 80.1% accuracy, 84.7% specificity, 68.9% sensitivity, 67.0% F1-score, and 76.8% balanced accuracy. In contrast, traditional logistic regression yielded an AUC of 0.67 (95% CI: 0.54–0.78), with neoplastic portal vein invasion showing a trend toward significance (OR: 2.79, 95% CI: 0.98–7.92, p = 0.053) in multivariable analysis.
Conclusion: A multimodal artificial intelligence approach integrating CT imaging with clinical data demonstrates promising capability in predicting early disease progression in HCC patients treated with atezolizumab-bevacizumab. While preliminary and requiring external validation, these findings suggest that deep learning frameworks may enhance risk stratification and support personalized treatment decisions in advanced hepatocellular carcinoma.

FRI-227

Multimodal deep learning for therapeutic decision support in hepatocellular carcinoma: integrating clinical data and computed tomography imaging

Ciro Celsa[1], Salvatore Contino[2], Mauro Giuffrè[3], Roberto Cannella[4], Simona Restuccia[1], Luca Cruciata[2], Alessandro Grova[1], Gaetano Giusino[1], Guido Cusimano[1], Sofia Calascibetta[1], Alessio Quartararo[1], Francesco Mercurio[1], Claudia La Mantia[1], Giuseppe Cabibbo[1], Giansalvo Cirrincione[5], Roberto Pirrone[2], Calogero Cammà[1]. Email: calogero.camma@unipa.it

Background and aims: Multidisciplinary management of hepatocellular carcinoma (HCC) requires complex decision-making integrating tumor burden, liver function, and performance status. Although multidisciplinary management can improve outcomes, it is resource-intensive and not universally feasible. We developed a multimodal deep learning framework integrating clinical text reports and computed tomography (CT) imaging to predict therapeutic decisions in HCC patients.

Method: We retrospectively analyzed 240 unstructured clinical reports with corresponding CT images from 204 patients evaluated at a tertiary referral center between September 2020 and November 2024. Therapeutic decisions were classified into seven categories: liver transplantation, surgical resection, percutaneous ablation, transarterial treatments, systemic therapy, best supportive care, and continued follow-up. A multimodal architecture combining BioBERT for clinical text analysis with a convolutional neural network for CT image feature extraction was developed. The model was trained using an 80:20 split and evaluated using accuracy, sensitivity, specificity, precision, F1-score, and balanced accuracy.

Results: The cohort included 204 patients (mean age 71.6 ± 10.3 years, 71.2% male). Therapeutic decisions comprised transplantation (3.8%), resection (5%), ablation (7%), transarterial treatments (8.7%), systemic therapy (32%), best supportive care (22%), and follow-up (21.2%). The multimodal model achieved 95.5% overall accuracy, 95.0% sensitivity, 94.0% precision, 94.4% F1-score, 95.0% balanced accuracy, and 84.7% specificity in replicating expert clinical decisions. The confusion matrix demonstrated excellent discrimination across all therapeutic classes, with minimal misclassification between treatment categories.

Conclusion: A multimodal artificial intelligence framework integrating unstructured clinical reports and radiological imaging accurately predicts therapeutic decisions in HCC with performance exceeding 95%. While requiring prospective validation and interpretability enhancement, this approach demonstrates potential as a clinical decision support tool to standardize care, optimize multidisciplinary team workflows, and support evidence-based treatment selection in HCC management.

FRI-228-YI

Dose–response relationship and clinical outcomes after Yttrium-90 transarterial radioembolization for hepatocellular carcinoma: GALAXY-90 study

Email: pierce.chow@duke-nus.edu.sg

Background and aims: Yttrium-90 transarterial radioembolization (Y-90 TARE) has evolved from palliation to curative intent for hepatocellular carcinoma (HCC) with higher doses. The Generalized Analysis of Locoregional Approach by eXamining outcomes with Yttrium-90 (GALAXY-90) study is the first in Asia, where larger HCC is more prevalent, to evaluate the dose-response relationship across a broad range of tumour doses within two evaluation time windows.

Method: We retrospectively analyzed consecutive patients with solitary HCC with or without portal vein invasion treated with Y-90 TARE at National Cancer Centre Singapore and Singapore General Hospital (2019–2024). Tumor response was evaluated using localized mRECIST; best objective and disease-control rates (BORR, BDCR) were assessed at ≤ 6 and ≤ 9 months. Overall survival (OS) and progression-free survival (PFS) were analyzed using the Kaplan–Meier method. Safety was evaluated by adverse events (AEs) graded per CTCAE v5.0.

Results: Among 429 patients who received Y-90 during the study period, 110 patients were included (median tumor size 6.6 cm). Predicted mean doses were stratified into <120, 120–200, 200–300, and ≥300 Gy (median 191 Gy, range 41.2–647.8). From ≤ 6 to ≤ 9 months, overall BORR improved from 78.0% to 91.7%, with significant trends across the four dose intervals ($p = 0.003$; $p = 0.019$). Complete response rose from 13.8% to 34.9% between ≤ 6 to ≤ 9 months evaluations. Doses ≥ 200 Gy achieved significantly higher BORR than < 200 Gy ($p = 0.002$ at ≤ 6 m; $p = 0.004$ at ≤ 9 m). In the paired-window subset ($n = 88$), late responders between 6 and 9 months accounted for the BORR improvement ($p = 0.002$). Overall BDCR remained 99.0%, reaching 100% in doses ≥120 Gy ($p = 0.174$). Median OS and PFS were 44 (95% CI 38–61) and 16 months (95% CI 13–26), respectively. AEs were infrequent and showed no dose-dependence ($p > 0.05$).

Conclusion: Our GALAXY-90 study identifies ≥ 200 Gy as a threshold for optimal tumor response without added toxicity for large HCCs. Extending follow-up to 9 months captured late responders, supporting a policy of threshold-dose escalation and extended response assessment in Y-90 for HCC, achieving high BORR.

FRI-229

Application and evaluation of whole process management model for liver cancer patients undergone Yttrium-90 selective internal radiation therapy (Y-90 SIRT): a retrospective cohort study

Xiaolong Chen[1], Quan Jiang[1], Kangshou Liu[1], Xuejiao Li[2], Zhiwei Chen[1], Zhilong Liu[1]. [1]*Department of Hepatobiliary surgery, The First Affiliated Hospital of Jinan University, GuangZhou, China;* [2]*Department of Hepatology lab, The Third Affiliated Hospital of Sun Yat-sen University, GuangZhou, China*
Email: chxl1446@126.com

Background and aims: To construct a comprehensive and standardized whole-process management model for liver cancer patients undergoing Yttrium-90 selective internal radiation therapy (Y-90 SIRT) and systematically evaluate its clinical efficacy, safety, and impact on medical resource utilization.
Method: A retrospective cohort study was conducted on 365 liver cancer patients who received Y-90 SIRT at The First Affiliated Hospital of Jinan University from August 2022 to October 2025. Excluding those who were lost to follow-up, did not complete the questionnaire, or participated in the Y-90 SIRT clinical trial, 314 patients were enrolled in this study. Patients were divided into the intervention group (163 cases, January2025–October 2025) receiving the whole-process management model and the control group (151 cases, August 2022–December 2024) receiving routine management. Incidence of adverse events (AEs), patient satisfaction, postoperative self-rating anxiety and depression scores, length of hospital stay, and hospitalization costs were assessed between groups.
Results: Baseline characteristics were comparable between the two groups ($P > 0.05$). The overall incidence of adverse events (AEs) in the intervention group was 11% (18/163), which was significantly lower than that in the control group (30%, 45/151; $P < 0.001$). Moreover, the intervention group exhibited notably lower scores on the Self-Rating Anxiety Scale (42.73 ± 6.51 vs. 48.08 ± 8.98, $P = 0.001$) and Self-Rating Depression Scale (48.54 ± 6.75 vs. 50.83 ± 8.25, $P = 0.007$), along with a significantly higher patient satisfaction score (25.63 ± 2.81 vs. 23.06 ± 2.9, $P < 0.001$). Additionally, the average hospitalization cost was lower in the intervention group than in the control group (¥405602 ± 62967 vs. ¥414674 ± 66035, $P = 0.0134$).
Conclusion: The whole-process management model for liver cancer patients undergoing Y-90 SIRT significantly reduces the incidence of adverse events, ameliorates patients' psychological status, improves patient satisfaction and optimizes medical resource utilization.

FRI-230
Impact of palliative care on end-of-life healthcare utilization among Asian patients with hepatocellular carcinoma

Email: matttcsh@connect.hku.hk

Background and aims: While palliative care (PC) is important in the management of hepatocellular carcinoma (HCC), its impact on the end-of-life healthcare utilisation is less clear.
Method: Patients diagnosed with HCC who had never received any oncological treatment and who have died between 2003 and 2024 were identified from a territory-wide electronic database in Hong Kong. Patients were classified into PC group (those who received any specialist PC consultation or inpatient hospice service within the last 3 months of life) or non-PC group (those who did not have any PC utilization). Data on intensive care unit (ICU) admission, resuscitation (cardiopulmonary resuscitation or intubation), nerve block, and use of opioid analgesics (including strong/ weak opioids) were evaluated. To evaluate the disease time burden, we assessed percentage of days at home (%DAH), defined as the percentage of time not requiring healthcare utilization (inpatient or emergency department admissions, day procedures, blood tests, and imaging) in the 3 months preceding death.
